This study focuses on the linguistic content of science lessons for 5-year-olds. We examined how teachers can promote 5-year-olds' developing abilities to verbalize their intuitive understanding of physics phenomena. Even though children have such intuitions, based in sensorimotor representations of previous exploration experiences, sharing insights in an efficient and meaningful way with peers and teachers can be challenging, yet is necessary to increase more abstract-conceptual understanding of science phenomena. In this study, we present the results of a teacher-focused intervention study. In a randomized design, 59 teachers and 230 children were observed twice (winter and late spring) during science lessons about light reflection and air pressure respectively. After the first round of observations, thirty teachers were randomly assigned to a training session in which they learned about AL and were made aware of the many affordances of early science lessons to promote AL in 5-year-olds. A second round of observations was used to determine whether training made a difference. Results show increased lexical richness of the conversations in the experimental group. More specifically, unlike in the control group, both teachers and children in the experimental group made more use of domain-specific words, such as air pressure and reflection, in the second observation compared to the first observation. For the use of general academic words, such as explore and discover, an increase was found for the children in the experimental group.

Aim

From infancy, children form visuo-spatial and sensorimotor representations of their personal experiences that include information about the temporal and causal structure of actions and events, its obligatory and optional components, and the associated functions (French, 2004; Nelson & et. al, 1986). In the present study, we focus on children's early understanding of physics; in particular the phenomena light reflection and air pressure. We presuppose that children as young as 5 years of age already have an intuitive understanding of these phenomena based in sensorimotor representations of previous exploration of these and similar phenomena. However, they still need to learn to map particular scientific words and expressions onto these representations in order to be able to articulate their insights in a conventional way and to share them with others. We propose that, in order to do so efficiently, children need to master command of what we refer to as 'academic language' (AL); the set of linguistic tools needed to efficiently convey cognitively complex content (Schleppegrell, 2001; Snow & Uccelli, 2009). Being able to share, to compare and to contrast intuitive ideas about scientific phenomena is seen as a prerequisite for developing deeper and more abstract knowledge of these phenomena.

Particular linguistic features distinguish academic language from daily informal language and determine the fact that academic language is needed to efficiently convey cognitively complex content. These features are (amongst others) a rich and technical vocabulary, the use of specific references to space, time and entities rather than relying on shared situational cues, and the use of multi clause sentences, connected by means of connective and cohesive devices. It is proposed that teacher's guidance is invaluable to children's process of mastering academic language (Henrichs, 2010). Science-related conversations provide excellent opportunities for children to practice academic language skills. While 'doing science' children can still partly rely on the shared physical environment, but are simultaneously challenged to find accurate wording for the phenomena they observe.

In this paper, we will describe how promoting teachers' knowledge of academic language and stressing the affordances of early science lessons for academic language use can in turn promote academic language use in children.

Method

Fifty-nine teachers and 230 children participated in the study. All teachers were observed twice during brief science lessons on the topics of air pressure and light reflection. The researcher provided the teachers with the relevant teaching materials and a basic (standardized) instruction on the content of the lessons. The first round of observations (henceforth: pretest) took place in winter, the second round of observations (henceforth: posttest) in late spring. All interactions were verbatim transcribed and coded for academic language features and scientific reasoning elements such as predicting, comparing, explaining, and generalizing.

The teachers were randomly assigned to an experimental group and a control group. The experimental group attended a half-day researcher-led training session in early spring. The comparison group received no training. The training consisted of two parts; theory and practice. In the theoretical part, teachers were provided with theoretical background on the concept of academic language, and the affordances of science lessons to promote academic language. In the practice part, teachers watched a pretest video and discussed in groups the presence of academic language features in the teacher-student discourse they observed.

Results

The pretest data show that teachers used very general wording to talk about the activities (air pressure and light reflection). For instance, the key word air pressure did not occur at all, and also the word reflection was highly infrequent. Teachers were reluctant to use these words, which they seemed to perceive as too complex. Also, more general academic words, such as explore, discover or result were not found as often as might be expected in science activity. Sentences were relatively short and aimed at describing the phenomena observed (e.g. "What do you see?" or "What is happening?") rather than challenging the children to reason about what they saw in terms of predictions, comparison, explanation and generalizing.

In the posttest data, the discourse of the experimental group showed quite a different pattern. Unlike in the comparison group, overall lexical richness of the conversations in the experimental group increased substantially. More specifically, both the trained teachers and their students showed increased use of domain-specific words (e.g. air pressure, force, reflection). For general academic words, such as explore and discover, however, only an increase was found for the children in the experimental group.

In addition to changes on the word level, we also found training effects on the syntactic level. Sentences containing causal, temporal and contrastive connectors occurred significantly more frequently in the discourse of the trained group (words such as because, by means of and constructions such as "the more...the more..."). Finally, the teachers from the trained group engaged the children more often in scientific reasoning rather than simply labeling or describing, challenging the children to produce more detailed and linguistically accurate verbalizations.

Implications

Our results indicate two key findings. Firstly, with a relatively light intervention, teacher-student discourse in science activities can be enriched substantially. Secondly, children need teacher guidance to optimize their linguistic potential. Merely providing interesting, science-related material does not suffice to elicit rich discourse. When teachers, however, are made aware of the affordances of these science lessons for academic language learning, this has positive implications for the quality of the conversations.

Formal scientific reasoning in preschool: Evaluating evidence

Susanne Koerber, University of Education Freiburg, Germany; Beate Sodian, University of Munich, Germany

Evaluating and – if necessary – revising own hypotheses in the light of new evidence is central to scientific reasoning. However, children often ignore, distort or only selectively attend to evidence that is inconsistent with a favored hypothesis/belief. We based our study on two positions which stress the impact of attending to evidence on the one hand and that of theory based reasoning (stressing explanations) on the other hand. In a between subject design 46 kindergarteners and 75 second-graders were presented with counterevidence of their belief about the relationship between two variables. In addition, half of the children received explanations for the counterevidence, illuminating the underlying mechanisms of the relationship between the two variables. The other children were presented with empirical data displayed in a bar graph, confirming the unexpected counterevidence. In both age groups we found significant numbers of belief revision with high certainty ratings concerning their new belief. This belief change was even more pronounced in elementary school, where the 2nd graders showed significantly more changes in the bar graph condition than in the explanation condition. In sum, our results demonstrate that the visualization of data might be especially helpful for children to acknowledge evidence and to reconsider own hypotheses.

Aim

Evaluating and – if necessary – revising own hypotheses in the light of new evidence is central to scientific reasoning. However, children often ignore, distort or only selectively attend to evidence that is inconsistent with a favored hypothesis/belief. The prominent role of prior knowledge and beliefs on individuals' evaluation of evidence is an often-cited phenomenon. Children tend to reconcile data and their own beliefs, but are usually biased in favor of their prior beliefs. Thus, they often seem to ignore, distort, or only selectively attend to evidence that is inconsistent with a

favorable hypothesis/belief. Recent studies have shown that these problems cannot be explained convincingly by a deficit theory (e.g., Kuhn, Amsel & O'Loughlin, 1988) that claims children might lack a general understanding of the relation between theory and evidence. In contrast, Koslowski (1996) claims that children's reluctance to give up their prior beliefs is based on a strong emphasis on beliefs and subjective theories, such that children have to be provided with explanations or alternative theories in addition to the counterevidence. Other researchers, such as Chinn and Malhotra (2002), focus more on the role of the evidence, showing that children often have problems with correctly perceiving the evidence in the first place. Correct inferences from data are thus only possible when evidence is correctly represented and taken seriously. In our study we examined these two positions more deeply and investigated the effect of an explanation about the mechanism of the relation between the two variables as well as the effect of graphically visualizing empirical data on children's understanding of the hypothesis-evidence relation.

Method

In a between-subject design we presented 46 kindergarteners and 75 second-graders with counterevidence of their strong belief about the relationship between two variables. For instance, children who believed that eating carrots would be more helpful for good vision than eating spinach were presented with evidence showing that in fact both vegetables are equally healthy. In addition to the counterevidence, half of the children in each age group received explanations for the counterevidence, illuminating the underlying mechanisms of the relationship between the two variables (e.g., carrots and spinach contain an equal amount of beta carotene / Vitamin A which supports good vision). The other children were presented with empirical data displayed in a bar graph confirming the unexpected counterevidence. Altogether, the children were presented with four tasks. In two tasks non-covariation served as counterevidence, in the other two tasks perfect covariation evidence counter to the child's hypothesis was presented. After check questions they were asked what they would think about the relationship between the two variables now, after seeing the data or listening to the explanation. In order to test for depth and consistency of the answers we included questions concerning the certainty of the children's own beliefs and another person's belief (change).

Results.

In both age groups we found significant numbers of belief revision with high certainty ratings concerning their new belief. Preschoolers changed their belief in a mean of 2.25 (sd = 1.15) and 2.09 (sd = 1.19) out of 4 contexts in the explanation and in the bar graph condition, respectively. This belief change is even more pronounced in elementary school, where the 2nd graders showed significantly more changes in the bar graph condition (mean = 3.3; sd = .7) than in the explanation condition (mean = 2.8; sd = 1.2), $F(1,72) = 5.9$, p

Implications.

Together, the findings suggest that even preschoolers are able to revise their beliefs when being presented with explanations for the counterevidence or when the perceptual salience of the counterevidence was emphasized via graphs. With increasing age the salience of the evidence seems to gain even more impact.

SYMPOSIUM

Religious and Spiritual Education: Issues of Effectiveness and Competence

Chairperson: Theo Van der Zee, Radboud University Nijmegen, Netherlands

Organiser: Terence Lovat, The University of Newcastle, Australia

Theo Van der Zee, Radboud University Nijmegen, Netherlands

Discussant: Kirsi Tirri, University of Helsinki, Finland

The symposium will explore updated research around the central issue of the effectiveness and competence of religious and spiritual education to address and deal with issues of concern and substance in society generally and among youth in particular. Issues around belief in the after life among primary students and of intercultural and interfaith conflict among secondary students will be explored as instances. Conceptual and empirical research will be used as means of illustrating effectiveness or not, as well as evaluating these programs. Additionally, the specific competence of the teacher and how best to train teachers to deal with such issues will be the subject of updated research.

Interfaith Religious and Values Education: A Judeo-Christian-Islamic Instance

Terence Lovat, The University of Newcastle, Australia; Robert Crotty, University of South Australia/Ethics Centre of South Australia, Bahamas

The works of Dietrich Bonhoeffer, John Hick and Mohamed Talbi will be used as examples of interfaith theology designed for relevance to a globalized community. Far from being movements towards reducing belief, as often purported by their accusers, they are deemed to be means of strengthening it in a world of competing faiths and non-

faith. Neither are they signs of a weaker or more marginalized theology but, on the contrary, of theology with capacity to play a vital role in humans understanding better their condition in the twenty-first century, the century's particular challenges and the role of faith in their midst. In this context, the role of religious education must broaden beyond its traditional denominational boundaries to match the globalized perspective and potency of interfaith theologies of the type proposed by Bonhoeffer, Hick and Talbi. The paper will expose the proposed shape, form and ramifications for religious and values education designed to explore the positive and negative perspectives on the relationship between Islam and the Judaeo-Christian 'West' and so prepare students for these realities. It will also explore ways in which such curricula can be and, in some cases have been, tested and evaluated for their effects.

The works of Dietrich Bonhoeffer (1959, 1998), John Hick (1973, 1980, 1988, 1995) and Mohamed Talbi (1995, 2002, et al., 2002) will be used as examples of interfaith theology designed for relevance to a globalized community. Far from being movements towards reducing belief, as often purported by their accusers, they are deemed to be means of strengthening it in a world of competing faiths and non-faith. Neither are they signs of a weaker or more marginalized theology but, on the contrary, of theology with capacity to play a vital role in humans understanding better their condition in the twenty-first century, the century's particular challenges and the role of faith in their midst.

In Bonhoeffer and Hick, we find reactions from within the Christian faith to traditional forms of Christian dogmatism and evangelical claims to be the only true religion. In Talbi, we find an equivalent critique from within Islam, a critique that employs Islam's own sacred sources to show that Islam should be a leader of interfaith dialogue and its allied theologies, rather than the exclusivist tradition that has become its stereotype in the early years of the twenty-first century. The paper will explore these conceptions and their pertinence to the kinds of religious and values education needed to inform and prepare students well for their multi-faith, multi-values world and in ways that maintain credibility for such curricula, including through their own testing and evaluation. It will furthermore explore the potential for building much-needed bridges between Christianity and Islam whose history is more around conflict between their narrow claims to be exclusively God's chosen faith. This conflict presents as arguably at the heart of the twenty-first century's principal threat to peace and so its resolution must present as a particularly urgent task for twenty-first century education to address.

The paper will expose the proposed shape, form and ramifications for religious and values education designed to deal with these issues. The religious and values education required for Westerners, and especially those of direct Jewish and Christian origin, to truly understand Islam is one that must make a difference, a difference not only to head knowledge but a difference in the way these Westerners ultimately act towards their fellow human beings. Concomitantly, the religious and values education required for Muslims, especially in Western environments, are ones that engage them in the fullness of learning about the verifiable facts of their own religious history, in contrast with the increasing attempts by Islamist commentary to skew these facts, and to bring the beliefs and values of Islam into the marketplace where they can be negotiated and evaluated along with all other beliefs and values of a polyglot society that is functioning for the benefit of all its participants.

The paper will explore two religious education syllabuses and one values education program that have been used in this way in recent times (Lovat, 2010; Lovat et al., 2010). Through the two religious education syllabuses, students have increased opportunity on those in former years to come to a fairly sophisticated knowledge and understanding of Islam and to bring Muslim and non-Muslim students into active conversation with each other about matters of faith. This knowledge and understanding is beyond descriptive knowing of the details about Islam's history, creeds and morality. The pedagogy, impelled by an explicit epistemology that distinguishes between technical, interpretive and reflective knowing, aims to engage students in learning that challenges their own beliefs and life-worlds and that can therefore make a difference in the way they approach Islam, either as their own faith or as the faith of the other.

The values education project was designed specifically to address issues of cultural and religious difference, in each case combining within-school pedagogy with an experiential component that impelled interfaith engagement. Schools were drawn from Muslim, non-Muslim and Government school sectors, with the specific and central focus being a broadening of understanding between Muslim and non-Muslim cultures. Beyond learning targeted at understanding the 'other' within the school, the cluster was involved in an array of organized excursions that took students out of their own environment and placed them in the environment of the other, complete with pedagogical attachment that ensured engagement with the other. The beyond-school pedagogy was heavily focussed on 'place' and 'space', with careful and even-handed movement of students from their own comfort zones into the comfort zones of the 'other'. One such place was a site where a particularly violent and public exchange had occurred between allegedly Muslim and non-Muslim youth and so served as a particular focus for the project in question, providing a sharp example of what can transpire when the goals of the project are not attempted and a mixed

community is left without communicative capacity, empathic character and self-reflectivity of the kind proposed as crucial to the aims of the values education intervention.

The paper will provide details of these programs as well as an evaluation that was conducted, with special reference to the latter project, designed to test and measure its effects (Lovat et al., 2009; Lovat et al., 2010). This involved quantitative and qualitative method and particular reference to the issue of intercultural tolerance purported to be central to the issue of interfaith engagement.

Primary school students' beliefs about the afterlife. A developmental perspective

Theo Van der Zee, Radboud University Nijmegen, Netherlands

In Religious Education (RE) students learn about various aspects of life as death and afterlife from a religious perspective. The plausibility of religious beliefs on these matters, however, is challenged by advanced biological knowledge. How do students deal with this challenge? From an educational perspective this question is in particular important because it touches the issue how students develop when they are exposed to seemingly incompatible conceptual systems.

Aim of our research is to find out how primary school students' beliefs about the afterlife develop. It can be expected that these students tend to develop two different conceptualizations of death: a biological and a religious one. What also isn't known yet is whether religious children deal with seemingly incompatible conceptualizations differently from non-religious children.

Our research questions are:

- (1) which functions do children attribute to people after death?
- (2) does age influence the attribution?
- (3) does religious affiliation influence the attribution?
- (4) does religious affiliation influence the explanation of attribution?

To answer our research questions, we interviewed 162 primary school students: 81 of grade 2 (7-8 years) and 81 of grade 6 (11-12 years of age), and from four different religious backgrounds. Results of analyses show that students attribute biological functions to a low and mental functions to a high extent, and also an influence of age and of religious affiliation. Findings are discussed with a view to the question how students cognitively develop when they are exposed to seemingly incompatible conceptual systems.

In Religious Education (RE) students learn about various aspects of life as death and afterlife from a religious perspective. These latter aspects aren't easy to grasp, because they pose perceptual and conceptual challenges. By participating at RE classroom practices, students can acquire religious beliefs about the afterlife. The plausibility of these beliefs, however, is challenged by advanced biological knowledge about life and death (Spilka, Hood, Hunsberger & Gorsuch, 2003). An intriguing question is how students deal with this challenge. From an educational perspective this question is in particular important because it touches the issue how students develop when they are exposed to seemingly incompatible conceptual systems (Gelman, 2009; Harris & Koenig, 2006).

Aim of our research is to find out how primary school students' beliefs about the afterlife develop. It can be expected that these students tend to develop two different conceptualizations of death: a biological and a religious one. It also appears that this tendency is more pronounced among older children (Bering & Bjorklund, 2004; Harris & Gimenez,

2005). What isn't known yet is whether religious children deal with seemingly incompatible conceptualizations differently from non-religious children (cf. Bering, Blasi, Bjorklund, 2005; Harris & Koenig, 2006).

From a cognitive science perspective on religion, it is hypothesized that people use various mental tools as theory of mind to process information about reality and to generate beliefs. These mechanisms all involve the concept of agency. Afterlife beliefs reflect how people understand reality after death. The understanding of death as the cessation of agency could be an important clue to the explanation how afterlife beliefs tend to develop and spread (Barrett & Behne, 2005; Barrett, 2004). Research provided evidence that people distinguish between biological (physical, sensory, psychobiological) and mental functions (desire, epistemic, emotional, moral) (Bering & Bjorklund, 2004; Harris & Gimenez, 2005).

Our research questions are as follows:

- (1) which biological and mental functions do children attribute to people after death?
- (2) does age influence the attribution?
- (3) does religious affiliation influence the attribution?
- (4) does religious affiliation influence the explanation of attribution?

To answer our research questions, we interviewed 162 primary school students: 81 of grade 2 (7-8 years) and 81 of grade 6 (11-12 years of age). The students are from four different religious backgrounds: Catholic, Protestant, Islamic and Non-religious, and they were recruited by teachers at their primary school and participated when their parents have given their consent. Three instruments are used: a questionnaire on personal characteristics, a test for vocabulary, and an interview on afterlife beliefs. The interview was composed of two narratives about the death of an elderly grandmother and grandfather, and of two times 14 questions about biological and mental functioning of the deceased and two times three open questions about the explanation of the functioning after death.

Results of descriptive analyses show that students attribute biological functions to a low extent ($M=.27$, $sd=.30$) and mental functions to a high extent ($M=.63$, $sd=.33$). Results of ANCOVA show that age (controlled for scores on vocabulary tests) influences the attribution of biological and mental functions, and results of Oneway ANOVA show that religious affiliation influences the attribution of biological functions, but not of mental functions. Results of content analyses on the answers of students on the open questions show differences with respect to religious affiliation. In particular, Protestant primary school students tend to explain afterlife differently than other students do.

Findings are discussed with a view to the question how these students cognitively develop when they are exposed to seemingly incompatible conceptual systems.

Perceptions of competence during training among RE student teachers

Martin Ubani, University of Helsinki, Finland

The purpose of this study is to explore the perceptions of competence among Finnish RE student teachers during their one-year pedagogical training. The concrete research questions are: 1. What do the RE teacher students perceive as the characteristics of a competent RE teacher during their pedagogical training? 2. How do they perceive their personal competence in teaching during their training? The participants were RE student teachers from the University of Helsinki, Finland ($N=86$). The data included qualitative and quantitative questionnaire data along with interviews.

According to the study, the perceptions on competence remained stable while perceptions of personal competence developed and generally feeling of self-efficacy increased.

The purpose of this study is to explore the perceptions of competence among Finnish RE student teachers during their one-year pedagogical training. In literature, the term competence refers to the combination of knowledge, skills and attitudes which actualise in the problem-solving task relevant to the area of competence (Baartman, et al., 2007). Research shows that the main difference in favour of experts over novices is grounded in the differing amounts of experience and motivation (Berliner, 1991; Pikers & Paas, 2005). Pedagogical expertise resembles other areas of expertise: it is a sophisticated form of knowledge which is not easily gained or mastered (Berliner, 1991). Self-efficacy refers to the amount of confidence the individual has in his/her ability to carry out a given courses of action or to achieve a desired outcome and has been verified as important element in effective teaching (Bandura 1982; 1997; 1995).

The concrete research questions are:

1. What do the RE teacher students perceive as the characteristics of a competent RE teacher during their pedagogical training?
2. How do they perceive their personal competence in teaching during their training?

Method

The data was gathered 2007-2008 and 2008-2009. The participants were RE student teachers from the University of Helsinki, Finland (N=86). There were 64 female participants and 22 male participants aged 20-43 years. Eight students were interviewed on personal views on expertise, profession and pedagogy in the beginning, middle and end of the training. Data was analysed with qualitative content analysis (Bos & Tarnai 1999).

The questionnaire data was gathered with a two-part form at the beginning and at the end of the. The first part of the form has open-ended questions and provides qualitative data. The second part is a survey questionnaire with 64 items. The questionnaire included 56 statements (5-point Likert: 1 = fully disagree, 5 = fully agree) based on Eraut's (1994) constructivist theory of professional development and competence (1-6) with three additional RE specific areas of competence (7-9): (1) knowledge of people, (2) situational knowledge, (3) knowledge of educational practice, (4) propositional knowledge, (5) process knowledge, (6) control knowledge, (7) theological content knowledge, (8) content specific psychological knowledge and (9) knowledge of context. In addition there was a question: "Please evaluate your personal competence at this moment" (1-5). T-test analysis was used (SPSS).

Perceptions of competence: Qualitative results

The categories were called Virtuous Personality, Skilful Practice and Expert Knowledge. Each of these categories consisted of three or four sub-categories (Table 1 & 2). The emphasis on Virtuous Person became less in Spring (33.1%-28.1%) and the emphasis on Expert knowledge increased in Spring (32.8%-37.2%). Skilful Practice remained relatively stable in size (34.0-34.7%).

The largest sub-categories were mastery of subject matter (C2), mastery of practice (B1), social communication (B3) and empathy and caring (A2). The size of the sub-categories remained relatively stable. Among other things, the comparison shows some decline in empathy and caring (13.3%-10.0%) and social communication (16.3%-13.2%) while mastery of subject matter (21.4%-23.8%) and mastery of practice (16.9%-19.5%) was emphasized more in the end of the pedagogical year.

Quantitative results

In the quantitative data there were no statistically significant changes in the perceptions of competence areas (Table 3). Generally all categories scored relatively high which is quite likely due to the fact that the study focused on ideals. It should be noted, however, that the statements included also negative claims. The participants appreciated both in the beginning and in the end process knowledge ($M1 = 4.2$, $SD = .31$ – $M2 = 4.2$, $SD = .35$), situational knowledge ($M1 = 4.1$, $SD = .26$ – $M2 = 4.3$, $SD = .42$), content specific psychological knowledge ($M1 = 4.1$, $SD = .29$ – $M2 = 3.9$, $SD = .46$) and contextual knowledge ($M1 = 4.1$, $SD = .26$ – $M2 = 3.9$, $SD = .44$). In principle the standard deviation in the end of the studies was higher than in the beginning implying some differentiation during the pedagogical training among participants.

However, there was a statistically significant increase in perceived self-competence ($t(155) = -6.90$, p). The interviews showed that the each of the students had one or two constant foci concerning competence in RE teaching throughout their pedagogical training year. All shared subject matter as a focus while the second focus varied between methods and classroom interaction. Generally the perceptions concerning subject-matter shifted from emphasising content-

knowledge to information skills, sense of incompetence concerning methods remained stable while confidence increased concerning classroom interaction and management.

Concluding remarks

In addition, to self-efficacy, future studies concerning RE student teachers should include areas such as professionalism and vocation, and more qualitative changes in the understanding of teacher competence.

SYMPOSIUM

Immoral Behavior: A Result of a Lack of Moral Motivation?

Chairperson: Karin Heinrichs, Goethe-University in Frankfurt, Germany

Organiser: Karin Heinrichs, Goethe-University in Frankfurt, Germany

Fritz Oser, Universität Freiburg, Switzerland

Discussant: Karin Heinrichs, Goethe-University in Frankfurt, Germany

People are getting more and more involved in global communication processes via the internet, email and online-games. We register that in these contexts new kinds of immoral behavior emerge, e.g., cyberbullying, in addition to immoral behavior which is apparent all over the world. In order to prevent immoral behavior and to support moral development, we need deeper insights in how immoral behavior develops and how moral behavior can be fostered. In this symposium we refer to James Rest's (1999) four component model of moral action. The model assumes that moral motivation is one necessary component for acting in a morally adequate manner. To date, a large body of research exists of two Rest's components: moral judgment and moral sensitivity. But we do not know enough about the impact of these components on moral behavior. Additionally the component of moral motivation has been insufficiently elaborated for a long time, but is now becoming the focus of an increasing number of studies. In this symposium the papers represent some of the current approaches to moral motivation. The contributions all (a) focus on the question whether immoral behavior can be explained by a lack of moral motivation; and (b) point out empirical results from both quantitative and qualitative studies. In the general discussion, new ideas about potential ways to foster moral motivation in childhood and adolescence will be presented.

Moral Emotions - Motives For (Im)Moral Behavior?

Eveline Gutzwiller-Helfenfinger, The Institute of Pedagogical Professionalism and School Culture, Switzerland; Brigitte Latzko, University Leipzig, Germany; Luciano Gasser, PH Luzern, Switzerland; Tina Malti, University Toronto, Canada

Schools and teachers are highly relevant for the socialization of the upcoming generation who is responsible for the future global networked society. Facing the bold changes in modern societies due to globalization, educators have to foster children's and adolescents' moral growth to enable them to preserve moral and democratic values in these increasingly diversified societies.

This paper provides an empirical approach to discuss how developmental research on children's and adolescents' moral emotions can help us understand how both immoral and morally relevant behavior evolve. Are moral emotions related to children's moral, prosocial behavior, as well as to their immoral, aggressive behavior? We present three studies that investigate the link between these aspects. Based on the findings we discuss how moral emotions might serve as motives for (im)moral behavior. We argue that studying how moral emotions can serve as motives for (im)moral action tendencies may not only be of conceptual significance to developmental researchers, but also of practical importance to educators.

Facing the bold changes in modern societies in the course of globalization, it is highly relevant for all educators to foster children's and adolescents' moral growth to enable them to preserve moral and democratic values in increasingly diversified societies. Moreover, being able to understand themselves as socially embedded, mutually interdependent (i.e., networked) agents helps students to become more open towards and tolerant of various kinds of "other-ness", for example cultural diversity. Moral learning and understanding encompass far more than just knowing about rules and values. If these rules and values are to become relevant to the self, children and adolescents must attach valence and meaning to them and gain a deeper understanding of what it means to consider other peoples' welfare. Because emotions give meaning and valence to interactions, actions, and events (e.g., Ellsworth & Scherer, 2003) they play a central role in moral learning.

Accordingly this paper provides an empirical approach to discuss how developmental research on children's and adolescents' moral emotions can help us understand how both morally relevant and immoral behaviour evolve. The central question is whether moral emotions are related to children's moral, prosocial behavior, as well as to their immoral, aggressive behaviour. We present three studies investigating the link between moral emotions and eventual (im)moral behaviour. Based on the findings we discuss how moral emotions might serve as motives for (im)moral behavior.

Study 1 investigated the question how moral emotions evolve during the course of childhood by comparing at-risk children's moral emotions and moral judgments with those of children attending an ordinary elementary school. At-risk children differ from "normal" children by having problems with discipline, being more aggressive towards both teachers and classmates, and by behaving immorally and transgressing moral rules. Drawing conceptually on the happy-victimizer-approach, at-risk children were assumed to a) accept moral rule transgression more often; b) attribute positive feelings to the victimizer more often; and c) express less empathy towards the victim than control children. 80 boys aged 9 to 11 were asked to judge moral rule transgressions as well as to attribute emotions to the transgressor and to the victim and to justify these judgements and attributions. Content analysis (Mayring, 2002) was performed (Cohen's $k = .84$). Although no differences were found for rule knowledge, we found notable differences regarding moral reasoning and emotion attributions. At-risk children showed a higher acceptance of rule transgressions and less moral justifications for non-acceptance. With respect to the victim, the at-risk group had difficulties attributing any emotions at all, and more frequently reported to have no idea what harming someone means as compared to control children. The results show that educating moral emotions seems to be as important as educating moral reasoning. Emotional experiences can be meaningfully used as a basis for initiating children's moral learning.

Study 2 investigated the relations between physical and relational aggression and moral knowledge and emotions in a sample of 237 7- and 9-year-old primary school children. Firstly, we expected that physical aggression would be associated with deficits in moral knowledge and moral emotions. Secondly, we hypothesized that relational aggression is negatively associated with moral emotions, but is not associated with moral knowledge. Both relational and physical aggression were assessed by peer nominations and teacher ratings. Moral knowledge was measured by moral judgments and justifications of these judgments', moral emotions were measured by emotion attributions and corresponding justifications. Hierarchical regression analyses revealed that physical aggression was associated with deficits in moral knowledge and moral emotions. Relational aggression, however, was not associated with moral deficits, but with an advanced understanding of moral emotions, suggesting that children with high levels of relational aggression use their advanced understanding of moral emotion for strategic purposes.

Study 3 investigated whether children's moral judgments, emotion attributions, and justifications produced in real-life narratives differ from those generated in hypothetical scenarios. The sample consisted of 190 Swiss kindergarten and primary school children. Based on Wainryb et al.'s (2005) procedure, a narrative of an own interpersonal moral transgression was elicited from each child, followed by a half-standardized interview to probe children's motives, moral judgments, justifications for these judgments, emotions attributed to both themselves (perpetrator) and others (victim), and justifications for the emotions attributed to the self. Children were also presented with two hypothetical scenarios of moral transgressions. They had to morally judge these transgressions, justify their judgments, attribute emotions to both perpetrator and victim, and justify the emotions attributed to the perpetrator. Narratives were content analysed (Cohen's $\kappa = .74$). Results revealed distinct patterns for real-life and hypothetical transgressions: 9-year-old girls attributed more fear to the perpetrator than 9-year old boys in the hypothetical context, whereas no differences were found in the real-life context. Children gave more moral, sanction-oriented, legitimate, hedonistic, and undifferentiated justifications for hypothetical transgressions. Hypothetical transgressions were judged as more severe than real-life transgressions and were given more moral justifications (by older children) and more undifferentiated justifications (by younger children). In contrast, real-life transgressions were more often

presented as justified or legitimate, and moral judgments were more often justified by proposing an alternative strategy.

The data of the three studies indicate that although children understand the validity of moral rules, they do not necessarily understand the emotional consequences of following or breaking them. This is especially true for at-risk and physically aggressive children. Accordingly, we argue that immoral conduct is, in part, related to this deficit regarding moral emotions. Therefore it is important to systematically introduce a wide range of moral emotions into educational practice. Studying how moral emotions can serve as motives for (im)moral action tendencies is not only conceptually significant to developmental researchers, but also of practical importance to educators, in particular to teachers. Before establishing educational programs on moral learning in school settings we need to know more about the underlying developmental mechanisms. By studying specific real-life conflict situations and the emotions invoked in the child, teachers can help inculcate sociomoral sensitivity. Sensitizing educators to the variety of interventions they can use in specific situations is a key to stimulating children's moral growth.

Juvenile Delinquency: Lack of Moral Motivation or Moral Ambivalence?

Stefan Weyers, Institut für Erziehungswissenschaft, Germany

Initially, this presentation deals with approaches to moral motivation and to denial of responsibility. Subsequently, it examines 30 imprisoned delinquents, examining their moral judgment, moral orientations and biographical self-interpretations. The findings show that many delinquents have an ambivalent attitude toward moral norms. Six different types of biographical self-presentation could be identified, that represent different moral perspectives concerning themselves and their offences and different structures of motivation. It is argued that the actual process of maintaining moral identity is more important than the moral-cognitive structure with respect to delinquency and its retrospective interpretation. All in all, juvenile delinquency seems to relate more to an ambivalent moral motivation than to a lack of moral sense. However, the findings clearly indicate that the subjects differ strongly from one another with regard to important dimensions of moral development. These different developmental conditions must also be taken into account in social work with juvenile delinquents. Finally, some educational implications of the study are discussed. For example, the results imply that purely cognitive approaches of moral education have only a limited impact.

Aims:

Delinquency is often attributed to moral deficits. However, the relationship between morality and delinquency is still unclear and is intensely debated. Depending on the point of view, relevant factors can include a lack of moral sense, a sub-cultural system of norms, an alternative identity or strategies for denial of responsibility (Cohen 1955; Emler 1984; Shields/Whitehall 1994). In contrast, Kohlberg (1978) hypothesized that juvenile offenders have strong developmental delays and that their moral judgment is predominantly at low moral stages 1 and 2. These assumptions are used as the basis for programmes to facilitate moral judgment in penal institutions. In this contribution, an alternative moral-theoretical interpretation of delinquency is depicted, which focuses instead on the moral motivation and the biography of the subjects. The empirical basis is a study of detained juvenile delinquents. It examines their moral judgments, moral orientations and biographical reconstructions of their offences. The results should contribute to an empirical basis for theories of moral development and socialization, and of educational interventions.

Methodology:

The sample consisted of 30 randomly selected male inmates of a German juvenile detention centre, between 16 and 23 years of age. The subjects mainly committed more serious offences – including murder, robbery and assault - and were given sentences ranging from 1.5 to 8 years. A wide empirical analysis included cognitive as well as motivational moral aspects. Additionally, the way how the subjects reconstructed their own biographies and offences were taken into account, because the retrospective reaction to the own immoral behaviour is an important indicator of the moral self (Blasi 1993). The moral level was assessed using Kohlberg's "Moral Judgment Interview" and evaluated with the "Standard Issue Scoring". The biographical self-presentation and reconstruction of the offences were obtained using biographical interviews for data collection. Interpretative methods of biography research were applied for analysis. The biographical descriptions were also compared with the factual reconstructions as exposed in the official court documents.

Findings:

The findings contradict Kohlberg's assumption that juvenile offenders' moral judgment is predominantly at the low moral stages. A relationship between moral stage and the seriousness of the offence could also not be found.

However, the results show a connection between the "moral type", which encompasses motivational orientation to a greater extent, and the seriousness of the offence (Weyers 2004).

The results of the biographical interviews indicate that many delin[®]quents have an ambivalent attitude towards moral norms. The subjects strongly differ from one another with respect to their biographical self-presentations and to their reconstructions of their own offences: Six types, representing different moral perspectives on themselves and their actions, could be identified. The presentation introduces the six types: the "remorseful sinner", the "victim", the "hero", the "stupid boy", the "new adult" and the "criminal deviant". Moreover, the interviews suggest that moral development can play an important role for biographical changing with regard to delinquency. All in all, juvenile delinquency seems to relate more to an ambivalent moral motivation than to a lack of moral sense.

Theoretical significance:

The findings are discussed, with emphasis on the ambivalent attitude of many delin[®]quents towards moral norms. It is argued that processes of maintaining moral identity are more important than moral-cognitive structures with respect to delinquency and its retrospective interpretation (Blasi 1993): moral knowledge is learned early, but the development of moral self-obligation is a separate process, which is completed more or less (Nunner-Winkler 1993). The deciding factor is how comprehensively moral standards are established. Interacting with other persons makes people learn that moral standards are valid, but they also recognize that moral standards are ignored in many contexts. When children are exposed to a strong discrepancy between the need for moral standards and their application it becomes increasingly difficult to establish stable moral standards. The consequence is an ambivalent attitude: standards are generally accepted, but they are only applicable in certain contexts. In other situations, violations of these standards are considered acceptable and do not endanger self-perception. The biographical interviews indicate that the majority of subjects consider their offences as wrong, but not as badly wrong. Many crimes are not even perceived as morally relevant. This goes hand in hand with the use of strategies of neutralization to resist moral obligations and with creating a consistency between actions and self-perception.

Educational significance:

The results imply that purely cognitive approaches of moral education have a limited impact. Methods for facilitating moral development in penal insti[®]tutions have to take into account the motivational dimension of morality and the coping strategies with regard to criminal actions. The findings indicate that the subjects differ strongly from one another. These differing conditions of moral development must be taken into consideration in social work with juvenile delinquents. The biographical interviews also indicate that moral development can play an important role in modifying the self-biography. When working with juveniles who describe their delinquency in terms of the "remorseful sinner" or "new adult" types, there is a chance to influence the self-biographical changes positively. With the "hero", "victim" or "criminal deviant" types however, more substantial psycho-social measures are required to avoid further embedding of the delinquent behaviour and orientation.

Self-centeredness as Drive Towards Antisocial Behavior

Daniel Brugman, utrecht university, Netherlands

Several theories that aim to explain the origin, development, and maintenance of antisocial behavior stress the importance of self-serving cognitive distortions (SSCDs). SSCDs are deficiencies in the interpretation of social events that enhance antisocial behavior. Primary SSCDs are self-centered attitudes and beliefs that may drive individuals towards antisocial behavior. Secondary SSCDs are pre- or posttransgression rationalizations that serve to neutralize

conscience, potential empathy, and guilt, and thereby prevent damage to the self-image when an individual engages in antisocial behavior. The prevalence of SSCDs in adolescents is related to gender, educational level, ethnic background, and delinquency. Results of a MTMM study are presented that show an increase in the amount of explained variance in antisocial behavior by SSCDs. Moreover findings of SSCDs in children (aged 7 to 12 years) are presented. Possibilities for prevention in school programs are discussed.

SYMPOSIUM

Classroom Assessment and Feedback as Tools to Foster Learning in Mathematics and Science Education

Chairperson: Katrin Rakoczy, German Institute for International Educational Res, Germany

Organiser: Katrin Rakoczy, German Institute for International Educational Res, Germany

Birgit Harks, German Institute for International Educational Research, Germany

Discussant: Peter Tymms, University of Durham, United Kingdom

Assessment of student competencies is an essential component of instruction. Particularly formative assessment turned out to be important because there is strong evidence that it has the potential to support student learning. Formative assessment implies competence diagnostics and competence feedback as two central elements. It should be designed to inform students about their strengths and weaknesses and how they should continue in order to reach their learning goals. In spite of the consensus on the importance of formative assessment in the scientific context, practices of formative assessment are rarely realized in everyday instruction. Taking this contrast into consideration the symposium tries to clarify the preconditions for formative assessment and investigates how formative assessment impacts student learning. In detail, the first contribution (Taut) analyses the preconditions for formative assessment in policy and teacher practice at the example of Chile. The second paper (Rakoczy et al.) examines the impact of written teacher feedback on motivation and achievement development. And the third contribution (Gan) takes a closer look at peer feedback. It investigates how the coaching of students influences students in providing each other with feedback. The symposium contributes to the understanding of how teachers and students can be supported in providing learners with helpful feedback, finally clearing the way for a more frequent and more appropriate implementation of formative assessment practices in school.

Classroom assessment in Chile: A diagnosis of policies and practices

Sandy Taut, P. Universidad Catolica de Chile, Chile; Daniela Jimenez, German Institute for International Educational Research, Germany

This study addresses classroom assessment policies and practices in Chile. The paper explores the policy context related to classroom assessment and describes assessment practices in math and science classrooms using data from (a) teacher surveys that are part of the national student achievement testing system (SIMCE), (b) the national teacher performance assessment system, and (c) the Third International Math and Science Study (TIMSS). Preliminary findings suggest that policies as well as teaching practices focus mainly on summative assessment, with the exception that the official teaching standards explicitly demand a formative use of classroom assessment. The teacher performance assessment data show that assessment skills are consistently among the weakest performance areas, both regarding the quality of the assessment instruments and the use of these assessments for teaching and learning. SIMCE survey data indicate that math and science teachers' assessments are mostly graded written exams delivered at the end of (but not at the beginning or during) a learning cycle, and that these exams often consist of a mix of constructed-response and multiple-choice items. TIMSS responses are similar, although here teachers report somewhat more use of constructed-response-only exams in math, but not in science, where assessment formats differ substantially from the TIMSS international average.

Significance for research and policy

Student assessment is an important part of what teachers do in the classroom. Particularly formative assessment plays an important role because there is strong evidence of its potential to support student learning (Black & Wiliam, 1998; Marzano, Pickering & Pollock, 2001; Wiliam, Lee, Harrison & Black, 2004). An OECD review of Chile's education system stated that classroom assessment was particularly weak (OECD, 2004) and another recent review of the education assessment system calls for more research on the topic (Ramirez, 2010). This paper responds to the need to fill the research void regarding classroom assessment policies and practices in Chile. Findings will inform a future research agenda and help policy-makers understand the needs in this area.

Aims and research questions

The aims of this study are to analyze educational policies relevant to classroom assessment (CA) and to learn more about teachers' actual CA practices and competencies in Chile:

1. What does the CA policy context look like, particularly regarding formative assessment?

2. What CA practices in math and science do teachers report?
3. What are math and science teachers' CA competencies?
4. How do these practices and policies relate to research-based best practices and successful implementation policies internationally?

Contextual background

For this study an important first step is analyzing relevant policy approaches related to CA in Chile. For example, we found that legislative documents focus on summative assessment, leaving the main responsibility for defining assessment practice in more detail in the hands of each school (MINEDUC, 1997, 1999, 2001, 2003) but so far we do not know what these local definitions actually look like. In the guidelines on effective teaching (MINEDUC, 2004), which are the basis for the national teacher performance assessment system, classroom assessment is mentioned by three specific criteria, one of which focuses on summative purposes (A.5) while the other two require formative assessment strategies and uses (C.6 & D.1). The paper will provide more detailed information on the following issues: (a) leadership, tools, and exemplars, (b) innovative programs, (c) teacher initial training and professional development, (d) alignment of summative and formative approaches at different levels of the system (see OECD, 2005).

Research methods

We descriptively analyze relevant items from existing educational databases:

- a) teacher survey from national student achievement testing system (SIMCE) 2008 10th grade math and 2007 8th grade math and natural science;
- b) TIMSS 2003 8th grade math and science teacher survey for Chile;
- c) national teacher performance assessment, 2006 – 2009.

SIMCE tests all students of the country in 4th, 8th and 10th grade in language, math, social science and natural science. TIMSS covered a representative sample of 8th grade students in math and natural science. The national teacher performance assessment provides data for all public school teachers in the country.

Additionally, the study includes document reviews, and interviews with a small purposive sample of professionals in charge of curricular decisions in initial teacher training programs (N=3), professionals at the Ministry of Education (N=3), and municipal education authorities (N=3).

Preliminary empirical results

SIMCE teacher survey

- Most common assessment procedure are traditional written exams, especially those using a mix of question formats (e.g., constructed-response and multiple-choice items);
- most teachers apply graded written exams at the end of a teaching unit, but only occasionally use graded and non-graded exams as diagnostic tools at the start or during the implementation of a teaching unit.

Further analyses will explore the correlations between assessment practices on the one hand, and student achievement on the other hand.

TIMSS teacher survey

- Similar to the international average, the majority of Chilean 8th grade math teachers report using exams containing only or mostly constructed-response items (corresponding to 55% of tested students);
- large majority of Chilean science teachers (corresponding to 71% of tested students) use tests containing about half constructed-response and half multiple-choice items, while internationally this type of test is used by 60%.
- Science tests containing only constructed-response questions are used less frequently (13% - compared to the international average of 28%).

Further analyses will look at the contents covered by Chilean math and science assessments, as well as the relationship with TIMSS student achievement.

National teacher performance assessment

- Eight dimensions of teaching performance are assessed by the assessment's portfolio instrument;
- two of them have to do with CA: (C) "Quality of the teaching unit's assessment"; (D) "Reflection on classroom assessment results;"
- evaluation scale: 1=unsatisfactory, 2=basic, 3=competent (expected performance described by the standards), and 4=outstanding;
- using data from 2006-2009, these two dimensions consistently among the three dimensions with lowest results, that is, fluctuating between 1.7 and 2.1 (total N=56 323);
- cross-tabulation by subject matter: overall, math and science teachers do not differ from teachers of other subjects regarding CA skills.

Further analyses will consider information at indicator level, as well as correlations with overall performance and the relationship with teacher characteristics.

The Impact of Process-Oriented Feedback on Motivation and Achievement in Mathematics

Katrin Rakoczy, German Institute for International Educational Res, Germany; Birgit Harks, German Institute for International Educational Research, Germany; Anika Buergermeister, DIPF, Germany; Eckhard Klieme, Deutsches Institut fur Intern. Padagogische Forschung, Germany

Feedback theories as well as self-determination theory provide empirical evidence that feedback which contains information how the discrepancy between current and desired understanding can be reduced (process-oriented feedback) has a positive impact on motivation and achievement development. In the present study we want to take a closer look at how and under which conditions these positive effects come about by investigating three research questions: 1) Do students experience process-oriented feedback as more useful and competence supportive as social comparative feedback which is the most frequent version of feedback in everyday instruction? 2) Does the positive experience depend on the goal orientation? 3) Does the process-oriented feedback show an indirect effect on achievement development via the experience of usefulness and self-efficacy (a) and an indirect effect on motivation via the perceived competence support and interest (b)?

To test our research questions a one factor experiment was conducted with 146 ninth grade students in Germany. Students were assigned to either process-oriented or social comparative feedback. The other variables were assessed by questionnaires or achievement tests.

Results of path analyses confirm that process-oriented feedback is experienced as more useful and competence supportive compared to social comparative feedback (1). They also show the expected moderation effect for the experienced usefulness but not for the perceived competence support (2). Finally, our results show that process oriented feedback has an indirect effect on achievement via usefulness, but not via self-efficacy (3a) and an indirect effect on motivation via competence support and interest (3b).

Theoretical Background

For formative assessment to unfold its positive impact on student learning it is essential that feedback is designed theoretically well-founded. Feedback theories (e.g. Hattie & Timperley, 2007) as well as self-determination theory (e.g. Ryan & Deci, 2002) provide criteria how feedback should be designed to foster achievement and motivation. Hattie and Timperley distinguish four levels on which feedback can operate: the level of a) task performance, b) process of understanding, c) the regulatory or metacognitive process level, and d) the self level. Feedback has differing effects across these levels. Feedback on the levels of task performance and process of understanding (referred to as process-oriented feedback in the following) contains information how the discrepancy between current and desired understanding can be reduced. There is much empirical evidence that this kind of feedback is experienced as particularly useful by the learners to reach their learning goal and that it shows a positive impact on achievement development, as well. To describe „useful“ in more detail and to understand how the impact of feedback on achievement via the experience of usefulness comes about we refer to the construct of behavioural adaptivity investigated by Dresel and Ziegler (2007). They prove a positive impact of behavioural adaptivity after failure on future achievement as well as a positive relationship with self-efficacy.

Scholars in the context of self-determination theory assume that feedback is particularly supportive for motivation and achievement development when it supports the need for competence. The support of the need for competence,

in turn, was shown to lead to a higher interest in the learning activity (e.g. Krapp, 1999) and to a higher level of intrinsic motivation (Sansone, 1986). An interested learning activity, again, is accompanied with positive emotional experience, including intrinsic motivation. However, the assumed indirect effect of feedback on motivation and achievement via the support of the need for competence is rarely empirically tested (Deci, Koestner & Ryan, 1999). Several studies revealed that feedback impacts learning differently depending on specific preconditions of the learners. According to Butler & Winne (1995) goal orientation is an important precondition for the impact of feedback. They summarise that feedback which focuses on the individual learning process is particularly beneficial for students with a learning goal orientation.

Aim and Research Questions

With the present study we want to better understand how and under which conditions process-oriented feedback has a positive impact on motivation and achievement development by investigating three research questions: 1) Do students experience process-oriented feedback as more useful and supportive with regard to the need for competence as social comparative feedback which is the most frequent version of feedback in everyday instruction? 2) Does the positive experience of process-oriented feedback compared to social comparative feedback depend on the goal orientation? 3) Does process-oriented feedback show an indirect effect on achievement development via the experience of usefulness and self-efficacy (a) and an indirect effect on motivation via the perceived support of the need for competence and interest (b)?

Methods

To test our research questions a one factor, bivariate experiment was conducted with 146 ninth grade students of the intermediate school track in Germany. Students were assigned to two feedback conditions and tested individually according to the following procedure. First of all, the students were asked in a questionnaire about their goal orientation. Then, the students worked on a mathematics test on Pythagorean Theorem, Linear Equations or problems of the German national standards. Third, they received a written feedback on their test performance which was process-oriented in the experimental group and social comparative in the comparison group. Fourth, the students filled in a questionnaire in which we asked them how useful and supportive with regard to the need for competence they experienced the feedback. Moreover, the questionnaire contained items to examine students' self-efficacy and interest with regard to a second mathematics test. Finally, students worked on the second mathematics test on the same topic and filled in a questionnaire on their intrinsic motivation.

Findings & Conclusion

Results of path analyses confirm that process-oriented feedback is experienced as more useful and supportive with regard to the need for competence compared to social comparative feedback (1). The results also show that process-oriented feedback is experienced as particularly useful by students with a high learning goal orientation. Against our expectation this moderation effect could not be shown for the perceived support of competence (2). Finally, our results show that process oriented feedback has an indirect effect on achievement via the experience of usefulness, but not via self-efficacy (3a) and an indirect effect on motivation via competence support and interest (3b).

In summary, it can be stated that process oriented feedback is experienced as useful and supportive with regard to the need for competence and this positive experience leads at least partly to a better achievement and higher motivation in a second mathematics test. So, process-oriented feedback seems to be a promising tool for teachers to implement formative assessment in mathematics instruction.

Peer feedback in chemistry: Supporting cognitive and meta-cognitive engagement during investigations

Mark Gan, University of Auckland, New Zealand

A central tenet of 'assessment for learning' and peer assessment is the need for effective peer feedback (Black & Wiliam, 1998; Dochy et al., 1999; Topping, 1998). While most researchers and educators recognise the crucial role that peer feedback plays in learning, there are fewer consensuses on how best to support that role within the classroom. This study focuses on developing students' ability to engage with peer feedback by explicitly coaching them to recognise the learning gap and how to formulate progressive peer feedback to help their classmates to 'close' the gap and move towards the learning goal. In particular, a graphic organiser was designed based on feedback levels (Hattie & Timperley, 2007) that guide students in generating peer feedback at the task, process and meta-cognitive levels of engagement. Eight classes of students ($n=332$, 14-15 year olds) from four Singapore secondary schools participated in this study. Students in the experimental group received instruction on feedback levels and practice giving written feedback on crafted laboratory reports with the help of a graphic organiser. Students in the control group spent the same amount of lesson time on a lecture about how to carry out an investigation. The results indicated that explicit coaching facilitated the formulation of more task, process and meta-cognitive ($d > .80$) peer feedback compared to the control class. This study supports the view that helping students to visualise peer feedback as progressive, involving task, process and meta-cognitive levels, facilitates cognitive and meta-cognitive engagement with the learning task.

Background:

This study develops the notion of peer feedback quality by building on two interconnecting perspectives that underpin feedback research in the classroom. One view of peer feedback quality suggests that feedback information is useful when it helps learners to close the learning gap (Ramaprasad, 1983; Sadler, 1998). Viewing feedback through this lens has helped to identify the shortcomings of feedback interaction, often construed as a passive receptive-transmissive approach. Another perspective on peer feedback quality builds on the notion of reducing the 'discrepancies between current understanding and performance' by focusing on the learner's engagement with the feedback information at the task, process, meta-cognitive and self levels (Hattie & Timperley, 2007). In this feedback model, interventions involving feedback are likely to be more effective when the learner's attention is drawn to cognitive outcomes related to the task, task processing strategies and the meta-cognitive strategies adopted, rather than focusing on the self. Both perspectives helped to frame the notion of peer feedback quality as involving progressive feedback information targeted at the task, process and meta-cognitive levels. By suggesting a progressive view of feedback, this study suggests a shift in focus on feedback interaction from recognising a learning gap and finding corrective solutions, to supporting one in which the learning gap is seen as an opportunity for the learner to interact with feedback information at different levels of cognitive engagement.

Besides developing peer feedback quality, this study argues for the positioning of peers as a resource for feedback interaction during chemistry investigative tasks. Instead of teachers providing students with the answers to their queries, students can help each other by formulating feedback that focused on improving their investigation. Here, the involvements of peers, who are classmates of the same age group, are seen as important for three reasons. First, peers serve as a rich and available resource for giving and receiving feedback. Feedback from peers can be more immediate, timely, and individualised than teacher feedback (Topping, 2010). Second, engendering peer feedback will mean that students have the opportunity for collaborative peer discourse. Students not only learn with each other but also from each other as well as from the feedback process. Third, the involvement of students suggests that students have the potential to be responsible for their own learning and peer feedback provides an avenue to do so.

Aim:

The aim of the present research was to examine the effects of explicit coaching on students' ability to generate peer feedback at the task, process and meta-cognitive levels of engagement.

Samples:

In this study, eight classes of students (14-15 year olds, $n=332$) from four secondary schools in Singapore participated. All students were in their first year of a two year Chemistry course, leading to GCE 'O' level certification.

Method:

This study adopted a quasi-experimental pretest-treatment-posttest design. There were two conditions: peer feedback with coaching condition and peer feedback without coaching. In both conditions, students were provided with a feedback form with question prompts. Students in the coaching condition received explicit instruction on the different feedback levels (task, process and meta-cognitive) and practise using a graphic organiser (designed with feedback levels) to formulate peer feedback on chemistry investigation reports. Students in the control group were given a

lecture on the design of investigation and practise using the feedback form to give feedback on a crafted task without a graphic organiser. The coaching was carried out by the researcher over two lessons, with each lesson lasting 50 minutes.

Results:

A closer look at the effect size of individual classes showed that for all the treatment classes, there is a large effect of coaching on students providing more meta-cognitive level feedback to their peers ($d > .80$). This is not observed in the control class, which showed a low effect for all three feedback levels

Conclusions:

This finding indicates that instructional intervention which engages students to recognise and differentiate feedback at task, process and meta-cognitive levels, provides opportunities for students to practice and interpret different feedback levels. This enhances students' ability to generate higher-order peer feedback which enables them to engage more deeply with the learning task. The significance of this study can be attributed to the following three aspects:

1. Building on a theory of feedback in relation to task, process and meta-cognition to develop instructional support for peer feedback during investigations;
2. providing further evidence that coaching is a pre-requisite for students to provide quality peer feedback responses; and,
3. developing a coding scheme to characterise the quality of peer feedback in terms of levels.

Implications:

First, the notion of peer learning through the use of peer feedback does not usually occur without instructional support of some kind. The findings of this study showed that instructional support in the form of a visual graphic organiser with explicit examples may enhance the learning experience of students in formulating feedback to their peers. The graphic organiser provides a common platform for teachers and students to engage in discussing how each feedback level can be formulated, the relation to other levels and the matching of levels (as well as challenge) to the receiver's understanding or response.

Second, conceptualising feedback in terms of levels (task, process and meta-cognitive) provides teachers as well as students with a working definition of what feedback looks like and how it can be interpreted and applied to learning.

Third, the practice of giving and receiving peer feedback at different levels opens up opportunities for formative assessment discourse in the classroom, especially in building students' (as well as teachers) capacity for assessment by drawing attention to evaluating criteria, reviewing learning goals and communicating meaningful feedback.

SYMPOSIUM

Procedural learning, strategy use, and conceptual understanding

Chairperson: Kristina Reiss, Technische Universität München, Germany

Organiser: Kristina Reiss, Technische Universität München, Germany

Discussant: Erno Lehtinen, University of Turku, Finland

Children's experiences with early mathematics have an important impact on their subsequent learning. Research suggests in particular that approving children's spontaneous strategies and independent activities is an important prerequisite for successful learning processes. The symposium aims at sharing knowledge in this field of research. It focuses on the development of mathematical competencies in primary school children from a point of view that takes their individual dispositions into account. Using the examples of basic arithmetics, probability, and early algebra, the contributors will present research how children adopt spontaneous strategies, how their strategy choice differs according to a more mathematical or a more everyday context as well as according to their age and characteristics of the tasks and how they take advantage of self-explaining activities in their learning. These questions will be addressed from an interdisciplinary perspective that regards subject matter education as well as pedagogical and developmental psychology. Accordingly, the symposium contributes to scientific knowledge by analyzing and discussing qualitative and quantitative empirical data of second to sixth graders' mathematical competencies under these different

perspectives. Moreover, the results can be interpreted in terms of their relevance for learning and instruction at school and will be discussed with a specific view on the primary mathematics classroom.

Do children use the indirect addition strategy in the number domain up to 20?

Greet Peters, K.U.Leuven, Belgium; Bert De Smedt, University of Leuven, Belgium; Joke Torbeyns, K.U.Leuven & GROUPE T - Leuven University College, Belgium; Pol Ghesquiere, Katholieke Universiteit Leuven, Belgium; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

Mentally solving subtraction problems can be done by means of various strategies, including the indirect addition strategy, in which the subject determines how much needs to be added to the smaller number to get to the larger one. In most of the previous research focussing on indirect addition children were asked to verbally report the strategy they used to solve a problem. However, it could be argued that such verbal protocol data may be less suited to identify indirect addition, because this strategy is typically executed very fast and (quasi) automatic. Therefore, we investigated children's use of indirect addition by means of reaction time analyses. We presented 106 third- to sixth-graders with 32 large non-tie single-digit problems in both subtraction ($12 - 9 = ?$) and addition format ($9 + ? = 12$). For both formats, we examined the fit of 3 regression models, which represented the consistent use of direct subtraction, the consistent use of indirect addition, and the flexible switching between both strategies based on the relative size of the subtrahend. Findings revealed that, in all grades, children did not switch flexibly between the two strategies, as adults do, but that they rely on direct subtraction for problems presented in subtraction format and on indirect addition for problems in addition format. We end with some theoretical, methodological, and educational implications of these results.

Various strategies can be used to mentally solve subtraction problems, including the indirect addition strategy, in which the subject determines how much needs to be added to the smaller number to get to the larger one (e.g., solving $11 - 7$ by doing $7 + 3 = 10$ and $10 + 1 = 11$, so the answer is $3 + 1 = 4$). This strategy can be distinguished from direct subtraction, in which the smaller number is directly subtracted from the larger one (e.g., $11 - 7$ via $11 - [1 + 6] = 10 - 6 = 4$). A rational task analysis indicates that indirect addition is particularly efficient on subtractions with relatively large subtrahends, whereas direct subtraction is more efficient when the subtrahend is relatively small (compare $11 - 9$ and $11 - 2$). Peters et al. (2010a) recently studied if adults choose flexibly between indirect addition and direct subtraction based on the size of the subtrahend when solving large single-digit subtractions. When the distance between subtrahend and difference was large (as in $12 - 3$ or $12 - 9$), indirect addition was used when the subtrahend was larger than the difference, whereas direct subtraction was used when the subtrahend was smaller than the difference. However, when the subtrahend and the difference were close to each other (as in $12 - 5$ or $12 - 7$), strategy selection was not based on the size of the subtrahend and both strategies were used to the same extent. Remarkably, there is hardly any research concerning children's use of indirect addition on large single-digit subtraction problems. The variation and flexibility in children's strategy use have been more intensively investigated in multi-digit subtraction problems (Torbeyns et al., 2009). However, in the majority of these studies, verbal self-reports have been used to infer strategy use, and it could be argued that such data may be less suited to identify indirect addition, because this strategy is typically executed very fast and (quasi) automatic (Kirk & Ashcraft, 2001). When solving a problem such as $12 - 9$, children may be unaware of the calculation steps they executed, they may experience difficulties in articulating how they found the answer, or they may even hide their actual strategy use because they think it is not valued or allowed. In this respect, we refer to a remarkable result of a post-hoc analysis of a study by De Smedt et al. (2010) on two-digit subtractions, which revealed that children's verbal protocol data did not reliably capture the actually applied strategies. More specifically, this analysis indicated that the indirect addition strategy might have been used more frequently than suggested by the verbal protocols. This justifies the application of other, non-verbal, methods to infer strategy use.

We adopted the regression-based approach that Groen and Poll (1973) and Woods et al. (1975) used in the number domain up to 10 – a method that we have already successfully applied for analysing adult's strategy use on two-digit subtractions (Peters et al., 2010b). We presented 106 third- to sixth-graders with 32 large non-tie single-digit problems in both subtraction ($12 - 9 = ?$) and addition format ($9 + ? = 12$), and examined the fit of three linear regression models, which represented different strategy patterns: 1. If children only used direct subtraction (Model_1), their reaction times should be best predicted by the size of the subtrahend, because it takes longer to subtract 9 from a given number than to subtract 3 from that number. 2. If they consistently used indirect addition (Model_2), their reaction times should be best predicted by the size of the difference, because it takes longer to determine how much needs to be added to get at a given number when the difference between both numbers is large than when it is small (compare how much needs to be added to 3 or to 9 to get to 12). 3. If children switched flexibly between both strategies depending on efficiency (Model_3), reaction times should be best predicted by the minimum of subtrahend and difference: Short reaction times are then expected for problems with a small subtrahend

($12-3=?$) because they are quickly solved by direct subtraction, as well as for problems with a small difference ($12-9=?$) because they can be quickly solved by indirect addition. All regression models were fitted to the mean reaction time of each problem per grade.

Findings revealed that, in all grades, Model_1 fitted best to the reaction times of problems in subtraction format, whereas Model_2 fitted best for the problems in addition format (see Table_1). These results indicate that children did not switch flexibly between the two strategies, as adults did (Peters et al., 2010a). Instead, they show that children relied on direct subtraction for problems presented in subtraction format and on indirect addition for problems in addition format. These findings can be of great relevance for elementary mathematics education, since they show that (a) indirect addition is part of children's spontaneous strategy repertoire when solving subtractions presented in addition format, and (b) children's strategy choices for subtraction are determined more by structural than by numerical task features.

The impact of self-explaining and example-generation on learning similar concepts in mathematics

Esther Ziegler, ETH Zurich, Switzerland; Elsbeth Stern, ETH Zurich, Switzerland

An active engagement of students can be seen as an important parameter in learning processes. Such activation can be evoked through various methods, among them the instruction to self-explain given examples or to generate one's own examples. In the current study, we examined the potential of self-explanations and example-generation in a school setting by conducting a training study with a self-learning program on addition and multiplication in algebra. The learning program consisted of worked algebra examples, a self-study part, and tests. A total of 153 sixth-graders (mean age = 12.3) were randomly assigned to two training conditions: (1) the self-explaining condition with a small number of generated examples and (2) the example-generation condition without self-explanations but with an extended generation of examples. In three post-tests (one day, one week and ten weeks later) procedural and conceptual knowledge, including misconceptions, were assessed.

In accordance with our hypotheses, the results showed a significant advantage of the self-explaining group in procedural knowledge. The impact of self explanations on conceptual knowledge was ambiguous: on the one hand the self-explainers showed a reduced amount of misconceptions, on the other hand they performed worse in tests on conceptual knowledge than the example-generators did. The fact that they have many misconceptions may indicate that they do not possess better conceptual knowledge, but that their training focus on examples helped them to formulate the concept rules. Summarized, the self-explaining training fostered students' performance in algebra best. Further investigations have to show where this advantage exactly comes from.

In mathematics classes, teachers often introduce concepts by first demonstrating how to solve a particular problem (e.g. $xy+xy+xy=3xy$) and then ask their students to solve a certain amount of similar tasks. The major problem of this kind of instruction is that students just memorize procedures but do not possess a deeper conceptual understanding (Kamii & Dominick, 1997). This often becomes obvious when students inappropriately apply the strategies to similarly looking problems (e.g. $xy?xy?xy=3xy$). According to a constructivist view of learning, knowledge cannot be directly transmitted from teachers to learners, but rather has to be constructed by the learner on the basis of the already existing knowledge (Bransford, Brown, & Cocking, 1999). Hence, in order to foster the acquisition of conceptual knowledge, learning environments have to prompt active cognitive engagement, which can be evoked through various methods. In our study on understanding addition and subtraction in algebra, we want to investigate the effects of two

established methods: (a) the instruction to self-explain examples (Renkl, 1997; Rittle-Johnson, 2006), and (b) the instruction to generate own examples (Hazzan & Zazkis, 1999; Watson & Mason, 2002). Both learning techniques demand attention and effort and help students to engage in active elaboration of learning materials.

A pilot study, in which we tested a learning program which applied both of these learning strategies, revealed that students who preferred the example-generation part and wrote only minimalist self-explanations showed comparable learning outcomes. Thus, the aim of this study was to differentiate between the contribution of the self-explanation and the example-generation part. We used the existing learning program and constructed an additional condition without self-explanations but with an extended example-generation part. The hypothesis remained: The combination of self-explaining with a small example-generation part helps students more than an extended example-generation.

Method

The self-learning program introduced two mathematical concepts: addition and multiplication in algebra. The programs were processed in 2-hour learning sessions on four successive days and students had to work through 9 self-study work sheets. These sheets consisted of worked examples and a self-study part. After every sheet students did a test as an indicator for immediate learning. A total of 153 sixth graders (mean age= 12.3 years, 52.1% girls) participated and were randomly assigned to one of two training conditions: (1) the self-explaining condition and (2) the example-generating condition. In the self-explaining instruction, students were asked to self-explain worked examples and to generate a small number of their own examples. In the example-generating instruction, students were asked to generate an extended amount of their own examples. Besides this, learning materials were identical.

All students participated in three post-tests (one day, one week and ten weeks later) where we measured procedural knowledge, conceptual knowledge and misconceptions as indicators for long-term learning. In addition, we analyzed conceptual knowledge for the number of defining features students reported in their written explanations. We conducted two successive experiments with different participants and with an adapted post-test instruction: "control all tasks before submitting them".

Results

As the main effect of group was similar in both experiments, with only slightly different significant levels, we merged the two experiments into one evaluation.

There were no group differences in the learning tests, indicating that immediate learning was equal in both conditions. For all the post-test measures, we used repeated measurement ANOVAs with the factor Group (self-explaining versus example-generating) x Time (T1: one day, T2: one week, T3: ten weeks). There was a main effect of Group for procedural knowledge (pDiscussionAs expected, the results suggest that self-explanations help to gain procedural knowledge and to reduce misconceptions. The result concerning conceptual knowledge is ambiguous: the overall conceptual knowledge was higher in the example-generating group, although they had significantly more misconceptions. The fact of high misconceptions in example-generating learners may indicate that they do not have better conceptual knowledge, but that their training focus on examples helped them to formulate the concept rules which they could explicitly illustrate with examples. Further evidence comes from the sub-analyses which showed that there was no difference in reporting defining features in the written concept explanations. In addition, the effect of better conceptual knowledge had disappeared ten weeks later. Interestingly, the self-explaining group performed only better in the post-tests but not in the immediate learning tests. As there is no hint of the self-explaining effect in the learning phase, one can imagine that teachers may fail to notice the advantage of self-explanations. Summarized, the self-explanation training fostered students' performance in algebra best. However, as the self-explainers also generated a few of their own examples, it would be interesting to investigate whether self-explanations work without any example-generation. Hence, future research has to differentiate under which conditions self-explanations bring the best learning benefit.

Children's probability concepts and intuitive strategy use in the evaluation of contingency tables

Petra Barchfeld, Ludwig Maximilians University-Munich, Germany; Anke Lindmeier, Technische Universität München, Germany; Stefan Ufer, University of Munich, Germany; Kristina Reiss, Technische Universität München, Germany; Beate Sodian, LMU München, Germany

The ability to evaluate covariation data is not explicitly addressed in the elementary school curriculum. Although even preschool children can infer causation from perfect covariation between two variables, deficits in reasoning from more complex patterns of imperfect covariation persist into adulthood. In the present study, we address the early development of statistical reasoning abilities in elementary school. A series of 2 x 2 contingency tables were presented to children of the grades 2, 4, and 6 in two context conditions. The results show that children prefer inadequate maximum strategies and additive comparisons between two cells of the tables in both contexts. A failure to understand basic probability concepts was also confirmed by the results of a second study, designed after Shtulman and Carey (2007), indicating context-independent difficulties to differentiate between improbable and impossible events in children up to grade 4. Findings are discussed with respect to the development of basic stochastic knowledge and its relevance in elementary school mathematics education.

The ability to evaluate covariation data is an important aspect of stochastic reasoning. However, it is not explicitly addressed in elementary school curriculum. Data evaluation skills are also necessary for a basic understanding of the theory-evidence relation in science (Kuhn & Franklin, 2006). Even preschool children can interpret perfect covariation patterns (Ruffman, Perner, Olson, & Doherty, 1993; Koerber, Sodian, Thoermer & Nett, 2005). On the other hand, pervasive deficits have been found in children and adults for more complex tasks requiring intuitive statistical reasoning (e.g., Shaklee, Holt, Elk, & Hall, 1988). However, little research has addressed the early development of contingency table analysis in elementary school age. The present research aims at analyzing the initial competencies in statistical reasoning of elementary school children in some depth and relating it to the development of probability concepts. In Study 1, we examined the analysis of 2 x 2 contingency tables of varying difficulty in two context conditions, an everyday and a more formal-mathematical context. The sample consisted of N=186 children (60.2% male, 39.8% female) of grades 2, 4, and 6. 62 2nd graders (mean age = 8.08 years, SD = 0.39), 63 4th graders (mean age = 10.14 years, SD = 0.56) and 61 6th graders (mean age = 12.48, SD = 0.57).

In the everyday context condition, children were told a story about researchers. These wanted to find out whether a red or a yellow fertilizer would work best with different plants. Contingency tables depicting the effect of the two fertilizers on growth of either trees, carrots, flowers or cacti were presented. Children evaluated perfect covariation, non covariation and different types of imperfect covariation including random distributions. Judgments and justifications were assessed.

In the formal context condition, an opaque bag was presented to the children and they were told that this bag contained red and blue marbles and dice. Children were shown contingency tables depicting the distribution of marbles and dice of the particular color after taking one item and putting it back 40 times in a row. The distributions of these game tables were identical to that of the fertilizer tables. The rules demanded to draw a blue item from the bag without looking into it. Students had to make their choice (dice or marble) based on the distributions and had to justify their choice.

The results showed that in case of perfect covariation or non-covariation even 2nd graders, regardless of the context, were able to infer the correct conclusions. However, when the covariation was imperfect or random, no systematic progress from 2nd to 6th grade could be observed, and this did not depend on the specific context. In particular, children tended to consider only those cells which provided a positive effect (in this case cells depicting growth or cells with pieces of the critical color and shape) and which contained a large number of items. These findings are consistent with those of Shaklee et al. (1988) who reported that children used inadequate strategies of addition and subtraction rather than of multiplication or considered only a limited number of cells. The judgments and justifications suggested not only inadequate strategy choice but also basic misconceptions with respect to the probability concept. According to Shtulman and Carey (2007), children up to the age of 8 years had difficulties with basic probability understanding when requested to discriminate between improbable and impossible events. The majority of children rated improbable events as impossible. In Study 2, we replicated and extended Shtulman and Carey's study, including a methodologically comparable abstract setting. Whereas the majority of 2nd graders rated improbable events as impossible in both contexts, 4th and 6th graders could generally differentiate between these conditions, but showed solution rates below 65%.

The results from both studies indicate difficulties with the concept of probability and the analysis of contingency tables. Deficits in basic stochastic knowledge and missing methodological concepts on evidence evaluation (e.g. also

considering cells depicting negative events and comparing the probabilities for different conditions) may have contributed to children's performance. However, it is unclear whether the distributions used e.g. by Shaklee et al. (1988) were suited to assess students' full competencies in analyzing contingency tables. For example, an easy numerical structure of a distribution might facilitate the analysis for primary children. Nonetheless, the items might be used as a starting point to investigate different strategies and the adaptive selection of strategies according to the characteristics of a distribution. Standards for school mathematics postulate that children should be familiarized with these concepts at an early point in time. However, there is hardly any empirical evidence for this proposal. Further studies aiming at a better understanding of the underlying processes should be carried out in order to understand the early development of probability concepts and to design instructional interventions.

SYMPOSIUM

Fostering Metacognitive Monitoring and Regulation of Learning in Children and College Students

Chairperson: Tamara Van Gog, Erasmus University Rotterdam, Netherlands

Organiser: Anique de Bruin, Maastricht University, Netherlands

Discussant: Eduardo Vidal-Abarca, Universidad de Valencia, Spain

Students of all ages exhibit great difficulty monitoring their learning and self-regulating their study behavior. As these metacognitive skills can have a large effect on learning outcomes, research should focus on how these skills can be improved in learners of different ages. The aim of this symposium is to present and discuss a number of studies that examined the effects of different instructional interventions designed to foster metacognitive monitoring and regulation of learning. These interventions (including concept mapping and sentence generation) turned out to be suitable even for primary education students in the domain of text and language learning, and easy to incorporate in everyday education by teachers. Moreover, they allowed for quantitative measurement of metacognitive variables as self-monitoring and self-regulation. Most importantly, the interventions positively affected students' self-monitoring and self-regulatory study behavior. Finally, the third study highlights a thus far neglected, but potentially important cause of poor self-monitoring and self-regulatory behavior, that is, the effect of students' expectations of teachers' grading procedure on students' metacognitive judgments.

Using Concept Map Construction to Improve Metacomprehension Accuracy in 7th Graders

Keith Thiede, Boise State University, United States; Josh Redford, Boise State University, United States; Jennifer Wiley, University of Illinois at Chicago, United States; Thomas Griffin, University of Illinois at Chicago, United States

Across two experiments we evaluated the effects of constructing concept maps on metacomprehension accuracy (the accuracy with which students can discriminate which texts they understood more versus less). We found that 7th grade students were not adept at monitoring their own comprehension. However, constructing concept maps improved metacomprehension accuracy. Moreover, when instruction included practice texts and tests, with explicit instruction on how the concept maps could aid comprehension, producing concept maps produced higher levels of metacomprehension accuracy.

Learning from texts often involves reading and then rereading materials. To make good decisions about what to reread (regulation of study), students must accurately monitor their comprehension (Thiede, Anderson, & Theriault, 2003). Although the accuracy of comprehension monitoring (metacomprehension accuracy) is typically quite poor (Dunlosky & Lipko, 2007), recently, techniques have been discovered to improve metacomprehension accuracy for college students (for a review of research see Thiede, Griffin, Wiley, & Redford, 2009). One of these techniques, for example, requires students to generate keywords of the studied texts prior to judging comprehension (Thiede et al., 2003). In a different study, students were required to first provide a summary of the text (Thiede & Anderson, 2003). In both cases, metacomprehension accuracy improved drastically, but only at a delay after text study. However, these kinds of techniques have not been evaluated with younger students.

Across two experiments, we evaluated whether instructing 7th grade students to construct concept maps prior to judging comprehension would improve metacomprehension accuracy—as it had with college students (Thiede, Griffin, Wiley, & Anderson, 2010). Students were tested in the classroom in a regular teaching situation with the teacher present.

In Experiment 1, prior to completing the experimental procedure of studying texts, judging comprehension and taking a test for each text, 59 7th graders received eight sessions of instruction on how to construct concept maps. For the critical trial, students were randomly assigned to a concept mapping group (who constructed concept maps prior to judging their comprehension) and a no concept mapping—control—group (who reread texts instead of constructing concept maps). Metacomprehension accuracy was calculated as a gamma correlation between students' comprehension judgments and test performance. Metacomprehension accuracy was marginally better for the concept mapping group (mean gamma = .05, SEM = .17) than for the control group (mean gamma = -.41, SEM = .21), $t(43) = 1.70$, p

Experiment 2 differed from Experiment 1 in one respect. In Experiment 2, prior to completing the experimental procedure, 71 7th graders received instruction on how to construct concept maps, AND additional instruction on how concept maps could be useful in answering test questions. All students received five practice texts and tests, which provided experience with the inference test questions used in the experiment. For the critical trial, students were randomly assigned to either a concept mapping group (in which students constructed concept maps prior to judging comprehension, as in Experiment 1) or a comparison group (which was provided a concept map for each text for review prior to judging comprehension). Although metacomprehension accuracy did not differ across groups, $t(48)$ Metacomprehension accuracy was better than chance for the concept mapping group (mean gamma = .34, SEM = .16), $t(19) = 2.08$, $p = .05$; whereas metacomprehension accuracy was not different than zero for the control group (mean gamma = .18, SEM = .17), $t(29) = 1.06$, $p > .05$. Moreover, the additional instruction that emphasized how concepts could be useful in answering test questions produced higher levels of metacomprehension accuracy than those reported in Experiment 1.

In sum, these experiments show that 7th graders are generally not adept at monitoring their comprehension. As the results reveal, the control group in Experiment 1 had metacomprehension accuracy significantly below zero. However, our findings show that constructing concept maps improved metacomprehension accuracy, even though accuracy was still quite low. These results underline that concept mapping might not only have beneficial effects on learning as is usually assumed, but also on students' metacognitive monitoring. Additional instruction that provides information about the utility of using constructing and using concept maps could be a promising approach to improving metacomprehension accuracy adolescents.

Children's Metacomprehension: The Effect of Delay and Sentence Generation on Monitoring and Regul

Mariette van Loon, Maastricht University, Netherlands; Anique de Bruin, Maastricht University, Netherlands; Tamara Van Gog, Erasmus University Rotterdam, Netherlands; Jeroen Van Merriënboer, Maastricht University, Netherlands

Children's metacognitive skills are often poor when they judge their comprehension of text materials, which has the effect that they cannot effectively decide what they need to restudy. We aimed to find an instruction to improve judgments of learning and subsequent restudy skills for young learners in the classroom. Primary school children ($n = 94$, 9 – 13 years) completed a comprehension task. They studied idioms, judged their learning, and selected items for restudy before performing a comprehension test. We used an experimental between-subjects design: participants judged their learning either immediately; after a delay; or after generating new sentences with the previously studied idioms. When judging learning immediately after study, people rely on their short-term memory; whereas after a delay, people rely on retrieval from long-term memory (LTM). It is assumed that, when judging learning after sentence generation, people focus on the way new information is linked to existing knowledge, instead of on isolated retrieval from LTM. Results showed that monitoring of comprehension significantly improved after a delay. In addition, the sentence generation instruction led to the most effective selection of items for restudy, independent of working memory capacity and grade level. These results indicate that the novel sentence generation instruction gives young learners an accurate indication of what they do know and what they need to restudy. This provides evidence that metacognitive skills, and therefore learning outcomes, can be improved in primary education with an easily applicable instruction.

It has been suggested that metacognitive monitoring and regulation play an important role in learning from text (Thiede, Anderson, & Theriault, 2003). Monitoring accuracy refers to knowledge of learning and memory processes; self-regulation refers to the control of these processes. When a person studies, he or she monitors how well the

material has been learned, and the output from monitoring is then used as a basis for deciding whether to terminate or continue to study (Nelson & Narens, 1990). Effective regulation of study is important for academic achievement (Ertmer & Newby, 1996). Unfortunately, monitoring accuracy when trying to comprehend text (which is called metacomprehension) is often quite low. It does not seem likely that learners will then effectively regulate their learning to improve comprehension. The aim of the present study was to improve monitoring accuracy and subsequent regulation of study for young learners in the classroom.

Researchers have found ways to improve monitoring accuracy and subsequent regulation of study. An instruction which improves monitoring accuracy is the delayed judgment of learning (JOL) instruction (Nelson & Dunlosky, 1991). When people study simple materials, such as word pairs, providing a JOL after a delay drastically improves monitoring, when compared to providing a JOL immediately after studying each item. The proposed explanation for this effect is that a delayed JOL instruction helps learners to attend to valid cues which accurately predict future performance on the test. When monitoring at a delay, JOLs will be based primarily on retrieval from long-term memory (LTM). The same kind of LTM retrieval is required during testing, therefore delayed JOLs lead to more accurate judgments of memory.

However, this delayed JOL instruction does not have the same effect when people study more complex materials, for example expository text (Maki, 1998). On a comprehension test, people have to show that they understand the gist information of the studied material, instead of literally providing the studied information. This means that LTM retrieval is not as predictive of future memory on a test as it is when people study simple materials, such as word-pairs. Other instructions have been found to improve metacomprehension (e.g. Thiede et al., 2003). These instructions ask learners to focus on their mental network which is constructed when comprehending text. According to Kintsch (1998), the process of comprehending text exists of forming a mental representation of a text, which is called a situation model and constructed when new idea units from the text form an interrelated mental network with the reader's prior knowledge. It has been assumed that, when people focus on their situation model instead of on isolated retrieval from LTM, metacomprehension and subsequent regulation of study will improve (e.g. Thiede et al., 2003; Anderson & Thiede, 2008).

Little is known about how instructions that ask young learners to focus on their situation model can improve monitoring of comprehension in a classroom setting. Until now, research aiming to improve metacomprehension has mainly focused at adult learners. Only one study has investigated how activation of the situation model can improve metacognitive skills in young learners (De Bruin, Thiede, Camp, & Redford, submitted). Their results showed that instructions, which asked young learners to focus on their situation model, improved metacomprehension accuracy and subsequent regulation of study for 6th and 7th graders. However, in their study, 4th graders still showed poor metacomprehension accuracy. The researchers assumed that the utilized materials and instructions were too complex for young learners. This points out that there is a need for new techniques, suitable for young learners, to improve metacomprehension skills.

Method

We used an idiom comprehension task, a task which is educationally relevant and less complex than the expository text comprehension task used by De Bruin et al. (submitted). We used a sentence generation instruction, which was intended to focus readers on their situation model. This instruction is assumed to be less complex and therefore suitable for younger learners.

Our design was experimental and between-subjects, primary school children ($n = 94$, age 9 – 13) were asked to study idioms with the aim of showing comprehension on a final test. Prior to the comprehension test, participants provided a judgment about their future comprehension. These JOLs were provided either immediately, after a delay, or after sentence generation.

Metacomprehension accuracy was operationalized as the correlation between JOLs and test performance; and regulation of study as the correlation between JOLs and items selected for restudy.

Results

We found a main effect of instruction on metacomprehension accuracy, $F(2, 83) = 11.87$, $p < .01$, $F(2, 86) = 17.462$, $p < .01$ instructions. The delayed JOL instruction improved regulation of study when compared to the immediate JOL instruction.

Discussion

Our results provide evidence that a simple instruction, which focuses readers on their situation model, can improve metacomprehension skills, even for fourth graders. This is an important finding, because improved metacomprehension will lead to improved learning outcomes (Ertmer & Newby, 1996; Thiede et al, 2003). Sentence generation seems to be a promising instruction for young learners, and this instruction is easily applicable in the classroom. However, more research is needed to identify how sentence generation, and focusing readers on their situation model in general, can improve metacomprehension for young learners. In future studies we will examine whether the sentence generation instruction has the same beneficial effect when young readers study other materials, such as expository text, foreign language or key terms.

Expectations of Grading Affect Students' Judgments and Regulation of Learning

Anique de Bruin, Maastricht University, Netherlands; Gino Camp, Erasmus University Rotterdam, Netherlands

College students tend to massively overestimate performance on tests of text material. This poor metacognitive monitoring has a detrimental effect on future study behavior, and thereby on academic achievement. An until now neglected but potentially important factor contributing to overconfidence on test taking could be students' expectations of how their responses will be graded by teachers. Specifically, students might expect to receive at least partial credit for each provided response, irrespective of the quality of the content. In two experiments, we examined how expectation of partial credit affected students' monitoring and regulation of learning from texts. The results revealed that students often erroneously judged their responses as correct when the partial credit option was absent, leading to even greater overconfidence. However, when students were forced to judge whether their responses were indeed fully correct, overconfidence decreased, self-monitoring improved, and study times increased. These findings demonstrate an until now neglected cause of poor self-monitoring and self-regulation. Poor metacognitive skills are in part due to students' expectations of how they will be graded, and their judgments are specifically influenced by the partial credit option, which is omnipresent in everyday testing.

Students are usually poor at judging how they will do on an upcoming test of text material. These inadequate self-monitoring skills are detrimental to learning, as they lead to incorrect estimations of whether the texts need restudying. To improve accuracy of students' judgments, Dunlosky, Rawson, and Middleton (2005) had students predict performance for specific terms of the text, and recall the definition of each term prior to judging performance, to ensure that they self-tested their knowledge. As a result of this procedure students' judgments improved considerably. However, they still overestimated performance on responses that were classified as commission errors (i.e., completely incorrect responses). It is possible that students might have erroneously assumed that a partial answer would at least be awarded some credit. In two experiments, we examined to what extent students' judgments and regulation of learning are affected by perception of how responses are scored. We hypothesized that the partial credit option would lead students to overestimate their performance, as they tended to judge their incorrect responses as partially correct, not needing restudy.

Experiment 1 Method

Thirty-nine undergraduates participated. Twenty students served in the no partial credit group and eighteen in the partial credit group. We used six expository texts (270 - 303 words). Each text contained four key terms, followed by a definition of approximately 20 words. Participants read each text, and afterwards had to provide the correct definition of each key term. Then, participants were required to self-score their responses. Participants in the partial credit group received the instruction: "If the definition you just wrote was being graded, do you think you would receive 0 credit points (incorrect response), half a credit point (partially correct response), or 1 credit point (fully correct response)?" For participants in the no partial credit group the phrase "half a credit point (partially correct response)" was deleted. The self-scores were transformed to 0, 50%, and 100% prior to analysis. Finally, participants indicated whether they wanted to restudy the text, by clicking 'y' (yes) or 'n' (no). As the criterion test, participants were required to provide the correct definitions for each key term.

Results

There was no difference in the percentage of 0 self-scores between the partial credit and the no partial credit group, $t(37) = 1.30$, $p = .20$. However, the no partial credit group provided significantly more 100% self-scores, $t(26.24) = 3.79$, p

A 2 (group) \times 2 (self-score) analysis of variance on the commission errors showed a significant interaction between group and self-score, $F(1, 70) = 4.30$, p

Discussion

Contrary to our expectations, students in the no partial credit group more often awarded their responses a 100% self-score compared to the partial credit group. Possibly, students reasoned that, because they provided an answer, it was

unlikely that it would be awarded 0 credits. The question is, however, whether students believed their answer was fully correct, or whether they merely avoided the 0 self-score because they considered it improbable. This was further examined in Experiment 2.

Experiment 2 Method

The Method was similar to Experiment 1, except that participants in the no partial credit group ($n = 25$, partial credit group $n = 24$) judged whether their prejudgment recall response was completely correct (yes/no) in the self-score phase. Instead of selecting texts for restudy, self-regulation of learning was determined by providing students all texts by text segment for restudy, and analyzing study time allocation. Study times were log transformed prior to analysis.

Results

There was no difference between groups in the number of 100% self-scores, $t(47) = 1.74$, $p > .05$. However, the no partial credit group provided significantly more 0 self-scores, $t(47) = 8.82$, p

Discussion

The data show that judgment options not only affect students' perceptions of the correctness of their responses, but also time dedicated to text studying. Learners tended to judge their responses as completely correct when the partial credit option was absent (Experiment 1), even though they realized that these responses were actually incorrect (Experiment 2). The stricter phrasing of the self-score instruction in Experiment 2 led to longer study times, on both the first and second read of the texts. Students' judgments and regulation of learning are influenced by how they perceive their responses will be graded.

SYMPOSIUM

Research in non-university higher education: perceptions on research competence and its importance

Chairperson: Jan Elen, Katholieke Universiteit Leuven, Belgium

Organiser: Jan Elen, Katholieke Universiteit Leuven, Belgium

Discussant: Lynn McAlpine, University of Oxford, United Kingdom

The role of non-university higher education is changing in Europe. In the Netherlands and in Flanders non-university higher education institutions are recently granted the opportunity to conduct research. Teachers in these institutions are demanded to complement their traditional teaching tasks with research activities. This implies changes in the tasks of teachers and in the way students are taught. This also implies changes for the managers of institutions of non-university higher education, as they have to coach and evaluate teachers on these new tasks.

This symposium aims at illuminating the perception of the importance and the capability to perform different aspects of research. Each paper in the symposium investigates this for a different actor. The first paper (Schouteden, Verburgh & Elen) investigates Flemish teachers' conceptions about the importance of research aspects for students' professional life. The second paper (Griffioen, De Jong, Jak) concentrates on Dutch teachers' self-perception on research competence. The third paper (Boerma, Griffioen, De Jong) illuminates the managers' side of the issue, by investigation managers' opinion about how competent their teachers are on different aspects of research competence.

By focusing on non-university higher education, this symposium provides insight on how teachers and managers make sense of the research challenges coming at them. Potential differences with the more purely academic contexts will be looked at in the discussion part of each paper. The insights are valuable for policy makers, managers, and educational developers in the aim of strengthening research and research integration in non-university higher education.

Non-university teachers' perceptions about research and its importance for students

Wendy Schouteden, K.U.Leuven, Centre for Instructional Psychology and -Technology (Vesaliusstraat 2, 3000 Leuven), Belgium; An Verburgh, Katholieke Universiteit Leuven, Belgium; Jan Elen, Katholieke Universiteit Leuven, Belgium

This paper reports on a study on the perception of non-university teachers on research and its importance. Research is a relative new task for non-university higher education, and therefore it is most probable that teachers in these institutions have a different perception of research than their colleagues at the university. It is unclear to what extent the results of studies on conceptions of research of university lecturers are applicable for non-university higher education. Fifty-five teachers participated in focus group discussions about research, research features and their importance for students' professional lives. An analytic framework was developed to analyze these discussions. Four different categories of research features were identified (research steps, sequence of the research steps,

characteristics of the researcher and linking research with practice). Characteristics of the researcher was the most frequently mentioned feature of research. Critical thinking, as an aspects of the characteristics of the researcher, was the most important feature of research relevant for students professional lives. The analyses reveal that non-university teachers think it is not necessary for their students to be able to do each research step by themselves, but that it is more important that they understand research results and that they can transfer it to their profession. In other words they stress the functional nature of research.

Aims

During the last decade there has been a growing debate about the relation between teaching and research in university and non-university higher education (Brew, 2006; Griffiths, 2004; Verhoeven, 2010). As research integration is an intended policy aim, it is important to understand how teachers perceive research and how important they think it is for their students. It is most probable that the perception of research of non-university teachers differs from the perception in traditional universities because in non-university higher education research is a relatively new task. Hence, research and the relationship between research and teaching might be an even more complex and sensitive issue in comparison to universities (Kyvik & Skodvin, 2003, Verhoeven, 2010). Currently it is unclear to what extent results of studies on the perception of research are applicable to non-university higher education.

This study builds on research on university teachers' conceptions of research (e.g. Akerlind, 2008; Brew, 2001; Prosser, Martin, Trigwell, Ramsden, & Middleton, 2008; Visser-Wijnveen, 2009). Brew (2001) interviewed senior university researchers. She identified four qualitatively different ways in which research is understood (trading, journey, layer, domino), according to (a) whether they have an external product or an internal process orientation and (b) the extent to which the researchers' personal concerns influence their research conceptions. Visser-Wijnveen (2009) interviewed academics about their research conceptions using metaphors. She distinguished five categories of research (disclosing patterns, searching for patterns, explaining patterns, pointing out patterns, creating patterns).

A limitation of these studies is that they are restricted to conceptions of research, and these conceptions are rather abstract. Moreover the conceptions of research do not reveal the perceived importance of research for students' professional lives. This perceived importance is relevant because it might be an important factor in designing curricula and implementing research-integration. Therefore, the current study investigates (1) non-university teachers' perceptions about research, more precisely their perception on what (doing) research involves, and (2) how important they assume that these features of (doing) research are for their students' professional lives.

Methodology

Data were collected by focus group interviews (Hannes, 2009). Teachers were first asked to think individually about a person who is doing research, and subsequently visually represent what the person was doing. After five minutes of drawing and drafting, they were asked to explain their drawings to the other participants. These explanations allowed the moderator to inquire deeper about the research conceptions, details of the drawings, etc. Next the moderator identified, in cooperation with the participants, key topics in the descriptions of the drawings, and wrote them down on small cards. The words on the cards form a set of activities or conditions related to research (referred to as 'research features' in the following). The moderator tried to use the words used by the participants, and not her own wordings. Such a key topic could be 'asking relevant questions', 'thinking thoroughly', or 'perseverance'. Then participants were asked to rank these topics according to the importance for their students' professional lives.

In total eight focus groups were organized, and fifty-five teachers from five different non-university higher education programmes participated. Each focus group consisted of four to eight teachers from the same programme. All focus groups were audio taped and transcribed verbatim.

Data in this study were analyzed qualitatively. The drawings were analyzed first, following the approach elaborated by Briell, Elen, Depaepe and Clarebout (in press). This resulted in an analytic framework that was used to analyze the key topics on the cards and the transcripts of the focusgroups. Considering reliability, the analyses were performed by multiple researchers.

Findings

Four main categories of research features were identified. The first category labelled 'research-steps' concerns different steps in undertaking research. Seven steps were discerned: formulating questions, gathering existing information, research approach, data collection, data analysis, formulating conclusions and report. The second category labelled 'sequence of research steps' concerns the order of research steps, for example research is a linear process or a cyclical process. The third category was called 'characteristics of the researcher', as a condition for doing

good research, subcategories are for example critical thinking, organisational capabilities and social interaction skills. A fourth category concerns 'linking research with practice', for example to improve the professional practice.

Overall the category on the 'characteristics of the researcher' is the most frequent mentioned feature of research, more specifically almost half of the cards belong to this category (49/106). The category of the research steps is the next category that is mentioned most frequently (40), of which posing questions (11), is the most common.

Concerning the importance of the different features, data reveal that critical thinking as part of 'characteristics of the researcher' is considered as the most important for students' professional lives, followed by the 'linking research with practice'. Although teachers consider the different identified steps in research as important for doing good research, they do not perceive each research step as important for their students' professional lives. For example they consider it less important that students are able to conduct each research step than that students are able to pose relevant questions, understand research results and that they can identify the relevance of it for their professional practice. In the paper a more detailed analyses will be described.

Discussion

The study reveals that for teachers in non-university higher education (doing) research involves multiple features, and that diverse characteristics of the researcher are considered important in doing research. In comparison with research on research conceptions of university lecturers, the study reveals that teachers in non-university higher educational institutions stress the functional nature of research rather than its theoretical importance. Research is not directed towards questioning theoretical insights or statements but towards using the theoretical insights in professional settings. For students professional lives posing questions and being able to understand results of research is considered as more important than doing research themselves. This finding provides the basis for a better understanding of differences between university and non-university curricula and the specific role of integrating research into teaching.

Self-efficacy of teachers in non-university higher education: research as a new task

Didi Griffioen, Hogeschool van Amsterdam, Netherlands; Uulke de Jong, UVA, Netherlands; Suzanne Jak, Hogeschool van Amsterdam, Netherlands

During the last decade, the relation between university and non-university institutes for higher education has changed. As contribution to the knowledge economy, non-university institutes for higher education are expected to educate their students in research activities, as well as to conduct research. Previously, research activities were virtually non-existent in the past and the means were mostly absent. Teachers were selected on other criteria than their research abilities. This paper reports the outcomes of a study that considers the belief of teachers in non-university higher education in their own research ability (research self-efficacy). In a survey study conducted among teachers (N=790) the research self-efficacy of teachers has been measured. A Structural Equation Model shows the effect of personal aspects, mastery experience, and organisational context on the research self-efficacy of teachers. Research self-efficacy is also modeled in relation to teachers' needs to be trained in research activities. Results show that research self-efficacy is mostly influenced by aspects of mastery experience, in which the context is similar to the requested task. This is in line with Bandura's idea of mastery experience, which influences self-efficacy when sufficiently accommodated to the context and content of a task. Implications are discussed.

Introduction

During the last decades has the relation between university and non-university institutes for higher education changed in several European countries (Kyvik, 2004; Kyvik & Skodvin, 2003; Witte, Wende, & Huisman, 2008). In practice, research activities were virtually non-existent in non-university institutes (Witte, et al., 2008). Today, teachers at these institutions are increasingly expected to be involved in research activities (de Jong & de Jager, 2007; Kyvik & Skodvin, 2003). The focus of this research is on whether teachers belief they are able to perform the new research tasks scheduled, and how these beliefs influence their willingness to participate in training activities.

Research self-efficacy of teachers

Self-efficacy concerns people's own beliefs in their capabilities to produce given attainments in given contexts (Bandura, 2006). The construct of self-efficacy is based on the self-perception of the competence, rather than on the actual level of competence (Bandura, 1997; 2006; Tschannen - Moran & Woolfolk Hoy, 2007). The presumption in this study is that several personal and contextual factors are important in explaining the research self-efficacy of teachers in higher vocational education.

Personal factors. Age and Gender are part of the broader discussion on the accessibility of research as a profession (Brouwer, 2003; Tschannen – Moran & Woolfolk Hoy, 2007) and therefore included as control variables.

Factors of mastery experience are according to Bandura (2006) the most influential aspects in increasing self-efficacy. Previous research shows that personal efficacy scores of teachers increase with a higher level of education (Dembo & Gibson, 1985), and by involvement of teachers in research activities (Henson, 2001). Another aspect of mastery experience is the number of years working in educational context (Dembo & Gibson, 1985; Ghaith & Yaghi, 1997; Hoy & Spero, 2005; Tsannen – Moran & Woolfolk Hoy, 2007).

Factors of work context.

The different research disciplines ask for different skills of their researchers, since their research methods differ. Previous research shows how differences between disciplines matter for research self-efficacy (Busch, Fallan, & Pettersen, 1998), but also what the influence can be of leadership styles and organisational culture (Tsannen – Moran & Woolfolk Hoy, 2007). The differences in organizational context can also be relevant since the research culture of these non-universities higher education institutes is still less developed than, for instance, in research universities (Griffioen & Boei, accepted).

Training needs. Self-efficacy is expected to influence the willingness of teachers to participate in training activities (Clifton, 1997; DeForest & Hughes, 1992; Noe & Wilk, 1993; Runhaar, Sanders, & Yang, 2010). This willingness is important since most teachers were not selected on their research skills, but are nevertheless expected to fulfil (teaching in) research tasks.

Method: Research questions.

- 1) How do teachers in non-university higher education perceive their research self-efficacy?
- 2) What influences the research self-efficacy of teachers?
- 3) How large is the influences of research self-efficacy on training needs in different contexts?

Sample: The employees of five Dutch Universities of Applied Sciences (UAS, non-university higher education) were asked to complete a questionnaire on research-related topics. This research includes only the responses of teachers who have scores on all variables used (N= 790).

Measures: Research in the UAS consists of four different contexts: a) individually, b) with students, c) with colleagues, and d) with external organisations. In conducting research, five aspects play a role: 1) reading, finding and understanding research literature, 2) applying results of research, 3) designing research, 4) collecting data, and 5) interpreting and reporting results. The (4 x 5=) 20 items (Likert-4) combined result in the scale 'research self-efficacy' (C. Alpha = .94).

For all four contexts it is asked whether or not one takes part in research activities (yes/no), and if one has the need to be trained in research (yes/no). Also, personal aspects (gender, age), aspects of mastery experience (educational level, years of working in educational surroundings, currently doing research elsewhere) and the working context (discipline, years of employment at this institution) are measured.

Analysis.

Before conducting the analyses, the data were screened for non-response. This resulted in N=790. For data screening and descriptive analysis, SPSS is used. For path modelling Mplus (Muthéén & Muthéén, 2007) is used.

Results

The descriptive analyses show the teachers of the UAS are rather positive about their own ability to conduct research in all four contexts. The involvement in research with colleagues, external and self is relatively low (23-34%), while the involvement in research with students is rather high (71%). Almost 50% of the teachers have a training need for research skills in each context.

The fit of the first structural model (figure 1) was satisfactory, with CHISQ = 193.825, df = 64, p

Implications

The educational level of the teachers is important for the research self-efficacy of teachers. Also, being involved in research has a positive influence on the research self-efficacy of teachers. On the other hand, doing research outside of the institute where the teacher is employed has no effect on the research self-efficacy of the teacher. One can conclude that the context in which one can contribute to mastery is important for the sense of self-efficacy in that context. Experiences outside that context do not contribute to mastery. The effect of research self-efficacy on the training needs of teachers differs in different contexts, although the explained variance is small. All results seem in line with Bandura's (2006) concept of the relation between mastery experience and self-efficacy: context matters.

The executives' standard on research competence of teachers in Dutch non-university higher education

Josefine Katelijne Boerma, University Of Applied Science Of Amsterdam, Netherlands; Didi Griffioen, Hogeschool van Amsterdam, Netherlands; Uulke de Jong, UVA, Netherlands

In 2001, Dutch non-university higher education institutions gained the financial right and means to conduct research (Netherlands Association of Universities of Applied Sciences, 2004). Today, research activities are expected to be a part of the curriculum. Before 2001, the primary task of Dutch non-university focussed on providing vocational education. Nowadays, in addition to their pedagogical activities and knowledge of a specific vocation, teachers are expected more and more to be involved in research activities. In this paper the results of a study on the executive managers' standard on research related competence of teachers are discussed. It is important to know what their standard is as executive managers are responsible for the overall quality and content of the curriculum. The results of Q-methodology reflect the patterns of viewpoints of executive managers, which are compared to the self-perceived research efficacy of teachers as examined by Griffioen and de Jong (2009c). The outcomes show that the standard of executive managers on research competence of teachers exhibits similarity to the ordering in beliefs of ability by teachers: to be able to conduct research with students is most important while research competence with external organisations is the least important. Additionally, teachers feel that they are able to comply with the research competence requirements of executive managers.

Aim of this research

Nowadays research skills are part of the competencies of higher educated professionals (Borgdorff, van Staa & van der Vos, 2007). Therefore, research activities are part of the educational reality in non-university (van Lieshout & Borgdorff, 2005). The aim of this study is to determine the way, which the teachers' executive managers perceive the necessary competence of this new task. The standard of executive managers might give direction to the nature of research activities in non-university institutions.

In 2008, Griffioen and De Jong (2009b) asked teachers about their research self-efficacy. The present study can be seen as a follow-up, in which the results of a study into the self-perceived research competence of teachers are compared to the standard of executive managers on research competence of teachers. The results indicate in what way norms of executive managers and beliefs in capability of teachers correspond with each other.

Theoretical background

In the context of implementing research activities in the curricula of non-university higher education institutions, little attention has been given to position of the executive managers. The lecturers are responsible for conducting research and thus seen as the carriers of these activities. Nevertheless, it is relevant to study the viewpoints of executive managers as they are responsible for developing the curricula and creating the necessary conditions for teachers in which research competence and research activities can evolve (Geijssels, Meijers & Wardekker, 2007; Moolenaar, Daly & Slegers, 2010).

Teachers, however, are considered to be the link between research activities and the students who need to become the critical professionals. Therefore it is important to understand how teachers perceive their own competence in implementing and carrying out research: research self-efficacy. Self-efficacy relates to the self-assessment of a person to comply with the requirements of a specific situation.

This belief is independent of the actual empirical result, and derived from other concepts of the self, such as: confidence and self-esteem (Tschannen-Moran, Woolfolk Hoy & Hoy, 1998). Generally, when discussing self-efficacy of teachers, they refer to the teachers' level of self-confidence in their dexterity to work as education providers (Tschannen-Moran & Woolfolk Hoy, 2001).

Methodology

Research question. In which way does the standard of executive managers regarding the research competence of teachers match with the perception of teachers on research efficacy?

Sample. Executive managers of a Dutch university of applied sciences were asked to rank-order a set of twenty statements about research related tasks of teachers. Only executive managers with the task to directly monitor the performance of teachers were included (N= 59, response ratio = 82%).

Measures. In order to answer the research question, five stages of doing research within four contexts (Figure 1) are used as a base to design twenty statements. The 5x4 design is comparable to the design of Griffioen and de Jong

(2009a). Each statement represents one research dimension in which one context is combined with one research task. The respondents were presented with a set of twenty cards each containing a statement and a frame for a Q-sort. Q-methodology was used to rank-order the statements. This methodology is an attempt to analyse subjectivity in all its forms (Barry & Proops, 1999; Exel & de Graaf, 2005). The results of Q-methodology were used to establish the viewpoints of executive managers. The respondents were asked to sort the statements into a Q-sort frame (see Figure 2 for an example). Important research tasks had to be placed to the right, less important tasks to the left.

Each statement, based on his position in the Q-sort, received a quantitative score (0,5 – 4). The result of the sorting is a normally divided distribution of statements of each respondent. All distributions combined, reflect the standard of executive managers regarding research competence of teachers.

Findings

The descriptive analyses show a higher mean for the research tasks with students and a lower mean for research tasks with external organisations (e.g. 'the teacher is capable of supporting students to interpret en report results' to 'the teacher is capable of supporting external organizations to collect data').

A Principal Component Analysis confirmed that three out of four scales as used by Griffioen and de Jong (2009b) can be formed out of the data in the current study: a) individual research b) research with colleagues, c) research with external organisations (C. Alpha= .63 to .69). The reliability of the scale of 'research with students' as used in the study of Griffioen and de Jong is too low and therefore excluded for further research. With the three scales used, the explained variance is 67 percent. The ordering of importance of tasks for teachers in the eyes of executives managers shows that the group of statements resembling individual research competence is most important (M= 2.6) and the statements resembling research competence with external organisations (M= 1.3) is least important. This ordering is also confirmed by a student's t-test ($p = .001$).

Based on these preliminary results it can be concluded that the standard on research competence by the direct executives is comparable to the ordering in beliefs of ability by the teachers: research tasks with students are most important, while research tasks with external organisations are least important.

Theoretical significance

Because of the dependent arranging of statements, Q-methodology has proven to be a valuable instrument to establish a holistic view on the importance of educational tasks. However, the different levels of data constrain the statistical comparability between both studies.

Both teachers and managers have a primary focus on educational research competencies such as individual tasks and tasks with students. This outcome is in accordance with the study of Griffioen and de Jong (2009b) in which is shown that research goals with the aim of improving daily the educational practice are most important.

The teachers' research self-efficacy corresponds with the level that is required by executive managers. Concluding: executive managers focus on the same research competence requirements as teachers feel they are able to comply with.

SYMPOSIUM

Invited SIG

Cognitive and Affective Processes in Multimedia Learning: In Memory of Dr. Roxana Moreno - Part I

Chairperson: Jan L. Plass, New York University, United States

Organiser: Babette Park, Saarland University, Germany

Roland Bruenken, Saarland University, Germany

Discussant: Detlev Leutner, Duisburg-Essen University, Germany

This invited SIG 6 symposium on Instructional Design is dedicated to Dr. Roxana Moreno, who passed away in summer 2010. Our community lost one of our most prolific researchers, highly productive scholars, and a wonderful human being who will be missed by many. With this symposium we would like to inspire more research related to Dr. Moreno's Cognitive-Affective Theory of Learning with Media (CATLM; Moreno, 2006). Therefore, seven contributions are presented that focus on cognitive and/or on affective processes in multimedia learning (De Koning, Tabbers, & Paas; Imhof, Scheiter, Gerjets, & Edelmann; Kirschner, Phielix, & Prins; Magner, Schwonke, Renkl, Aleven, & Popescu; Park, Seufert, Moreno, & Brünken; Um & Plass; van den Boom, Kirschner, & van Merriënboer). Kirschner et al. discuss

self- and group awareness of cognitive and social behaviour. Magner et al. concentrate on the effects of decorative illustrations and their distracting or motivating function. Imhof et al. present different visualizations, which facilitate mental animation. Park et al. show that combined effects of different cognitive load inducing factors are not necessarily additive and how to motivate learners to make full use of their cognitive resources during learning. Um and Plass describe how experienced positive emotions facilitate cognitive processing and improve cognitive and affective outcomes. Van den Boom et al. discuss prompting to stimulate self-regulated learning competence. Finally, De Koning et al. present their results on the function of gesturing as a means to foster understanding. Detlev Leutner will be discussant for the papers presented in the symposium.

Self- and Group Awareness of Cognitive and Social Behavior in a CSCL Environment

Paul A. Kirschner, Open Universiteit, Netherlands; Chris Phielix, Leiden University, Netherlands; Frans Prins, Dept of Pedagogical and Educational Sciences, Utrecht University, Netherlands

A major pitfall of collaborative learning in a computer-supported environment is neglecting the social- and affective aspects of working in a group (Kreijns, Kirschner, & Jochems, 2003). Moreno (2006) took this idea a step further in her Cognitive-Affective Theory of Learning with Media, positing that motivational factors mediate learning by increasing or decreasing cognitive engagement. In a series of experiments, the effects of a self- and peer assessment with the aid of a feedback tool and reflection on the feedback via a reflection tool on group performance in a computer-supported collaborative learning environment were studied. The underlying assumption is that group performance can be positively influenced by making group members aware of how their social and cognitive behaviour is perceived by themselves, their peers, and the group as a whole. Results show that groups using tools perceived their team as being better developed, experienced higher levels of group satisfaction and lower levels of conflicts, than groups not using the tools. They also make it clear that awareness, stimulated by self- and peer assessment and reflection tools, enhances the cognitive performance of a CSCL-group.

Background

Computer supported collaborative learning (CSCL) has been found to enhance learners' cognitive performance (Johnson & Johnson, 1999) and stimulate them to construct knowledge (Stahl, 2004). Students working in CSCL-environments report higher levels of learning (Hertz-Lazarowitz & Bar-Natan, 2002), make higher quality decisions, deliver completer reports, participate more equally (Fjermestad, 2004; Janssen, Erkens, Kanselaar, & Jaspers, 2007), and engage in more complex and challenging discussions (Benbunan-Fich, Hiltz, & Turoff, 2003). They also report higher levels of satisfaction compared to students in contiguous groups (Fjermestad). There are, however, also contradictory results. Students in CSCL-environments sometimes perceive discussions as being more confusing (Thompson & Coover, 2003), less productive (Straus, 1997; Straus & McGrath, 1994) and more time-consuming (Fjermestad, 2004). They may also to experience lower participation (Lipponen, Rahikainen, Lallimo, & Hakkarainen, 2003), more conflict (Hobman, Bordia, Irmer, & Chang, 2002), less group-cohesiveness (Straus; Straus & McGrath) and less satisfaction (Baltes, Dickson, Sherman, Bauer, & LaGanke, 2002). CSCL learners, thus, do not always reach their full potential. This discrepancy is due to the design of the CSCL-environment, and/or the social and cognitive behaviour of the group members. With respect to design, environments often concentrate on functionality, focussing on the cognitive processes needed for task completion and/or problem solving to the detriment of socio-emotional processes (Kirschner, Beers, Boshuizen, & Gijssels, 2008) essential for developing social relationships, group cohesiveness, feelings of trust, and a sense of community (Jehng, 1997). With respect to social and cognitive behaviour, group members form interpersonal perceptions during interaction (Kenny, 1994). Based on what they experience, they form impressions about themselves, the group, other group members, and what the other group members think of them. These perceptions are based on the cognitive and social behaviours perceived during interaction. Research, however, shows that group members often perceive their own performance (i.e., self-perception) and group performance are unrealistically (Stroebe, Diehl, & Abakoumkin, 1992). Therefore, it is necessary to first make students aware of their group functioning (through peer feedback) AND have then reflect on the feedback to make it more effective (Prins, Sluijsmans, & Kirschner, 2006). To overcome these problems, CSCL environments can be augmented with tools that act as social-contextual facilitators relevant for the learner's social interaction which can positively affect social and cognitive performance (Kirschner, Strijbos, Kreijns, & Beers, 2004). Two such tools were used in a series of research projects, namely a self- and peer feedback tool (Radar) to make group members aware of the social and cognitive behaviour of themselves and their peers and a reflection tool (Reflector) to stimulate group members to reflect upon their own behaviour, why their peers see them the way they do, and to co-reflect on the performance of the group as a whole.

Research Questions

- 1) What are the effects of Radar and/or Reflector on a group's social development?
- 2) What are the effects of Radar and/or Reflector on group learning?

Method

Participants: Participants in the different experiments were either academic high school or university students randomly assigned to dyads, triads and groups of four, and randomly assigned to one of the experimental conditions. Group compositions were heterogeneous in ability and gender.

Design: In the different studies experimental and control conditions were used. The experimental conditions received either one or both of the tools within their CSCL-environment. Control conditions did not received tools during collaboration.

Measures: In the different studies the following measures were used: Social performance. To measure social performance, previously validated instruments (Strijbos, Martens, Jochems, & Broers, 2007) were used, namely the Team Development scale which provides information on perceived group cohesion, the Group-process Satisfaction scale which provides information on perceived group satisfaction, the Intra-group Conflicts scale which provides information on perceived conflict level between group members and the Attitude towards Collaborative Problem Solving scale which provides information on the perceived level of group effectiveness and how group members felt about working and solving problems in a group. Cognitive performance: The grade given to the groups' collaborative writing task.

Tasks and General Procedure: Students collaborated in groups of two, three or four on a collaborative writing task. Every student worked at a computer. The groups collaborated in a CSCL environment called Virtual Collaborative Research Institute (VCRI; Jaspers, Broeken, & Erkens, 2002), which is a groupware program designed to support collaborative learning on research projects and inquiry tasks.

Instruments: The Virtual Collaborative Research Institute (VCRI) is a groupware program that supports collaborative working and learning on research projects and inquiry tasks. VCRI contains more than 10 different tools, but only 5 were used for this experiment. VCRI was augmented with a peer feedback tool for stimulating and facilitating exchange of information on their social and cognitive behaviour visualized in a radar diagram. Radar provides users with anonymous information on how their social and cognitive behavior is perceived by themselves, their peers, and the group as a whole. The information gathered is based on specific traits that have been found to tacitly affect how one 'rates' other people. Radar provides information on four traits related to social or interpersonal behaviour: influence, friendliness, cooperation and reliability and two related to cognitive behaviour: productivity and quality of contribution. These traits are derived from studies on interpersonal perceptions, interaction, group functioning, and group effectiveness (e.g., Bales, 1988; Brok, Brekelmans, & Wubbels, 2006; Kenny, 1994).

Output of group assessment: Reflection tool (Reflector)VCRI was augmented with a tool containing six reflective questions to stimulate reflection on different aspects of the group processes. Four questions were answered individually; reflection and two final questions required writing a shared conclusion and formulating goals; co-reflection.

Data Analyses: For all measures, one way between-groups ANOVAs with planned comparisons and/or multilevel analyses were conducted.

Results

Results show that groups using tools perceived their team as being better developed, experienced higher levels of group satisfaction and lower levels of conflicts, than groups not using the tools. They also make it clear that awareness, stimulated by self- and peer assessment and reflection tools, enhances the cognitive performance of a CSCL-group.

This submission reports on a series of experiments. The word limit prohibits discussing the specific results of each of the experiments, thus the abstract and extended summary only discuss the methods, procedures and results in general.

Distracting or Motivating: The Effects of Decorational Illustrations in Computer-Based Learning

Ulrike Magner, University of Freiburg, Germany; Rolf Schwonke, University of Freiburg, Germany; Alexander Renkl, University of Freiburg, Germany; Vincent Aleven, Carnegie Mellon University, United States; Octav Popescu, Carnegie Mellon University, United States

Do decorational illustrations distract from learning and, thus, decrease learning outcomes, as suggested by Cognitive Theory of Multimedia Learning? Or can decorational illustrations trigger interest and thereby enhance the willingness to learn as suggested by interest theories? Although these approaches seem to contradict each other, we assume that they are compatible: Decorational illustrations may hinder short-term learning but could raise interest and engagement so that in the medium run learning may be enhanced. The assumption was measured with 52 8th grade student of a German secondary school. They had to work with one of two computer-based learning environment for intersecting lines (geometry); either enriched with interesting decorational illustration or without. Our results showed

an interaction effect of prior knowledge and conditions. Students with low prior knowledge who worked with a computer-based learning environment with interesting decorative illustrations learn less than students without interesting decorative illustrations. However, students with high prior knowledge learn more in the condition with interesting decorative illustrations than students who had no decorative illustrations immediately after the learning phase. For the delayed posttest prior knowledge was the only main effect. Decorative illustrations do not distract per se. Actually they seem to support learning for students with high prior knowledge who can be seen as less vulnerable to distraction. However, medium run learning could not be enhanced by decorative illustrations.

Background

Student 1: „Why does your geometry problems show illustrations and not mine? Your one looks much more interesting and than my ones". Student 2: "I prefer your version; you can concentrate on the geometry problems better than me as there are no illustrations to draw away your attention." This real communication between two 8th grade students nicely illustrates our main research question: Are such decorative illustrations seductive details (Harp & Mayer, 1997) that impede learning, or do they trigger interest and, thereby enhance learning? Cognitive Theory of Multimedia Learning (Mayer, 2005) predicts that illustrations which are interesting but not relevant to the central learning goals should be omitted (Harp & Mayer, 1997). Accordingly, computer-based multimedia environments should not contain goal-irrelevant decorative illustrations. In recent years, cognitive researchers increasingly call for the consideration of motivational aspects, especially Moreno (2006) with her Cognitive Affective Theory of Learning with Media. Against this background, the construct of situational interest seems especially relevant (Hidi, 2001). Hidi (2001) defines situational interest as a person-object relation that arises as a reaction to environmental input. Situational interest eases comprehension (Hidi, 2001) and learning (Ainley, Hidi & Berndorff, 2002; Hidi, 2001). Novelty, concreteness, and visual imagery (Hidi, 2001) are factors that trigger situational interest. One way to rely on such interest-eliciting factors in computer-based multimedia environments is the use of concrete, meaningful and context-oriented decorative illustrations. Although the different theoretical perspectives seem to contradict each other ("seduction" versus interest elicitation), we assume they are compatible: Decorative illustration may hinder short-term learning, but can raise situational interest and engagement so that in the medium-term learning is enhanced. We also assume that different prior knowledge levels may moderate the effects of such illustrations, because in particular low-prior knowledge learners may be hindered by distracting features in learning materials. We tested our assumptions in the context of learning in an intelligent tutoring system (Cognitive Tutor ; Anderson, Corbett, Koedinger & Pelletier, 1995)

Method

Fifty-two 8th grade students of a German secondary school (29 male; 23 female; age: $M = 13.46$ years; $SD = 0.65$) were randomly assigned to two experimental conditions. They worked with a computer-based tutored learning environment either with interesting decorative illustrations or without any decorative illustrations. Learning outcomes were assessed by two posttests (immediate and delayed) which included items requiring near transfer (similar tasks) and far transfer (new tasks). A first experimental session lasted about 90 minutes, the second session (two weeks later) took about 45 minutes. In the first session all students were tested about their prior knowledge of intersecting lines (geometry). Then the students had to solve intersecting line problems in the Cognitive Tutor. Afterwards the learning outcomes were measured and the students answered a set of demographic questions. Between the immediate posttest and the delayed posttest, students could solve further geometry problems with an optional learning booklet. In the delayed posttest students had to solve additional tasks (referring to the learning booklet).

Results

An ANCOVA including the immediately posttest scores showed main effects for condition ($F(1,45) = 4.49$, $p = .04$, $\eta^2 = .09$) and prior knowledge ($F(1,45) = 21.27$, p (see Appendix) Figure 1: Learning outcomes (near/far transfer) However, students with high prior knowledge learned more in the condition with interesting decorative illustrations. Additionally, we looked at a potential behavioural effect of interest, that is, the use of the learning booklet. Only 40.6 % of the students worked with the booklet (no condition difference, $t(17) = 0.33$, $p = .75$). In addition, we could not find any differences between the conditions with respect to the duration of the booklet use ($t(18) = -1.70$, $p = .11$). A second ANCOVA including the delayed posttest showed only a main effect for prior knowledge ($F(1,45) = 24.92$, p Discussion In sum, we found an interesting interaction effect of decorative illustrations and prior knowledge, at least with respect to the immediate learning outcomes. For high-prior knowledge learners the effect of interest elicitation seemed to have dominated. It is assumed that learners with a good knowledge base can form larger chunks when encoding the learning materials. They have some cognitive capacity left for successfully "coping" with potentially distracting pictures that do not contain relevant information. For low prior knowledge learners the distraction effect dominated. They are obviously more vulnerable to distraction because they may work near the limit of their cognitive capacity when encoding and processing content-related (i.e., the geometry)

information. We have found no mid-term effects, neither with respect to the use of the booklets provided for further learning nor the delayed learning outcomes. Informal observations show that the pictures raised interest primarily in the computer environment but not in the learning contents.

Testing the Additivity Hypothesis of Cognitive Load Theory – A Modality and Coherence Study

Babette Park, Saarland University, Germany; Tina Seufert, Ulm University, Germany; Roxana Moreno, University of New Mexico, United States; Roland Bruenken, Saarland University, Germany

According to cognitive load theory, the multiple sources of cognitive load experienced during learning are additive. Using a 2x2 experimental design we tested this hypothesis by asking a group of high-school students (N = 100) to learn about biology with a multimedia environment that combined one factor related to extraneous load with one factor related to germane load: modality of verbal explanation (narration vs. on-screen text) and support for coherence formation (support vs. no support). In two preliminary studies the beneficial effects of narration and support were shown when using the same multimedia environment. Results of the present study suggest that combined effects of load factors are not necessarily additive. While no main effects for modality or support could be found in transfer performance (learning scale of preliminary studies) and cognitive load, an interaction effect in cognitive load shows a modality-specific pattern. Learners rated their load to be lower under the narration condition, when learning without support. This pattern however reverses, when learning with support. Moreover, we found a support for coherence formation effect in comprehension performance, another learning success subscale of the present study. This effect was comparable for learners of the narration or the on-screen text condition. In line with the idea that students need to become motivated to make full use of their cognitive resources during learning (Moreno, 2006), this result indicates that the support is especially useful to animate learners to learn longer and to use the invested time-on-task to reach higher levels of comprehension performance.

Theoretical Framework and Objectives

According to cognitive load theory's additivity hypothesis, the different sources of cognitive load (intrinsic, extraneous, germane) are additive, therefore, posing the threat of exceeding students' working memory capacity and hindering learning (Paas, Renkl, & Sweller, 2003). Until now, this core assumption of CLT has never been empirically tested. To fill this gap, we have conducted a series of studies on the combined variation of different cognitive load factors. A first study of our research program shows that the combination of two factors related to extraneous load do not result in cumulative effects on learning performance and cognitive load measures (Park, Moreno, Seufert, & Brýnken, in press). However, what happens when combining one of these factors related to extraneous load with a factor related to germane load? According to CLT, when visual representations (e.g., pictures, diagrams, animations) are combined with simultaneous visual explanations (text), they force students to split their visual attention during learning, therefore hurting learning performance (Sweller, & Chandler, 1994). The learning benefits of replacing visual explanations with auditory explanations (also called the modality effect), is quite robust (Ginns, 2005; Rummer, Schweppe, Fýrstenberg, Seufert, & Brýnken, 2010). The modality effect suggests that forcing students to split their visual attention between the text and the pictures creates an extraneous source of cognitive load. Furthermore, several studies have shown that adding support for coherence formation to instructional materials foster learning (Seufert, 2003; Seufert & Brýnken, 2006; Seufert, Schýtze & Brýnken, 2009). This support is associated with germane cognitive load, as it causes effortful learning activities resulting in schema construction and automation (Sweller, 2005). Consistent with these findings, we were able to confirm the beneficial effect of audio-visual material (modality effect: narration vs. on-screen text) and the learning-conducive effect of support for coherence formation (support vs. no support) in two preliminary studies. In the present study we combined the two effects. The additivity hypothesis predicts the highest levels of total cognitive load and a medium level of learning performance when multimedia instruction combines on-screen text with support. The lowest levels of total cognitive load and a medium level of learning performance are

predicted when multimedia instruction includes narration and no support. Under the other two conditions, including only one of the loading factors (on-screen text without support or narration with support), a medium level of total cognitive load is predicted and the learning performance should differ in the way that narration with support should foster learning the best.

Methods and Data Sources

Modality of the verbal explanation (text vs. narration) and support for coherence formation (support vs. no support) were varied in a 2x2 factorial design, leading to four learning conditions: text-support; text-no support; narration-support; narration-no support. Participants (N = 100 high-school students) were randomly assigned to one of the four experimental groups. The learning instruction consisted of a self-paced multimedia environment about the structure and function of a cellular molecule. Spatial ability, prior knowledge, and time-on-task served as control measures. Learning success was assessed with a learning performance test. Total cognitive load was measured by subjective ratings of mental effort (Paas, 1992). Results and Conclusions The first ANCOVA showed that there are no main and no interaction effects in learning success (F_s). In sum, the present findings point to the need to reconsider the additivity hypothesis raised by CLT, which does not predict a compensation of learning effects when combining them in multimedia instruction. Moreover, CLT does not predict any interaction effects as found in the present study in the subjective rating scale of total cognitive load. Within our research program the first study (Park et al., in press) could already show that modality (the first extraneous cognitive load factor of this study) moderates the seductive details effect (the second extraneous cognitive load factor of this study), which is one more interaction effect that was not predicted by CLT. Further research is needed to accomplish our first results. Thus, one more study is in progress in order to test the additivity hypothesis when combining two germane load factors. Moreover, the found modality-specific pattern in cognitive load ratings is perhaps due to the fact that participants rated rather a "management aspect" of the learning material than the invested learning-enhancing effort. Thus, new methods for a sensitive measurement of cognitive load should be implemented to get further insights into cognitive load. Moreover, in line with the idea that students need to become motivated to make full use of their cognitive resources during learning (Moreno, 2006), results indicate that the support is especially useful to animate learners to learn longer and to use the invested time-on-task to reach higher levels of comprehension performance. Variation in Meaning and Understandings of Subject Matter

Chairperson: Jo McKenzie, University of Technology Sydney, Australia

Organiser: Jo McKenzie, University of Technology Sydney, Australia

Discussant: Noel Entwistle, The University of Edinburgh, United Kingdom

Research has shown the value for learning of understanding variation in students' understandings of subject matter and of using patterns of differences and similarity to bring about new understandings. This symposium explores three different ways of researching student learning of subject matter from a variation perspective. The first study focuses on the interplay between understanding, meaning and expressions used by learners. It looks at variation in learners' use of language to approach subject matter in Newtonian Physics, and variation in how learners see themselves as language users. The second study focuses on the outcomes for students and teachers of the use of phenomenography and the variation theory of learning to design and trial a curriculum approach for improving learning of threshold concepts in Law and Physics in higher education. The third study focuses on a controlled learning experiment in Economics that compares students' learning from three sets of independent learning resources that vary only in the relationship between examples that are chosen. The combination of these studies extends research on variation and students' learning from language, learning and teaching perspectives with the aim of improving our understanding of the learning and teaching of educationally important subject matter.

The interplay between understanding, meaning and expressions used by learners

Annika Akerblom, Lund University, Sweden

The aim of this paper is to present research about how children in three age groups use verbal language in making sense of a problem presented to them in a special dialogue setting. The intentional-expressive research approach, focusing on the epistemological role of language was used as theoretical frame in order to look at the interplay between understanding, meaning and expressions used by the learners close to a problem presented. An analysis of the results from three studies based on the same empirical investigation was made in order to distinguish critical educational aspects for learning to make sense with language.

The results show a large variation in the ways children/pupils use language to approach a specific content and how they see themselves as language users. The first study concerns ambiguity of word meaning and the large variation of meanings given the same expressions by the children/pupils. The second study focuses on awareness of language use and the third study describes four different ways to approach the problem presented. The findings point at the importance to consider the epistemological role of language use in learning and to emphasize the active and creative role of the agent in learning to make sense of subject matter.

Aims:

Prior studies emphasizing the role of language use in learning, from an intentional expressive perspective have concerned students in higher education. However the research presented here involves children from preschool to elementary school and how they understand themselves as language users. The overall aim of the studies was to explore, analyze and describe how children/pupils of three different age groups (6, 10 and 14 years) express their way understanding of problems that could be described in Newtonian physics and basic astronomy, using verbal expressions attempting to make sense about these phenomena as well as their own use of language. An additional aim was to consider aspects of language use that are critical for learning, and to discuss theoretical and practical implications for pedagogical contexts. The intentional expressive research approach emphasizes how a learner approaches a phenomenon through use of verbal language. Learning involves a change in the relation between expressions and what is meant by these expressions, as well as in how they relate to the content of the learner's conception. Prior studies point to the dynamic, ambiguous and varying way expressions are used as well as the meanings those expressions are given by the learner related to a specific content.

Methodology:

65 children in preschool and grades 4 and 8 in elementary school (six, ten and 14 years old respectively) participated in the empirical investigation. Data was collected in a dialogue structure, developed within the intentional-expressive approach. The questions were intended to make the children express their understanding of a problem. The children/pupils were asked the questions: What happens when you throw a ball obliquely up in the air? and Why doesn't the moon fall down? Developing their conceptions they were invited to reflect on a number of key expressions they had used when describing their conception of the problem. Thus focus was shifted through the dialogue, from the conception of a problem, towards reflection on how understanding was expressed. The dialogues were recorded and transcribed and the transcript analysed by means of qualitative contextual analysis. The data-collection and the data analysis carried out will be described in detail in the paper

Findings:

In one of the studies the expressions 'air' and 'attraction force' were selected and analyzed. The expressions were given a large variation of meanings by the children and pupils. However although the older pupils used more scientific terms, their conceptions of physical motion didn't differ to the same extent. In another study the children showed a variation of awareness of their own language use and the ambiguity of meanings. Although a part of the six-year olds didn't conceptualize language as something to reflect over and speak about many of them were able to distinguish language form from language meaning. There was a close connection between language awareness and understanding themselves as language users. In a third study the variation of approach to subject matter using language was analyzed and four categories were described as exploring approach, tentative approach, associating approach and conscious approach. In two of these categories, exploring and conscious approach, the children and pupils made efforts to make sense of the problem presented to them. The associating approach concerned mainly some of the 6 year olds who didn't reflect over their language use. Also pupils using a tentative approach did not explore their own language use in any large extent and spoke of their own language use in terms of 'remembering' and to reproduce the 'right' expressions with given meanings. Notably the tentative approach was most common among the oldest pupils (14 years old). In the contrary many 10 year olds were aware of their own active and creative role as language users in conceptualisation and spontaneously referred to the reflective dialogue as a learning activity.

Theoretical/Educational significance of the findings:

The findings point at the importance of considering the epistemological role of language use, when language is used to make sense of a specific object, which is different from a communicative role (where language is not visible to the user in the activity). Making sense with language, in contrast to reproduction of language patterns and correct terms, emphasizes the active and creative role of the agent in learning, where the learner is active in his/her approaching the world, and acts as the author of saying and of making sense. The open character of relation between expressions, meanings and the content of the conception is seen as critical, as the language user must actively constitute the relations in order to make sense. When language is seen as expressive, expressions get their meanings in the actual use, and not as mediating or representing, where language meaning is seen as bound to cognitive or social/discursive systems of meaning. A pedagogic implication of the findings is that children/ pupils should be supported to explore

and become aware of their own language use in relation to subject matter using reflective dialogues in pedagogical settings in order to learn to make sense with language.

Using phenomenography and variation theory to improve understandings of threshold concepts

Gerlese Sachse Akerlind, University of Canberra, Australia; Jo McKenzie, University of Technology Sydney, Australia; Mandy Lupton, Queensland University of Technology, Australia

This paper describes some findings from a project that aimed to develop and trial a model for teaching disciplinary threshold concepts in the curriculum, drawing on phenomenography and the variation theory of learning. The project involved a team of educational researchers working with teams of academics from two contrasting disciplines, Law and Physics, focusing on the concepts of Legal Reasoning and Uncertainty in measurement. Each team conducted phenomenographic research to investigate differences in students' understandings of the concept then used variation theory to redesign parts of the curriculum to enable students to notice and integrate critical features of these concepts and expand their understandings. The redesigned parts of the curriculum were enacted in different ways by different teachers. This paper will present analysis of the relations between the enacted curriculum and students' learning outcomes in some of the classes. It will also describe the benefits of engagement in the project for the participating teachers and highlight the benefits and challenges of implementing a variation theory approach in higher education contexts.

Threshold concepts can transform students' experience of the discipline but are often troublesome for students to understand (Meyer & Land, 2003; 2005; 2006). Ways of improving students' understandings of threshold concepts are consequently an increasing focus of pedagogical research. This paper describes some findings from a project funded by the Australian Learning and Teaching Council (ALTC) that aimed to develop and trial a model for teaching disciplinary threshold concepts in the curriculum, drawing on phenomenography and the variation theory of learning (Marton & Booth, 1997; Marton & Bowden, 1998; Marton & Tsui, 2004; Marton & Pang, 2006). While academics may be aware that particular concepts are troublesome, they may be less certain about how students are (mis)understanding these concepts. Phenomenographic research (Marton & Booth, 1997; Bowden and Green, 2005) provides a way of identifying differences in student understandings of a concept, and the critical features of the concept that students perceive (or don't perceive) that relate to different understandings. The variation theory of learning then provides a way of planning curriculum experiences to focus on patterns of difference and similarity that may enable students to notice and integrate these critical features. Variation theory also enables analysis of how different patterns of examples might create or confuse opportunities for students to develop their understanding. Some empirical research shows dramatic results from the introduction of variation theory into curriculum design (Pang and Marton, 2005). The impact on development of the teachers involved can also be substantial (Pang, 2006). The project described in this paper involved a team of educational researchers working with disciplinary academics from two contrasting disciplines, Law and Physics. The aim was to develop a theoretically and empirically informed curriculum model of broad disciplinary value and trial its potential to improve students' understandings of selected threshold concepts. Methodology: The project was underpinned by a collaborative action research approach. The research team of educational researchers from four universities, worked with teams comprising four Law lecturers from three universities and five Physics lecturers from four universities. The disciplinary teams also involved tutors, who participated at different stages of the project to increase disciplinary collaboration and reduce individual workloads. The action research approach involved a set of phases over two years.

1. Each disciplinary team identified a common threshold concept for first-year students in their discipline and described their usual practices for teaching this concept.
2. Disciplinary teams conducted phenomenographic research into differences in students' (mis)understandings of that concept. The lecturers or their tutors interviewed 24 students in each discipline, using trigger examples and open questions. In Law, eight students were interviewed in each of three universities. In Physics, students were interviewed across four universities. Each lecturer or tutor involved therefore gained some experience of interviewing students. The transcripts were analysed phenomenographically (Marton & Booth, 1997), by the researchers and disciplinary teams working collaboratively to identify critical differences in student understandings.
3. The outcomes of this research and the variation theory of learning were used to collaboratively redesign aspects of the first-year curriculum to focus on the patterns of similarity and difference necessary to improve student understandings.
4. Revised curriculum designs were implemented, to different extents by different members of the disciplinary teams. Selected classes were videorecorded to capture how the designs were enacted in the classroom. Student learning outcomes were assessed using either questions at the end of the selected class or specific questions in examinations or both.
5. The research team analysed the relations between how the revised curriculum design was enacted in the classroom and the learning outcomes achieved by students, in cases where it was feasible to do so. Towards the end of the

project, an independent researcher interviewed the disciplinary lecturers about the effects of their project involvement on their own understandings and practices.

This paper focuses in particular on two aspects. The first is the relation between the enacted curriculum design and student learning outcomes for three curriculum implementations which used the same set of materials in the same session format. The second is the findings of the interviews with lecturers and tutors from both Law and Physics who participated in the project. Findings: The selected concepts were Legal reasoning in Law and Uncertainty in Physics. The phenomenographic research identified four qualitatively different ways in which Law students understood Legal Reasoning and five different ways in which Physics students understood Uncertainty. Interestingly, for both concepts there were critical differences between a focus on procedures alone to an integration of procedures with broader meanings. Aspects of these findings have been reported elsewhere (Akerlind et al, 2010; McKenzie et al, 2010; Wilson et al, 2010). The relations between the phenomenographic findings and the planned and implemented curriculum designs differed between the Physics and Law teams. In the Physics team, one lecturer was able to implement a new design across lecture, tutorial and laboratory sessions while another was only able to implement it in aspects of a lecture. In the Law team, all lecturers agreed on the use of a common case scenario with four variations that progressively opened up different dimensions of a desired way of understanding legal reasoning. Three of the Law tutors at two universities were able to implement the design in single specific classroom sessions designed for this purpose, with the lecturer at the third university integrating it into regular lectures. Analysis is underway of the relations between the patterns of similarity and difference enacted in the three common Law sessions, and students' responses to questions about legal reasoning posed at the end of these sessions. The results will be reported in this presentation. Analysis of the interviews with the lecturers and tutors revealed benefits of their project participation in terms of: their understanding differences in students' understandings of Uncertainty or Legal Reasoning; changes in how they would teach and/or assess these concepts and their own understandings of these concepts. Details of these findings will also be reported.

Significance:

The findings are theoretically significant in extending understandings of how phenomenography and variation theory can contribute to understandings of disciplinary threshold concepts. They have practical significance for illustrating some of the complexities of working collaboratively with variation theory in higher education contexts and the benefits and challenges for students and teachers in engaging with this approach.

Effects of similarities and differences in examples chosen to facilitate learning

Ming Fai Pang, University of Hong Kong, China; Ference Marton, Goteborg University, Sweden

Teachers who teach the same concept, principle, or method of problem solving use different sets of examples to illustrate that concept, principle, or method. In certain cases, examples are chosen systematically, and there is a coherent system of similarities and differences between them. In other cases, although the examples are related to the object of learning (what is to be learned), they are not systematically related to each other. In previous studies conducted, teachers have used a type of learning theory – variation theory – to build systematic relationships, with dramatic positive effects on learning outcomes. By building in theoretical principles in the pedagogical artefact we want to put those principles to test without possible "teacher bias".

We have already carried out one study which supported our assumptions, but are in the process of carrying out a further experiment and it is from that we are going to report. The learning experiment is carried out with the economic concept, the effect on prices of a simultaneous change in supply and demand. Six classes of students from five different schools participate in the study. Within each class, the students are randomly divided into three groups which use three different sets of learning resources to learn the concept in an independent learning session. The learning conditions are identical, except for the relationships between the examples that are chosen. A pre-test, post-test and delayed-post-test which feature an open-ended written task are administered to evaluate student learning with the three sets of learning resources.

The study reported concerns the relationship between what happens in the classroom and what students learn there. We have found that what students learn in different classes may differ radically even when learning is organized in the same way, even if the students are equally capable and motivated, and even if the teachers are equally well-educated and experienced. We have found that these radical differences frequently originate in the way in which learning content is handled and structured in the interactions between teachers and students. These differences involve what the students are able to discern through what is said or exemplified and what the commonalities and differences are in the systems of examples, problems, and illustrations that are used in the classroom. According to the variation theory of learning, learning is seen as a function of the differences and commonalities in what learners experience.

The results of several studies indicate that this theory could be a remarkably powerful tool for teachers to use in bringing about learning. Some of the teachers in these studies made use of the theory, and others did not. The differences in learning outcomes seemed to correspond to whether or not the teaching was theory-based. By building in theoretical principles in the pedagogical artefact we want to put those principles to test without possible "teacher bias". We have already carried out one study which supported our assumptions, but are in the process of carrying out a further experiment and it is from that we are going to report. The theory: Variation theory puts emphasis on the way in which we learn to discern various entities and their different features. To be aware of something, learners must discern it, and to discern it they have to experience how it differs from other things. The way in which something is experienced can be characterized in terms of which features a person simultaneously manages to discern (that is, which differences he/she notices) and focus on (Pang, 2003).

The presence of differences is a necessary, although insufficient, condition for experiencing differences. To experience differences (variation) in certain respects, things have to remain invariant in other respects. This pattern of variation and invariance both constrains and opens up the possibilities of what can be learned. According to the theory (Marton and Booth, 1997; Bowden and Marton, 1998; Marton and Tsui, 2004), the likelihood of learning a concept is a function of the particular pattern of variation and invariance that is experienced when learners encounter it. This relationship between learning and the pattern of variation and invariance that is inherent in the conditions of learning has been demonstrated empirically in a great number of cases (see, for instance, Pang, 2002; Marton and Tsui, 2004; Lo et al., 2004, 2005; Holmqvist, 2006). The pedagogical implications tested in this study originate from the previous study conducted (Pang & Marton, 2005; Marton & Pang, 2006). The aim of the study was to help Grade 10 students to grasp a principle of economics – the effect on prices of a simultaneous change in supply and demand. A pair of teachers engaged in learning study and used variation theory as a resource to plan and carry out their lessons. The mastery of this principle by their students after a series of three lessons was compared with the mastery of the same principle by a group of students who had been taught by another group of three teachers under conditions that were the same apart from the use of variation theory. The difference in learning outcomes in the post-test was striking. About 84.4% of the students in the learning study group showed that they had managed to take into account the relative magnitude of changes in supply and demand when looking at price changes (which was the intended object of learning). In the lesson study group, however, only 22.8% of the students reached this level of understanding. We found a systematic relationship between the differences in the way in which the topic was taught and the differences in student understanding of it. We found that the critical difference in teaching also had to do with the relationship between the examples that were used to illustrate the principle.

Methodology:

We want to create conditions that differ in exactly this particular respect, but remain the same in other respects. Rather than looking at differences in teaching, however, we aim to create different learning resources that three groups of students will use under equal conditions. Six classes of students from five different schools participated in the study. Within each class, the students are randomly divided into three groups. Each group of students is then given a particular learning resource to learn the concept in an independent learning session. The conditions are identical, except for the relationships between the examples that are chosen. To ascertain their existing level of understanding of the object of learning before they engage with the learning resources, the teachers first administer a pre-test to the students. This forms the baseline for a comparison of the learning outcomes of the three groups of students. Immediately after the learning sessions, a post-test is conducted with the students to probe their levels of understanding and to chart their progress. Finally, a delayed post-test is arranged for four weeks later to evaluate the long-term effects of the learning resources. All of the tests feature an open-ended written task, in which students are asked to handle problems that relate to complex real-life scenarios that embody the principles in question. Based on the data that are obtained, both inter- and intra-group comparisons are carried out. Significance: The study makes both theoretical and practical contributions to the field of education. Theoretically, it further tests the tenets of variation theory and thus makes significant contributions to the advancement of this learning theory and also contributes to the current research on student learning in general. Practically, it widens the application of the theory to include the design of instructional tools and learning resources.

SYMPOSIUM

Invited SIG

Collaboration of learners in technologically enhanced inquiry learning environments

Chairperson: Margus Pedaste, University of Tartu, Estonia

Organiser: Margus Pedaste, University of Tartu, Estonia

Zacharias Zacharia, University of Cyprus, Cyprus

Discussant: Sten Ludvigsen, University of Oslo, Norway

Recent studies in the field of technologically enhanced inquiry learning demonstrate that cognitive and metacognitive support given by computers is effective if it is adapted to the learners' individual needs. Innovative data mining techniques for describing and operationalizing variety of learners can provide us with a tool for building adaptive support systems. However, these developments are taking only their first steps. In this reason there should be set emphasis on integrating learners with different knowledge and skills. Peers are able to give appropriate individual guidance and to teach other learners based on their experiences. Therefore, inquiry learning environments should facilitate collaboration of learners. In this symposium, we discover recent outcomes in studies of support and collaboration in the use of computer supported inquiry learning environments and provide important input for building adaptive support systems in an internationally acknowledged level.

Learning with multiple representations in computer-based inquiry environments

Anniken Furberg, University of Oslo, Norway; Anders Kluge, InterMedia, University of Oslo, Norway; Sten Ludvigsen, University of Oslo, Norway

This paper reports on a study of students' engagement with multiple representations within a computer-based inquiry environment aimed at supporting students' conceptual understanding of energy and heat transfer. Previous research on students' engagement with multiple representations show divergent findings. Some studies document positive effects. Nevertheless, several studies also find that students have difficulties of moving across or connecting multiple representations. By taking a socio-cultural approach, the aim of this paper is to explore and understand how students can benefit conceptually from engaging with multiple representations. In order to pursue this aim, the analytical focus is on settings where students' talk and interaction is conceptually oriented while engaging with representations. The empirical data were produced during the initial round of the EU project Science Created by You (SCY). The central resource for introducing students to the energy and heat transfer curriculum was the computer-based learning environment SCY-Lab, containing a variety of visual and textual representations such as graphical representations, diagrams and simulation tools. Analyses of student group interaction show that the students' engagement with the multiple representations enables them to reframe and reconstruct information presented to them either by the teacher or within the computer-environment prior to their use of the representations. In other words the representations become resources students employ in order to reconstruct and make sense of conceptually oriented information presented to them prior to the situation. Findings are discussed and explored in accordance with findings from previous studies on students' engagement with multiple representations.

Aims

This paper reports on a study of students' engagement with multiple representations within a computer-based inquiry environment aimed at supporting students' conceptual understanding of energy and heat transfer. In the learning sciences visual displays of concepts, processes and phenomena are acknowledged as an important part of individuals' learning processes (Gardner, 1987; Säljö, 2000). Accordingly, within science education visualizing and modeling representations has been given a central role.

Findings from studies on students' engagement with multiple representations such as simulations, diagrams and graphs in computer-based settings show divergent findings. Positive findings are for instance that especially students with medium level of prior knowledge seem to benefit from multiple representations. Furthermore, multiple representations seem to be effective for students' recall performances (Seufert, 2003). Other studies demonstrate that students struggle to use multiple representations effectively (Ainsworth, 2006). For instance, in contrast to experts, students have difficulty moving across or connecting multiple representations (Kozma, 2003). Furthermore, a common finding in studies on students' engagement with computer-environments is that the use of these environments is more effective with regards to enhancing students' acquisition of procedural inquiry skills than the students' acquisition of conceptual understanding (van Joolingen et al., 2007). The procedural versus conceptual finding constitute a general challenge for all educational settings, whereas the overall aim of schooling is not only to support the students' acquisition of procedural skills, but also to support their acquisition of conceptual understanding.

Most studies on students' engagement with multiple representations focus on the effect of specific types of representational tools. In contrast, the focus of this study is on the very process where students engage with multiple representations. A socio-cultural approach is taken (Vygotsky, 1978) to investigate this process. The aim is to explore and understand how students can benefit conceptually from engaging with multiple representations. The analytical focus is on settings where students' talk and interaction is characterized by being conceptually oriented while engaging with representations. Based on this background, the research questions are: How do students engage with

multiple representations presented to them in a computer-based inquiry environment?. How are these representations integrated as structuring resources in the students' process of conceptual sense making?

Methodology

The empirical data were produced during the initial round of the EU project Science Created by You (SCY). The project was carried out in 20 school lessons over the course of 4 weeks with 20 participating students aged 16–17 years. The central resource for introducing students to the energy and heat transfer curriculum was the computer-based learning environment SCY-Lab containing visual and textual representations such as graphical representations, diagrams and simulation tools, supplemented with information from the Web. 40 hours of video recorded student group interaction while engaging with the SCY-Lab environment, and the students' textual and visual productions constitute the data corpus. Initial analyses of settings involving engagement with multiple representations in conceptually oriented settings made it possible to identify typical aspects of such situations. In order to visualize and discuss these typical aspects, extracts from students' interaction within two exemplifying settings are analyzed in detail (Jordan and Henderson, 1995).

Findings

Characteristic for both analyzed settings is that the students' engagement with the multiple representations enables them to reframe and reconstruct information presented to them either by the teacher or within the computer-environment prior to their use of the representations. Within the first analyzed setting, the students try to make sense of the teacher's explanation of the solar cellar process by means of using multiple representations such as depictions, models and text found on the Internet. Here the students manage to reconstruct and represent the teacher's explanation by including elements from the textual and visual representations. Within the second setting, the students try to make sense of house construction and energy loss. Arguing for effectiveness, the students manage to try out their self-made hypotheses by manipulating variables in a simulation tool. This finding can be seen in relation to what Cote et al. (1998) refer to as the important link between students' preexisting knowledge and the information provided by e.g. a text. In other words, the analyses show that the representations become resources students employ in order to reconstruct and make sense of conceptually oriented information presented to them prior to the situation.

Theoretical and educational significance

A socio-cultural approach can give deep insight into how students may benefit conceptually from engaging with multiple representations in computer-based inquiry environments. By focusing on local contingencies we can understand how and why productive interaction is constituted and what this means for the students' process of conceptual understanding. Furthermore, under certain conditions, engagement with multiple representations can enhance students' understanding of scientific concepts. These potentials can be realized if the teachers, the technologies and the collaborative patterns create directions that make both procedural and conceptual talk possible and relevant for the students.

This study was conducted in the context of the Science Created by You project and EC Grant agreement 212814

Investigating Web-based peer feedback in collaborative, inquiry-based learning

Peer interactions can serve as powerful motivators for learning, as they provide opportunities for exchanging and critiquing ideas. Cases of cognitive conflict can be particularly influential, as peers can argue, negotiate meaning, or even restructure their own understanding. Students' reactions to peer feedback are distinct from students' reactions to adults questioning their ideas: for example, while interacting with teachers most children succumb to the adult ideas because of the asymmetrical nature of the adult-child relationship. In this paper, we explore the relationship of peer feedback, mediated through a web-based inquiry support tool, and students' inquiry process. We report on an exploratory study, examining students' collaborative use of synchronous and asynchronous tools to provide feedback to peers. In this context we pursue the following questions: What peer feedback structures exist? How did the technology mediate peer interactions? Data were collected from two classes of 6th grade students ($n_1=20$, $n_2=19$), working in small groups. The groups were engaged in problem-solving a data-rich, socio-scientific problem, and used a scaffolded, web-based learning environment to critique their paired group's work. Data included videotapes of group interactions, computer logs of the feedback provided, and students' written work on the computer. The topic of peer feedback has primarily been explored in more formalized assessment opportunities in higher education settings and as it related to individual students. Currently, there is a lack of literature examining peer feedback in complex, computer-supported, collaborative settings. This work can contribute to a better understanding of how technology can support collaborative learning.

Aims

In recent years arguments about the potential of learning from peers have become increasingly popular (Kollar & Fischer, 2010; Tsivitanidou, Zacharia, & Hovardas; van Zundert, Sluijsmans, & van Merriënboer, 2010) for pragmatic, cognitive, and pedagogical reasons (O'Malley, 1992). In a review of the literature, van Zundert et al. (2010) concluded that there is scant published work on peer assessment, relating to higher education settings with only a handful focusing on elementary or secondary school students. Furthermore, there appears to be a gap in the literature pertaining to the examination of peer feedback in computer-supported collaborative settings. The goal of this work was to explore a web-based tool, designed to support peer feedback, and peer interactions, as students worked collaboratively to solve a complex, web-based inquiry problem, using Activity Theory (Engeström, Miettinen, & Punamäki, 1999) as the guiding analytical framework. This design-based work can contribute to a better understanding of how technology can support collaborative learning.

Methodology

We report on an exploratory study, examining students' collaborative use of synchronous and asynchronous tools to provide peer feedback. Two intact 6th grade classes ($n_1=20$, $n_2=19$) of a public school in Cyprus participated in this study. Students were working in pairs or triads (7 groups in each class). The context of the investigation, which was hosted on the STOCHASMOS platform (Kyza & Constantinou, 2007), was a topical socio-scientific issue. Each group of students assumed the role of scientists representing different organizations, as a means for illustrating that scientists' agendas may lead to different scientific claims on the same issue. The students' goal was to study the data and construct scientific claims on how the problem could be best solved. The learning sequence included two phases for peer reviewing using the STOCHASMOS collaboration tools (the Workspace Sharing area and the STOCHASMOS chat tool). The tools were used by students in order to apply epistemological criteria for assessing scientific claims which were developed in the context of this learning environment. The Workspace Sharing area offers students the opportunity to collaborate with other groups asynchronously, by allowing them to share their Workspace pages (e.g. data pages) in order to obtain and provide peer feedback. The implementation took place during 12 80-minute sessions and was kept the same in the two classrooms. During the peer review phases, each group was paired with a group from the other class. The data sources included in this study were videotapes of three groups' peer review sessions from each class, computer logs of the peer feedback provided by the 14 groups, and the groups' written work on STOCHASMOS. The data were coded to capture the type of feedback provided and were analyzed qualitatively, according to design-based research principles, to explore peer feedback structures and the socio-technical system mediating peer interactions.

Findings

Based on the Activity Theory framework, three different states of activities were identified, all situated within the community of the classroom: students' written peer-review comments, students' discourse and activity around these comments, and intergroup communication using the chat tool. The examination of each of the states reveals a different aspect of the peer review sessions. Examining the written feedback we found that the paired groups reviewed a total of 34 Workspace pages during Peer Review Session 1 (PRS1) and 13 pages during Peer Review Session 2 (PRS2). A content analysis of the feedback provided by the groups indicated that the written feedback, even though

brief, was contextualized, specific and relevant to the peer review task students were asked to perform, with no off-task comments provided. In addition, the comments provided went beyond what was requested and focused on the reviewed group's interpretations, indicating agreement, or disagreement, and asking for more complete articulations of students' interpretations. An analysis of the chat conversations indicated that students used the chat tool mostly for phatic communication and for coordinating the sharing of data in the WorkSpace Sharing space. In the cases when students argued about claims, these discussions lacked the contextualization and the support of data. A third analysis of the group's videotaped discourse during the peer review sessions revealed that socio-technical and task structuring decisions delayed the process of providing feedback and limited the quality of discussions around the task. This analysis also revealed that the teacher had an important mediating role, which also coupled as a formative assessment mechanism. These results, which will be presented in more detail at the conference, suggest that representational tools can successfully mediate students' feedback providing behavior and that different tools serve different purposes. At the same time, our findings suggest that certain aspects of the feedback system need to be redesigned so that they can serve a more effective communicative role.

Significance

This exploratory study contributes to knowledge about peer feedback processes in collaborative, inquiry based learning, a topic currently understudied. The study has provided evidence that a) peer feedback is feasible even at the elementary school level, and b) representational and communication tools can support different aspects of the peer feedback process. The findings have implications for designing interactive spaces to facilitate peer feedback and for understanding the mechanisms that are guiding peer feedback processes.

Students' regulation of inquiry in a computer-based simulation

Mario Maeots, University of Tartu, Estonia; Margus Pedaste, University of Tartu, Estonia; Tago Sarapuu, University of Tartu, Estonia

In this study we analyzed the application of the web-based learning environment "Young Researcher" (<http://bio.edu.ee/teadlane>) in developing students' transformative and regulative inquiry skills. 268 teams with 536 volunteer students from the 6th to 12th grades (aged 10-18) participated in an all-Estonian competition. The teams of two people registered to a three-week competition. During the competition, five problem-solving tasks in the learning environment "Young Researcher" were solved. The comparison of the process and results in solving the first and the last tasks were used for evaluating students' development in inquiry learning. The learning process of each task contained the problem identification, formulating research questions and hypothesis, experiment planning, carrying out an experiment, analysis and interpretation of the results, and making conclusions. Students had to carry out real or virtual experiments with web-based tools. The tasks were designed for developing students' transformative and regulative skills. In order to increase students' awareness about the regulation of the inquiry processes, different forms of support were offered by the learning environment. Our goals were i) to find how the inquiry learning environment "Young Researcher" developed students' transformative and regulative inquiry skills, and ii) what is the influence of the students' regulative skills on the development of their transformative skills. According to the results, the students' transformative skills developed statistically significantly. Among the processes of regulation, the skills needed for planning, monitoring and evaluating were under investigation. Several problems which might affect students' abilities to regulate their learning process were detected and are discussed in this presentation.

Introduction

The concept of inquiry learning originates from the works of Bruner (Bruner, 1960). In general, we define inquiry learning as a process of discovering new relations, where learner formulates hypothesis and tests them by making experiments or observations (de Jong & van Joolingen, 1998; Zachos, et al., 2000; Wilhelm, 2001). The aim of inquiry

learning is to develop the skills needed for making up discoveries (Pedaste, 2006). De Jong & Njoo (1992) divide inquiry skills into transformative and regulative ones. Transformative skills relate to processes in which domain information is transformed into knowledge (de Jong & Njoo, 1992). While regulative skills refer to executive control of the study process, which keeps track of the progress that has been made in transformative processes (de Jong & Njoo, 1992; Njoo & de Jong, 1993). Several authors have described different skills needed for transformative processes, which can be classified into seven stages: problem identification, research question formulation, hypothesis formulation, experiment planning, carrying out an experiment, analysis and interpretation of results, and drawing conclusions (Freidler et al., 1990; Harlen & Jelly, 1997; Veermans, 2002; Pedaste, 2006). These stages lead a learner step by step towards the solution of the problem (Pedaste, 2006). The success of the transformative activities largely depends on regulation of inquiry. This means that learners regulate their own learning by planning, monitoring and evaluating their task performance (Veermans, 2002; Zhang, et al., 2004, de Jong, et al., 2005). In this study, we define planning as a design of the learning process (setting performance goals; predicting the course of the learning process; planning time; making a strategic plan for learning activities and their sequence), monitoring as a process where learner observes and keeps track of his/her own study process (taking and viewing notes; deciding to change the plan; checking study time), and evaluating as a process where the learner evaluates the learning process and task performance (checking whether learning goals have been reached; commenting the execution of the task and the entire learning progress; checking the correctness of the actions and results at a conceptual level; thinking about the course of learning and information processing for the future).

Methods

Procedure, participants and data analysis: The study was carried out during an all-Estonian competition where participated 268 teams with 536 volunteer students from the 6th to 12th grades (aged 10-18). The teams of two people registered to a three-week competition. During the competition, five problem-solving tasks in the learning environment "Young Researcher" were solved. The tasks and tests were validated by the experts' discussion. 132 teams were used in the data analysis because they finished the competition on time.

Learning environment: The web-based learning environment "Young Researcher" (<http://bio.edu.ee/teadlane>) has been designed for achieving the objectives of Estonian science curriculum for students from the 6th to 12th grades (aged 10-18) through inquiry approach. There are five different inquiry tasks under the topics of "Why is it hard to catch a falling body?", "Why does our pulse and breathing rate change?", "Why muscles wear down differently?", "Why does extra weight accumulate?", and "Why does organism need water?". The learning process of each task contains the problem identification, formulating research questions and hypothesis, experiment planning, carrying out an experiment, analysis and interpretation of the results, making conclusions. Students have to carry out real or virtual experiments with web-based tools. To support student's regulation of inquiry, different forms of support are offered.

Results and discussion: The current research focused on the developing students' transformative and regulative inquiry skills. Analysis showed that all transformative inquiry skills developed statistically significantly: research question formulation ($Z=-8.2$; $p < .001$) has appeared that the regulation of the learning process plays a crucial role in students' learning activities while a statistically significant correlation was found between regulative and transformative skills. Our results demonstrated that the higher level of regulative skills lead to the higher development of transformative skills. De Jong et al. (2005) have shown similar results, where successfulness of the learning processes depends on effective regulation. For conclusion, we can clarify that the learning environment "Young Researcher" is applicable for developing students' transformative and regulative inquiry skills.

SYMPOSIUM

Mental versus written computation: Contributions from cognitive psychology

Chairperson: Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

Organiser: Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

Discussant: Terezinha Nunes, University of Oxford, United Kingdom

Solution strategies for solving mathematical tasks have been an important research topic, not only for (mathematics) educators but also for (cognitive) psychologists. Until recently, the studies were mostly focused on elementary (single-digit and two-digit) arithmetic: solving additions, subtractions, multiplications, and divisions in the number domain up to 100. Complex multi-digit arithmetic, which is part of the curriculum of the middle and higher grades of elementary school, has not received much attention from researchers. However, both from theoretical and practical reasons, systematic empirical research in complex multi-digit arithmetic is needed. Theoretically, because in complex multi-digit arithmetic several aspects (e.g., understanding the decimal number system, self-regulatory skills...) play a more important role. Practically, because several recent surveys in various countries (including the U.S., the U.K., and The Netherlands) suggest that children's performance in this curricular subdomain is (drastically) descending. According to some researchers, this trend is directly related to recent reforms in the goals, content, and methods of (elementary) mathematics education, particularly a depreciation of the standard written algorithms and an overemphasis of mental calculation strategies. The three papers in this symposium address, from a cognitive psychological perspective, this tension between mental and written algorithm, by investigating critical issues such as the relative efficiency of both kinds of strategies, children's choices between both kinds of strategies, and (lack of) transfer from one kind to the other. The papers will be discussed by a scholar who is internationally well-known for her research in this particular topic.

Solution strategies and adaptivity in complex division: A choice/no-choice study

Cornelis M. van Putten, University of Leiden, Netherlands; Marian Hickendorff, Leiden University, Netherlands; Marije Fagginger Auer, Leiden University, Netherlands

The current study systematically investigated mental and written solution strategies for solving complex division problems (e.g., $306 : 17$), with the main focus on strategy adaptivity. Eighty-six Dutch 12-year-olds were tested using the choice/no-choice design. They first solved division problems in the free strategy choice condition, and consecutively with forced mental and forced written computation in the two respective no-choice conditions. Strategy choice and strategy performance (accuracy and speed) were recorded. Findings showed that mental computation was usually chosen for reasons of speed, while choices for written computation were fit to accuracy characteristics. Moreover, there were individual differences in the relative preference for accuracy and speed in choosing between mental and written strategies, and these were related to gender and mathematics achievement level of the student.

The present study focused on solution strategies for complex division problems (problems in which the quotient is a multidigit number and the divisor may be multidigit too, e.g., $306 : 17$). The main focus was on the distinction between written and mental computation. Secondary analyses on Dutch national assessment results showed that this was a very relevant distinction in explaining the negative performance trend on complex division between 1997 and 2004: use of mental strategies increased over time, but their success rates lagged far behind those of written strategies (Hickendorff, Heiser, Van Putten, & Verhelst, 2009).

The findings of a previous study (Hickendorff, Van Putten, Verhelst, & Heiser, 2010) into mental and written solution strategies on complex division suggested that students made a suboptimal strategy choice for mental computation

regarding accuracy. However, in that study strategy speed could not be taken into account, and there were no unbiased strategy efficiency data regarding mental computation. The present study aimed to overcome these two limitations.

The aim was to systematically investigate strategic competence in the domain of complex division problem solving. Lemaire and Siegler's (1995) four-dimensional framework of strategic competence was used, distinguishing between strategy repertoire, strategy distribution, strategy performance (accuracy and speed), and strategy adaptivity. The main focus was on the adaptivity of the strategy choices: To what extent do individual strategy performance characteristics (accuracy and speed) predict the choice of a strategy? Are there group differences in relative preference for accuracy and for speed?

Method

Eighty-six Dutch 12-year-olds solved a total of 12 complex division problems in a choice/no choice design (Siegler & Lemaire, 1997). They first solved 4 problems in the free strategy choice condition, in which they could choose between mental and written computation. Consecutively, they solved 4 similar problems in the no-choice 'written' condition, and 4 again similar problems in the no-choice 'mental' condition. All students were tested individually, and responses - correctness of answer, solution strategy, and solution time - were collected on a trial-by-trial basis. To account for dependency of observations within students in the statistical analyses, (generalized) linear mixed regression models were used.

Results

Strategy repertoire. Approximately half of the students (49 %) used written as well as mental strategies in the choice condition. The majority of the other half used only written strategies (38 %), and a small part used only mental strategies (13 %).

Strategy distribution. The relative frequencies of mental and written strategies in the choice condition showed that each item was solved most frequently by written calculation (average 67 %).

Strategy performance. Accuracy and speed data from the two no-choice conditions yielded unbiased strategy performance data. On average, mental strategies were significantly less accurate than written strategies (proportion correct of .50 versus .61, respectively). However, they were significantly faster than written strategies (mean solution times 80s. versus 91s).

Strategy adaptivity. It was assessed whether the strategy selected in the choice condition was the most 'appropriate' one, as evidenced by the unbiased strategy performance information from the no-choice conditions. Analyses on the student level showed that there were significant correlations between the frequency of choosing a mental strategy in the choice condition and, first, the difference in accuracy between forced mental and forced written strategies (Spearman's $\rho = .28$) and second, the solution time difference between forced mental and forced written strategies (Spearman's $\rho = -.32$). Gender and general mathematics level affected these correlations. Girls' strategy choices were significantly related to accuracy differences ($\rho = .40$) but not to speed differences ($\rho = -.07$), while boys' strategy choices showed the opposite pattern, being nonsignificantly related to accuracy differences ($\rho = .26$) but significantly to speed differences ($\rho = -.52$). Moreover, above-average achievers fitted their strategy choice to accuracy differences ($\rho = .56$) as well as speed differences ($\rho = -.47$), while below-average achievers did neither ($\rho = .00$ and $\rho = -.15$, respectively).

Conclusions and discussion

An interesting finding of the present study is that there were group differences in the adaptivity of choosing between mental and written computation on complex division problems: Girls appeared to take accuracy considerations into account, ignoring speed, while boys fitted their strategy choices more to speed than to accuracy. In addition, above-average achievers' strategy choices were related to both aspects of strategy performance, while below-average achievers' choices were not related to either speed or accuracy.

There are theoretical and educational implications of these results. Theoretically, these individual differences in speed-accuracy preference have not been explicitly addressed in the cognitive models of strategy choice and adaptivity. From an educational perspective, we argue that it is important to acknowledge these individual differences in the classroom, and create an environment in which accuracy is valued over speed, and using an external aid is not necessarily less valuable than working in the head.

Children's mental and written computation strategies: A choice/no-choice study with Flemish children

Joke Torbeyns, K.U.Leuven & GROUP T - Leuven University College, Belgium; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

This study analyzed children's use of mental computation strategies and standard written algorithms in the domain of multi-digit addition and subtraction, using the theoretical model of strategy change and the choice/no-choice method. 21 Flemish fourth-graders solved items that either stimulated the use of mental computation strategies or a standard written algorithm, in one choice and two no-choice conditions. In the choice condition, children could use their preferential strategy on each item; in the two no-choice conditions, they had to solve all items with, respectively, a mental computation strategy (no-choice mental condition) and the standard written algorithm (no-choice written condition). The results revealed that children preferred the use of the written algorithm on multi-digit sums, even on sums that evoke a mental computation strategy. Moreover, they executed the standard written algorithms with high efficiency and flexibility, also on the sums that elicit a mental computation strategy. We discuss these (unexpected) results in terms of the current mathematics educational culture and practices with its strong focus on the mastery of standard written algorithms from an early age on.

Theoretical and empirical background and research question

During the last decades, strategy variety and strategy flexibility have become highly important topics in both cognitive and educational psychological research and math educational practice (e.g., Baroody & Dowker, 2003; Kilpatrick et al., 2001; Verschaffel et al., 2009). Numerous studies focused on the flexible application of different strategies on single-digit and two-digit addition and subtraction. Unfortunately, our insight in these topics is far more limited in the domain of multi-digit addition and subtraction.

Multi-digit sums can be solved using different types of strategies, including mental computation strategies and standard written algorithms. In many reform-based documents, strong pleas are made, on various grounds, for teaching children mental arithmetic strategies before and besides the standard written algorithms. It is expected that children will continue to use these mental strategies to solve multi-digit additions and subtractions involving particular numerical features (e.g., continue to solve $534+299$ with the compensation strategy via $534+(300-1)=834-1=833$, and not the written algorithm). However, empirical studies indicate that children tend to inefficiently and inflexibly rely on (almost) only written algorithms once these algorithms are instructed and practiced in the classroom (e.g., Selter, 2001). In ongoing heated discussions between advocates and opponents of reform-based mathematics education in countries such as the U.S., the U.K., and The Netherlands, these disappointing findings concerning the scarce and inefficient use of mental arithmetic play an important role. Within this scientific and societal context, we aimed at analyzing children's strategy competencies in the domain of multi-digit addition and subtraction, with special attention for the efficiency and flexibility with which they apply mental computation strategies and standard written algorithms.

We employed the model of strategy change (Lemaire & Siegler, 1995) to analyze children's strategy competencies. This model distinguishes among four parameters to examine (changes in) strategy use, namely (a) strategy repertoire, (b) strategy frequency, (c) strategy efficiency, i.e., the accuracy and speed of strategy execution, and (d) strategy flexibility, i.e., the adaptiveness of individual strategy choices, defined as selecting the strategy that leads fastest to an accurate answer to the problem.

Children's strategy competencies were studied using the choice/no-choice method (Siegler & Lemaire, 1997). This method involves offering items in two different types of conditions: a choice condition, in which children can solve each item with their preferential strategy, and one or more no-choice conditions, in which they have to solve all items with one given strategy.

Method

Twenty-one 4th-graders participated to the study. As is typically the case in elementary mathematics education in Flanders, all children had received explicit instruction in mental computation strategies on multi-digit additions and subtractions starting in 2nd grade and had intensively practiced the standard written algorithms for these sums for one year. All children individually solved a series of four additions and four subtractions up to 1000 in three conditions. We selected two item types, namely (a) MC-items, that can be solved efficiently with a mental

computation strategy, i.e. compensation (e.g., 498+263; 601-126), and (b) WA-items, that are not assumed to evoke compensation or any other mental computation strategy (e.g., 456+266; 632-164). In the choice condition, children could choose between mental computation strategies and the standard written algorithms on each item. In the no-choice mental condition, all items had to be answered by mental computation. In the no-choice written condition, a written algorithm had to be used on all items. We expected (a) that children would solve the items in the choice condition using both mental computation strategies and standard written algorithms, (b) that mental computation strategies would be applied more frequently and more efficiently on MC-items, and (c) that children would fit their strategy choices to their individual strategy performance characteristics during the strategy selection process, by using most frequently in the choice condition the type of strategy they mastered best (as evidenced by the no-choice efficiency data).

Results

While most children (57%) applied both mental computation strategies and standard written algorithms at least once in the choice condition, mental computation was used on only 19% of the items from the choice condition. We observed no frequency differences between the two item types ($p > .05$), meaning that not only WA items but also MC-items were answered less frequently with mental computation than with the written algorithms. Next, the accuracy and speed data from the no-choice conditions indicated that the written algorithms resulted in higher accuracy rates (89% correct) and shorter solution times (27s) than mental computation strategies (resp. 67% correct and 37s).

Discussion

This study revealed that, after one year of practice of the standard written algorithms, Flemish elementary school children frequently apply these algorithms to solve multi-digit additions and subtractions. In line with previous findings, they prefer these algorithms even on sums that are assumed to maximally stimulate the use of mental computation strategies. Unexpectedly, children also use the standard written algorithms highly efficiently and flexibly, even on sums that are thought to favor mental computation. These unexpected results might be explained by the strong instructional focus on the routine mastery of the standard written algorithms starting in 3rd grade, accompanied by a serious drop in instructional attention for and practice of mental computation strategies and a general lack of attention to strategy flexibility. These findings, which need to be replicated in future studies, yield important information for the ongoing debate about the relative importance of mental computation and written algorithms in elementary mathematics education.

Training mental addition generalizes to new problems but does not transfer to written addition

Catherine Thevenot, University of Geneva, Switzerland

Over a 6-day period, adults were trained in single-digit and two-digit mental addition. We showed that there was a clear training effect for both type of problems, even if two-digit additions were different from one day to the other. Moreover, participants were tested on their written calculation abilities before and after the training program. We showed that participants who entered the mental arithmetic training program did not progress more in written arithmetic than participants who were trained in a Tetris game or who did not receive any training between the pre- and the post tests. The implications of these results and the possible reasons for the lack of transfer from mental to written arithmetic will be discussed in this presentation.

Theoretical and empirical background

Even if it is common sense to assume that mental and written calculation share common components, neuropsychological evidence shows that written calculation can be dissociated from other numerical abilities. Of course, this is not to say that some arithmetical components are not common to multi-digit written calculation and mental arithmetic. Indeed, good performance in written and mental arithmetic necessarily relies on quick and efficient arithmetic fact retrieval. Moreover, the knowledge of calculation procedures is required to solve written and mental multi-digit calculation. However, these procedures are not necessarily the same. In mental multi-digit addition, two main strategies have been identified (Lemaire & Callies, 2009; Lucangeli, Tressoldi, Bendotti, Bonanomi, & Siegel, 2003 for example). First, the full decomposition strategy consists in decomposing both tens and units (e.g., $53 + 44 = 50 + 40$; $3 + 4 = 7$; $90 + 7 = 97$). Second, the partial decomposition strategy consists in decomposing only the second addend (e.g., $34 + 65 = 34 + 60 = 94$; $94 + 5 = 99$). In written addition, the common strategy is the one taught at school consisting in adding the units, then the tens and so on, using carrying when necessary (Lucangeli et al., 2003).

Research question

It is therefore worth investigating whether or not a transfer from mental to written calculation is possible through the practice of shared components between the two abilities or, on the contrary, if a transfer is impossible because of written calculation specificities.

Method

In order to answer this question, we trained 26 adults on single and multi-digit additions over a 6-day-period. Each training session took approximately 15 minutes. Whereas single-digit additions were the same from one day to another, different multi-digit additions were presented every day. As in previous studies, we logically predicted an effect of training on single-digit problems. Moreover, our participants were tested using the well-known written arithmetic fluency test (i.e., subset of the French kit, French, Ekstrom, & Price, 1963) before and after the training period. It was then possible for us to determine if practicing mental arithmetic transfers to written calculation. In order to ensure that potential score improvement on the French kit was not only due to a test-retest effect, the results obtained by participants trained on mental arithmetic skills were compared to the results obtained by 22 participants trained on a non-numeric task (the famous Tetris game) and by 39 participants who were not trained at all.

Results

In accordance with our first prediction, there was a clear training effect over sessions and participants were quicker to solve one-digit additions during Session 6 (1960 ms) than during Session 1 (2962 ms). It was the same for more complex additions, which were solved faster during Session 6 (4304 ms) than during Session 1 (6718 ms). As already mentioned here, because two-digit additions were different from one day to another, this result attests that training complex mental addition generalizes to new problems. More relevant for the object of this presentation, arithmetic scores on the written test were higher during the post-test than during the pre-test. However, the score progression on this test did not differ as a function of the training group. In fact, all three groups performed better during the post-test than during the pre-test. In other words, the improvement in performance in the arithmetic group can be attributed to a simple test-retest advantage. A similar result was obtained by Imbo and Vandierendonck (2008) who showed that adults who were trained on simple addition did not score better on the French kit than adults who did not receive any practice. However, because their participants were tested on the written arithmetic test only after practice and not before, it was difficult to put forward definite conclusions about transfer.

Conclusion

Therefore, it seems that the procedures used and reactivated by our participants during the training program were irrelevant for written arithmetic. These results comfort neuropsychological research conclusions that written arithmetic is a specific ability, which can be dissociated from other numerical competencies. In written arithmetic, individuals apply routinely the common strategy taught at school, whereas in mental arithmetic, the strategies used by individuals are more flexible because they depend on problems' characteristics. If an adult is asked to solve $59 + 47$ mentally, he or she can use the full decomposition or partial decomposition already described here, but can also figure out that $60 + 47$ is 107 and therefore that $59 + 47$ is $107 - 1$. Again, if the same problem is presented vertically and asked to be solved with a pen and paper, it is more probable that the "units then tens" procedure will be applied mechanically. These interpretations are comforted by Lemaire and Callies' study (2009) where the authors showed that both children and adults use the partial decomposition strategy more often when problems are presented horizontally than vertically.

Educational implications

The results of this study bring to light two new interesting findings that could have implications for education. First, the fact that training complex mental addition generalizes to new problems shows that practice can be considered as a useful method of learning. Of course, as already suggested in the literature, long-term effects of such training are expected if, in combination to procedural training, conceptual knowledge is not neglected (Rittle-Johnson, Siegler, & Alibali, 2001). Second, the fact that there is no transfer of training from mental to written arithmetic seems to indicate that using mental arithmetic as a didactical stepstone to written arithmetic (as is typically done in reform-based mathematics education programs) is not a simple matter, which requires carefully designed instructional interventions aimed at making the transition from mental to written arithmetic transparent to the learners.

SYMPOSIUM

Quantitative methods for research on conceptual change and belief change

Chairperson: Michael Schneider, ETH Zurich, Switzerland

Organiser: Michael Schneider, ETH Zurich, Switzerland

Discussant: Han L.J. van der Maas, UvA, Netherlands

Conceptual knowledge gives students a broad and abstract understanding of general principles and their interrelations in a domain. It is a major aim of school instruction. Therefore, it is an important question how we can measure and model changes in students' conceptual knowledge. Research on conceptual change, belief change and conceptual

development so far has made extensive use of interviews. However, interview data adequately reflect the content of learners' knowledge but yield only very indirect evidence about the structure the learners' knowledge. The symposium is based on the conviction that, with an increasing variety of research questions, researchers should also employ a greater variety of assessment techniques, quantitative models, and theoretical approaches. The studies presented in this symposium set out to explore a range of different data collection and modeling techniques, including their practical applicability and their theoretical implications. The studies employ concept inventories with various item types as well as reaction time measures. The data are analyzed using a multitude of quantitative techniques including factor analyses and latent variable modeling. The results are interpreted with respect to qualitative and quantitative changes in the students' conceptual knowledge, e.g. theory change, belief revision, knowledge fragmentation and integration, and influences of entrenched presuppositions. The investigated content domains are biological evolution, mental models of the earth and number concepts. The discussion will integrate the new empirical findings and focus on the potentials and limitations of the methods for broadening mainstream approaches in research on knowledge acquisition and development.

Natural number bias in adults: In search for reaction time evidence

Wim Van Dooren, K.U. Leuven, Belgium; Xenia Vamvakoussi, Greece; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

Studies conducted from a conceptual change perspective have shown that in several mathematical domains (e.g., rational number, algebraic notation, (non-)linear problems), students' prior knowledge comes in contrast with new information coming from instruction, and interferes with further learning. It has been argued that children's prior knowledge is organized on the basis of certain presuppositions, which children may be unaware of. These robust presuppositions continue to influence their reasoning, even after being exposed to formal instruction. This study focuses on the natural number bias, i.e., the inclination to transfer features and properties of the natural numbers to non-natural numbers.

We looked for evidence that the natural number bias is still present in adults, even when they do not give erroneous responses. To do this, we looked for reaction time evidence in a variety of items that are related to the natural number bias. It was found that for several types of items, adult participants committed more errors to incongruent items (not in line with presuppositions) than to congruent items (in line with presuppositions). Moreover, even in cases when participants committed no errors, generally there was an effect with respect to reaction times showing that adults are still showing a bias.

Theoretical and empirical background

Recent conceptual change research has shown that in several domains, like fractions (Stafylidou & Vosniadou, 2004), rational numbers (Merenluoto & Lehtinen, 2004; Vamvakoussi & Vosniadou, 2004), non-linearity (Van Dooren et al., 2004), algebraic notation (Christou & Vosniadou, 2007), and infinite sets (Tirosh & Tsamir, 2006), students' initial understanding can act as a barrier. It has assumed that children's prior knowledge is organized on the basis of certain tacit presuppositions, that continue to influence their reasoning, even after formal instruction. Evidence shows that adults often make errors similar to those of pupils, indicating that they have not always entirely overcome such presuppositions.

This study focuses on the interference of the so-called natural number bias in students (Ni & Zhou, 2005; Smith, Solomon, & Carey, 2005). Before students are exposed to other kinds of numbers, they have already consolidated a naive theory of number which is tied to their knowledge and experience of natural numbers and comprises tacit assumptions about what a number is and how it is supposed to behave. This phenomenon has been widely documented in various mathematical tasks, targeting the properties of rational and real numbers. Students typically make mistakes reflecting beliefs such as “-b can only be a negative number”, “longer decimals are bigger”, “multiplication always makes bigger”, “adding a number leads to a larger result”, and “between two given numbers, there is a finite number of other numbers”, which are valid in the domain of natural numbers, but not for rational or real numbers.

Adults in principle possess the knowledge to solve the tasks correctly. However, there are indications that they sometimes commit errors similar to students, suggesting that they are still influenced by the presuppositions that also underlie students' reasoning.

Rationale and research questions

With a reaction time study, we wanted to gain process based evidence for the claim that adults – and even adults who do not longer commit errors in the above-mentioned areas – are still affected by the natural number bias.

When presuppositions are not entirely overcome while the correct knowledge is acquired, a dual process theoretical account may explain the occurrence of errors. Dual process accounts of reasoning (e.g., Stanovich & West, 2000) assume that humans have an intuitive/heuristic system (S1) that is fast, automatic, associative and undemanding of working memory capacity, and an analytic system (S2) that is controlled, deliberate and effortful. Fast S1-heuristics often provide correct responses, but sometimes, S2 needs to override responses. Hence, errors may be attributed to the pervasiveness of S1 and the failure of S2 to intervene.

Several of the assumptions of dual process theory have previously been validated in reaction time research. More specifically, the idea is that when students are confronted with a counterintuitive mathematical task, the answer coming to mind first is an intuitive one, in line with the students' presuppositions in the particular domain. This needs to be inhibited for a correct, counterintuitive answer to be given.

Predictions

A natural number bias could therefore be shown in their behavior in two ways: Either subjects commit mistakes which are in line with the above-mentioned naive theories of number, or they do not make mistakes, but take longer to give correct responses to items in which the involved presuppositions have to be inhibited than to items where the involved presuppositions are in line with the correct answer. Therefore, we predicted more correct responses in items where correct responses are inline with the presupposition (congruent tasks) than in items where they are not in line with it (incongruent task). Moreover, we expected correct answers to be given faster in congruent tasks than in incongruent tasks.

Method

A group of 40 adult subjects who possess the required domain-specific knowledge worked on a series of computer-based reasoning tasks, while their reaction times are measured. Each time, they had to judge the correctness of a claim.

The tasks were divided in 10 different blocks, which were all related to the natural number bias. Some related to the dense structure of the rational number system (Vamvakoussi & Vosniadou, 2004), others to algebraic notation (Christou & Vosniadou, 2007), and still others to the effect of operations (e.g. multiplication and addition make bigger).

For each block, congruent tasks (presupposition leads to correct answer) and incongruent tasks (presupposition leads to wrong answer) were used. The tasks were presented on a computer screen and each participant solved a set of tasks with no time limit, and a second set of similar tasks under time pressure.

Results and conclusions

The results of this study are in the process of being analyzed. Preliminary analyses have already shown that for certain items (e.g. those related to the dense structure of the rational number system), subjects make indeed more mistakes to incongruent items than to congruent ones. For these items, the expected effect in reaction times is also present: Responding correctly to incongruent items takes significantly more time than responding correctly to congruent items.

For other items (e.g. in which fractions have to be ordered and in which subjects could be misled by the size of the nominator and denominator), there were no differences in the number of correct responses (there was almost a 100% accuracy for both congruent and incongruent items), but the difference in reaction time was still present.

Taken as a whole, we found evidence of a natural number bias in adult participants – even in cases when they do not commit mistakes – by looking at reaction time patterns. However, for certain types of items, the bias is stronger than for others. In future research, we plan to extend the age/expertise range and do similar research with considerably younger students (in order to see whether certain biases are stronger present in terms of the number of mistakes made and whether similar reaction time patterns can be observed), and with expert mathematicians (who can be expected to make no mistakes at all on our items, but who might still be biased in terms of reaction times).

Children's knowledge of the earth: A new methodological and statistical approach

Marthe Straatemeier, University of Amsterdam, Netherlands; Han L.J. van der Maas, UvA, Netherlands; Brenda Jansen, University of Amsterdam, Netherlands

The question whether children's naive knowledge is coherent or fragmented is highly debated in the field of children's knowledge of the earth. According to adherents of the mental model account (e.g., Vosniadou & Brewer, 1992),

children of all ages, even young children, construct coherent mental models of the earth. In contrast, adherents of the fragmentation account (e.g., Nobes et al., 2003) believe that the development of children's knowledge is characterized by a gradual accumulation of fragments of information up until they acquire the correct scientific theory.

In this study we use a new methodological and statistical approach for studying children's knowledge of the earth to contribute to the coherent versus fragmentation debate. We conducted two experiments with large samples ($N = 328$ and $N = 381$) using a new paper-and-pencil test, denoted the EARTH (Earth Representation Test for cHildren). In these experiments the EARTH was compared to methods used in previous research; drawings and interviews.

We performed latent class analyses on the responses to the EARTH to test whether children construct non-scientific mental models of the earth. Each mental model found in previous research (Vosniadou & Brewer, 1992) was expected to correspond to one of the latent classes in the best fitting latent class model. However, the non-scientific mental models were not detected. Moreover, the results indicated that children's knowledge becomes more consistent as children grow older. These results are consistent with a gradual accumulation of knowledge fragments of the earth (i.e., the fragmentation account).

Introduction

In the field of children's knowledge of the earth, much debate has concerned the question of whether children's naive knowledge is coherent (i.e., theory-like) or fragmented. The mental model account (Vosniadou & Brewer, 1992) states that children of all ages, even young children, construct coherent mental models of the earth. In contrast, the fragmentation account (Nobes et al., 2003) describes the development of children's knowledge of the earth as a gradual accumulation of fragments of information up until children acquire the coherent scientific theory of the earth. In this study (Straatemeier, van der Maas, & Jansen, 2008) we use a new methodological and statistical approach for studying children's knowledge of the earth in order to contribute to the ongoing debate about children's knowledge of the earth, and conceptual development in general.

Children's knowledge of the earth has mainly been studied using drawings and interviews, by which only small samples of children could be tested. We suggest using a structured, nonverbal, forced-choice test that can be administered without one-to-one supervision. With such a test the social interaction is minimal and more children can be tested at the same time. Moreover, the use of complex coding systems and the training of experimenters is not required. Therefore, we constructed a new paper-and-pencil test (the EARTH Representation Test for cHildren; EARTH) in which the most prevalent models found in earlier studies with Western countries were represented (Vosniadou & Brewer, 1992; Vosniadou et al., 2004).

We conducted two studies with large samples using the EARTH. The large samples enabled us to use the more advanced latent class analysis (LCA), as opposed to the rule assessment methodology (RAM; Siegler, 1976), used in previous research. LCA can contribute to the discussion of coherent versus fragmented knowledge of the earth, as this analysis allows children to be classified in underlying discrete latent classes (e.g., Jansen & van der Maas, 2002; Raijmakers, Jansen, & van der Maas, 2004). If the mental model account is correct each latent class of a latent class model should correspond to one of the mental models found in previous research.

Method

Two experiments were conducted with two versions of the EARTH. In Experiment 1 ($N = 328$, age 4-11) the EARTH-1 was compared to drawings, which children made either before or after completing the EARTH-1. In Experiment 2 ($N = 381$, age 4-9) the EARTH-2 was compared to answers to an interview with open-ended questions of 68 of the children, which were also performed either before or after completing the EARTH-2. The EARTH tests were presented in a booklet and consisted of 8 (EARTH-1) or 9 (EARTH-2) items. Every item consisted of a question about the earth with four, five or six pictures printed below the questions, from which the child had to choose the correct picture. The items of the EARTH concerned the shape of the earth, gravity, and the day/night cycle. More information about the EARTH tests and these experiments can be found at <http://users.fmg.uva.nl/hvandermaas>.

Results

The proportion of correspondence between the responses to the EARTH and the mental models, formulated by Vosniadou and Brewer (1992), was calculated with the rule assessment methodology (RAM; Siegler, 1976). Every child was assigned to the mental model with respect to which he or she had the highest consistency score. Figure 1 shows that the percentage of children with a mental model, as established using the EARTH-2 in Experiment 2, is low when strict cut-off scores were used for minimum consistency (.8 to 1). Even with lenient cut-off scores the answers of a large proportion of children could not be classified. Moreover, most children, from whom the responses could be

classified, had a scientific model of the earth. The same pattern was also found for the consistency scores of children's answers to the interview, see Figure 1. Similar results were found in Experiment 1.

Figure 2 shows that in Experiment 1 both the amount of children's knowledge of the earth and the consistency of children's responses with one of the mental models (i.e., almost always the scientific model) increases with age. Moreover, positive associations (Experiment 1: $r_s = .86$, $p < .001$; Experiment 2: $r_s = .67$, $p < .001$) were found between the amount of knowledge children have and the consistency of their responses. Similar results were found in Experiment 2.

LCA was performed on the responses to the EARTH of the two samples. If the mental model account is correct the latent classes of the best fitting latent class model should correspond to the mental models found by Vosniadou and Brewer (1992). However, the LCA provided no evidence for the existence of non-scientific mental models. The scientific model was the only model that was detected.

Discussion

Both the results of the RAM and the LCA question the claim that children form mental models, at least of the kind formulated by Vosniadou and Brewer (1992). Moreover, we found that the older children are, the more knowledge they have of the earth, and the more consistent this knowledge is. These results are consistent with a gradual accumulation of knowledge fragments of the earth (i.e., the fragmentation account).

We believe that our methodological and statistical approach is a valuable new approach for the empirical comparison of the coherence versus fragmentation view of children's knowledge of the earth. This approach can also be applied to advance the coherence versus fragmentation debate in other domains of conceptual development.

The use of qualitative and quantitative measures for tracing conceptual change

Andrew Shtulman, Occidental College, United States

Conceptual change involves more than just a quantitative increase in knowledge; it involves a qualitative restructuring of that knowledge. The qualitative nature of conceptual change has led many researchers to study conceptual change using strictly qualitative methods, like content analyses of written narratives and semi-structured interviews. The present study describes a method for supplementing the descriptive power of qualitative analyses with the inferential power of quantitative data – a method that has proven useful at tracking changes in the interrelations among domain-specific concepts over time. College undergraduates enrolled in a course on evolution and ecology ($n = 151$) completed a series of open-ended tasks designed to assess their understanding of six evolutionary phenomena: variation, inheritance, adaptation, domestication, speciation, and extinction. Content analyses were used to differentiate correct, selection-based conceptions from incorrect, need-based conceptions, which were then converted into a three-point numeric scale. Scores were summed across tasks assessing the same evolutionary phenomena, yielding six diverse measures of evolutionary reasoning along the same interval-scale metric. Statistical comparison of these measures before and after instruction revealed a consistent decoupling of microevolutionary concepts from macroevolutionary concepts in participants' progress toward achieving conceptual change. This decoupling has not been observed in previous studies of conceptual change within the same domain, either by those employing strictly qualitative methods or by those employing strictly quantitative methods, implying that the combined use of quantitative and qualitative measures may capture nuances of conceptual-change learning not captured by either method on its own.

Conceptual change is knowledge restructuring at the level of individual concepts, resulting in a qualitative difference between learners' initial knowledge states and final knowledge states. Because this difference is qualitative in nature, attempts to track conceptual change over time or across instruction have typically employed qualitative methods – i.e., content analyses of verbal responses to semi-structured interviews. These methods allow researchers to ascertain exact, highly detailed descriptions of learners' initial and final knowledge states, but they are not amenable to precise quantification of (a) interrelations among different conceptual dimensions within the same domain or (b) patterns of change within, and across, those dimensions over time. At the other end of the spectrum from semi-structured interviews are multiple-choice concept inventories (e.g., Anderson, Fisher, & Norman, 2002). While such inventories allow for precise quantification of change over time, they run the risk of underspecifying, or even mischaracterizing, learners' actual knowledge states due to their use of experimenter-generated, rather than participant-generated, response options.

Here, I will outline an approach to studying conceptual change that combines the descriptive sensitivity of semi-structured interviews with the quantificational precision of concept inventories. The target domain was biology, and

the target instance of conceptual change was the transition from an essentialist, need-based understanding of evolution to a variational, selection-based understanding of evolution (Shtulman, 2006; Shtulman & Schulz, 2008). A series of inferential-reasoning tasks was developed for diagnosing students' understanding of six evolutionary phenomena: variation, inheritance, adaptation, domestication, speciation, and extinction. Each task was designed to elicit one of two historically antecedent interpretations of the phenomenon at hand: a "transformational" interpretation, consistent with pre-Darwinian theories of evolution in which evolution was (incorrectly) construed as the cross-generational transformation of all species members, or a "variational" interpretation, consistent with post-Darwinian theories of evolution, in which evolution is (correctly) construed as the selective propagation of within-species variation. The tasks were generally open-ended in nature, allowing participants to articulate their own understandings (or misunderstandings) of the relevant phenomena, but responses to those tasks were coded numerically along a common metric. Transformational responses received -1 points, variational responses received +1 points, and vague or ambiguous responses received 0 points. Scores were summed across tasks assessing the same evolutionary phenomena, yielding six composite scores ranging from -5 to +5 (one each for variation, inheritance, adaptation, domestication, speciation, and extinction).

The comprehension assessment was administered to 188 college undergraduates at the beginning and end of a one-semester course on evolution and ecology. Consistent with previous research (Shtulman, 2006), the majority of participants (151, or 80%) demonstrated pervasive transformational misconceptions on the pretest. Those 151 participants were separated from the other 37 in an attempt to determine whether, and how, their misconceptions had changed over the course of the semester. A 6 (section) x 2 (time) repeated-measures ANOVA revealed that participants' scores were significantly greater at posttest than at pretest ($M = -7.1$ vs. $M = -10.9$; $F(1,750) = 41.93$, $p < .001$) but that this difference was not uniform across the six sections, as indicated by a significant interaction between section and time ($F(5,750) = 5.23$, $p < .001$). Paired-samples comparisons for each section revealed significant pre-post gains for all sections except speciation and extinction, as shown in Figure 1. That is, participants who began the semester with inaccurate theories of evolution made significant (though incomplete) progress in their understanding of microevolution (e.g., variation, inheritance, adaptation, domestication) but made no discernible progress in their understanding macroevolution (e.g., speciation, extinction).

While it is possible this difference was due to the nature of the instruction participants received during the intervening semester, the participants actually came from four different classes taught by two different instructors. Separate analyses for each course and each instructor revealed the same pattern of results, indicating that this pattern was robust across different instructional contexts and different instructional strategies. Additional confirmation of the robustness of this pattern came from a factor analysis of the difference in participants' section scores from pretest to posttest. This analysis revealed two main factors (explaining 26% and 19% of the variance in participants' difference scores, respectively): one factor on which the four microevolutionary concepts loaded highly but the two macroevolutionary concepts did not and one factor on which the two macroevolutionary concepts loaded highly but the four microevolutionary concepts did not (see Figure 2). Achieving a variational understanding of macroevolutionary concepts thus appears to be distinct from, and possibly subsequent to, achieving a variational understanding of microevolutionary concepts.

This decoupling of macroevolutionary concepts from microevolutionary concepts in the learning of evolutionary biology is consistent with biologists' claim that "tree thinking" and "population thinking" are fundamentally competencies that require fundamentally different instruction (Catley, 2006) but has not been previously observed in the evolution education literature, either by studies that have relied mainly on open-ended interviews or by studies that have relied mainly on closed-ended concept inventories (e.g., Bishop & Anderson, 1990). While the former may not have been sufficiently sensitive to the interrelations among different facets of evolutionary reasoning, the latter may not have been sufficiently sensitive to the specific nature of students' preinstructional misconceptions. The combined use of quantitative and qualitative measures thus appears to capture nuances of conceptual-change learning not captured by either method on its own.

SYMPOSIUM

Scaffolding: Treasuring learning oriented interaction

Chairperson: Geerdina Van der Aalsvoort, University of Applied Sciences (Hogeschool Utrecht), Netherlands

Organiser: Justine Howard, Swansea University, United Kingdom

Miriam Leuchter, University of Munster, Germany

Discussant: Kathy Sylva, University of Oxford, United Kingdom

Scaffolding, a concept first suggested by Wood, Bruner and Ross (1976) refers ideally to the following. "The teacher explains the problem and involves the child in the problem-solving process, giving him or her a chance to give an answer to the questions that arise at every intermediate stage of the search for the solution" (Grigorenko, 1998, p. 209). There are different opinions as to whether scaffolding refers to the more knowledgeable other (Vygotsky), to assisted performance in general (Tharp & Gallimore), to dialogic enquiry (Wells), to guided participation (Rogoff) or to a dynamic system in which patterns emerge in both adult and child's behavior (Van Geert & Steenbeek, 2005). This symposium bridges the concepts of scaffolding from the perspective of children (Howard), teachers (Leuchter & Saalbach) and from a dynamic perspective (Steenbeek et al.). Howard presents scaffolding as a concept related to play. She states that if children do not accept adults onto their play then scaffolding within the context of a play based curriculum becomes contentious. She reports her findings from several experiments carried out in kindergarten. Leuchter and Saalbach present findings with regard to the extent and the quality of scaffolding processes when kindergarten and primary school teachers work with a challenging science learning environment in their classrooms. Steenbeek, Van der Steen, Meindertsma, Van Dijk and Van Geert explore scaffolding as a microgenetic intrinsic dynamic notion that comes forward during scientific reasoning tasks with young children.

Co-constructing playful learning environments: the scaffolding potential of play

Justine Howard, Swansea University, United Kingdom

By understanding children's perceptions of what makes an activity play or not play, experimental designs have repeatedly shown that when children approach an activity as if it were play (by their own definition), they perform significantly better on problem solving tasks, demonstrate increased meta-cognitive and self regulatory behaviour and are more motivated and engaged, than when they approach the same activity as though it were not play. From a theoretical perspective, it is argued that these beneficial effects of play are a result of the fact that a playful state scaffolds development by providing a protected environment where behavioural thresholds are lowered and as a result, exploration and experimentation can occur. Crucially, children use cues within their environments to make play and not play distinctions and these appear to be based on their experiences. They develop scripts to determine whether an activity is approached as play or not play, and the chosen approach influences their behaviour and performance. Three particular types of cue are common; whether or not an activity is self chosen, whether an activity occurs at a table or elsewhere and, of particular importance to classroom practice and scaffolding techniques, whether or not an adult is present. As to whether or not children hold these cues to play depends on the nature of their previous experiences. The paper utilises findings from multiple studies that focus on children's perceptions of their own classroom activities, to demonstrate how scaffolding children's learning experiences within a play based curriculum can be maximised via co-construction.

Originating from the work of Vygotsky, scaffolding (Wood, Bruner & Ross, 1976) and other similar support mechanisms to enhance learning and development such as assisted performance (Tharp & Gallimore, 1988), dialogic enquiry (Wells, 1999), guided participation (Rogoff, 1990) and more recently, sustained shared thinking (Siraj-Blatchford, 2007) are most commonly associated with children's interaction with others. This can include child-child interaction as well as adult-child interaction. In the context of classroom practice, such forms of support often need to occur within the context of play. The notion that play itself can act as a form of scaffolding is also alluded to in Vygotsky's work and he proposed that "play creates a zone of proximal development [where] a child always behaves beyond his average age, above his daily behaviour.... as though he were a head taller than himself" (Vygotsky, 1978, p. 102). This paper describes a dual conceptualisation of scaffolding in relation to play; the inherent scaffolding potential of children adopting a playful state, and the potential for others to support and enhance opportunities for development via maintenance of this state. The paper utilises findings from multiple studies that focus on children's perceptions of their own classroom activities, to demonstrate how scaffolding children's learning experiences within a play based curriculum can be maximised via co-construction. With reference to studies that have focused on children's perceptions of their classroom activities, the paper will outline what kinds of characteristics or cues, children associate with play and not play (e.g. Wing, 1995; Howard, 2002; Howard & McInnes, 2010; Keating Fabian, Jordan, Mavers & Roberts, 2000). Three particular types of cue are common; whether or not an activity is self chosen, whether an activity occurs at a table or elsewhere, and of particular importance to classroom practice in relation to scaffolding,

whether or not an adult is present. By understanding children's perceptions of what makes an activity play or not play, the paper will then go on to consider experimental designs that have repeatedly shown that when children approach an activity as if it were play (by their own definition), they perform significantly better on problem solving tasks, demonstrate increased meta-cognitive and self regulatory behaviour and are more motivated and engaged, than when they approach the same activity as though it were not play (e.g. Thomas, Howard & Miles, 2006; McInnes, Howard, Miles & Crowley, 2009; Whitebread, 2010). A theoretical model of play that incorporates these findings will then be proposed suggesting that the beneficial effects of play manifest as a result of a playful state which scaffolds development by providing a protected environment where behavioural thresholds are lowered and as a result, exploration, trial and error can occur. The way in which play serves as a resource for children to meet intellectual and emotional challenge will then be presented (Howard, 2010). The cues children use to make play and not play distinctions appear to be based on their experiences. They develop scripts to determine whether an activity is approached as play or not play, and the chosen approach influences their behaviour and performance. This is a crucial point in respect of the utility value of scaffolding techniques associated with quality early years experiences. If children do not accept adults into their play (ie. they regard activities where adults are present as not play), then scaffolding within the context of a play based curriculum becomes contentious. With reference to studies of children's perceptions across contexts and cultures, the paper will demonstrate that whether or not children use particular cues to play (particularly the acceptance of adults as play partners) depends on the nature of their previous experiences. This evidence for the contextual nature of children's perceptions will be used to demonstrate that through informed classroom planning practitioners can support and enhance children's development using scaffolding techniques whilst at the same time maintaining their playful state. The paper will conclude by suggesting that the challenge of reconciling play and pedagogy (Wood, 2007) can be reduced via understanding and attending to children's perceptions of their activities and that this encapsulates an authentic co-constructed approach to play practice.

Teachers' scaffolding competencies in science in pre- and primary school

Miriam Leuchter, University of Munster, Germany; Henrik Saalbach, ETH Zurich, Switzerland

Recent research shows that the amount and the quality of teachers' scaffolding activities in kindergarten and primary school need to be improved. Focusing on science teaching these findings are specified in the results demonstrating that teachers find it hard to take into account children's naïve conceptual understanding and to stimulate their comparison processes (Appleton, 2008). The present research investigates teachers' scaffolding competencies with respect to the conceptual learning and teaching of science in the context of "floating and sinking" in K/1+2. In order to gain insight into teachers' highly specific classroom action, we videotaped K/1+2 teachers' instructional support in a science learning environment. The videotaped sequences were part of a four-week curriculum for kindergarten and

primary school which was implemented in 15 preschool and 15 primary school (1st and 2nd) classrooms with a total of 444 children. The videotaped lesson units provided a basis for a microanalysis of teachers' instruction which was rated on the basis of a high-inference rating system. This design allowed us to use frequency and variance analysis to test whether and to which extent teachers' instruction can be seen as scaffolding (i.e. activation of prior knowledge, stimulating comparison) and to find differences in the teachers' scaffolding techniques.

Based on recent research findings on the instructional quality in kindergarten and primary school we know that the stimulation of development and learning should refer to children's previous knowledge and stimulate conceptual change. This can be supported on the one hand by using attractive materials in structured learning environments and on the other hand by the teachers' interaction with the children: sustained shared thinking understood as challenging, stimulating teacher-student interaction and communication can act as "cognitive scaffolds" that help the children grasping the domain-specific contents (Appleton, 2008). However, scaffolding is still found too seldom in kindergarten and primary school. Studying the general quality of the teacher-child interaction, one must conclude that scaffolding is used very rarely and that direct instruction is dominating teachers' interaction in both kindergarten (Siraj-Blatchford & Manni, 2008) and primary school classes (Reiser, 2004). It can be assumed that these deficits in scaffolding activities depend on the lack of preconditions necessary for scaffolding, e.g. teachers' professional knowledge and competencies as well as challenging play and learning environments. Focusing on science teaching, it is known that teachers do not possess enough knowledge to discern children's misconceptions and stimulate their learning as they hardly ever take into account results on research on conceptual change (Appleton, 2008). This may be one of the reasons why especially in science teaching materials that are conducive to learning are not used often enough and that stimulating interaction is used too seldom. In this study we wanted to find out to what extent and in what quality scaffolding processes can be observed when kindergarten and primary school teachers work with a challenging learning environment in their classrooms. Thus, we designed four sequential and problem-based units for science learning which were applied during four weeks. The learning environment aimed at building up precursors of a scientific understanding in the domain of "floating and sinking". For each week the learning environment included three phases: First, learning materials and tasks were introduced in the whole group; on the following days children worked on the tasks on their own or in small groups, supported by teachers. At the beginning of the following week, children's questions, findings, and insights were reflected on in the whole group before the next learning environment was introduced. Teachers received a one-hour introduction where they were instructed about supporting children's construction of knowledge by e.g. stimulating comparison processes, emphasizing material labels, activating prior knowledge and assisting conceptual restructuring through sustained shared thinking. The curriculum was introduced in 15 preschool and 15 primary school (1st and 2nd) classrooms with a total of 444 children (Mean class size 19 children). Children attended school in middle-class rural areas of Central Switzerland. The age of the preschool children was between 4.4 - 7.1 years (mean: 5.1 years); the age of the primary school children was 6.2 - 9.6 years (mean: 7.9 years).

Teachers were 90% female and had at preschool level 3-33 years of experience with a mean of 11.5 years. At primary school level teachers had 4-39 years of experience with a mean of 16 years. The teachers were educated in the former system with a different study structure for the two professions. As a baseline of each teacher, 15 minutes of the teacher's support of the children during the student work phase before the implementation was recorded. This was used to contrast the instructional actions on an individual basis. During the first implementation week 15 minutes of the teachers' support of the children were videotaped. Due to the standardized content the videotaped lesson units of the implementation showed a very high degree of comparability. Videotaped instruction during implementation was rated on the basis of a newly developed high-inference rating system by two raters. This design allowed us to use frequency and variance analysis on specific scaffolding techniques. The videotaped baseline of the teachers showed very little interaction time, teachers being mostly occupied with organizational and disciplinary tasks, and not interacting with the children.

The results of the rated videotaped lesson units of the implementation show that only 30% of the teachers explicitly elicit comparisons or cognitive conflicts, and this also only to a mean extent of less than 10% of the videotaped time. 75% of the teachers asked at some point or other for reasons. This interaction type was observed during a mean of 17% of the videotaped interaction time. 95% of the teachers instructed directly or asked simple knowledge questions to a great extent (a mean of 30% of the videotaped time). During a mean of 2% of the videotaped time 20% of the teachers did not interact with children at all. The results also revealed significant differences between kindergarten and primary school teachers: Primary school teachers spent more time on eliciting cognitive conflicts than the kindergarten teachers (11% vs. 3% of the videotaped time). These results based upon case analysis show that even though teachers show deficits in both eliciting children's scientific reasoning and in stimulating children's comparison processes, the quantity and quality of interaction seems to increase with the use of a well-structured and problem-based learning environment. On the basis of variance analysis we found that kindergarten and primary school

teachers differed in their competencies. This may be the result of a different educational system for both professions. These findings have to be taken into account for actual Swiss pre-service and in-service teacher education, where nowadays both professions are jointly instructed in one study structure.

Curious Minds: The role of scaffolding in scientific reasoning talents of young children

Henderien Steenbeek, Rijksuniversiteit Groningen, Netherlands; heidy Meindertsma, University of Groningen, Netherlands; steffie van der Steen, University of Groningen, Netherlands

Young children already show much insight into Science and Technology (STEM, Dijkgraaf, van Benthem & de Lange, 2007). We assume that these talents are 'distributed', emergent characteristics, which come forward in transactions between a talented child and a talent eliciting context, e.g. in interaction with an adult while performing a STEM task (Barab & Plucker, 2002; Dai, 2005). Secondly, we assume that on the basis on these here-and-now experiences, different forms of STEM talent trajectories of children emerge. Scaffolding plays an important role in these here-and-now experiences. Scaffolding can be understood as a microgenetic, intrinsic dynamic notion (Granott, Fischer & Parziale, 2002; van Geert & Steenbeek, 2005): A particular level of knowledge or skill in a student changes as a result of the scaffolding process and vice versa. In this presentation we explore the interplay between the complexity level of insight in the question of the adult and in the answers of the child (first study, van der Steen), and the interplay between level of 'openness' in the question of the adult to the initiatives of the child under different conditions (second study, Meindertsma). Our results indicate that both individual child's level of insight as well as level of insight used by the adult within tasks and over time are highly fluctuating. The level of openness seems to be related to the degree of standardization of the task. In the presentation we will examine the surplus value of using a dynamic process approach to understanding the dynamics of scaffolding.

This research project is part of a Dutch, nation wide program entitled 'Curious Minds', which aims at exploring aspects of scientific reasoning talents of young children in order to be able to stimulate these talents in an optimal manner. Young students of four to six year old already show a lot of insights into science and technology, i.e. they display STEM talents (Dijkgraaf, van Benthem & de Lange, 2007). We assume that these STEM talents are 'distributed', emergent characteristics, which come forward in transactions between a talented child and a talent eliciting context, e.g. in interaction with an adult while performing a STEM task (Barab & Plucker, 2002; Dai, 2005). Secondly, we assume that on the basis on these here-and-now experiences, different forms of STEM talent trajectories of children emerge. Scaffolding plays an important role in these here-and-now experiences; i.e. in these interactions between child and adult while exploring a STEM activity (as can be seen in the CuriousMinds-videoclips; www.TalentenKracht.nl). Scaffolding can be received of as an intrinsic dynamic notion (Granott, Fischer, & Parziale, 2002; van Geert & Steenbeek, 2005) in which a particular level of knowledge or skill in a student changes as a result of the scaffolding process. That is, scaffolding implies a coupling between two changing levels: the level of insights embodied in the student on the one hand, and the level of insights embodied in the level of scaffolding the adult uses, on the other hand. In this presentation, we aim to explore two aspects of this coupling of two changing levels of insight, i.e. of the scaffolding dynamics between child and adult, using a microgenetic perspective. The first study (van der Steen) aims at unravelling the interplay between the complexity level of insights incorporated in the question of the adult and the complexity level of insights of the child, both on the short-term time scale of one task and on the long-term time scale of several months. Our hypotheses is that – under the condition of optimal scaffolding – young children will very quickly display relatively high level of complexity of insights, comparable with the level of insight incorporated in the questions of the adult. The second study (Meindertsma) examines the level of 'openness' in the question of the adult to the initiatives of the child under different conditions of a scientific reasoning task. Four conditions were administered in which the adult had a different role: She used different forms of instruction and scaffolding, ranging from 'static instruction' towards 'free exploration'. We hypothesized that in the most open condition, the child would show the most exploration of the STEM-task. A group of 32 four to six year old children participated. They were working on a STEM-task together with an adult for fifteen minutes. The task was videotaped. Two series of STEM-tasks were used. The first series of tasks was about gravity, inertia and acceleration; the second series was about air pressure and Boyle's law. The Scientific Reasoning Scale (RuG/UU) based on hierarchical complexity scale (Fischer & Bidell, 1998; Fischer & Dawson, 2008) was used to code the level of complexity in the insights of the child, and in the insights incorporated in the questions of the adult. First results indicate that the

individual child's level of insight is highly fluctuating, as is the level of insights the adult uses, both within tasks and over time (van der Steen, Steenbeek, & van Geert, in preparation). In addition, the level of openness seems to be related to the degree of standardization of the task (Meindertsma, van Dijk & van Geert, 2010). In the presentation we will discuss these findings and examine the surplus value of using a dynamic process approach to understanding the dynamics of scaffolding.

SYMPOSIUM

Interventions for students with mathematical learning difficulties

Chairperson: Johannes E.H. Van Luit, Langeveld Institute, Netherlands

Organiser: Evelyn Kroesbergen, University of Utrecht, Netherlands

Ilona Friso-van den Bos, Utrecht University, Netherlands

Discussant: Annemie Desoete, Ghent University, Belgium

In this symposium, three different interventions are presented that focus on improving low-performers basic math skills. Remediating these skills is essential for children to perform adequately at school and in daily life. Two of the studies presented in this symposium focus on the age group in which children have to acquire these skills, and the third is meant for older children who have not adequately achieved basic math skills. Trainings were designed to improve children's basic math skills, such as number knowledge, counting, base-ten system and automatization of basic facts. In one study, the effects of a math intervention were also compared to an intervention that combined mathematics with a possible underlying factor of math difficulties: working memory. One study examined the effects of a computer-based intervention. The interventions in the three studies were given to different groups: a non-selected sample, at-risk children, and children with low math scores. All interventions were effective. Together, these results contribute to the discussion about the effectiveness of distinct interventions, the most beneficial timing of interventions with various areas of focus, and the child-variables that are associated with the effect of the intervention, such as IQ.

Training numerical skills and working memory in Kindergarten: An international perspective

Kaisa Kanerva, University of Helsinki, Finland; Minna Kyttälä, University of Turku, Finland; Maria Chiara Passolunghi, University of Trieste, Italy; Nadia Sollazzo, University of Trieste, Italy; Evelyn Kroesbergen, University of Utrecht, Netherlands

In this study, we aimed to investigate whether simultaneous training of working memory and mathematics is more effective in enhancing young children's early mathematical skills than training mathematics alone. Sixty-one Finnish five to six year-old children (Mean age = 70.4; SD=8.6 months) were assigned to three different groups, 1) mathematics intervention (G1; N=21), 2) mathematics and working memory intervention (G2; N=23) and 3) control group (Gc; N=17). The two experimental groups received training twice a week, for half an hour at the time, during a four-week span. Preliminary pretest-posttest comparisons revealed that the mathematics intervention group (G1) performed statistically significantly better on counting tasks after the intervention. No statistically significant effect between pretest and posttest was found under the mathematics and working memory intervention group (G2) or the control group (Gc). Our preliminary results show that domain-specific mathematics training was more effective than simultaneous training of mathematics and working memory in enhancing young children's counting skills. The results of our study will be compared with the results from Italy and the Netherlands which both took part in the same international intervention project.

Aims

Even before formal schooling, there are significant differences in children's early mathematical skills which predict mathematics development and later performance (e.g. Aunola, Leskinen, Lerkkanen, & Nurmi, 2004). Those early mathematical skills can be successfully enhanced by training (for a meta-analysis, see Kroesbergen & Van Luit, 2003). However, along with early mathematical skills, also working memory (WM) has been observed to be a potential precursor for mathematics learning. The term 'working memory' refers to humans' limited capacity information processing system capable of storing and manipulating information during a range of cognitive tasks (Baddeley, 1986). Research has established close links between WM deficits and mathematical difficulties (Andersson & Lyxell, 2007; McLean & Hitch, 1999). Working memory skills measured at preschool years or at early school years also tend to predict mathematics performance later on (Alloway et al., 2005; Passolunghi, et al., 2007). Previous studies show that training improves WM performance, at least among those individuals with low WM span (Turley-Ames & Whitfield, 2003). Functional MRI-studies have showed evidence of plasticity in neural systems underlying WM induced by WM training indicating a typical skill learning pattern. Some of the studies also show that rehearsing can produce transfer effects to other cognitive functions (e.g. fluid intelligence; Jaeggi et al., 2008), at least in situations when trained tasks and transfer tasks employ overlapping brain regions (Dahlin, et al., 2008).

Deriving from previous studies, it could be hypothesized that training both WM (the supporting system behind math performance) and mathematics could produce better results than training only math. Therefore, in this study, we aimed to investigate whether simultaneous training of working memory and mathematics is more effective in enhancing young children's early mathematical skills than training mathematics alone.

Methodology

The participants in the study were 61 (29 girls and 32 boys) Finnish children from 11 metropolitan kindergartens. At the time of the pretests, the children were about five years old (Mean age=70.4; SD=8.6 months) and about to start preschool in three months.

The participating children were divided into three different experimental groups: G1 (mathematics training), G2 (mathematics and WM training) and Gcontrols group (age-matched control group) based on their age, gender and kindergarten. The pretests were conducted in April 2010 during a two-week span. The intervention took place in May 2010 and lasted for four weeks. There were two intervention sessions per week, each lasting 30 minutes. The interventions were conducted in small groups (4-5 children). The posttests were administered in the beginning of June 2010 during a one-week span.

Pre- and posttests.

Children's early numeracy was measured by using the counting tasks of Early Numeracy Test (Van Luit, Van de Rijt, & Aunio, 2006). Different components of working memory were measured: visuo-spatial storage: Matrix task, visuo-spatial processing: Odd-One-Out, verbal storage: Word recall forward, Digit recall forward, verbal processing: Backwards word recall, digit recall backwards. Intelligence was measured with the subtests Vocabulary and Block design from the WIPPSI.

Interventions.

The domain-specific mathematics training focused mainly on basic number word sequence skills (0-20), enumeration skills and number line skills. In the mathematics-WM training, tasks included same type of numerical materials but with stronger WM demands.

Findings

Preliminary pretest-posttest comparisons revealed that the mathematics intervention group (G1) performed statistically significantly better on counting tasks after the intervention. No statistically significant effect between pretest and posttest was found for the mathematics and working memory intervention group (G2) or the control group (Gc). A repeated measures ANOVA, revealed a significant interaction effect on group by type of training ($F[2,61]=3.51$, $p=.11$). However, in pairwise comparisons, post-hoc tests (Scheffé) could not detect significant differences between the groups ($p > .05$), although the difference between G1 (mathematics only) and Gcontrols was close to the level of statistical significance ($p=.06$). The three groups did not differ on age, intelligence or early numeracy performance before the intervention. We will continue with more detailed analyses and the final results will be presented in the EARLI 2011. The results of our study will be compared with the results from Italy and the Netherlands which both took part in the same international intervention project. The preliminary results from Italy show a statistically significant interaction effect on group by type of training (mathematics, no training; $F[1,53]=10.40$, $p=.17$). The results from the Netherlands show a slightly more positive effect for the combined group than the Finnish data.

Theoretical and educational significance

Our preliminary results suggest that domain-specific mathematics training might be more effective than simultaneous training of mathematics and working memory in enhancing young children's counting skills. The final results from Finland and from other two participating countries will increase knowledge about the possibilities to train WM, and about the possible transfer effects to other skills (theoretical significance). The results will also increase knowledge about the effects of early mathematics training in different cultural and lingual contexts (theoretical significance). Finally, the results can produce information to be used in early childhood education when planning group interventions (educational significance).

Fostering children with learning disabilities in mathematics in secondary school

Elisabeth Moser Opitz, Institut of Educational Research, Switzerland; Okka Freeseemann, Technical University Dortmund, Germany; Ina Matull, Technical University Dortmund, Germany; Susanne Prediger, Technische Universität Dortmund, Germany; Stephan Hußmann, Technische Universität Dortmund, Germany

Research has shown that pupils with learning disabilities in higher grades have not or have only partially acquired specific concepts of primary school mathematics, the so called "basic subject matter" (counting, place value, problem solving etc.). These knowledge deficits prevent students from learning successfully and might negatively affect their chances of achievement. Based on these findings, a longitudinal study in grade 5 (sponsored by "Bundesministerium für Bildung und Forschung") evaluated (a) if the backlog can be cleared, (b) if special needs instruction improves achievement in mathematics, and (c) if the type of instruction influences or affects the progress. The study was conducted with a sample of 125 pupils in Nordrhein-Westfalen (Germany) in two intervention groups (A: instruction in small groups; B: classroom instruction) and one control group (groups matched by math achievement, IQ, age, gender). During 14 weeks, pupils were taught basic concepts like counting, place value and basic operations. Post-tests were carried out at the end of this period and three months later. An ANOVA with post-hoc test (Scheffé) showed a significant effect for the classroom instruction group for post-test 2, and a MANOVA with IQ as a covariate revealed a significant interaction effect for intervention and IQ.

Aims

Research has shown that pupils with learning disabilities in higher grades have not or have only partially acquired specific concepts of primary school mathematics, the so called "basic subject matter" (e.g., Humbach, 2008; Moser Opitz, 2007). These pupils often memorize the mathematical procedures like a recipe and have difficulties in problem solving (e.g., Andersson, 2008). They have problems with retrieving results (e.g., Geary, 2004; Mabbott & Bisanz, 2008), use finger counting strategies, and have difficulties in understanding the concept of place value (Humbach, 2008; Moser Opitz, 2007). Although these issues are widely known, successful intervention programs are lacking. Maccini, Mulcahy, and Wilson (2007) concluded that many studies failed to find practical significance because of inadequate intervention. However, some research revealed important clues for intervention programs (e.g. Kroesbergen & van Luit, 2002; Woodward and Brown, 2006).

The purpose of our study was to develop and to evaluate an intervention program, which improves the knowledge of "basic subject matters" in two different conditions: Instruction in a small group and guided instruction in the classroom.

Hypotheses

H1: Pupils in grade 5 with below average performance in mathematics who participate in an intervention program covering basic subject matter, improve their mathematical competence more than pupils who do not attend the program.

H2: Pupils in grade 5 with below average performance in mathematics who participate in an intervention program in small groups, improve their mathematical competence more than pupils attending a program with classroom instruction.

Methodology

The participants were 5th graders with mathematical competence below average (measured with an own, standardized test). The math pre-test and an IQ-test (CFT-20R) were carried out with a sample of 607 pupils from 9 schools (most pupils in lowest level of secondary school) in Nordrhein-Westfalen (Germany). Based on these results, 143 pupils from 34 classes were selected. Groups of 3-5 pupils from the same class were randomly assigned to two types of intervention and the control group. These groups were matched by math achievement ($F [2,140] = .872, p > .05$); IQ ($F [2,140] = .262, p > .05$), age ($F [2,140] = .972, p > .05$), and gender. Note that the mean IQ of the total sample was rather low ($M = 82, SD = 10.5$).

Math performance was measured with a pre-test at the beginning of grade 5 (t_1), after the intervention (t_2 ; 6 months after the pre-test) and with a follow-up (t_3) three months later. The intervention focused on the base ten system (base ten grouping, place value, number line notation), on developing meaning for the operations, on verbal counting (counting by steps of 2, 10, 100, 1000), and on automation of basic facts (e.g., completion of 100). The material was identical for both intervention groups.

Instruction in small groups (A): During 14 weeks, 12 groups of 3-5 pupils attended the program of 90 min/week carried out by a higher-grade special education student. The instruction included the components (1) warm-up (e.g., automation of basic facts), (2) discussion of the week activity, (3) guided practice on new concepts and problem solving, (4) introduction of the week activity (work sheet).

Guided instruction in classroom (B): This intervention provided material for individual work in classroom (two difficulty levels). 12 groups of 3-5 pupils with learning disabilities in mathematics weekly attended an introduction of 45 minutes. This introduction, carried out by a higher-grade special education student, involved the components (1) "diagnostic check" (assessment), (2) selection of an appropriate math problem for each pupil, (3) pupils' individual

work, and (4) final assessment. Additionally, these pupils worked individually on their program in the classroom 90 minutes per week, assisted by the teacher.

The control group followed the ordinary curriculum.

Findings

Because of some dropouts, the post-test was conducted with 132 pupils, the follow-up with 125 pupils. For the post-test (t2) a 2x3 ANOVA showed a significant effect for time ($F [1, 129] = 218.9, p < .001, \eta^2 = .63$), but no significance for the interaction between time and the type of intervention ($F [2, 129] = 0.94, p > .05, \eta^2 = .01$). A 3x3 ANOVA for the follow-up (t3) showed a significant effect for time ($F [2, 121] = 159.8, p < .001, \eta^2 = .73$) and a non-significant interaction effect for time and type of intervention ($F [4, 242] = .90, p > .05; \eta^2 = .02$). However, post-hoc test (Scheffé) showed a significant effect for the classroom intervention group ($p < .05$). With IQ as a covariate (3x3 MANOVA), a significant interaction effect for time and IQ could be found ($F [2, 120] = 5.22, p < .05, \eta^2 = .08$). Hence, the cognitive ability impacts the increase of math performance. For the interaction between the type of intervention and IQ, we only found a tendency for Roy's largest root ($F [2, 121] = 2.7, p = 0.07, \eta^2 = .04$). Contrast analyses revealed that the classroom instruction group outperformed the control group ($p < .05$).

Theoretical and educational significance

Even if we did not find effects directly after the training, H2 (advantage for the training in small groups) had to be rejected, and the effects for the follow-up reached the significance level with restrictions, some interesting results are available. Firstly, the intervention seems to have a long-term impact on math performance: The difference in math performance between the intervention groups and the control group increased from t2 to t3. Secondly, as the groups were small, it seems reasonable to assume that a larger sample could have shown significant effects. Intelligence seems to be an important factor in terms of progress for children with rather low cognitive abilities. Moreover, the intervention period was very short according to the problems of the pupils. Although more research is needed, this study gives promising results for the remediation of math learning problems.

The effects of the Graphogame Math computer game on early numeracy skills of kindergarten children

Jonna Salminen, Niilo Mäki Institute, Finland; Tuire Koponen, Niilo Mäki Instituutti, Finland; Pirjo Aunio, University of Helsinki, Finland; Pekka Rasanen, Niilo Mäki Institute, Finland

We studied how a short and intensive intervention of playing an educational computer game (Graphogame Math) would support kindergarteners' early numeracy skills (counting skills, enumeration, number knowledge and basic arithmetic). A treatment group of 6 year old children with weak early numeracy skills was assigned to play daily Graphogame Math (GGM) ($n=8$, mean age 79 months) for three weeks. The GGM group was compared to a performance level control group ($n=7$, mean age 78.7 months) matched by the initial level of cognitive (Corsi Blocks, non-word repetition and rapid serial naming of colors) and early numeracy skills and also to a reference group ($n=8$, mean age 78.9 months) matched by age and kindergarten. The control group was assigned to play same amount another mathematical computer game (Number Race). The reference group did not get any extra training. The results of within-group indicated statistically significant gains for counting skills and enumeration for the GGM group and for basic arithmetic skills for the NR group. The reference group gained significantly in counting skills.

Aims

Longitudinal studies have demonstrated that there is a notable difference in the early numeracy skills between children with low and average math performance already in kindergarten and the difference typically increases at school age (Aunola et al. 2004; Desoete and Grégoire 2006; Jordan et al. 2006; McClelland et al. 2006). In the present study a computer assisted intervention (later CAI) method (Graphogame Math) was targeted for kindergarteners (6 year old) to find out the possibilities of CAI to give special support for young children.

The main purpose of this study was to find out to what extent the short and intensive intervention (three weeks daily) of playing Graphogame Math (GGM) computer game supports kindergarteners' early numeracy skills. We measured counting skills, enumeration, number knowledge and basic arithmetic skills separately which enabled us to analyze the effects of intervention in more detail. This study included two control groups. One group was matched with the initial level of cognitive and early numeracy skills and they played the Number Race computer game (NR). The other reference group was typically performing kindergarteners with no extra training.

Methodology

Participants. The original group sizes were thirty children in the low performing and thirty children in the reference group. Because the aim of this study was to exam whether the playing GGM would increase especially weak numeracy skills we selected for the analysis only those children who performed 1.5 SD below the mean in the counting task.

There were eight (6 boys, 2 girls) in the GGM group (mean age = 79.0 months, SD = 3.2) and seven (4 boys, 3 girls) in the NR group (mean age = 78.7 months, SD = 4.3). The reference group consisted of eight average performing children (2 boys, 6 girls; mean age = 78.9 months, SD = 2.9) who followed the kindergarten program during the intervention.

Data collection. The present study consisted of two pre tests and one post test. The first pre test consisted of three cognitive and four numerical tasks which were presented in the following order: Corsi Blocks, Non-Word Repetition, Enumeration (computerized test), Number Knowledge (computerized test), Counting Skills, Basic Arithmetic and Rapid Serial Naming of colors. The second pre test and the post test consisted of four numerical tasks and one cognitive task which were also presented in the same order: Enumeration (computerized test), Number Knowledge (computerized test), Counting Skills, Basic Arithmetic and Rapid Serial Naming of colors. Children were assessed individually. The mean of the two pre tests was used in comparisons. The content of the intervention programs were matching exact magnitudes, number symbols and arithmetical combinations in GGM (Mäkkänen et al., 2010) and activating the approximate comparison process to enhance quantity representation (Wilson et al. 2006a; Wilson et al. 2006b).

Procedure. After two pre tests the experiment groups were randomly divided into two sub groups. Both groups were desired to play individually 12-15 times for three weeks, 4-5 times per week. All sessions were recommended to last 10 to 15 minutes. Teachers were asked to report the number of intervention sessions and playing time. There were no statistically significant differences between two playing groups in the number of intervention sessions (mean of the GGM group 10.75 and the NR group 11.29) nor in playing time (mean of the GGM group 187 minutes and the NR group 232 minutes).

Findings

In the preliminary analysis the performance of the GGM group in cognitive and numerical skills in base line measurement was compared to the performance level control group (the NR group) and to normally performing reference group (the Reference group) with analyses of the Mann-Whitney U-test. The second set of analyses focused on the within-group differences, also with non-parametric tests. There was a significant difference between the GGM and the Reference group in the Corsi Blocks, Mann-Whitney U = 10.5, $p = .01$. There was also a statistically significant difference in the Counting Skills between the GGM and the Reference group U = .00, $p = .055$. In Basic Arithmetic the effect of intervention was significant in the NR group, $Z = -2.333$, p

Theoretical and Educational Significance

Our results are parallel to earlier studies: short and intensive CAIs with specific mathematical contents have found to be effective (Kroesbergen & Van Luit 2003; Kulik & Kulik 1991). Even a short training lasting less than daily 15 minutes for few weeks seems to produce significant effects (Elliot & Hall 1997; Howard et al. 1994; McCollister et al. 1986). This kind of short and intensive CAI will be important to introduce in preschools and kindergartens as well as at homes to support young children's early numeracy skills. Despite of our positive results more evidence for the effectiveness of CAI (e.g., Clements 1986; Din & Calao 2001; McCollister et al. 1986) is needed. Especially the longtime effects (Fuchs et al. 2006) are important to examine.

SYMPOSIUM

Identifying key learning activities in strategy instruction in various ill defined domains. Part III

Chairperson: Raquel Fidalgo, University of Leon, Spain, Spain

Organiser: Gert Rijlaarsdam, University of Amsterdam, Netherlands

Discussant: P. Karen Murphy, The Pennsylvania State University, United States

The symposium aims at the identification of effective instructional strategies in various domains of learning, in ill structured tasks. General idea is to bring together and to analyze intervention studies that focus on strategy development. The symposium will address the question 'What works in strategy instruction and why?' with variations in content (the strategy learned), the learning activity and the content domain.

Therefore, we selected studies that were set up as componential analysis of instructional components (e.g. Fidalgo et al. in this symposium), studies that analyzed data from complex interventions with multi-components to isolate the contributions of each component to the total effect (for instance Glaser et al. in this symposium), and experiments that aimed at studying the effect of a single learning activity (Groenendijk et al., focusing on observation as learning activity). In three sessions, the symposium will deal with various domains (visual arts: divergent thinking; history: historical thinking and language arts: writing and reading literary texts). The domains have in common that they aim at thinking skills, and are seen as ill-structured.

Predicting and questioning story content; Two effective learning activities in the domain of literat

Tanja Janssen, Universiteit van Amsterdam, Netherlands

This contribution focuses on two learning activities, designed to enhance students' reading engagement and story appreciation; 'predicting' and 'self-questioning'. The effectiveness of these approaches was examined in two studies, involving Dutch 10th grade students. Study 1 focused on the effects of predicting story content on students' reading process and story appreciation. 53 Students participated, each reading two short stories under think aloud conditions. The experimental group was asked to predict story content by writing a story guess before reading, the control group did not write. Think aloud responses were analyzed for reading activities used. Story appreciation was measured by having students rate both stories on a ten-point scale. Results showed that experimental students were more emotionally engaged during reading and more appreciative of the stories than the control students. In Study 2 the effects of instruction in self-questioning was examined on students' reading process and appreciation of stories. 67 Students participated, randomly assigned to one of two conditions: an experimental condition, in which students were taught to ask questions in response to short stories, and a control condition, in which students responded to instructor-made questions. Both conditions included five sessions. Pre- and posttests included a think aloud task, a written response to a story, and rating a story on a ten-point scale. Results indicated that the experimental students generated more questions during reading at posttest than the control group, after controlling for pretest scores. In addition, experimental students were significantly more appreciative of stories at posttest than the control students.

One of the major challenges of teachers of literature is how to motivate adolescents to read and interpret literary texts. In the upper grades of Dutch secondary education students' reading motivation appears to diminish (Van Schooten, 2005). Solutions are sought in broadening the range of texts to be discussed in the literature classroom, in incorporating multiple forms of media (video, song lyrics), and/or in matching reading material to the literary competence level of each student (Witte, 2008). In addition, instructional strategies can be implemented that may help students' to become more engaged and appreciative readers of literature. In this contribution two such strategies are discussed: predicting and self-questioning. The first strategy refers to making predictions about what might occur in a story to be read subsequently. By making predictions students are induced to activate prior knowledge and to make connections between their prior knowledge and the text at hand. Students may become curious about a story, wanting to compare their own predictions to the author's solutions. In previous studies beneficial effects have been found of generating predictions on students' story comprehension and recall. Denner, Rickards and Albenese (2003), for instance, gave students key phrases of a narrative, prior to reading. Students were asked to compose a 'story guess' on the basis of those key phrases, and then to read the actual narrative. We applied this method to short literary stories. Instead of key phrases, we provided students with story beginnings. Students were asked to write their own stories, based on these beginnings, prior to reading the authors' stories. The second strategy refers to generating questions during reading. Previous research indicated that self-questioning is an effective reading strategy, improving students' text comprehension and recall (Janssen, 2002; Rosenshine et al., 1996). However, self-questioning is not just an individual reading strategy. It can also be part of dialogical learning, in which authentic, reader-based questions and discussion between peers are valued (Applebee et al., 2003). Therefore, a discussion-based approach was developed, comprising five steps:

- 1) ask yourself questions during reading a story,
- 2) choose a key question for discussion,
- 3) discuss your key question with peers,
- 4) formulate tentative answers to your key question (story interpretations), and
- 5) underpin your interpretations by referring to the story at hand.

The effects of these strategies on students' engagement with short literary stories were examined in two studies, involving 10th grade students from several Dutch secondary schools. The students were enrolled in higher general and pre-university education. Study 1 examined the effects of predicting story content on students' reading process and story appreciation. 53 Students participated, each reading two short stories under think aloud conditions. The stories were written by recognized authors of modern fiction: Jeanette Winterson and Primo Levi. The experimental group (N = 18) wrote a story guess prior to reading, the control group (N = 35) did not write. Students' think aloud responses were transcribed and analyzed for the reading activities students used (Andringa, 1995; Pressley & Afflerbach, 1995). Story appreciation was measured by having students rate both stories on a ten-point scale (strong dislike – strong liking of the story). Results showed that students who predicted story content by writing a story guess, produced significantly more emotional responses (laughs, sighs, exclamations) during reading the actual story than control students. Moreover, the experimental group was more appreciative of the stories after reading than the control group. In Study 2 the effects of instruction in self-questioning on students' reading process and story appreciation were examined. 67 Students participated, randomly assigned to one of two conditions. In the experimental condition students (N= 35) were taught to generate questions in response to short stories, following the five steps approach. In the control condition students (N = 32) did not generate questions themselves, but responded to given questions. Both conditions included five sessions, held after schooltime at the university. Pre- and posttests included a think aloud task, writing a review about a story, and rating that story on a ten-point scale. Students' written reviews were

rated by three independent raters using a three-point scale (weak, fair, good interpretation). Results indicated that the experimental students generated more questions during reading and thinking aloud at posttest than the control group, after controlling for pretest scores. Also, experimental students were significantly more appreciative of stories at posttest than the control students. No difference was found in quality of interpretation between conditions.

All in all, both instructional approaches positively influenced students' reading engagement. However, the utility of predicting story content by writing a story guess is limited, since students are not taught a reading strategy that they can use independently (Denner et al., 2003). Self-questioning on the other hand can be used independently by students, as indicated by the analysis of students' think aloud protocols.

Effects of Meta-cognitive Instruction on Divergent Thinking in the Domain of the Visual Arts

Marie-Therese van de Kamp, UvA, Netherlands; Wilfried Admiraal, University of Amsterdam, Netherlands

Divergent thinking is considered to have positive effects on creativity, the quality of creative processes and products. Contemporary art education mainly focuses on learning art-techniques based on the assumption that divergent thinking skills are acquired by producing art works. However, in a previous study with 199 students, many students proved to have difficulties in using divergent thinking skills in the orientation phase of creative, visual-art processes. In a subsequent study, effects of a meta-cognitive instruction are studied on students' declarative and procedural knowledge on divergent thinking in the domain of the visual arts in secondary education in the Netherlands. This intervention is evaluated using a pretest posttest control group design with switching replications (N= 149).

The intervention consists of an instruction on declarative knowledge – students learn about the nature and the relevance of divergent thinking as a learning strategy in creative, visual processes – and procedural knowledge – through a specific training in divergent thinking in the visual arts. Preliminary results of the effect study show that the meta-cognitive intervention has a positive effect on both declarative and procedural knowledge as well as on the level of students' reflection and the quality of their art processes and products. Furthermore, students' divergent thinking is stimulated showing higher fluency, originality, flexibility and elaboration – all indicators of divergent thinking.

Objectives and theoretical framework Divergent thinking skills are crucial in the orientation phase of creative processes showing positive effects on the quality of creative, visual products (cf., Getzels & Csikszentmihalyi, 1976; Ma, 2009). Indicators of divergent thinking are fluency, originality, flexibility and elaboration, including general as well as domain-specific skills (Runco, 1991; Baer, 1993; Chand, I., Runco, M.A., 1993). In a previous study with 199 students in secondary education, 75 percent of the students showed a lack of either declarative or procedural knowledge in divergent thinking in creative, visual processes. Furthermore, many students did not show divergent thinking skills. Therefore, we designed and tested a meta-cognitive instruction, in which students acquire basic knowledge about divergent thinking (declarative and procedural knowledge) and in which students train skills in divergent thinking. The intervention consists of four stages:

(1) Teacher's direct instruction on the nature of creative processes and of divergent thinking (declarative knowledge). They learn about (a) the different nature of divergent thinking compared with other thinking strategies like convergent thinking and problem-solving strategies, and (b) the relevance of divergent thinking skills in the orientation phase of creative, visual processes (conditional knowledge).

(2) Guided practice in divergent thinking skills: a training with various tasks in which students experience visually the nature of divergent thinking, through a metaphorical comparison for divergent thinking – an analogy of focus versus

divergence in visual perception. Students practice with two unusual uses tests (verbal and figural through photography), in which they are asked to think of as many as possible, different kinds of original uses for several items. They learn about the indicators of fluency, flexibility and originality and elaboration and to use specific techniques (synthesis) within the domain of visual art.

(3). Guided practice with (peer- and teacher) feedback to apply divergent thinking to go beyond clichés and produce their own original solutions.

(4) Application in students' own visual art processes. Students first experiment with as many different, common shiny materials they can think of (using divergent thinking strategies) to find their own design-research question (problem finding).

Method

The intervention is tested in a pre-test post-test control group design with switching replications (Shadish, Cook, & Campbell, 2002) on students' knowledge and skills in divergent thinking, their reflection and the quality of their art products. Five groups of students (N=149), aged 16/17, from cultural and arts education participate. Three groups first receive the intervention. Two groups receive it at a later date and initially serve as no-treatment control group. Divergent thinking is indicated by fluency, originality, flexibility and originality. Synthesis is added as a specific variable of divergent thinking skills for the visual domain. Divergent thinking skills are measured by a verbal test (with use of the Creative Task Creator, Pretz & Link, 2009) and a figural test, using photography, supplemented with a score on originality (Silvia et al., 2008; Torrance, 1979). Creative visual products are judged by two rates. A criterion-based rating procedure for both the visual arts process and product is adapted from procedures of Dutch final exams in visual arts, additionally informed by other research (Eça: 2004; Lindstrom: 1999; Pretz & Link : 2008; Seidel et al. : 2009; Silvia et al.: 2009). To measure reflection, participants write a reflection on their process using pre-structured form. Multivariate covariance analyses are used to establish the effects on knowledge and skills in divergent thinking, reflection and quality of visual arts products; participants' ability, school motivation and background variables (age, gender) are included as learner variables.

Preliminary results and conclusions

Preliminary results of the effect study show that the meta-cognitive intervention has a positive effect on both declarative and procedural knowledge as well as on the level of students' reflection and the quality of their art processes and products. Furthermore, students' divergent thinking is stimulated showing higher fluency, originality, flexibility and elaboration – all indicators of divergent thinking.

Creating concept maps to trigger historical consciousness in secondary education

An important goal of Dutch history education in primary and secondary education is the development of students' historical consciousness, including historical overview knowledge and historical reasoning skills. Creating concept maps – graphical tools for organizing and representing knowledge – might be an effective tool to trigger historical consciousnesses. In this study we examine the effects of the use of concept maps on historical overview knowledge and reasoning skills in lower secondary education in the Netherlands. A pre-test post-test control group design with some 200 students is used to determine the effects of the use of concept maps on historical consciousness. The process of creating concept maps is taped on video and analyzed qualitatively. Multivariate covariance analysis is used to determine the effects of the use of concept maps on historical knowledge and reasoning, measured by a digital test with a random selection of 50 out of a corpus of 150 multiple choice questions. Prior to the effect study, various concept maps – ranging from pre-structured to ill-structured- have been piloted and evaluated on usability and learning possibilities. Results show that all types of concept maps tested triggered positive effects on pupils' motivation and perceived learning outcomes, albeit the ill-structured concept maps resulting in the least engagement and motivation. Preliminary results of the effect study indicate an effect of the use of concept maps on both knowledge and skills.

An important goal of Dutch History education in primary and secondary education is the development of historical consciousness including a chronological frame of reference (historical overview knowledge) as well as historical thinking skills (Commission historical and social formation, 2001). The overview knowledge includes a frame of reference with ten chronological periods with associate labels characterized by a set of 49 key aspects and some 100 key concepts. With respect to historical thinking, Van Drie and Van Boxtel (2008) used the term historical reasoning for all activities in which a person organizes information about the past in order to describe, compare, and/or explain historical phenomena. In doing this, he or she asks historical question, contextualizes, makes use of substantive and meta-concepts of history, and supports proposed claim with arguments bases on evidence from sources that give information about the past. So, historical reasoning is used for all activities in which a person organizes information about the past in order to describe, compare, and/or explain historical phenomena. In the development of historical consciousness, the use of concepts is very important. Comprehension of these concepts can be promoted by relating specific phenomena to abstract concepts, or by connecting concepts of a lower level of abstraction with concepts of a higher level of abstraction (Wilschut, Van Straaten, & Van Riessen, 2004). Concepts might not only play an important role in historical knowledge; constructing a conceptual framework is an essential historical skill as well. For example, a student who uses the concepts of Enlightenment and French Revolution might conceptualize this linkage as a cause. So, the use of concept maps might be an effective tool to trigger both historical knowledge and reasoning skills. Novak and Cañas (2008,p1) describe concept maps as graphical tools for organizing and representing knowledge including concept,- usually enclosed in circles or boxes of some type- and relationships between concepts -indicated by a connecting line linking two concepts/. Various studies have shown effects of the use of concept maps on achievement (Kou-en, You-Ting, & Ine-Dai, 2002, Oliver, 2009, and for an over view Cañas, et al., 2003). But most of these studies are about Science education; in the current study we focus on History. By using concept maps in History education students visually connect concepts of different levels of abstraction, synthesize a certain chronological era, and reflect on what is important to be included. We have formulated two research questions:

1. Does the use of concept maps increase students' historical overview knowledge, and
2. Does the use of concept maps improve students' historical reasoning skills?

Method

The research has been carried out in two stages. The first stage includes an evaluation study on three types of concept maps – (1) 'fill in the gaps' (pre-structured assignment), (2) 'create a map with pre-selected concepts' (moderate-structured assignment) and (3) 'create a map from scratch' (ill-structured assignment)- with 114 students from lower secondary education. Data has been gathered by a questionnaire on usability, motivation and perceived learning outcomes, by observation of the process to measure the usability and student engagement, and by the resulting concept maps to analyze differences in quality. In the second stage, we redesigned the use of concept maps based on these results and feedback of teachers. The intervention consists of a total of seven concept maps assignments: the first two assignments are pre-structured and the last five are moderate-structured. We did not include The ill-structured assignment as it showed to be too difficult.

In a pre-test post-test control group design we test the effects of concept map creation on historical overview knowledge and reasoning skills. The participants are about 200 students, aged 13-15 from eight groups and two similar secondary schools. Four groups acquire historical knowledge and reasoning skills by creating concept maps. The other four groups use materials provided in the regular Dutch History curriculum. The intervention takes three months. All students participate in a digital pre- and posttest, which is part of the regular curriculum. This test includes

a random selection of 50 out of a set of a corpus of 150 multiple choice questions referring to both historical overview knowledge and historical reasoning. (reliability 0.80 (KR-20)). Multivariate covariance analysis is used to determine the effects of the creation of concept maps. The process of creating concept maps is taped on video and analyzed qualitatively to understand the process and interpret the results of quantitative analyses. Results of stage 1 show that all types of concept maps tested triggered positive effects on pupils' motivation and perceived learning outcomes, albeit the ill-structured concept maps resulting in the least motivation and engagement. Preliminary results of the effect study indicate an effect of the use of concept maps on both knowledge and skills. Low ability students gain more than high ability students (interaction effect).

SYMPOSIUM

Predictors of Students' Academic Emotions

Chairperson: Gerda Hagenauer, University of Salzburg, Austria

Organiser: Gerda Hagenauer, University of Salzburg, Austria

Discussant: Tina Hascher, University of Salzburg, Austria

Recent research has documented the important role of emotions for students' learning in school (e.g., Schutz & Pekrun, 2007; Hascher, 2010). As a common and important result it was outlined that positive emotions foster the learning process while negative emotions can impede successful learning in school. Thus, there is a need for scholastic instruction to support the development of positive emotions and to prevent maladaptive negative emotions in school. Research, however, also has shown that negative emotions increase and positive emotions decrease after the early elementary school years. As a consequence, research is needed which identifies precursors and predictors of emotions in school.

The symposium, hence, focuses on the origins of students' emotions and their role of emotional development in school. Four research groups present research findings on antecedents of students' emotions. The presentations highlight social (e.g., peers and teachers) as well as cognitive (e.g, achievement and attitudes towards school) aspects; they analyze the general school situation as well as specific learning contexts (e.g, portfolio instruction); they investigate the development of state (e.g., enjoyment, anxiety) as well as trait emotions (e.g., well-being); they include data from qualitative (e.g., interview) as well as quantitative (questionnaire) research; they capitalize on the strengths of cross-sectional as well as longitudinal research designs. The common aim of all presentations is to identify relevant scholastic factors which have to be considered in order to provide supportive learning environments and student-orientated instructional designs in school.

Students' emotions in portfolio based instruction

Michaela Glaeser-Zikuda, University of Jena, Germany; Julia Noack, University of Jena, Germany

In research on learning and instruction it is meanwhile considered that emotional dispositions and emotional experiences in specific learning situations are relevant conditions for learning, information processing, cognition, motivation, and social interaction. As school and instruction are often related to students' negative emotional experiences it is an important aim for research and school development to create learning environments more emotionally-oriented. An intervention study based on the portfolio approach aiming at a positive influence of learners'

emotion, motivation, problem-solving and social competencies, as well as achievement is presented. Main characteristics of the portfolio based learning environment are competence-oriented learning demands, multiple opportunities of self-regulation and self-determination, a high quality of interactions between learners and teachers, and cooperation, and continuous self-reflection. The presentation focuses on instructional and individual conditions of students' emotions in portfolio based and regular physics instruction.

Generally, research on learning and instruction in the last years has recognized that emotional dispositions and emotional experiences are crucial conditions for learning, information processing, cognition, motivation, and social interaction. Emotions have an evaluational relation to learning, instruction, and achievement. In orientation to appraisal theories, and especially for the context of learning and achievement, the control-value approach (Pekrun et al., 2007) points out that subjective control of the learning and achievement situation, as well as the subjective value of learning process and achievement are crucial for the interpretation of a situation. Students experience different situations in instruction and value these situations depending on previous experiences, the social context, their personal goals, their interests, and other personality factors. Instruction, the personal and social value system, concession of autonomy, expectancies and learning and achievement goals, but also teachers' support, assessment strategies, and achievement feedback are assumed to have an influence on students' emotions. Emotions also have an effect on learning and achievement, mediated by attention, self-concept, self-regulation, and motivation, thus directing the person toward or away from learning matters in learning situations. Positive emotions may also facilitate self-regulation in learning. The experience of competence and autonomy in learning has been stressed out as important for self-regulation and the experience of self-determination (Deci & Ryan, 1985). Furthermore, information processing and learning strategies are influenced by emotions.

Generally, school and learning are associated by most of the students with more negative experiences and emotions. And it even seems that school itself contributes to this negative estimation. Therefore, it is an important issue for school, and for research in this context to focus particularly on a reduction of boredom, anxiety, and hopelessness, and an enhancement of enjoyment, satisfaction, or pride. Consequently, a theoretically and systematically oriented development of instructional approaches and interventions is needed. Modifications in school and instruction are essential focusing more on students' individual needs by creating a student and competence oriented learning culture, developing adequate methods of assessment, and by organizing schools as more life oriented environments.

The portfolio approach represents an educational concept with a focus on more student oriented instruction to enable learners to be more self-regulated and self-determined. Similarly to a learning diary or learning protocol, a portfolio combines numerous perspectives and functions. Characteristics of a portfolio are self-reflection, documentation of processes and learning outcomes, as well as their evaluation and assessment (Paulson, Paulson & Meyer, 1991). Portfolios focus on the participation of the learner in planning, realizing, and evaluating the own learning process. Generally, two main perspectives of portfolio in education are discussed: First, the enhancement of self-regulated learning and second, development of criteria and methods of alternative assessment. The application of portfolios may be seen as an example for the shift from teaching to learning. From this point of view educational institutions are seen as a well prepared learning environment to support individual learning processes. Main characteristics of those learning environments are problem centered and competence oriented learning demands and tasks, high quality of interactions between learners and teachers, cooperative and reflexive learning, and a well balanced relation between structured instructional phases and open, self-regulated learning phases. In addition, the portfolio-approach is associated with the positive influence on motivation, and emotion (cf. Gläser-Zikuda & Järvelä, 2008). Up to now, there is a lack of empirical studies that examine the effects of the portfolio approach on learning, competencies, motivation and emotion.

The presentation will focus on first results of an intervention study based on the portfolio approach. Students' emotions were measured in portfolio based instruction and in regular teaching situations in 8th grade physics classrooms. Both, the treatment and control class are taught by the same teacher. In total, four physics teachers and approximately 200 students participate in this study. In a quasi-experimental treatment-control-group design with pre-, post- and follow-up tests different variables were measured: Students' well-being, learning emotions, interest, learning motivation, learning strategies, self-concept, and achievement. As characteristics of the learning environment the classroom climate, and teacher competencies are evaluated. Beyond, teacher interviews and checklists to document the quality of the portfolio implementation are applied. First results from descriptive, and correlative analyses will be reported. Furthermore, students' emotions in portfolio based physics instruction will be compared with regular physics instruction to the same topic. Results and implications for further development of instruction will be discussed.

Origins of Achievement Emotions: The Impact of Individual and Class-level Ability

Reinhard Pekrun, University of Munich, Germany; Kou Murakou, Tokyo University, Japan; Anne Christiane Frenzel, Universität Augsburg, Germany; Thomas Goetz, Faculty for Humanities, Germany

The present research tested a theoretical model describing the effects of individual and class-level ability on students' achievement emotions. The model is based on propositions from Pekrun's (2006) control-value theory of achievement emotions and Marsh's (1987) Big-Fish-Little-Pond Effect model of self-concept of ability. Data from one cross-sectional and two longitudinal studies on students' development in mathematics were used (Study 1: N = 1,610, grades 5 to 10; Study 2: N = 1,759, grade 5 to 6; Study 3: N = 4,353, grade 9 to 10). In line with hypotheses, individual mathematical ability was a positive predictor of students' enjoyment and pride in mathematics, and a negative predictor of their anger, anxiety, shame, and hopelessness in mathematics, across all three studies. In contrast, class-level mathematical ability had negative contextual effects on enjoyment and pride, and positive contextual effects on anger, anxiety, shame, and hopelessness, in all three studies. Self-concept of ability in mathematics was a mediator for the effects of both individual and class-level ability. Overall, these findings document the importance of objective and self-perceived ability for the development of students' emotions. Suggestions for future research and implications for educational practice will be discussed.

Traditionally, students' achievement emotions have been neglected by educational research, with just a few notable exceptions (test anxiety research, Zeidner, 1998; attributional studies, Zeidner, 1998). During the past ten years, however, there has been an increase in the number of studies. This research has shown that achievement emotions are of fundamental importance for students' motivation, development, and educational achievement (Schutz & Pekrun, 2007).

Given the relevance of achievement emotions, it is important to acquire information on their antecedents, so that recommendations can be derived for how academic contexts can be shaped in emotionally adaptive ways. Individual abilities are one especially promising set of antecedents, as abilities shape self-perceived competence underlying the development of students' emotions. In addition, the abilities of others may also be critically important. Specifically, social comparison and the group level of ability in reference groups have been shown to influence competence appraisals, suggesting that others' abilities can influence individual achievement emotions as well.

Empirical research addressing these possible linkages is largely lacking to date (except Goetz et al., 2004; Zeidner & Schleyer, 1998). The present research was designed to address these gaps in the achievement emotion and self-concept literatures and, therefore, to facilitate the integration of two important research traditions. Specifically, we sought to examine the joint and mediated impact of individual ability, class-level ability, and self-concept of ability on students' achievement emotions.

Theoretical Framework

The conceptual framework used brings together propositions from Pekrun's (2006) control-value theory of achievement emotions and Marsh's (1987) Big-Fish-Little-Pond Effect (BFLPE) model of self-concept. The control-value theory posits that achievement emotions depend on the perceived controllability of important achievement activities and their outcomes. Since appraisals of control over achievement depend on perceived ability, factors influencing perceived ability should influence students' achievement emotions. Specifically, we posit the following effects.

- (1) Individual ability exerts positive effects on self-concept of ability, provided that information about ability is salient, important, and consistent. These conditions are met in schools providing students with consistent, distinct information about their performance.
- (2) Group-level ability exerts negative contextual effects on self-concept of ability (BFLPE). The strength of the BFLPE is thought to be pronounced in educational systems using normative grading that is based on local class norms rather than regional or state norms, thus conveying ability information pertaining to the immediate reference group (Zell & Alicke, 2010).
- (3) Self-concept of ability positively influences students' enjoyment and pride, and negative influences their anger, anxiety, shame, and hopelessness.

(4) By implication, individual ability positively influences enjoyment and pride, and negatively influences anger, anxiety, shame, and hopelessness. In contrast, class-level ability negatively influences enjoyment and pride, and positively influences anger, anxiety, shame, and hopelessness. All these effects of ability are thought to be mediated by self-concept of ability.

Aims of the Present Studies

Data from three studies targeting students' emotions in mathematics were used to examine the hypothesized effects. Subject-specific emotions were assessed since achievement emotions tend to be organized in domain-specific ways (Goetz et al., 2007). Emotions assessed included students' enjoyment, pride, anger, anxiety, shame, and hopelessness in mathematics.

Method: Study designs and samples

Study 1 was cross-sectional and assessed students' mathematical ability and emotions within one session (N = 1,610 German high school students [48% female] from 69 classrooms [grades 5 to 10]). Study 2 was based on the longitudinal Project for the Analysis of Learning and Achievement in Mathematics (PALMA; Pekrun et al., 2007; N = 1,759 students, 50% female, from 78 classrooms). Mathematical ability and self-concept of ability were assessed in grade 5 and emotions were assessed in grade 6. Study 3 used the longitudinal PISA-I-Plus investigation (Prenzel et al., 2006; N = 4,353 [57% female] from 194 classrooms). Mathematical ability and self-concept of ability were assessed in grade 9, and emotions in grade 10. All three samples represented a wide range of students in terms of ability, socio-economic background, and school type.

Method: Measures

In all three studies, emotions were assessed using the Achievement Emotions Questionnaire-Mathematics (AEQ-M; Pekrun et al., in press; Alphas > .80 for all scales in all studies). Mathematics ability was assessed using mathematics achievement tests and test scores were derived from IRT scaling (PALMA Mathematics Achievement Test, Studies 1 and 2; PISA mathematics test, Study 3). Self-concept of ability in mathematics was measured using the PALMA and PISA self-concept scales (all Alphas > .80).

Method: Data analysis

Multi-level modelling (MPlus) was used to analyze the data, with students at level 1 and classrooms at level 2. Student-level ability scores were group-mean centered. Multilevel mediation analysis was used to examine indirect effects (Preacher, Zyphur, & Zhang, 2010), and parametric bootstrapping was used to test the significance of these effects. Results and Discussion

In all three studies, individual ability was a positive predictor of enjoyment and pride, and a negative predictor of anger, anxiety, shame, and hopelessness. In contrast, across all three studies, the contextual effects of class ability on enjoyment and pride were negative, and the contextual effects of class ability on anger, anxiety, shame, and hopelessness were positive.

These findings confirm the importance of ability as an antecedent of students' achievement emotions and corroborate that the effects of individual ability and the ability level of the classroom bear opposite signs.

Furthermore, individual ability had positive effects on students' self-concept of ability in mathematics, whereas class-level ability had a negative contextual effect on self-concept, in line with previous research on the BFLPE on self-concept. Self-concept of ability, in turn, was a positive predictor of enjoyment and pride, and a negative predictor of anger, anxiety, shame, and hopelessness. Finally, multi-level mediation analysis documented indirect effects of individual ability on emotion, as well as indirect contextual effects of class ability on emotion, that were mediated by self-concept, thus supporting our mediational hypotheses.

In sum, the findings document the important role of both individual and group-level ability for the development of students' achievement emotions. Furthermore, they show that self-concept of ability mediates the impact of ability on emotions. Suggestions for future research and implications for educational practice will be discussed.

School success and school alienation of boys and girls at secondary schools: The role of the teacher

Andreas Hadjar, University of Luxembourg, Faculty of Language and Literature, Humanities, Arts and Educational Sciences (FLSHASE), Luxembourg; Stefanie Gysin, School of Education, Bern, Switzerland

This presentation aims at an explanation of school success of male and female school students. Taking into account the current debates on failing boys, a gender perspective will be employed. Analyses will center around school

alienation as a main emotional and motivational predictor of school success. Dealing with the question, how school alienation and a lack of interest can be explained, it will be focused on the role of the teacher - on teaching style and gender as an ascriptive teacher characteristic. Quantitative as well as qualitative results of a Swiss study on school success will be presented. The research design of this study includes a questionnaire survey of 872 male and female school students in grade 8 at Swiss secondary schools, group discussions with gender-homogeneous groups of 8 graders as well as video observations of German and Math lectures.

This presentation aims at an explanation of school success of male and female school students. Taking into account the current debates on failing boys – male school students receive lower school marks and attend less often university-bound school tracks than girls –, a gender perspective will be employed. This paper combines different theoretical as well as methodological approaches to explain school success. Analyses will center on school alienation as a main emotional and motivational predictor of school success. Regarding a quantitative measurement, school alienation is specified as a second-order construct that consists of three first-order factors: negative attitudes towards school, lack of task orientation and lack of intrinsic motivation.

Quantitative as well as qualitative results of a Swiss study on school success – research project „Lazy boys and ambitious girls?“ (School of Teacher Education Bern, University of Bern) – will be presented. The research design of this study includes a questionnaire survey of 872 male and female school students (14 to 15-year-olds) at Swiss secondary schools, group discussions with gender-homogeneous groups of school students and video observations of German and Mathematics lectures.

Dealing with the question, how school alienation and a lack of school success can be explained, it will be focused on peers, teachers, parents, and on students' behaviour (deviance). Peer groups may be understood in terms of social capital since peer groups can provide support (e.g. regarding school tasks) on the one hand. On the other hand, peer groups also have a motivation function – since they define whether or not learning activities are desired or not, and members of peer groups receive approval by sticking to the notion of the peer group regarding school. Teachers may be also seen as a social capital, since they provide support and motivate school students. Concerning the questionnaire survey, the perception of the school students, if the teacher deploys a rather authoritative style (including interest in school students, support, etc.) is measured. During group discussions, school students also mentioned teacher characteristics that may influence school students' well-being at school. What also needs to be recognized is influences of social origin, i.e. parental educational levels, cultural activities of the family, authoritative support of the parents. School deviance, e.g. destroying things, intimidating teachers, beating other school students, is assumed to be one of the mediators between school alienation and school success, and will therefore be included into the analyses. Deviance is on the one hand sanctioned by the teachers and on the other hand distracts school students from learning.

Quantitative results show that school alienation is the main predictor of school success. School alienation is higher among school students who are part of peer groups that are characterised by rather negative attitudes towards school. Authoritative teacher support reduces school alienation and therefore supports school success. School alienation goes along with a higher deviance which leads – interestingly only among boys – to a lower school success. Taking into account that boys' peer groups have more negative views on school, that boys are more alienated from school and therefore more deviant than girls, their lower school success becomes plausible.

As indicated in the quantitative results, an authoritative teacher support may reduce school alienation among boys and girls. Qualitative results reveal even more characteristics of school teachers that support students' well being and reduce school alienation (from the perspective of the school students): A teacher should employ a balanced style between the dimensions "demanding" and "casual". They should be able to gain the students' respect, but the teacher-student relation should also have informal aspects. For school students, teaching methods are more important than the subjects of teaching. School students want to participate actively. They want to have opportunities of self-managed learning and they prefer team work and teaching styles that allow them to exchange ideas.

SYMPOSIUM

Challenges of developing academic futures... possibly careers... in a changing world

Chairperson: Lynn McAlpine, University of Oxford, United Kingdom

Organiser: Lynn McAlpine, University of Oxford, United Kingdom

Discussant: Dai Hounsell, University of Edinburgh, United Kingdom

Wherever one looks in higher education, global competitiveness and public oversight are fundamentally altering the context and practices of academic work. Such changes have contributed to a view of academia as a place with no time

to reflect. As well, individuals can no longer assume that if they want a permanent academic position this is easily achievable. In this context, what are the challenges facing doctoral students, post-docs and pre-tenure academics? Answers to this question have profound pedagogical and policy implications. If individuals do not see a way to address the present challenges they perceive in academic work, they may choose not to remain in academia. Thus, the potential impact on higher education of their experiences in all three roles (doctoral student, post-doc and pre-tenure academic) could be significant for years to come – both through lost or inappropriate interactions with future generations of students and lost or unfulfilled research contributions over a career. Papers from Canada, Finland and the UK describe the challenges experienced by doctoral students, post-docs, and/or pre-tenure academics imagining and constructing their careers. Each paper examines at least one of the three roles within the relevant policy context and proposes policy and pedagogical implications. The aim is to generate an international perspective on the ways in which the challenges of doctoral, post-doctoral, and pre-tenure experience are similar and different. the extent to which different policy contexts may influence those constructing academic careers. the pedagogical and policy implications for all those attending the session

Perceptions of the thesis work and being a PhD student

Jenni Stubb, Helsinki University, Finland; Kirsti Lonka, University of Helsinki, Finland; Kirsi Pyhälto, Helsinki University, Finland

Previous studies suggest that there is variation in how researchers perceive the research work (Brew 2001; Åkerlind 2008). However, such investigations have focused on the perceptions of established researchers, and only little is known about the ideas of young academics. This study focuses on investigating how doctoral students perceive research and themselves as researchers. The data were collected with semi-structured interviews that were analysed in a phenomenography-inspired way. The participants were 37 students from a research intensive university in Finland from three disciplines: medicine, natural sciences, and behavioral sciences. Results showed that PhD students' ideas of doing research and being a researcher varied in terms of whether it was seen as 1) fulfilling duties and expectations, 2) acquiring personal qualifications and merits, 3) learning and personal development, or 4) enabling a change in the discipline. The perceptions in each category varied in terms of how atomistic vs. holistic, product vs. process-oriented, and person-center vs. community-centered they were. These four 'profiles' were not exclusive: often students reported conceptions that overlapped: there were at least two different kinds of ways of seeing research work and of being a researcher. The perceptions were not discipline-related, but instead, all of the four ways of seeing research were present in each of the three domains of study. It is important to acknowledge and understand these different ways of perceiving research work as they can serve as the frame of reference for learning and promoting academic expertise.

Researchers have varying ideas about doing research and being a researcher (Åkerlind 2008). Brew (2001) suggested that perceptions of doing research vary, for instance, based on whether researchers emphasize the product or the process of doing research, and whether they see it as work following certain specific phases or, in contrast, as a more cyclic process. The main focus has been exploring those members of academia who have already established their membership in the scholarly community. Thus, little is known about the perceptions that young academics, such as PhD students, have. However, understanding these perceptions in part serves as a key to understanding the process of becoming a scholar (Pearson and Brew 2002). The present study focuses on investigating the ways in which doctoral students understand the thesis work and how they perceive themselves as researchers. This study is a part of a larger national research project on PhD education in Finland (Pyhälto, Stubb, & Lonka, 2009).

Participants.

The participants were 37 PhD students (men= 5, women= 33) from a research intensive university in Finland. The participants represented three disciplines: medicine, natural sciences, and behavioral sciences. The research contexts were chosen based on their high-quality academic achievements and the large number of doctoral students. These cases were considered representative of research intensive units and well-organized doctoral education. The participants were in different phases of their PhD process: some had just started their PhD studies while others were more advanced. A few of the participants had just graduated. The majority of the students were working full-time with their thesis.

Data collection.

The semi-structured interviews were designed to study doctoral students' perceptions of their thesis process and of themselves in the process. The questions concerned the circumstances in which the students had started their PhD project, their motivation, perceptions about doing a PhD, and their experiences of supervision. The interview focused both retrospectively on previous experiences of the PhD process as well as the present situation. Each interview lasted approximately one hour.

Analysis.

A phenomenography-inspired analysis was adopted to study the variation in the perceptions that students had about doing research and being a researcher. In the first phase, all the text segments that described students' ideas about doing research and being a researcher were coded into hermeneutic categories. Then, four different ways of perceiving the research work and being a researcher were identified. The categories were: fulfilling duties and expectations, acquiring personal qualifications and merits, learning and personal development, and enabling a change in the discipline. The perceptions in each category varied in terms of how: (a) atomistic vs. holistic, (b) product vs. process-oriented, and (c) person-centered vs. community-centered they were. More specifically, they varied from each other in terms of how the following were experienced: the reason for doing a PhD, the nature of research work, and the intended outcome. The first two categories were more atomistic and product as well as person oriented while the other two were more holistic, process-focused and both person and community-oriented. Results. First, students describing research as fulfilling duties and expectations reported doing a PhD because it was defined as being part of their job description and they saw research as a series of different tasks that were done in order to identify a question and then to answer it. The outcome was defined as something concrete: a thesis or an article, for example. Second, those emphasizing acquiring personal qualifications and merits reported that the PhD was done in order to be more qualified or competent. Essential to doing research was the possibility of finding something new and making a scientific breakthrough. The prospective outcome was described as establishing one's own position in the field. Third, students who emphasized learning and personal development described a PhD project as a possibility to focus on questions of their own interest. Doing a PhD was reported as pursuing the development of one's own thinking and understanding. Fourth, typical for students' descriptions that emphasized enabling a change in the discipline was that doing a PhD was considered as making a contribution. These students emphasized the importance of questions that were relevant to the disciplines and the community. Striving for something that would benefit the whole community or the domain was considered important.

These four 'profiles' were not exclusive: often students reported conceptions that reflected a variety of ways to perceive research. The perceptions were not domain specific. For instance, in some cases descriptions of PhD students in medicine resembled more those of PhD students in natural sciences than those of their own colleagues. Further, it seemed that from these profiles, there emerged two different ways of describing oneself as a researcher: (a) me as an academic worker/employee and (b) me as a researcher. For seeing oneself as an academic worker, it was often more typical to consider research as fulfilling duties and expectations or acquiring personal qualifications and merits. For seeing oneself as a researcher, it was more typical to consider research as source of learning and personal development, or enabling a change in the discipline.

Discussion.

Results show that students have varying perceptions about doing research. It is important to understand the different kinds of ways of perceiving the research work identified in the present study. Such views may be considered as the frame of reference of the PhD students, affecting the ways of acquiring academic expertise. This poses a challenge for how to foster construction of coherent academic identities that form the basis for PhD students' future academic careers.

Establishing oneself as an academic: Experiences of PhDs, post-docs and pre-tenure academics

Cheryl Amundsen, Simon Fraser University, Canada; Lynn McAlpine, University of Oxford, United Kingdom

The goal of our research program is to contribute to a better understanding and conceptualization of early career academic experience (doctoral student, post-doc, pre-tenure academic) in today's increasingly pressured academic landscape. We propose the notion of an 'identity-trajectory' emphasizing the integration of past-present-future in the experience of academic work. An identity-trajectory, which integrates the personal with the academic, emphasizes learning processes (including intentions and emotions) that emerge from a multitude of contexts, both past and present. In this paper, we use the identity-trajectory to examine the experiences of twenty-eight early career academics in the Life Sciences, an under-explored disciplinary area. We found similarities and differences between

the experiences of doctoral students, post-docs and pre-tenure academics as concerns, for example, perceived support for their feelings of being academic and establishing themselves as an academic, and dilemmas in reconciling academic and personal values. These findings add to those from the first phase of our research in Education.

The goal of our research program is to contribute to a better conceptualization of early career academic experience (doctoral student, post-doc, pre-tenure academic) in today's increasingly pressured academic landscape. Our research is situated in and motivated by the well-documented changes in higher education internationally and the impact of these changes on academic work (e.g., Enders, 2007). These changes can have profound implications for doctoral students who pursue an academic career, and new appointees trying to establish themselves; these individuals are "the first to suffer from the stress that has befallen this system" (Laudel & Glaser, 2008, p. 388). Having completed the first phase of our research in the field of Education (e.g., Amundsen & McAlpine, 2009), we have begun the second phase, extending our work into the Life Sciences, an under-explored disciplinary area. This paper presents our first analysis of these data, focusing on the day-to-day experiences of participants over one year with a focus on their perceptions, actions and emotions in seeking to establish themselves as an academic. Conceptual framework Phase one of our program gave rise to the notion of an 'identity-trajectory' emphasizing the integration of past-present-future in the experience of academic work (McAlpine et al, 2010). In phase two, we are extending and refining this framework. Overall, identity-trajectory, which integrates the personal with the academic, emphasizes learning processes (including intentions and emotions) that emerge from a multitude of contexts, both past and present. These are generally informal learning experiences, emerging not just through doing work but also importantly from reflecting on work—learning that Clandinin & Connelly (1990) have called personal practical knowledge, or what Schön (1983) has called knowing-in-practice. Reflection on one's trajectory may provide a way to draw together the past and present to inform new intentions and directions. Focusing on the intentionality of individuals through time provides a counter discourse to policy arguments, which tend to privilege the expectations and regulation of different institutional roles.

Methodology

Data from 15 doctoral students, 6 post-docs, and 7 pre-tenure academics from the Life Sciences at two different universities in Canada, form the basis for the analysis in this paper. For each participant, three types of data were collected over a one-year period: 3-4 activity/experience logs, a pre-interview questionnaire and one interview, which drew on the previously collected protocols. From these data, case summaries (data displays) were constructed for each individual, followed by analysis looking across participants that used a priori codes (from our identity-trajectory framework) and emerging codes (Huberman & Miles, 2002).

Findings

We could locate the work of doctoral students, post-docs and pre-tenure academics in the identity-trajectory framework. The majority of participants were working with considerable intentionality while experiencing challenges (as well as pleasures). For instance, doctoral students were aware of the lack of academic positions that would be available to them; yet, they continued to seek to teach (as well as publish) knowing both would be essential if they were to be competitive positions available. Post-docs felt like 'newcomers' in the first year of their appointments; by the beginning of the second year they were suddenly 'experienced' in eyes of others and having to think about where they would go next. Doctoral students noted departmental activities and structures that supported their feeling of being an academic, whereas post-docs commented on not feeling they had similar kinds of supports. Participants in all roles expressed concern over what they perceived as an unbalanced work-life relationship. For instance, both PhDs and post-docs commented on the challenges of being or hoping to be parents while progressing their careers, and the pre-tenure academics reported dilemmas in reconciling their preferred research environment with the positions available and their family responsibilities. As has been reported elsewhere (e.g., Hakala, 2009), this may reflect the laboratory/research team structure with a tight research agenda to which, regardless of role, one can and is expected to contribute.

Theoretical and educational significance of the research

No previous research that we know of has bridged the roles of doctoral candidate, post-doc and new appointee longitudinally and addressed the day-to-day experience of intention and emotion on academic identity construction. Through the identity-trajectory framework, we hope to offer a means for individuals to reflect on their experiences and consider ways in which they might be more intentional in addressing their futures. We want to effect practice as well as theory development and future research. To facilitate this, we have employed an action research methodology, which extends beyond other interpretive traditions of research to direct action in generating plans, projects, policies that follow from research evidence. In the first phase, our findings were the basis for new activities/processes and recommendations at the department, faculty and institutional levels (Amundsen & McAlpine, in press). We continue in this tradition with phase two of our work.

"It's just been a huge learning experience" – how new supervisors learn to do doctoral supervision

Gill Turner, University of Oxford, United Kingdom

Despite lacking tenure, research staff and pre-tenure academics undertake doctoral supervision, often assuming substantial responsibility for the progress of their students. Those early career academics who are new to doctoral supervision recount it as being hard work, receive minimal training, and practice it as a solitary pursuit. Relying heavily on their own time as a doctoral student and lacking an initial awareness of how the wider context would impact on them in this role, their development as doctoral supervisors comes mostly through on the job experience. We report here on a UK-based study of new doctoral supervisors from a range of disciplines and, amidst the challenge of undertaking doctoral supervision with little or no training, show how their learning about doing doctoral supervision is influenced by their own experience as a doctoral student, co-supervision, and the supervisor-supervisee relationship. We highlight some of the challenges that are involved in learning supervision and suggest these findings raise questions about how to better equip and support new doctoral supervisors.

Aims

Most existing literature on doctoral supervision focuses on experienced supervisors. These studies evidence such themes as supervisory models, orientations and styles, the supervisor-student relationship, supervision pedagogy, and doctoral supervision as professional work. Only recently has research focused on early career academics as new supervisors (Sambrook et al, 2008; Amundsen and McAlpine, 2009; Turner, SRHE 2010, accepted). These show new supervisors find supervision hard work; draw heavily on their own time as a doctoral student; develop supervisory expertise on the job with minimal training and support; practice supervision as a solitary pursuit; and are uninformed about how the wider context will impact them. How they learn about doing supervision is relatively underexplored. Here we report a study on ECAs who are new to doctoral supervision. Having previously recounted some of the issues involved as they undertake this new role, we now contribute to the literature aspects on how they learn about doing supervision with a view to exploring how this knowledge might address the challenges they encounter.

Methodology

ECAs with less than six years research supervision experience and currently supervising at least one doctoral student were recruited from one UK research-intensive university, from lists of individuals who had attended introductory supervision seminars and via academics with graduate training responsibilities. Eleven new supervisors volunteered from a range of disciplines. Each participant completed a pre-interview questionnaire providing background information on their experience as research supervisors before being interviewed. The interviews were transcribed and a thematic analysis carried out.

Findings

Learning to be a doctoral supervisor All participants said they had received little or no training. Of these, 6 had attended introductory seminars on supervising doctoral students at the university. As an overview of the supervisory process these seminars had some merit, e.g. providing insights into doctoral supervision from the student's point of view and clarifying what is in place to help supervisors address problems with students. However, there was a perception that no general consensus seemed to exist about what good practice is for doctoral supervision and participants reported relying on their "own experiences of being a doctoral student" and even that "the best way

[training] would be to gather experiences and then develop something on the basis of that". In light of these comments we highlight how these new doctoral supervisors learned supervision by drawing on their own experience as a doctoral student, from co-supervision, and from their relationship with their own supervisees.

Own experience as a doctoral student

As in other studies, we found these new supervisors drew heavily on their time as a doctoral student, assuming what worked for them would work for their supervisees. We also saw they realised this experience did not fully prepare them as doctoral supervisors: their style did not suit all supervisees; they were ignorant of how to fit it into their other responsibilities; they were unaware of how the wider context would impact on them. Whilst adjusting their assumptions and practice, many of these new supervisors displayed a naiveté about how well their experience as a doctoral student had equipped them for their role as doctoral supervisor.

Co-supervision

Eight of these new supervisors were in co-supervisory relationships. Despite being in non-tenured positions all assumed the main supervisory responsibility for their students, e.g. directing the student's work, arranging resources and training, organising supervisory meetings. Co-supervision seemed beneficial with new supervisors drawing on co-supervisory relationships to: determine a united approach to a supervisory problem; be affirmed in their actions on behalf of their student; assure the quality of work; bring different perspectives, ideas and expertise. However, these co-supervisory interactions were principally directed at progressing the student's thesis and were rarely concerned with the new supervisor's development as a doctoral supervisor.

Own supervisees

The new supervisor's relationship with their supervisee was the foremost challenge to their notion that their time as a doctoral student was adequate preparation for being a supervisor i.e. they realised that what worked for them did not work necessarily for their students. Yet, this same relationship was also one from which they learned much about doing doctoral supervision. They discovered: not all students responded to the same approach; students' reasons for undertaking doctoral study varied and supervisors had to accommodate this range; competing demands from different students at the same time had to be dealt with; there was a balance to be found between supporting a supervisee and encouraging their independence.

Significance

We report here ways in which, through experience, new supervisors learn how to do doctoral supervision and tackle some of the challenges they encounter. We found new supervisors realising their time as a doctoral student was an inadequate model for their own supervisory style: firstly, their experience was only one way of doing supervision; secondly, their experience provided them only with the student's perspective of the role whilst that of the supervisor's had remained invisible. We saw co-supervision used to progress the student's thesis but not as a forum for deliberating their own supervisory development; learning from a co-supervisory relationship tended to be a by-product of co-supervisory interactions. The supervisor-supervisee relationship was important in learning to do doctoral supervision. It challenged taken-for-granted assumptions about supervision and doctoral education whilst, at the same time, stimulating and providing answers. Whilst literature on ECAs new to doctoral supervision indicates that they are poorly prepared for the role, these findings provide some insights into how they address their predicament. They also raise questions about how to better equip and support new doctoral supervisors, given that existing training and support structures appear inadequate.

SYMPOSIUM

Help seeking in technology-enriched learning situations

Chairperson: Minna Puustinen, Université de Poitiers & CNRS, France, France

Organiser: Minna Puustinen, Université de Poitiers & CNRS, France, France

Nathalie Huet, University of Toulouse, France

Discussant: Stuart Karabenick, University of Michigan, United States

The rapid transition of our societies towards more globalism and networking has profoundly modified student help-seeking opportunities. Seeking and obtaining help whenever necessary is possible for anyone connected to Internet and other remote communication devices. Within this context, the aim of this symposium is to present recent research on student help seeking in technology-enriched learning situations, by proposing three papers that examine the topic from different theoretical and methodological perspectives. From the theoretical point of view, the papers included in this symposium analyze student help seeking in technology-enriched learning situations in relation to existing research on task complexity (Schworm & Wuerfl), achievement goal theories (Huet et al.), and student-teacher interaction patterns (Puustinen et al.). Methodologically, the papers analyze students' help-seeking intentions but also their actual help-seeking behavior in technology-enriched learning situations using both experimental and natural data. The approaches adopted by the three papers are innovative, and the phenomena studied are currently un- or underexplored in the literature: the adaptive role of executive help seeking in learning (Schworm & Wuerfl), the help-seeking intentions vs. the actual help seeking (Huet et al.), and ineffective helping interactions between teachers and students (Puustinen et al.).

Help design in web-based learning environments: The influence of task-complexity on need for help

Silke Schworm, University of Regensburg, Germany; Magdalena Wuerfl, Institute of Educational Sciences, University of Regensburg, Germany

The present study deals with the influence of task complexity to learners' need for help during the task processing. Forty-eight students took part in the study. They worked with a computer-based learning environment on "Mental disorders in adolescents" and had to solve tasks of increasing complexity. After each task the participants had to choose from twelve alternatives which source of help they would have used to support their task solution. Help sources were distinguishable as instrumental (learning oriented) help and executive (performance oriented) help. Results show that task complexity influences the choice of instrumental help sources, but not that of executive help sources. On the comprehension and application level, instrumental help was preferred to executive help. For tasks on knowledge level, however, executive help was considered to be as useful as instrumental help. Subjects with high prior knowledge thereby considered the offered help less useful than subjects with low prior knowledge.

Intentions and actual use of help in a CBLE: The role of achievement goals and perceptions of help
Computer supported Learning Environments, Motivation, Self regulation

Nathalie Huet, University of Toulouse, France

Caroline Dupeyrat, Universite Toulouse 2, France

Franck Amadieu, CLLE-LTC (University of Toulouse), France

Jean-Christophe Sakdavong, University of Toulouse, CLLE-LTC CNRS, France

Prior research revealed that learners' help-seeking is often not appropriate. According to some authors (e.g., Karabenick, 1998), achievement goals and perceptions of help-seeking (perceived threat and costs/benefits) influence help-seeking. In the present study, the relationships between achievement goals, perceptions of help, and both help-seeking intentions and behaviours were explored in a computer-based learning environment on word processing. 65 undergraduate students were invited to learn how to create word processor style sheets on an Interactive Learning Environment and to perform exercises. After each exercise, the system detected the correctness of the procedure and if wrong, a feedback was provided. Students could choose one help among various types (e.g., screencast course) or reject it. Achievement goals (mastery, performance-approach and performance-avoidance goals), intentions, and perceptions of using help were assessed by questionnaire. Actual use of help was recorded. The main results indicated that mastery goals were positively associated to the intention of using help and negatively associated with the intention of avoiding help; both performance goals were positively associated to the intention of avoiding help but did not correlate with intentions of using help. However, in the actual learning situation, achievement goals were not related with the actual use of help.

Learning in computer-based learning environments requires that learners regulate their own learning. Self-regulation of learning includes seeking for help if learning tasks are not mastered successfully (e.g., Puustinen, 1998). Yet, prior research revealed that learners' help-seeking is often not appropriate (Aleven et al., 2003). One factor that can influence help-seeking is achievement goal orientation: intentions or purpose of the learner to achieve an academic

task. Traditionally two major classes of goals have been distinguished (e.g., Dweck & Leggett, 1988): mastery goals, in which the aim is to develop competence, and performance goals, in which the aim is to demonstrate competence relative to others by gaining favorable judgments (performance approach goals) or by avoiding unfavorable judgments of one's competence (performance avoidance goals).

In academic classroom environments, most studies showed that achievement goals influence help-seeking intentions (e.g. Cheong, Pajares, & Oberman, 2004). Students with high mastery goals showed a low help-seeking avoidance intention. Contradictory results were found concerning the role of performance-approach goals on learner avoidance of help-seeking intentions: sometimes they were unrelated, negatively related or positively related to avoidance of help-seeking intentions.

In computer-based learning environments, it was found that performance goals were negatively correlated with the actual use of help (Huet et al., in press). For mastery goals, results were contradictory: in one study, they were not associated with the actual use of help, in another they were negatively associated to the actual use of help.

Another factor that influences the use of help are the perceptions of (or attitudes towards) the use of help in the sense of perceived threat on self-esteem or autonomy and benefits of help-seeking (Karabenick, 1998). Studies showed that help-seeking can be considered by learners as a threat to their self-esteem because they perceive the seeking of help as a sign of their incompetence to resolve the problem by their own means. Consequently, they do not seek help because they want to continue projecting an impression of competence and to avoid other people's negative judgments. Studies indicated that the more learners perceive help-seeking as a threat to their self-esteem and especially on competency, the more they avoid seeking help (e.g., Karabenick 2003). Help-seeking can also be perceived negatively for another reason: learners can consider help-seeking as a dependent behavior that conflicts with their personal need for autonomy or independent mastery need and self-reliance. In other words, they do not seek help because they want to achieve the task without external help. Finally, the more learners report perceiving the benefits of help-seeking, the less they avoid help-seeking (e.g., Cheong et al., 2004).

The aim of the present research was to examine the relationships between achievement goals, perceptions of help and both intentions and actual use of help in an interactive learning environment.

Method

Participants were sixty-five human science students enrolled in a French university. Achievement goals were assessed with the P.A.L.S. Items assessing perceptions of help-seeking (perceived benefits, perceived threats to self-esteem, perceived threats on competency, and perceived threats to autonomy) were adapted from several questionnaires (e.g., Karabenick, 2003). Intentions of using help were assessed by an adaptation of the questionnaire used by Cheong and al. (2004).

After completing the questionnaires, the participants learned how to apply and create word processor style sheets from a multi-agent Interactive Learning Environment (ILE). Afterwards, they performed exercises requiring the use of style sheets on texts. After the exercise tasks, the multi-agent system, which detected the correctness of the procedure, provided a feedback in case of failure. The student could choose (or not) one type of help among various types of instrumental help (e.g., screencast course, screencast procedure...). In case of a wrong answer detected by the multi-agent system, the system offered to the learner the opportunity to use help or not. Then, whether the answer was right or wrong, another exercise similar to the previous one (i.e. requiring the same solving procedure) was proposed without the possibility of using help.

Results

The main results indicated that mastery goals were positively associated to intentions of using help ($r = .53$; p

In spite of these relations between achievements goals and intentions to use help, analyses conducted on the actual use of help did not highlight any relation between achievement goals and the use of help. However, the perception of help as a threat on competency influenced positively the intention of avoiding help ($r = .56$, p

The implications of these results for learning and help-seeking in computer-based learning environments will be discussed. Studies are needed which further examine the actual use of the help.

Seeking help on an online homework-help forum: An analysis of the student-teacher interaction
Computer supported Learning Environments, Self regulation, Social interaction

Minna Puustinen, Universite de Poitiers & CNRS, France, France

Olga Volckaert-Legrier, University of Toulouse, France

Michael Baker, CNRS - Telecom ParisTech, France

We analyzed the dynamics of student-teacher interactions in a written help-seeking situation taking place on an online homework-help forum. We used natural data, i.e. the archives of a French forum offering secondary school students individualized help in mathematics. We were particularly interested in cases in which the initial student-teacher interaction had failed, i.e. the student returned to the forum after having received the teacher's answer. Our data consisted of 54 written exchanges between 16-to-18-year old secondary school students and secondary school mathematics teachers. We conducted a qualitative analysis of the messages and then made an inductive pattern recognition analysis using the MEPA (Multiple Episode Protocol Analysis) software. The results revealed that 85% of the teachers' initial answers contained at least partial suggestions of procedure. In those cases, the students' messages gained in precision after the teachers' answers: their initial messages typically lacked details concerning e.g. their difficulties, whereas the messages typed after the teachers' suggestions contained more targeted information regarding their difficulties, the work already conducted, etc. The results further revealed that in 15% of the cases, the teachers' initial answers were exclusively composed of reminders of the forum rules and/or requests for precision; in those cases, the students were obliged to answer the teachers' remarks or questions in order to obtain any suggestions from the teachers.

SYMPOSIUM

New Modes of Assessment

Beyond assessment: analyzing student participation in the judgment process

Keywords: Assessment methods, Assessment of Competence, Higher education

Sig's: Assessment and Evaluation

Chairperson: David Carless, University of Hong Kong, Hong Kong

Organiser: David Carless, University of Hong Kong, Hong Kong

Discussant: Dominique Sluijsmans, HAN University of Applied Sciences, Netherlands

Aims Student involvement in assessment through peer- and self-assessment is viewed as a key aspect within 'new modes of assessment'. The rationale includes going beyond assessment as being something done to the student, in the direction of developing a shared ownership of assessment tasks, criteria and judgments. The aim of the symposium is to explore the topic of student participation in assessment processes through three empirical papers from different geographical sites. The first paper uses data from Australian universities to probe the development of student judgment through self-evaluation of their performance on their graded assignments. The second paper draws on a wide range of data from Spanish and Latin American universities, and outlines an agenda for enhancing student participation in assessment. The third paper, a case study of an award-winning teacher at the University of Hong Kong, illustrates how students use feedback from peers and the teacher to develop judgment of the quality of their own performance. Educational relevance In sum, the papers suggest that involving students actively in the assessment process is central to the improvement of learning outcomes, whilst unpacking some of the challenges for implementation of participative assessment. The discussion gives rise to a number of issues: What are the most

effective ways of promoting student participation in assessment? What kinds of students are most likely to benefit from active participation in assessment? How can institutional commitment and support for participative assessment be facilitated?

The development of student judgement: the role of practice in grade prediction

Assessment methods, Assessment of Competence, Higher education

David Boud, University of Technology, Sydney, Australia

A key feature of sustainable assessment is that students are enabled to make progressively effective judgements about their work within the subject domain of a course. Conventionally, this is not explicitly assessed, but it is assumed that students who satisfy normal assessment requirements meet this outcome. This paper explores one way of promoting and getting evidence about the development of judgment making through students making judgements about their performance with respect to criteria for assessment tasks throughout an undergraduate degree program. It examines the question of whether extended practice in self-assessment over time helps students develop the capacity to make better judgements about their work. It uses data collected as part of a pedagogic intervention about the assessment of graduate attributes to analyse convergence between student ratings of their performance on specific tasks and the marks allocated by tutors within a course module and across modules and semesters, and to identify whether some categories of student, for example high achievers, benefit more from such practices. The significance of the paper is that it uses authentic high-stakes assessment data from throughout an undergraduate course to examine ways in which grade prediction strategies can contribute to the calibration of student judgement and thus sustainable assessment.

Aims The development of student self-assessment capacities plays an important role in student participation in assessment. There have been studies of student self-assessment over many years and considerable advocacy for the effectiveness of practices in which students review their own work (e.g. Dochy et al. 1999). It has been well argued that students need to develop the capacity to make judgements about their own work if they are to be effective learners both as students and following graduation. The role of skills of self-judgement are central to the notion of sustainable assessment, that is 'assessment that meets the needs of the present without compromising the ability of students to meet their own future learning needs' (Boud, 2000, p. 151). The development of the ability to make judgements about their own work develops through practice over time, and the capacity to make good judgements does not necessarily transfer across knowledge domains. We suggest that learners' judgements need to be calibrated against the judgements of others who have a more sophisticated understanding of the type of work being assessed in order to promote the skill and for students to become aware that their judgments have improved. Through such a process of scaffolding, students can move progressively towards the kinds of quasi-independent judgements about self-performance needed for effective lifelong learning (Boud and Falchikov 2007). In this paper, the ability of students in predicting their grade for elements of an assessed task is taken as a surrogate for student self-judgement. This paper extends the base of previous empirical investigation to examine the following research questions: Does continued practice in grade prediction lead to convergence between teacher-generated grades and student-generated grades, over assessment tasks, over subject modules and over time? Does accuracy in grade prediction vary by student performance? In so doing it aims to illuminate the question of whether such practices assist students to calibrate their own judgements. **Methodology** The paper uses data from a pedagogical innovation obtained as part of the normal assessment practices in an undergraduate degree. The form and nature of the data used was constrained by the need for it to be used primarily both for high stakes assessment processes that influenced the progression of students and to provide feedback to students on their performance in self-assessment, rather than for the purposes of research. We used the full set of student assessment data in a set of linked modules conducted over three years of a Bachelors degree between 2008 and 2010. It was obtained through the medium of ReView. ReView is an online criteria-based assessment system that allows students to grade themselves on criteria for each assessment task in a subject module (as well as to provide an overall grade). This is completed before tutors' grades and feedback are available to them in ReView. Analysis has been undertaken of discrepancies between student and tutor marks for each assessment task for subjects over four separate semesters with a view to exploring changes within subjects and over time. It was hypothesised that as students practise making their own judgements, followed by their viewing of tutor's judgements, there would (a) be a convergence of marks for each iteration of assessment within a module, and (b) be an initial divergence at the beginning of each new subject which reduces in size over time. **Findings** Findings are consistent with the outcomes of a preliminary study undertaken by the authors in an undergraduate degree in another university. Initial analysis indicates the following: 1. Within each module there is convergence in discrepancies between student and tutor marks from the first assessed task to the final task. 2. Over modules (and thus over time), there is increased convergence between student and tutor marks. The gap between student and tutor marks lessens in the first assessed task in each subsequent module and plateaus. 3. In accordance with many findings on student self-marking, strong students (as defined by tutor marks) underestimate performance and weak

students overestimate performance. However, the degree of over- or underestimation diminishes over modules.4. The greatest learning benefit appears to accrue to mid-range students. Their absolute performance and performance in grade prediction increases at a greater rate than that of strong or weak students. Significance The study shows that students become more accurate in judging their own performance with extended practice over two or more modules using normal assessment tasks. Student satisfaction with the exercise was very high. In our original preliminary study, for example, significant numbers of students persisted in using the system even when it was not required and were not reminded to use it by tutors. The study does not, however, show that the improvement in self-judgement is due to the grade prediction exercise per se. It is particularly challenging to obtain independent measures of such improvements as the very act of assessment provides practice in the skill being measured. One of the most interesting findings of the study is the effect on mid-range students. High performing students are most likely to have developed skills of judging their own work—this is one of the features that make them high performing in the first place—and there is relatively little improvement. Low performing students start with poor self-judging skills, and show a modest improvement through practice. However, mid-range students seem to benefit most from the intervention. The paper concludes with a discussion of the use of such measures in promoting self-judgement and how this particular practice of sustainable assessment can be incorporated into the university curriculum. Between reality and desire: active participation of students in assessment in the digital age
Assessment methods, Assessment of Competence, Higher education

Gregorio Rodriguez Gomez, FACULTAD DE CC DE LA EDUCACION, Spain

Implementing assessment for learning at universities requires an essential condition: the active participation of students in the assessment process via the development of informed judgments about quality learning. As highlighted by various authors this participation may be carried out through strategies like self, peer and co-assessment. This paper focuses attention on the difficulties that faculties face in implementing these strategies. Although there are a wide range of difficulties in this matter we reflect mainly on two notions: previous conceptions of university teachers and students; and the relevant characteristics of information technology and communication (ITC). Those reflections about the limitations encountered regarding participative assessment are based upon the results of several educational research projects lead by EVALfor Research Group in recent years, using as main research methods document analysis, in-depth semi-structured interviews and surveys to teachers and students from Spanish and Latin American universities. The findings demonstrate that an active involvement of students through strategies such as self, peer and co-assessment is not widespread. Moreover, in many cases the use of information technologies does not seem to facilitate such participation. Implications indicate: the importance of implementing institutional strategies to support student participation in assessment; formative processes for both teachers and students to facilitate their training regarding participative assessment; and developing technological tools which allow and promote the active participation of students in the assessment processes.

Aims In recent times, EVALfor research group has focused its activity around the participation of students in the assessment for learning process, conducting several research projects: SISTEVAL, EvalPART, EvalCOMIX, EvalHIDA and Re-Evalúa. The main objective of the paper is to present the main results of those projects and their implications for teaching and institutional policies. SISTEVAL project (Ibarra, 2007, Ibarra and Rodríguez, 2010) aimed to analyse, describe and portray the current assessment systems (a set of criteria, standards and procedures) specified by the universities in their regulations and specific legislation, as well as those specified by the faculties and departments in their norms, guides or teaching programs. EvalPART Project (Rodríguez et al., 2010) was designed to analyse the perspective of university teachers and students about the participation of the latter in assessment; and EvalCOMIX (Ibarra, 2008) and EvalHIDA (Rodríguez, 2009) research projects were focused on the role of technologies in the assessment process. Finally, Re-Evalúa project is aimed to probe the results obtained through the incorporation of "e-learning oriented e-assessment" in the development of teaching capacities in university teachers and basic competences in graduate students. In this paper selected results of this project are presented, in particular those that are focused in the analysis of the assessment activity of university teachers (Quesada, 2010). Methodologies SISTEVAL project consisted of two main tasks: 1) a documentary analysis of the existing regulations (statutes, norms, guides, etc.) in nine Spanish universities participating in the project and 2) a documentary analysis of 582 subject programs. EvalPART project was based on two surveys with the participation of 3,459 students and 424 university

teachers from two Spanish universities and five Latin American universities based in Colombia, Costa Rica, Ecuador, Honduras and Guatemala. Eleven case studies were conducted in EvalCOMIX and EvalHIDA. Re-Evalúa project includes surveys and in-depth semi-structured interviews. The following research questions guided these investigations:

RQ 1 What is the dominant discourse on assessment in universities?

RQ 2 What possibilities and limitations have tools such as forums, wikis and blogs in participative assessment processes?

RQ 3 What is the teachers' perspective on students' participation in assessment?

RQ 4 What is the students' perspective on participation in assessment?

Findings One of the main conclusions drawn from SISTEVAL project was that the discourse of assessment could be characterized as "traditional". The data showed that students are not considered prominent in the assessment process; instead, they are seen as the object to be assessed, graded and classified. EvalPART project highlighted the limitations that tools, such as forums, wikis or blogs present regarding participative assessment process, mainly the practical difficulties of analyzing the quality of students' contributions. On the basis of EvalPART project results we can conclude: a) generally there is an agreement between students and university teachers on the importance of students' participation in the assessment process; b) there are differences between the opinion of teachers and students about the implementation of assessment practices; and c) there is an agreement of both students and teachers that peer and co-assessment are not frequently practiced. The results of Re-Evalúa project are focused on the tasks that university teachers perform in higher education regarding students' participation. Results are obtained from a self-report inventory completed by 145 university teachers about their assessment activity regarding students' participation. From this survey, the tasks considered most important by respondents are "Reach a consensus with students about the assessment object (determine what to assess)" and "Promote students' participation through self-assessment (assessment of the student/group of students about their own tasks and activities)". The tasks that are perceived as least important: "Agree with students the marking procedure" and "Promote students' participation in the assessment design". Regarding the competence to carry out those tasks, teachers consider themselves least prepared to "Promote students participation through co-assessment" and "Promote students' participation in the assessment design".

Significance The significance of this review lies in its contribution to the reality of students' participation in assessment in Higher Education in the settings studied. Active student participation is an essential condition of assessment for learning, but regarding the results obtained in these research studies we will need to: a) Adjust university assessment regulation and norms so that they are aligned with the advances produced about assessment for learning. b) Promote the training of university teachers to increase their educational knowledge to put in practice assessment strategies as learning activities. c) Promote and facilitate the training of students so that they can be supported to develop informed judgments about quality learning in their discipline. d) Develop technological tools to facilitate the active participation of students in the assessment process. In brief, in the universities under discussion it is necessary to develop an alternative assessment culture. The progressive incorporation of strategies that encourage students' participation at university as self, peer and co-assessment will make a significant contribution to this paradigm shift. In the same vein is framed our contribution in Re-Evalúa project, in which we are training university teachers offering them technological tools, such as EvalCOMIX (Ibarra et al., 2010), that facilitate the participation in assessment. With the collaboration in national and international groups we hope that assessment practices can be progressively further developed.

Sustainable feedback and the development of student self-evaluative capacities
Assessment methods, Assessment of Competence, Higher education

David Carless, University of Hong Kong, Hong Kong

This paper explores the notion of sustainable feedback: defined as feedback which informs the current task, whilst supporting students' abilities to develop their capacities to self-evaluate their performance independently of the teacher. The position taken is that only when students are developing increasingly sophisticated self-evaluative capacities are they in a position to use feedback productively. The research method involves classroom observations

and semi-structured interviews with a purposively selected award-winning teacher in the Faculty of Business in a research-intensive university. Student participants are also interviewed so as to gauge their insights into the teaching and learning process. The findings focus on selected classroom activities congruent with a framework of sustainable feedback. Students were generally positive about the classroom climate and the ways in which the teacher created classroom rapport which facilitated student participation. Related to this, trusting relationships between the teacher and the students, and between the students themselves supported practices of sustainable feedback. The significance of the paper lies in its contribution to re-conceptualizations of feedback as dialogic and interactive. Feedback is sustainable when it supports students to develop their ongoing capacities independently of the teacher. Implications for practice indicate the importance of teachers and students exploring the nature of quality work within the discipline.

Aims This paper highlights the student role in feedback processes as an important component of student participation in assessment. It builds on the notion of sustainable feedback (Carless et al., 2011; Hounsell, 2007) which prioritizes students' engagement with feedback so as to enhance their own self-evaluative capacities. This notion is a response to the multiple challenges of conventional feedback practices which are perceived by students as difficult to understand; lacking specific advice on how to improve; or difficult to act upon. Many of these problems are accentuated by the terseness and finality of one-way written comments within modularized systems. The notion of sustainable feedback is defined as feedback which informs the current task whilst supporting students' abilities to develop their judgment to self-evaluate their performance independently of the teacher. Central to sustainable feedback is dialogic feedback involving interactive exchanges in which interpretations are shared, meanings negotiated and expectations clarified. Dialogic approaches guide students on what is good performance by facilitating discussions of quality in relation to specific assessment tasks. The main objective of the paper is to probe the implementation of practices congruent with a framework of sustainable feedback. Through this exploration, the paper contributes to new ways of thinking about assessment and feedback.

Methodology The paper is based on a case study of an award-winning teacher in the Faculty of Business in a research-intensive university in Hong Kong. The objectives of the case study are to explore the strategies and underpinning rationale for sustainable feedback of the teacher. The first stage of the research process involved in-depth interviews with ten award-winning teachers in the university. The case of the teacher in the Faculty of Business was selected on the basis of the capacities of the teacher to implement practices congruent with a framework of sustainable feedback. The following research questions guide the investigation: RQ1 What sustainable feedback practices are observable in the practice of an award-winning teacher in the Faculty of Business? RQ2 What is the teachers' rationale for the practices which he adopted? RQ3 How are the students responding to the practices adopted? Two research methods are used: classroom observation and semi-structured interviews. Classroom observations are of 5 two-hour sessions taught by the teacher across two courses. The observation of selected classes is purposive on the basis of likely occurrence of practices congruent with the framework for sustainable feedback. Detailed field notes are collected. To obtain deeper understanding of the teacher's rationale for his teaching and feedback practices, three in-depth semi-structured interviews are carried out, before the course, during the course and at the end of the course. Individual interviews with 10 selected student participants provide their perspective of relevant classroom processes. Data were analyzed inductively using standard qualitative data analysis procedures, including coding, categorizing and respondent validation.

Findings The findings explore selected classroom activities which involved students in their assessment and had potential for developing their self-evaluative judgments. Oral presentations were part of the assessment for the course and were seen by the teacher as being a critical tool for a successful business career. A telling example was the use of video to record student oral presentations. Immediately after the presentation the teacher replayed short extracts and invited presenters to reflect on their performance. Interactive discussions ensued in which class participants engaged in reflections on the presentations. Through these processes, students were engaged in extending their appreciation of quality business presentations. Interviews with students revealed that trust was an important dimension facilitating and/or inhibiting student involvement and the development of self-evaluative capacities. Students noted that the teacher was able to construct an atmosphere in which students were encouraged to voice at length their opinions and that these contributions were perceived as being responded to and valued. Student confidence was more mixed, however, in relation to the ability of their peers to provide insightful critique of presentations. Concerns were also expressed about the time-consuming nature of these classroom activities which reduced the content coverage in the course.

Significance The significance of the study lies firstly in its contribution to the re-conceptualization of feedback in the direction of more dialogic less uni-directional orientation. Feedback is sustainable when it supports students to develop their ongoing capacities independently of the teacher. This notion prioritizes the student role in using productively the (inevitably) limited feedback which they receive. Trust is a factor which impacts on the implementation of sustainable feedback practices. A number of dimensions emerge: feedback requires lecturers and students to enter into a relationship of trust in which the former try to provide helpful comments that the latter attempt to use; peer feedback requires learners to place faith in others as they open up their performance to critique. The notion of trust is under-explored in relation to participative assessment and merits further attention. Finally, the study carries implications for the practice of

participative assessment. It is suggested that teachers should strive to conduct activities which illustrate the nature and characteristics of quality work within their discipline. Related to this, teachers and students may explore together good learning strategies within the discipline and how they might be further developed. SYMPOSIUM

Writing

The relationship between oral and written language

Keywords: Writing

Sig's: Writing

Chairperson: Sarah Critten, Oxford Brookes University, United Kingdom

Organiser: Sarah Critten, Oxford Brookes University, United Kingdom

Discussant: Barbara Arfe, Facolta di Scienze della Formazione, Italy

This symposium will share recent research elucidating the relationship between oral and written language to inform writing instruction in English and French. Writing a composition is a complex task drawing on a range of cognitive, motor and social skills; a task that many children and adolescents struggle with, particularly when linguistic difficulties are present (Graham & Harris, 2009). The symposium will begin with a longitudinal examination of the links between specific linguistic abilities and components of written text in a group of typically developing 7-9 year old children from the UK. The second paper will broaden the focus and discuss constraints for writing in children aged 9-10 years (also from the UK) with Specific Language Impairment (SLI) comparing their spelling attainment and nature of spelling errors in word and text level tasks to chronological age and language age matched controls. The final paper will also examine writing difficulties in children with language impairments but in a cross-cultural English-French comparison. An examination of the constraints on written text production is an essential step in developing and testing theoretical models of writing and in developing evidence based practice to help those with writing difficulties.

The Importance of Oral Language Skills for Component Writing Skills in 7-9 Year Old Children

Writing

Chloe Bate, University of Sheffield, United Kingdom

This presentation examines the relative importance of different oral language skills for component writing skills, in mainstream UK school children aged 7-9 years. Fifty-four monolingual children were tested at the end of Years 3 and 4 completing a written narrative task and standardised language, literacy and non-verbal cognition tasks. Written narratives were analysed using six components, derived from the UK National Curriculum: phonics and spelling; handwriting; sentence structure; punctuation; text structure and organisation; and composition and effect. Multiple regression analyses showed spelling and phonological processing were highly significant contributors and accounted for the most unique variance to all six writing components. Expressive language and vocabulary contributed highly significantly to the sentence structure, punctuation and composition and effect components. Results confirm the influence of spelling and phonological processing constraints on writing performance at this age while highlighting the importance of developing syntactic complexity orally to develop children's sentence structure, punctuation and composition skills in writing. The role of these oral language skills will be considered in relation to developmental writing models and the longitudinal data will add to our understanding of how particular oral language skills may support writing development within an educational setting

Background: Within any mainstream classroom, there will be a number of children with a range of language and literacy difficulties. Studies involving children with language impairments (e.g. Dockrell et al, 2007, Scott & Windsor, 2000) have highlighted the constraints of oral language difficulties upon written language. However, few studies have explored ways in which components of the oral language system can enhance or limit the production of written text (Dockrell and Connelly, 2009). Oral language is crucial for written language development: text generation involves turning ideas into units of language (Berninger et al., 1995), yet it is not specified as central in developmental writing models (Dockrell and Connelly, 2009) and it is still not clear how it impacts on different aspects of the writing process

(Connelly & Barnett, 2009). Indeed, little research has looked at explicit links between oral language and writing (Shanahan, 2006).

Aims: This presentation aims to explore the relationship between children's oral and written language skills. More specifically, it aims to examine the relative importance of different linguistic skills to component writing skills, in mainstream school children between the ages of 7 and 9.

Methodology: Fifty-four monolingual English-speaking children (F = 26, M = 28), in three mainstream UK schools with similar low socio-economic profiles were recruited and assessed at the end of year 3 (aged 7-8 years, mean age 8;4) and were assessed again at the end of year 4 (aged 8-9 years, mean age 9;4). The children completed a written narrative task, based on a picture prompt, as well as measures of phonological awareness, non-word repetition, expressive language (word structure, formulated sentences and recalling sentences subtests), receptive vocabulary, oral narrative, reading, spelling and non-verbal ability. Written narratives were analysed according to six different components, based on the UK National Curriculum assessment areas for writing: phonics and spelling; handwriting; sentence structure; punctuation; text structure and organisation; and composition and effect.

Because of the large number of independent variables and relatively small number of participants, a principal components analysis was carried out to group variables together that load on the same factor. This produced four factors: spelling and phonological processing (spelling, phonological awareness, non-word repetition); expressive language and vocabulary (the three expressive language subtests and receptive vocabulary); oral narrative (mean length utterance and content scores from the oral narrative measure); and non-verbal cognition (matrices and pattern construction subtests).

Findings: At the end of year 3 concurrent multiple regression analyses showed that these four factors together accounted for 70% of the total writing outcome. Spelling and phonological processing were highly significant contributors and accounted for the most unique variance to all six writing components. Expressive language and vocabulary contributed highly significantly to the sentence structure, punctuation and composition and effect components. Oral narrative contributed significant, unique variance to the punctuation and composition and effect components. Concurrent data from the end of year 4 will be presented, and the developmental role of linguistic skills in different component writing skills examined.

Theoretical and Educational Significance: Results from the end of year 3 concur with a developmental approach that lower level skills (e.g. spelling and phonological processing) impact on writing earlier (grades 1-3, aged 6-9 years), whereas language constraints may have more impact later (e.g. Abbott & Berninger, 1993). They also partly concur with a capacity approach, that automaticity in these lower level skills is needed before working memory capacity can be freed up for higher level compositional demands such as idea generation (e.g. Kellogg, 1996), highlighting the need for the embedding of these skills early on. However, the results also highlight the importance of developing syntactic complexity orally at this age (as measured by the expressive language sub-tests) to develop children's sentence structure, punctuation and composition skills in writing. These findings have implications not only for the role of oral language in relation to developmental models of writing, but also for teaching practice. The longitudinal data will illuminate how the relationships between oral and written language change over time. This will add to our understanding of how particular oral language skills may support writing development.

Writing development in children with language difficulties and the influence of spelling skill

Vince Connelly, Oxford Brookes University, United Kingdom; Sarah Critten, Oxford Brookes University, United Kingdom; Julie Dockrell, Institute of Education, United Kingdom; Kirsty Walter, Oxford Brookes University, United Kingdom

Children with specific language impairment (SLI) struggle with learning to write throughout schooling. They produce texts that are shorter with more spelling and grammatical mistakes in their writing. This study considers the relationship between the writing, spelling and oral language skills of children with SLI at age 10 and children of the same age and also children with the same language ability. It was found that type and amount of spelling mistakes were closely tied to compositional quality in writing across the groups. A detailed error classification of spelling mistakes revealed a subtle pattern of difference across groups. The children with SLI were producing more errors that were not developmentally appropriate and that differed from both their same age peers and, more interestingly, the language matched children. It was also found that children with SLI produced more non-phonologically based errors for derivational forms than either sets of control groups. The results are considered in relation to current developmental models of writing. The development of fluent spelling is critical for young writers and can significantly

constrain writing development in a number of ways. Spelling interventions need to be devised to the needs of the child and not just to their gross developmental level.

Aims:

Literacy development includes both learning to read and learning to write. Considerable advances have been made in understanding the cognitive processes underlying reading development, and this has led to effective interventions. In contrast, our understanding of the cognitive processes underpinning writing development is less advanced. Many children struggle with the production of written text especially those with language difficulties, who may be 'the most under identified and under deserved group at present' in schools. Unfortunately writing difficulties persist as an area of significant weakness for these children throughout their school careers and continues even when oral language narratives become age appropriate. There is little research into connections between writing and oral language and the ways in which language encoding processes support written text production especially beyond the single word level (Connelly & Dockrell 2009). As such, many models which purport to explain the writing difficulties of children with language difficulties are underspecified and the evidence base required for effective interventions is missing. There are powerful reasons to predict that oral language underpins the processes of text generation and that difficulties with oral language will constrain the development of written text production. Specific relationships between oral language competence and the production of written text have been reported both for children with continuing and those with resolved language problems, leading to the hypothesis that written language can be conceptualized as a window into residual language problems. Phonological processes impact directly on children's spelling while spelling is a prerequisite to extended text generation.

This study considers the relationship between the writing, spelling and oral language skills of a cohort of children with specific language impairment at age 10 and two cohorts of children; typically developing children of the same age and children with the same language ability.

Methodology.

Sample 1 consisted of 23 children with poor language skills (aged 10.5 years) matched with 23 children of the same chronological age (10.5 yrs) and 23 younger children (7.9 yrs) with the same language level. Children individually completed a range of measures including standardised writing and spelling tasks. The emphasis here was to examine spelling errors and links to competence in overall written text.

Sample 2 consisted of 34 children with poor language skills (aged 10.1 years) matched with 34 children of the same chronological age (10.1 yrs) and 34 younger children (8.2 yrs) with the same language level. Children individually completed a range of measures including standardised writing and spelling tasks with a particular focus on morphology. The children's use of both inflectional and derivational morphology was assessed in both the written and oral domains. Children also completed a number of tasks on a digital tablet that can be analyzed to determine differences in writing speed and other measures.

Findings

The children with language impairment showed no difference in overall spelling ability on a stand alone standardized spelling task compared to their language match controls but, as expected, they were significantly poorer than children of the same chronological age. In Sample1 we examined spelling within written composition and found that the children with language difficulties were producing the same proportion of spelling errors as their language matched peers and made significantly more mistakes than peers of the same age. However, a detailed classification revealed a more subtle pattern of errors. The children with language difficulties were producing more errors that were not developmentally appropriate and that differed from both their same age peers and, more interestingly, the language matched children. Using a scoring scheme developed from Silliman et al (2006) it was found that the children with language difficulties were significantly less accurate at producing correct letters and combining appropriate letter clusters when compared to the intended target words. Type and amount of spelling mistakes were closely tied to compositional quality in writing across the groups in Sample 1.

Sample 2 results focused in on the use of morphology in spelling. Here it was found that children with language difficulties were comparable to children of the same language age when it came to producing inflections in spelling. However, it was found that children with language difficulties produced more non-phonologically based errors for derivational forms than either sets of control groups. This mirrors similar findings in the oral domain for this population.

Theoretical and educational significance.

Children with language difficulties are particularly at risk for writing problems and the results are considered in relation to current developmental models of writing.

The children with language difficulties in our study were having great difficulty learning to write and the general writing support in schools was not sufficient to meet their needs. Two dimensions, vocabulary and spelling, that are both amenable to direct instruction (Hammill, 2004; Jitendra, Edwards, Sacks & Jacobson, 2004), accounted for a significant proportion of the variance in the children's written outputs. The development of fluent spelling is critical for young writers and can significantly constrain writing development in a number of ways.

Clear links between oral language competence, written spelling competence and overall writing quality were confirmed for children with language difficulties and importantly also with the control groups. The children with language difficulties had problems with the morphological aspects of spelling and in some cases this was worse than would be expected given their gross level of language ability.

Studies that aim to improve the writing of children with learning difficulties typically focus on the process of writing itself, including strategies related to such activities as planning, organizing, and revising (Graham, in press). These processes are linked to teaching children how to write. Our data suggest that for children with language difficulties addressing what to write and how to spell also continue to be important. Spelling interventions need to be devised to the needs of the child and not just to their developmental level as our error analysis illustrates subtle differences between groups that were seemingly matched.

Spoken and Written Narratives in French and English Speaking Children with Language Impairment

Judy Reilly, San Diego State University, United States; Jun O'Hara, San Diego State University, United States; Josie Bernicot, Universite de Poitiers-CNRS, France; Joel Uze, CRTL-Centre Hospitalier H.Laborit, Poitiers, France; Beverley Wulfeck, San Diego State University, United States; Mark Appelbaum, University of California, United States; Thierry Olive, Universite de Poitiers-CNRS, France; Monik Favart, Universite de Poitiers-CNRS, France

Children with Language Impairment (LI) show significant delays in spoken language development. The few studies on writing note continued problems with morphology; these are primarily English. In contrast to the impoverished and irregular morphology of English, French morphology is rich; but often silent, posing challenges for writing. Here, we focus on spoken and written narratives of American and French children and adolescents with LI and their controls (TD), addressing three issues: 1) Whether early problems with morphology persist and manifest in writing; 2) How performance differs in French and English; and 3) The role of complex syntax in narratives. Participants produced both spoken and written texts which were coded for measures of both Linguistic and Narrative structure. Despite morphological differences in English and French, LI groups displayed similar overall profiles: significantly more morphological errors than controls, and in the older groups comparable use of complex syntax to TD. For the LI groups, frequent use of complex subordinators, provides a coherent organizational structure for their texts. The juxtaposition of morphological and spelling errors to overall text coherence show an uneven developmental profile, common to both English and French adolescents with Language Impairment.

Aims:

Children with Language Impairment (LI) show significant delays in language development, but have apparently normal cognitive abilities. In spoken language, children with LI have difficulties in phonology, morphology and complex syntax. The few studies examining written discourse note continued problems with morphology; however, these studies are primarily with English speaking children. In contrast to the somewhat impoverished and irregular morphology of English, French morphology is rich; moreover, verb morphology, especially in -er verbs is silent, posing additional challenges for writing. Here, we compare spoken and written narratives of American (from California) and French (from Poitou-Charentes) children and adolescents with LI. Our research addresses the following questions: 1) Do early problems with morphology persist in both oral and written narratives? Is the profile comparable in the two languages and the two modalities (spoken/written)? 2) What is the role of complex syntax in narratives? And how does this manifest in children with LI in these two languages and modalities?

Method:

To address these questions, we have collected oral and written narratives from 16 French and 32 American children with LI (ages 7;00-16;00) and age/gender matched typically developing (TD) controls (32 French; 60 American). Children were asked to, "Tell about a time when you were mad or sad." After telling the story, they were asked to write about the same events. On completion of the written story, children could revise; then they re-read the texts aloud. Spoken narratives were transcribed using CHAT from CHILDES and Mirror transcripts were made for written stories. Both oral and written stories were coded for: 1) Language structure: length in propositions; type and frequency of morphological errors; frequency and types of complex syntax; 2) Narrative structure: setting, initiating

event, problem and resolution; quality of the setting (inclusion of place, time, situation); and written stories were also coded for Spelling: frequency and types of orthographic errors.

Results:

With respect to morphological errors, the challenge of the complex French written morphology is evident in the higher proportion of errors for all French speakers compared to their English speaking counterparts. However, the TD French group improves significantly with age whereas the LI group continues to make grammatical errors well into adolescence similar to their English speaking LI peers. For complex syntax, both the English and French children with LI in the younger groups (ages 7?11 years) used both fewer types and fewer tokens than controls. However, in the older groups (ages 12?16) both English and French LI groups used complex sentences with comparable diversity to the TD group. With respect to spelling, both groups of LI (English and French speaking), make more errors than their typically developing peers. Moreover, both the English and French TD and LI groups make fewer errors in adolescence. Interestingly in a qualitative study we found that whereas the errors in English from the LI group are word internal, such as, "uling" for ugly, the errors in French from the LI group also reflect problems with segmentation, as in, "Ses téê" for c' était, or "mavoler" for m'a voléê.

Theoretical and educational significance:

In sum, for the children and adolescents with Language Impairment, their persistent problems appear to be local, that is, predominantly in the morphology and spelling. More globally, the frequent use of complex subordinators that explicitly signal the relation between elements, provides a coherent organizational structure for their texts. The juxtaposition of local morphological and spelling errors and overall text coherence shows an interesting and uneven developmental profile that is reflected in both the English and French adolescents with Language Impairment. These findings have clear implications for designing interventions and educational policy regarding the importance of morphological knowledge in spelling instruction.

SYMPOSIUM

Philosophy with Children as Democratic Citizenship Education

Chairperson: Wiel Veugelers, University of Amsterdam, Netherlands

Organiser: Wiel Veugelers, University of Amsterdam, Netherlands

Discussant: Vivienne Baumfield, University of Glasgow, United Kingdom

In many schools programmes of Philosophy with Children have been introduced. These programmes focus on pedagogical goals as 'acquire argumentative competences', 'developing children's capacities as responsible citizens' and 'developing democratic skills and attitudes' and they include 'dialogical-reflective activities'. In this symposium three research groups will present their work. The research of Di Masi and Santi is on the 'Children Municipal Council' as 'a community of philosophical inquiry'. They focus on the capacity to judge moral arguments, the relationship between philosophical discussion and ability to understand and verbalize the emotions, and the ability to choose the arguments constructed on the others' idea.

Cassidy and Christie present a study on the 'Community of Philosophical Inquiry' approach. This approach emphasizes the quality of the philosophical dialogue, because 'one needs to challenge assumptions within one's life and the wider world.' The paper reports on the changes taking place in the children's ability to make informed choices and decisions and to articulate informed ethical views of complex issues.

Bartels, Onstenk and Veugelers present their research on 'Philosophy for Democracy'. The research involves questions and instruments on the different levels of the curriculum: abstract goals, curriculum material, operationalisation by the teachers, practice of the teachers, and experiences and effects on students. The first analysis shows that the programme is a democratic practice and that the children develop reasoning and dialogical skills.

The papers and the discussion adress the questions: what does the research say about effects of the programme, which elements of the programme contribute to these effects and in which way the programme prepares children for democratic citizenship.

Learning Democratic Thinking: Philosophy for Children as Citizen

Diego Di Masi, University of Padua, Italy

Marina Santi, University of Padua, Italy

This presentation presents the first results of wider research project aimed to develop a curriculum for citizenship to promote the competencies for an authentic participation, through the improvement of "community of philosophical inquiry" in school and town. The research follows the current debate that declined the word democracy in terms of

right to participate in deliberative process. If democracy means to participate in a public deliberation (Crocker, 2006; Sen, 2002), the democratic education turns around the development of those competences and capabilities (Sen, 1998) that enable such deliberation. In this approach democratic education is, first of all, to support participation opportunities to acquire argumentative competences (Audigier, 2005, Santi 2006).

The research is guided by the idea that the dialogical-reflective activities in "community of philosophical inquiry" based on constant practices of argumentation, negotiation and shared deliberation, improve the acquisition of the procedural citizenship's skills (Audigier, 2005). In the research the experiences of Municipal Councils has been conjugated with the P4C tradition and its world-wide scientific results in order to offer a possible educational design based on concrete practice of participation in democracy. Following the Philosophy for Children (P4C) programme, the Municipal Council of Children and the elected members' classroom had been converted in a "community of philosophical inquiry" to propose dialogical-reflective activities based on constant practice of argumentation, negotiation and shared deliberation, to improve the acquisition of those attitudes and skills useful in deliberative dialogue (Walton, 1996; Gregory, 2007). The inquiry approach becomes a methodology to improve the "complex thinking" (critical, creative, and care) and to improve the competences needed to participate in the present and future of democratic process (Lipman, 2003; Santi, 2006).

The project represents an implementation of Art. 12 of the UN Convention on the Rights of the Child and an educational design that takes in account the European Project "Education to Democratic Citizenship" framework. In according with the idea that the children is an agent, a subject able to act with others in order to construct his reality and chance his word, an Education to Citizenship programme have to foster moral and cognitive competences, supporting the opportunities, like as the Children Municipal Council, to develop the children's autonomy. The Children Municipal Council could be considered as a model of participatory democracy, in which children voices could be formed, expressed and taken into account to reach a consensus, participating to deliberative processes based on democracy of thinking and doing. At the same time the Municipal Council of Children can be interpreted as an activity to develop in the children involved their argumentative skills.

In the research the experiences of Municipal Councils has been conjugated with the P4C tradition and its world-wide scientific results in order to offer a possible educational design based on concrete practice of participation in democracy. Following the Philosophy for Children (P4C) programme, the Municipal Council of Children and the elected members' classroom had been converted in a "community of philosophical inquiry" to propose dialogical-reflective activities based on constant practice of argumentation, negotiation and shared deliberation, to improve the acquisition of those attitudes and skills useful in deliberative dialogue (Walton, 1996; Gregory, 2007). The inquiry approach becomes a methodology to improve the "complex thinking" (critical, creative, and care) and to improve the competences and dispositions needed to participate in the present and future of democratic process (Lipman, 2003; Santi, 2006).

The main research hypothesis is that "community of philosophical inquiry" as method and context which fosters argumentative thinking and its reflective and judgement dimensions, could be useful to develop the competences needed for meaningful and active participation of children in the Municipal Council and in the democratic life.

The aim is to transform the Council in a learning community and to support this experience through coordinated educational actions which start in the elected members' school and classroom context and activities. In this way school and town became a real enlarged "citizenship community" in which competences and dispositions to participate in the present and future of democracy are scaffolded and the charge and responsibility for thinking and reasoning are shared and distributed (Brown & Campione, 1996; Resnick, Levine & Teasley, 1990; Salomon, 1996). According to Kline (1998), when children have the opportunity to initiate and evaluate arguments, hear others make and examine arguments, and participate equally in resolving disputes, children improve their argument skills. P4C community of inquiry in the classrooms and Session in Municipal Council are both opportunities and contexts in which to apply and develop these skills.

The paper presented deals with these objectives: Develop in the children involved in the research, fundamental procedural skills implied for the realization of a democratic participation, such as the argumentative ones (Santi, 2006; Audigier, 2005). Promote the development of "caring thinking" (Lipman, 2003) fostering moral judgment (in its affective and cognitive dimensions) through the philosophical dialogue in the community of inquiry.

Method

Setting and subjects: The project regards a Children Municipal Council of a town situated in North-East Italy. The Council involves 40 children elected by peers from their school, distributed along the 6 educational district of the city. The project involves the classrooms of the 40 children elected (around 450 subjects, from 5th to 8th grade – 9 to 13

years old): in each classroom (22 classes) the P4C Program is implementing (1 hour/week, during 9 months, under the supervision of a CoI facilitator, expert trainers in Philosophy for Children), using specific materials created for the project, which follow the structure proposed in the P4C Curriculum.

Data collection and analysis: the research has the aim to evaluate the impact of the P4C program on the children elected, while they participate in deliberative processes during the activities of Municipal Council. To test the main research hypothesis a mixed method (quantitative and qualitative) is adopted using various instruments. In this presentation will presents the quatitative results.

1. Moral Judgement Test (Lind, 1979) to analyze how the philosophical discussion affects the capacity to judge moral arguments.
2. SAR (Baiocco, Giannini, Laghi, 2005) to study the relationship between philosophical discussion and ability to understand and verbalize the emotions.
3. Best Reasoning Test (Kunh, 2006; Santi and Giolo, 2008) to measures the ability to choose the arguments constructed on the others' idea.

Results and Discussion:

A first part of the data collection is already analysed (pre-interviews and pre-test on argumentation competences) and the first results show as the philosophical dialogue improve the consistency in moral judgement, the level of empathy and the capacity to develop a argumentative strategy based on the valorisation of others'ideas for the "commitment" in dialogue.

Community of Philosophical Inquiry: Citizenship in the Classroom.

Claire Cassidy, University of Strathclyde, United Kingdom; Donald Christie, University of Strathclyde, United Kingdom

The context for the study was the current curriculum reform in Scotland (Curriculum for Excellence) which demands that teachers enable children to become 'Responsible Citizens'. This paper reports a study which aimed to evaluate the use of Community of Philosophical Inquiry (CoPI) as a pedagogical tool to enhance citizenship attributes in Scottish children in a range of educational settings. Before and after an extended series of CoPI sessions, the children were presented with dilemmas designed to elicit responses which indicated their ability to make informed choices and decisions and to articulate informed, ethical views of complex issues. The sessions were facilitated by the class teachers who were trained in CoPI. Changes in these teachers' understandings of citizenship and pedagogy over the course of the study were also examined. The implications both for education for citizenship and the potential of Philosophy with Children to contribute to an enhanced school curriculum will be discussed.

The reformed school curriculum in Scotland (Curriculum for Excellence, Scottish Executive, 2004) calls upon teachers to encourage children and young people to become 'Responsible Citizens'. This entails children being able to: develop knowledge and understanding of the world and Scotland's place in it; understand different beliefs and cultures; make informed choices and decisions; evaluate environmental, scientific and technological issues; develop informed, ethical views of complex issues. The present paper reports how McCall's Community of Philosophical Inquiry (McCall, 1991) is being used to achieve these goals in a range of educational contexts.

There is a strong body of evidence in support of the educational value of doing Philosophy with Children (PwC) (e.g. Lipman, 2003; Garc a-Mori  n, Rebello & Colom, 2005; Cassidy, 2007; Daniel, 2008; McCall, 1991, 2009). The use of PwC is growing globally and variations and developments of Lipman's original practice have emerged. Garc a-Mori  n, et al. (2005) carried out a meta-analysis of over one hundred international empirical studies and concluded that doing philosophy with children had a positive impact on children's learning and, in particular, on their development of higher order thinking skills, an essential pre-requisite for critical citizenship (McCall, 1991; Gregory, 2008). The present study explores the value of PwC in relationship to education for citizenship specifically.

Aim

The principle aim of the present study was to evaluate the effectiveness of the Community of Philosophical Inquiry (CoPI) approach in developing children's capacities as responsible citizens. The study also was designed to explore teachers' understandings of citizenship and the pedagogy associated with the CoPI approach.

Methodology

The study involved eight teachers as co-researchers. All the teachers had received training in CoPI through a university postgraduate certificate course and worked across a range of educational sectors. Children were presented with a series of age-appropriate vignettes containing dilemmas designed to assess the children's ability to make informed choices and decisions and to develop informed, ethical views of complex issues. These vignettes were presented by the teachers as part of normal classroom activity both before and after a series of CoPI sessions that took place throughout the course of an academic year. The children responded to the vignettes individually and then in groups on both occasions. Teachers were encouraged to involve their children in at least two CoPI sessions per month throughout the year. A sample of CoPI sessions were recorded and transcribed for analysis. After completing the final vignette activity a sample of children were interviewed in order to elicit their reflections on their own learning and the degree to which they felt they had developed self-efficacy, personal agency and the capability to engage as a citizen.

McCall's Community of Philosophical Inquiry (CoPI) differs from other PwC practices in that its structure is consistent and does not vary according to the age or composition of the group participating. The facilitator presents a stimulus in response to which participants generate questions. The facilitator selects the question to initiate the dialogue (Cassidy, forthcoming). The structure of CoPI demands that participants make connections with previous contributions by agreeing or disagreeing with previous speakers while also providing reasons for that agreement or disagreement before expanding with their own contribution. The emphasis is on the quality of the philosophical dialogue as opposed to the need to reach a conclusion or consensus, thus allowing further consideration of the topic beyond the time of a single CoPI session while also promoting the notion that one needs to question continually and challenge ideas and assumptions within one's life and the wider world (Cassidy, 2007; McCall, 2009). The inclusiveness of the structure aims to engender respect for others' views, an appreciation of ideas and meanings as well as the need to be reflective in one's life. Thus, by equipping children and young people with the tools with which to engage critically with the world around them, CoPI aims to empower children to become more active, participative and political individuals (Cassidy, 2007, 2008).

Teachers were asked to define citizenship both at the beginning and the end of the study. The teachers also maintained reflective logs throughout the year in which they recorded critical incidents (e.g. Tripp, 1993) which highlighted aspects of citizenship behaviour on the part of the children. This revealed the ways in which teachers' understanding of the concept of citizenship evolved over the course of the year.

Findings

The paper will report on the changes taking place in the children's ability to make informed choices and decisions and to articulate informed, ethical views of complex issues as reflected in their responses to the dilemmas presented before and after engaging in regular sessions of CoPI. The changes in teachers' understandings of citizenship and pedagogy associated with CoPI will also be discussed together with illuminative examples from the children's dialogues recorded during CoPI sessions. Implications both for education for citizenship and the potential of PwC to contribute to an enhanced school curriculum will be discussed.

Philosophy for democracy

Rob Bartels, Hogeschool INHOLLAND, Netherlands; Wiel Veugelers, University of Amsterdam, Netherlands; Jeroen Onstenk, INHOLLAND Professional University, Netherlands

Philosophy for Democracy is a research project which aims to examine whether, in what way and to what extent Philosophy with Children contributes to the development of democratic skills and attitudes. The research outline is based on the curriculum theory as conceptualized by Goodlad who divides the curriculum into six levels. We used Goodlad's theory to research the development and implementation of a programme for philosophy of education. The first two levels, the ideal and the formal curriculum, consist of a study on P4C theory and on the learning material that has been developed. The second two levels, the interpreted and the operational curriculum, concern the teachers: how do they interpret Philosophy with Children, and what do they do in practice? The last two levels, the experienced and the effected curriculum, concern the children: what do they do in the Philosophy sessions, and what learning processes can be identified to contribute to democratic development? Philosophy for Democracy has been carried out in four Dutch primary schools where Philosophy is a regular practice. Through interviews, observations, registrations and analyses of philosophical inquiries, and questionnaires, we have collected the required data. The first findings of the study show that Philosophy with Children is a democratic practice and that children develop relevant reasoning and dialogical skills.

Philosophy for Democracy is a research project which aims to examine whether, in what way and to what extent Philosophy with Children contributes to the development of democratic skills and attitudes. It has been carried out in four primary schools in the Netherlands. Philosophy with Children, in the way we now find this in most European countries, has its origins in the work of the American philosopher Matthew Lipman. Lipman developed a theory, a methodology and a curriculum for Philosophy with Children. He explicitly places Philosophy with Children in the perspective of the democratic society. A democratic society like ours, Lipman argues, must do everything in its power to educate its citizens to become reasonable individuals. (Lipman, 1991). In a democratic society it is not sufficient for individuals to be rational in nature, i.e. for them to be able to argue in a mechanical and strict manner, as they also need to be capable of adapting to one another's thinking skills and abilities. Nor is it enough for individuals to be knowledgeable in a range of fields if they are not capable of applying this knowledge in the correct way. In a world that is constantly changing, a world that is increasingly multicultural, it is important to ensure that individuals develop into people with an advanced ability to judge. Two of the main goals of Philosophy with Children are: developing thinking skills and judiciousness of children, and the development of the dialogue (Sasseville, 2003).

Aims

Philosophy with Children can have an important contribution to Citizenship Education. To achieve this, a Philosophy programme for the primary school was developed in the Netherlands under the name of 'Filosoferen doe je zo' (Philosophising is done like this) (Bartels & Rossum van, 009). The main objective of the programme is the development of democratic skills and attitudes. The programme aims to contribute to the development of competencies, which are important for democratic citizenship. Philosophy with Children can be a democratic practice, a learning environment at school where children can practice democracy. Philosophy with Children is based on principles such as: children are equal, they consult and engage in dialogue with each other, they form an opinion on the basis of arguments and by themselves and differences of opinion are appreciated. The objectives and principles of Philosophy with Children are ambitious. Can these can have these pretensions be realised? Can we - in the practice of philosophising with children - perceive that children indeed acquire democratic citizenship competences?

Methodology

The research outline is based on the curriculum theory of Goodlad (1979) and others (Akker van den, 2003). The assumption of this theory is that a curriculum is active on – and can be analysed in – six levels. The first two levels, the ideal and the formal curriculum, consist of a study on P4C theory, the Lipman at pproach in particular, and of the

material that is used in the classroom. In this case the recently developed programme 'Filosoferen doe je zo' (Philosophising is done like this). The main objective of this programme is to develop democratic skills and attitudes. The second two levels, the interpreted and the operational curriculum, concern the teachers: how do they interpret Philosophy with Children, what are their objectives? How do they see their role? And on the operational level the question is: what do they do in practice?

The research has been carried out in four Dutch schools, which have been practising philosophy for several years, and which have worked with the programme on a regular basis. 300 children have participated in the study. With different methods we collected data on the distinguished levels. We used questionnaires and interviews to identify teachers' interpretation of Philosophy with Children. Furthermore, sixteen sessions of Philosophical Inquiry were observed, recorded and fully transcribed for an iterative process of content analyses. This was done not only to record the pedagogical actions of the teacher, but also to observe the actions of the children. The last two levels, the experienced and the effected curriculum, concern the children: what do they do in the Philosophy sessions, and what learning processes can be identified that contribute to democratic development? In addition to the recordings of the sessions, the participating children evaluated the inquiry afterwards. The research was finalised with an overall questionnaire for the children to evaluate the effects of philosophising.

Findings and relevance

Until recently, little systematic and empirical research has been carried out on the practice of Philosophy with Children in the framework of children's moral and social development. There is recent research in Scotland in which the development of thinking skills and those of the dialogue during philosophising, as well as the acquisition of social skills, was studied (Trickey, 2007). In Flanders and the Netherlands studies have been 'carried out', in which the effects of philosophising on the social climate in the classroom were investigated (Anthone, 2005; Bartels, 2007). The results of these studies gave strong indications that philosophising with children can contribute to democratic citizenship education. The research project Philosophy for Democracy builds on these former studies. The first findings in the present phase of the study (October 2010) show that Philosophy with Children is a democratic practice and that children develop relevant reasoning and dialogical skills. At the time of the symposium most of the data will have been analysed and can be presented. The paper will provide a understanding of the place Philosophy with Children can have in citizenship education.

SYMPOSIUM

Deconstructing knowledge construction: Multiple perspectives on identifying knowledge elements

Chairperson: Shulamit Kapon, University of California Berkeley, United States

Organiser: Shulamit Kapon, University of California Berkeley, United States

Mariana Levin, Michigan State University, United States

Discussant: Ferenc Marton, Goteborg University, Sweden

Learning takes place in a wide-variety of contexts and is mediated by many factors. The nature of that which changes as people learn—the organization of individual knowledge systems—remains of fundamental interest. Many researchers take a complex systems approach to conceptualizing the nature of individual knowledge. However, within this general perspective, researchers have different approaches and methodologies for describing the nature and form of the component parts of knowledge systems and how they interrelate.

The goals of this session are to (1) examine a range of methodological approaches to studying the construction of knowledge in the context of mathematics and science education, (2) to highlight differences, and (3) to try to provide a synthetic picture of the current understanding about knowledge constructs and their relation to learning. Presenters will elaborate their perspectives on what knowledge elements are and how they identify them in empirical data. Related questions include: What exactly is changing as knowledge is constructed? How does examining the

structure/content of knowledge at the level of elements help us get a better understanding of particular classes of learning processes and difficulties?

The session brings together researchers from three different research perspectives (Grounded Theory, Abstraction in Context, and Knowledge in Pieces) across multiple disciplines (mathematics, physics, and chemistry) with long-standing interest in developing tools to understand processes of knowledge construction. The discussant will add an additional perspective, drawing out points of contact and divergence between the approaches taken in the symposium and phenomenographical approaches.

The place of 'grounded' approaches to modelling the learner's cognitive resources and structure

Keith Taber, University of Cambridge, UK, United Kingdom; Mariana Levin, Michigan State University, United States

Grounded Theory, GT, was said to offer a 'scientific' approach to social research, moving from open-ended enquiry to tested theory. Yet, because of the characteristics of GT, there are very few genuine GT studies. However, GT approaches can inform research when understood to refer to a research programme rather than individual studies. This issue is of particular importance in research into aspects of learning that seek to model knowledge elements, conceptual structures, learning pathways and the like. There is a tension here between studies on individuals or small samples of participants – that can seldom be assumed to represent wider populations – and the desire to build up models that have generality. Our understanding of the grain-size, stability and interlinking of knowledge elements, is not currently well advanced. At this stage what is indicated are sufficiently in-depth studies of individual learners to allow us to build tentative models ground in the data (by an inductive analytical approach) to inform further work. Such exploratory studies will inevitably interpret and report data in somewhat idiosyncratic ways. However, within the research programme, such models can be tested by 'theoretical sampling' - across learner groups, contexts, etc. - to develop generally applicable models.

This presentation will consider methodological approaches for modelling knowledge structures, and conceptual learning in science. In particular, the rationale for employing in-depth case studies, with grounded perspectives on analysis in a 'scientific' field looking to develop general models to inform teaching, will be examined. Grounded Theory (Glaser & Strauss, 1967; Taber, 2000), GT, was said to offer a 'scientific' approach to social research, moving from open-ended enquiry to tested theory. Yet, because of the characteristics of GT (e.g. open-ended design, commitment to continuing 'theoretical sampling' until 'saturation' is reached), there are very few genuine GT studies. However, GT approaches can inform research when understood to refer to a research programme rather than individual studies.

An important feature of research is consistency between (i) the ontology assumed as part of the conceptual framework; (ii) the epistemological assumptions about what it is possible to find out; (iii) the specific focus or research questions deriving a study; and (iv) the methodology applied to collecting and analyzing data.

It is common to dichotomise research approaches according to various paradigmatic descriptors - positivist-interpretive, quantitative-qualitative; nomothetic-idiographic, for example, (Gilbert & Watts, 1983; Taber, 2007) - although some of these distinctions are questionable. As natural science is widely considered to have entered a post-positivist phase (NRC, 2002; Taber, 2009), it is acknowledged to inevitably involve interpretation - even though objectively is maintained as an aspiration and ideal. Similarly, the distinction between so-called quantitative and qualitative research seems mislabelled (being primarily about the inclusion of statistical hypothesis testing rather than quantification). Many researchers have rejected the notion that these descriptors represent incommensurable paradigms, which individual researchers must adopt as a 'paradigm for life'. Sometimes this rejection may be associated with notions of 'pragmatism', and the adoption of so-called 'mixed methods' research (Johnson & Onwuegbuzie, 2004). However, if this leads to a spirit 'anything goes', this can easily lead to a loss of the coherence characteristic of rigorous research.

This issue is of particular importance in research into aspects of learning that seek to model knowledge elements, conceptual structures, learning pathways and the like. There is a tension here between studies on individuals or small samples of participants – that can seldom be assumed to represent wider populations – and the desire to build up models that have generality. This tension is not a new phenomenon: it is reflected in Piaget's programme to build models of the epistemic subject (Piaget, 1972).

A better way to dichotomise research is in terms of exploratory and confirmatory studies (Biddle & Anderson, 1986). At different stages in a research programme, different ontological and epistemological commitments will be appropriate, according to the status of (and level of empirical support for) constructs, theories and models (Lakatos, 1970). Exploratory studies acknowledge that we still have very tenuous understanding of a phenomenon and seek to

build theory. Confirmatory research comes later, once exploratory research is able to offer well-motivated models for testing. A key feature of exploratory work is that it does not seek to test specific models or theories, or even adopt in advance particular concepts and constructs to make sense of data. In other words, it takes a grounded approach. That said, it is recognised that there is a limit to which an analyst can ever approach data with a totally open-mind. Indeed, the extent to which it is desirable to attempt to exclude the influence of existing theoretical ideas from a GT analysis is contended in the literature of GT methodology itself (Glaser, 1978; Glaser & Strauss, 1967; Strauss & Corbin, 1998).

The argument then is that our understanding of the grain-size and stability and structural interlinking of knowledge elements, and even of the extent to which such characteristics will be homogenous within an individual mind, is not currently well advanced (Taber, 2008). Certainly in science education this is reflected in the wide range of terms used in research to describe conjectured and reported knowledge elements. Much of this literature is very vague about exactly what the nature of the reported entities (misconceptions, alternative conceptions, intuitive theories) are, and so offers a limited basis for building up a solid understanding – for example to inform further research (Taber, 2009, Forthcoming). At this stage of the research programme (Taber, 2009), what is indicated is sufficiently in-depth studies of individual learners to allow us to build tentative models to inform further work. Clearly once such research is far enough advanced, the methodological pendulum will swing to indicate different forms of research that are able to test out the generality of such models in broader populations, and beyond the atypical, intense elicitation context of much case-study research.

This programmatic perspective will be illustrated with examples from research into students' understanding of basic chemical ideas. Here, features of student thinking identified in in-depth interviews have been followed-up through work using instruments more suitable for survey work, and in different educational contexts. Additionally, ideas about the grain-size and location within the cognitive system of particular conceptual resources deriving from physics education research have been used to interrogate data from chemistry education.

A genuine research programme will rely upon detailed investigation of thinking, across contexts, across time, that will allow us to identify what exactly knowledge elements are, how they change, how they link etc. Such exploratory studies that seek to build models ground in the data (by an inductive analytical approach) will inevitably interpret and report data in somewhat idiosyncratic ways (compare, for example, Caravita & Hallden, 1994; diSessa, 1993; Harrison & Treagust, 2000; Petri & Niedderer, 1998). Given the inevitability of individual analysts and teams being influenced by their own prior training and reading, this should be welcomed, as providing a suitably diverse set of models for further testing. Only when models from such exploratory studies have been selected and developed through considerable further testing against new data (the 'theoretical sampling' of GT) by different research groups might they become suitable as the basis for general claims about human knowledge and learning.

Abstraction as construction and partial construction of knowledge

Tommy Dreyfus, Tel Aviv University, Israel; Rina Hershkowitz, Weizmann Institute of Science, Israel; Gila Ron, Tel Aviv University, Israel

Abstraction in Context, or AiC, is a theoretical and methodological approach for investigating the constructing of knowledge. The development of the approach was led by the need for analysing and interpreting data that pointed to constructing of mathematical knowledge by means of mathematical thinking.

The main characteristics of the approach are:

- Abstraction is considered as a process of emergence and consolidation of knowledge constructs that are new to the learner, within the mathematics itself and by mathematical means.
- Processes of abstraction are investigated by longitudinal fine-grained observations, their analyses and interpretation.
- The above analyses and interpretation make theoretical as well as methodological use of a model of three nested observable epistemic actions, the RBC-model.
- The emergence of Partially Correct Constructs, or PaCCs - constructs that only partially match corresponding intended knowledge elements, is an important and natural process typically occurring during processes of abstraction.
- The RBC-model is appropriate to describe and analyse the emergence of PaCCs.
- The study of PaCCs is based on a priori content analysis of intended constructs, and this content analysis is often refined by the study of the emergence of PaCCs.

Abstraction in Context or AiC (Hershkowitz, Schwarz & Dreyfus, 2001; Schwarz, Dreyfus & Hershkowitz, 2009) is an empirically based approach to abstraction in mathematics education motivated by our need to give theoretical expression to the specific characteristics of our data. These data point to learners' constructing of knowledge by

means of mathematical thinking in contexts differing by their mathematical content and task type, social setting, and available tools.

Accordingly, we consider abstraction as a process of emergence of knowledge by "vertical mathematization" (Treffers & Goffree, 1985), specifically the emergence of new (to the learner) mathematical constructs within mathematics itself and by mathematical means. This view of abstraction follows van Oers (2001) in negating the role of decontextualization in abstraction, and embraces Davydov's dialectic approach (1990) in that it proceeds from an initial unrefined first form to a final coherent construct in a dialectic two-way relationship between the concrete and the abstract.

Activity theory (Leont'ev, 1981) proposes an adequate framework for processes that are fundamentally cognitive while taking into account their mathematical, historical, social and learning contexts. According to activity theory, outcomes of previous activities naturally turn to artefacts in further ones, a feature which is crucial to trace the genesis and the development of abstraction through a succession of activities. The kinds of actions we found to be relevant to abstraction are epistemic actions – actions that pertain to the knowing of the participants and are observable by researchers.

In our model, the epistemic actions serve as theoretical framework as well as methodological tool (Hershkowitz, 2009). The actions and the ways in which they are nested represent the process of abstraction. We found three epistemic actions useful for our purposes. Recognizing takes place when the learner recognizes that a specific previous knowledge construct is relevant to the problem he or she is dealing with. Building-with is an action comprising the combination of recognized constructs (whence R-actions are usually nested in B-actions), in order to achieve a localized goal, such as a justification or the solution of a problem. Constructing consists of building-with previous constructs (whence B- and R-actions are nested in C-actions) to produce a new construct, for example by assembling and integrating previous constructs by vertical mathematization.

Every epistemic action carried out by a learner is an action on one or several specific constructs within a given learning context. B-actions and C-actions act on previously known constructs; C-actions result in new (to the learner) constructs whereas B-actions do not. Constructing refers to the first time the new construct is expressed by the learner, possibly without full awareness.

While constructs are not observable, epistemic actions that refer to these constructs are expressed by the learner's utterances and behaviour and hence observable. In our micro-analysis, we consider the epistemic actions and the constructs they refer to. In this sense the RBC-model serves as a methodological tool. For example, epistemic actions can serve as tracers of active and emergent constructs.

Our a priori analysis of the learning design aims at identifying the intended constructs toward which the learning is purposely designed, and which we call (knowledge) elements. Elements can be mathematical concepts, methods, strategies, and so on. They are agreed upon notions underlying the learning context; they are not absolute but relative to an instructional activity. Our analysis of transcripts of learning events then focuses on identifying specific learner actions as R, B or C-actions on this learner's constructs that reflect these elements. Comparing intentions of the design with learner constructs may lead to modifications of our a priori list of elements, for example to the inclusion of alternative constructs.

Unsurprisingly, learners' emerging knowledge constructs do not necessarily fit the designer's intentions. We use the notion partially correct construct or PaCC for a construct that only partially matches a corresponding intended knowledge element. Here the elements intended by the design are used as the whole with respect to which a learner's constructs may be partial. Learners with PaCCs may show behaviour that is misleading or inconsistent, as our research demonstrates (Ron, Dreyfus & Hershkowitz, 2006, 2010).

Using the epistemic actions as tracers, the RBC model allows us to identify not only the existence of PaCCs but also their emergence and their nature. We distinguish between two categories, structural PaCCs and contextual PaCCs. In structural PaCCs the fit between the building blocks (or their connections) of the learner's construct and those of the element is partial. We found evidence of three types of structural PaCCs: missing-element PaCCs, incompatible-element PaCCs and disconnected-element PaCCs. In contextual PaCCs the partiality of the fit between the learner's construct and the element lies in the learners' (lack of) sensitivity to the boundaries of the context in which the construct is appropriate and necessary. We found evidence of two types of contextual PaCCs: narrow-context PaCCs and wide-context PaCCs.

In addition to identifying general types of PaCCs, as well as individual learners' PaCCs that can help understanding their behavior, the study of PaCCs also contributes to the refinement of the content analysis, by pointing to fine-grained constituent elements that may be absent from some learners' constructs.

Several characteristics of AiC are essential to the study of PaCCs. The study of PaCCs starts from a priori content analysis, while the researcher who traces the learning process, using the RBC actions as tracers, focuses on the learners' emerging constructs and their expression in the constructing of new knowledge, rather than on the content domain elements. This combination, together with the dynamically nested nature of the RBC model, enables tracing a construct, and identifying cases in which a learner's construction of an idea precedes the construction of its constituent elements, as well as various types of partial fit between intended knowledge elements and learner constructs.

Developing methodological principles for validating accounts of knowledge in use and in development

Shulamit Kapon, University of California Berkeley, United States; Mariana Levin, Michigan State University, United States; Andrea diSessa, University of California, Berkeley, United States

In this paper, we discuss methodological issues involved in studying the organization of individual knowledge systems using the Knowledge in Pieces epistemological perspective (diSessa, 1993). Knowledge in Pieces (KiP) is a powerful and evolving heuristic framework for describing knowledge in use and in development. Knowledge in Pieces models conceptual competence as a complex system comprised of many and diverse types of knowledge elements (Smith, diSessa, & Roschelle, 1994). To make progress on the program of understanding learners' knowledge systems and how they evolve, a goal of empirical work is to identify relevant forms of knowledge elements and learning mechanisms. In this paper, we discuss knowledge analysis (diSessa, 1993; Sherin, 2001), a methodological approach that is complementary to KiP. An inherent difficulty of knowledge analysis (KA) is that the researcher has no direct access to the learners' knowledge system. As such, knowledge analysis is a highly interpretive enterprise. In this presentation, we will discuss three specific types of knowledge elements described in different studies of student reasoning about physics and mathematics: p-prims, explanatory primitives, and variation schemes. For each of the knowledge elements discussed, we will give (1) a definition and explicit standards of what counts as the particular knowledge element in the analysis (2) explicit indication of how the knowledge element is implicated in the process of learning or conceptual change and (3) a matching between the data and the attributed knowledge element.

Introduction

Determining what individuals know and how this changes as they learn is an important and difficult question inextricably linked to one's epistemological perspective. In this paper, we discuss methodological issues involved in studying the organization of individual knowledge systems using the Knowledge in Pieces epistemological perspective (diSessa, 1993).

Theoretical perspective

Knowledge in Pieces (KiP) is a powerful and evolving heuristic framework for describing knowledge in use and in development. KiP grew out of the constructivist tradition of Piaget in which reasoning is conceptualized as a process of interpreting phenomena through existing knowledge structures. Thus, a major focus of research from this perspective involves modeling reasoning processes by explicitly identifying knowledge structures and mechanisms by which they are reorganized.

Knowledge in Pieces models conceptual competence as a complex system comprised of many and diverse types of knowledge elements (Smith, diSessa, & Roschelle, 1994). Naive knowledge systems are comprised of many, loosely-coupled knowledge elements whose activation and use is highly context-sensitive. The development of expertise largely involves the progressive systematization and re-organization of the naive knowledge system. Two constructivist principles that deeply inform Knowledge in Pieces include the principles of continuity and functionality. The continuity principle implies that more advanced understandings should be psychologically and epistemologically continuous with prior understandings. The functionality principle proposes a potentially productive role for students' prior knowledge in the development of expertise. In empirically studying how learners' knowledge systems function, often new knowledge ontologies and learning mechanisms must be identified to account for observed phenomena.

Methodological approach

The methodology discussed in this paper is knowledge analysis (diSessa, 1993; Sherin, 2001). In the analysis of empirical data for the purpose of developing theory about how knowledge systems function and evolve, knowledge analysis aims for joint accountability to both the content and the form of knowledge. The focus on content and form, as well as on the development of principles by which such accounts can be validated, distinguishes knowledge analysis

from other related approaches to conceptual analysis. An early point of reference on knowledge analysis is diSessa, 1993, in which a moderately large system of knowledge elements and their functions are explicitly described along with a set of methodological principles and heuristics for identifying them.

Methodological challenges

An inherent difficulty of knowledge analysis (KA) is that the researcher has no direct access to the learners' knowledge system. As such, knowledge analysis is a highly interpretive enterprise. To guard against capricious attributions of knowledge elements that are not psychologically meaningful, the identification of knowledge elements in empirical analyses should fulfill certain criteria. We will discuss criteria employed in identifying and validating three types of knowledge elements: p-prims, explanatory primitives, and variation schemes. Although each is formulated in a different study and in a different context, their empirical recognition and validation share interesting features.

Examples

The first and prototypical example we discuss is phenomenological primitives - p-prims (diSessa, 1993). The construct of p-prims was formulated to account for an empirically observed phenomenon regarding the explanations that individuals would generate concerning everyday phenomena (e.g. a ball toss). Subjects' explanations appeared to be highly context-sensitive and implicated many basic abstractions of the explainer's experience with the physical world.

The second type of knowledge element that we discuss, explanatory primitives, emerged from an analysis that sought to understand some striking variability in how students made sense of an instructional analogical sequence in physics (Kapon, 2010; Kapon & diSessa, in press). The explanatory primitive model proved to be productive in explaining differences in individuals' reactions to, and shifts in judgments about an instructional analogical sequence. In addition, the model accounts for individuals' patterns of reasoning in the target domain that are not explained by Structure Mapping Theory (Gentner, 1983).

The third type of knowledge element, variation schemes, was instrumental in deconstructing the process by which a pre-algebra student constructed a deterministic and essentially algebraic strategy for solving algebra word problems of an underlying linear structure (Levin, 2009). The approach of identifying specific knowledge elements (variation schemes) that were used, refined, and coordinated during the process of strategy construction gives a knowledge-based account for the process by which novel strategies are developed. This kind of account provides an alternative to the approach taken in the standard literature on strategy development (e.g. Siegler, 2006).

For each of the knowledge elements discussed, we will give (1) a definition and explicit standards of what counts as the particular knowledge element in the analysis (2) explicit indication of how the knowledge element is implicated in the process of learning or conceptual change and (3) a matching between the data and the attributed knowledge element. The attached diagram (Figure 1) summarizes the principles employed to validate the particular knowledge elements used in each of the analyses.

SYMPOSIUM

Impact of school inspection

Chairperson: Hans Anand Pant, Humboldt Universitaet zu Berlin, Germany
Organiser: Holger Gaertner, Freie Universitaet Berlin, Germany
Discussant: Hans Anand Pant, Humboldt Universitaet zu Berlin, Germany

There remains a strong trend towards introducing school inspections as a new component of education systems. SICI (The Standing International Conference of Inspectorates), the umbrella organisation for regional and national school inspectorates, counted 29 members (and rising) from Europe in 2010. This is due to the double function of school inspections: as a means of stimulating school improvement as well as generating steering data about the quality of schools. Despite this trend towards introducing school inspections in ever more countries, research on school inspections remains sparse and is quite heavily focussed on results from England. This symposium therefore presents new empirical approaches from Germany, the Netherlands and Switzerland to address questions about the effectiveness of school inspections. Such a comparison promises insights into the influence of contextual conditions on the effectiveness of school inspections. It also seeks to stimulate further discussion about the conceptual design of school inspections, so as to increase the likelihood of positive effects arising from these organisational diagnoses. Evidence-based governance through school inspection.

Expectations of different stakeholders

Vera Husfeldt, University of applied science north west switzerl, Switzerland; Carsten Quesel, University of Applied Sciences North-Western Switzerland, Switzerland

Since the late 1990s, school governance in Switzerland has been redesigned according to the logic of new public management. The function of leadership has been strengthened in order to create a locus for strong and flexible decision-making within schools. At the same time, the status of school inspection has been enhanced: evaluation reports are now a cornerstone of education monitoring; they are to be a useful tool for cooperative school improvement and are to provide substantial information for holding school leaders accountable for the performance of their institutions. Meanwhile, the demand to observe professional standards and scientific evidence in school management competes with traditional forms of lay participation: traditionally, the governance of public schools in Switzerland has been an important task of the local citizenry. It is debatable whether the long-established local school boards can be successfully integrated into a reformed public sector guided by the principles of evidence-based management. In a case study of the canton Argovia, we investigate how teachers, principals and members of local school boards assess the effectiveness of inspections. Using qualitative and quantitative research, we identify conflicting expectations, linked to claims of professional autonomy, managerial expediency and democratic control.

Objectives

As in many other countries, the history of school inspection in Switzerland can be traced back to the 19th century. Since the late 20th century, however, the aims and means of school inspection have come under scrutiny. The implementation of new public management reforms has enlarged the scope of supervisory tasks: now, school inspection considers not only compliance with applicable laws and the proper fulfilment of duties, but the quality of schooling as well. School inspection in the canton Argovia assesses the state of school leadership and professional cooperation as well as school and classroom climate and reports severe deficiencies to the Ministry of Education, which is obliged to intervene with measures of additional control and support. Implemented on the cantonal level, school inspection is intended to facilitate self-monitoring and self-determined school development on the local level. Thus, the policy of school inspection primarily targets hard and soft factors of the organisational setting, inducing an indirect effect on teacher performance and student learning. The evaluation report is devised as a diagnosis for the school and the authorities; the scope is limited to recommendations and does not trigger rewards, sanctions or other measures. This limitation was established in order to emphasize the developmental benefits of school inspection: As a device for learning organizations, the feedback shall be positioned as far away as possible from the 'shadow of hierarchy'. However, a total detachment of school inspection from governmental control is not intended: the shadow of hierarchy is conspicuous in the case of grave deficiencies – and the cantonal authorities may ask not only whether the principal is responsible for the failure, but whether the local school board is as well. Our study investigates how the attitudes of teachers, principals and school board members are influenced by this shadow of hierarchy.

Research design

Our research is based on a multi-dimensional model of school inspection as a political and pedagogical tool: school inspection provides data for (1) legitimation, (2) accountability, (3) school improvement and (4) scientific research. According to this model, different points of view have to be taken into account in order to assess the effectiveness of school inspection. Our research seeks to clarify how the expectations of teachers, principals and school board members are shaped by experiences in the course of public sector reforms in recent times.

Our research design includes qualitative and quantitative methods: from June to August 2010, group discussions with teachers, principals and school board members were conducted in order to formulate a typology of mindsets in an exploratory way. The questions were focused on

- the reform of Swiss school governance in the last decade
- the cantonal policy of school inspection
- opportunities and threats of evidence-based governance
- the informative value of school inspection for different stakeholders
- the relationship between inspection and accountability
- the relationship between inspection and political support
- local problems and perspectives of school development
- intentions and side effects of inspection.

Hardly any of the respondents present themselves as ardent believers in new public management, many articulate an attitude of change-orientated pragmatism and of sceptical loyalty, and more than a few argue that new managerial autonomy creates pseudo-autonomy and that school inspection may contribute to the bureaucratization of schooling. Scepticism is more present in the discourse of teachers and school board members, while principals accentuate their role as change agents while arguing for the benefits of professional external feedback.

In November 2010, this typology will be checked and validated by an online survey which includes samples of teachers, principals and school board members of 48 municipalities. Based on the first findings from the group discussions we expect that principals will show a strong determination to incorporate the new governance model in their schools and to use the results from school inspection with respect to the different functional domains. In particular, they might find it difficult to reconcile the accountability function and the development function. With regard to the teachers, we expect a strong tendency to protect the classroom as a pedagogical shelter, leading to ambiguities concerning the demand for more transparency. Therefore, they tend to have more critical attitudes towards school inspection. The qualitative data indicate that the school board members accept the logic of new public management but fear the decline of traditional lay participation due to the argument that bodies of deliberating citizens cannot meet the challenges of accountability.

For our study we chose to focus on the canton of Argonia, since it is a canton with a highly developed school inspection and with a strong tradition of lay participation in the field of school governance. The design of both the qualitative and the quantitative research draws on comparative approaches: one part of the respondents had already experienced the new type of inspection, the other part was to be inspected in the following years.

Theoretical and educational significance of the research

As in many other European countries, the reform of school inspection in Switzerland follows the line of policies which are intended to create a new balance between autonomy and efficiency. School inspections are considered to be a key feature in a system of multi-level governance which is shaped not only top-down by directives but by negotiations between stakeholders and interest groups. Our study clarifies the mindsets of stakeholders that play an active part in schooling and in the process of school inspection: the expectations of these stakeholders have to be taken into account in order to avoid constellations of resentment and antagonism in the course, and in the aftermath, of inspection. Beyond that, one must analyse which criteria need to be met for school governance in a highly professionalised democracy.

Strategic responses of schools to multiple measures in the Dutch accountability system

Melanie Ehren, University of Twente, Netherlands

School inspections are expected to have a great impact on what students learn and how they learn. The standards inspectorates use to assess educational quality and teaching and learning in schools during inspection visits, the sanctions for failing schools and the rewards for well-functioning schools stimulate and pressure schools to meet nationally defined targets and objectives. As a result, school inspections may lead to unintended negative consequences for teaching and learning in schools. This study analyses how the Dutch (risk-based) school inspections may lead to strategic behaviour in Dutch primary schools. We studied two types of strategic responses of schools: cheating on tests and reshaping of the test pool. The results of our study indicate that 5.5 percent of the schools do not comply with the guidelines for administering the test. One third of the schools also exclude one or more students from the test. These types of behaviour, however, do not appear to be related to specific measures in the Dutch school inspections or prior performance of schools on these measures.

Objectives or purposes

Available studies into effects and negative consequences of school inspections give a very mixed view of the type of changes in schools that result from school inspections and the causes of these changes in schools. A number of studies point out that strategic responses are particularly likely when accountability systems (such as school inspections) base important high-stakes decisions on a single measure of a limited number of aspects of teaching and learning. Several scholars (particularly in the US) therefore express the need for multiple accountability measures to hold schools accountable for broader goals (Koretz, 2003; Ladd, 2007). Multiple measures include measures of cognitive (student achievement) and non-cognitive outcomes (e.g. attendance, drop-out rates), or other direct measures of educational practices (school inspections/quality reviews) (Koretz, 2003). The Dutch Inspectorate of Education includes both measures of student achievement (test scores of students) and inspections of educational practices in the evaluation of schools. The objective of this study was to learn how these multiple measures may cause or prevent strategic responses of schools, particularly cheating on tests and reshaping of the test pool to improve the school's performance on the standards of student achievement.

Methodology

Until 2007, the Dutch Inspectorate of Education used measures of both cognitive student outcomes (test scores) as well as measures of educational practices (inspection visits) to monitor schools. After 2007, the inspection methodology changed, and measures of cognitive outcomes became central in holding schools to account. We expected an increase in strategic responses in schools as a result of this change. Strategic responses of schools before and after the change in inspection methodology were compared using a t-test and an analysis of variance.

The extent to which schools reshape their test pool was measured in all primary schools in the Netherlands from 2004 to 2009. School records, testing records and schools' responses on the annual inspection questionnaires were used to study the extent to which schools reshape their test pool both before and after the change in inspection methodology in 2007. We analysed which students are exempted from the Cito test in Grade 8, whether schools retain pupils in Grade 7 (prior to test taking) or refer students to special primary education or to (advanced) special education before Grade 8.

The extent to which schools cheat on tests was measured through observation of teachers during administration of the national Cito test (which is used to evaluate student achievement of schools). School inspectors visited 257 primary schools (3.7% of all primary schools) unannounced during the day the Cito test was scheduled to be administered to students in Grade 8, and observed whether the test was administered according to the guidelines of the testing company.

Findings

The results of our study indicate that 5.5 percent of the schools do not comply with the guidelines on administration of the test. The teachers in these schools allowed students to use scrap paper while making the test; they clarified test questions or prompted students with the correct answer. Some teachers also gave instruction to students just before administration of the test (after having read the test items) or put up explanations of spelling problems on the black board. One of the schools also administered the test one day before the official test administration day.

Our results also indicate that schools reshape their test pool to some extent, particularly by taking students out of the test pool who will be referred to regular secondary education with special learning support. Over the years of our study, at least one student does not participate in the Cito test in one out of every three to four schools. On average, in each primary school three to five percent of the students do not participate in the Cito test in Grade 8. The percentage of schools with students that do not take the Cito test also grows steadily over the years, but seems to stabilize after 2006. This may be related to a change in the testing guidelines. From 2007 onwards, schools were required to include in the test all students who would be referred to the learning support trajectory in secondary education. The introduction of risk-based school inspections in 2007 (which emphasized the cognitive outcomes of schools in the overall inspection methodology) may have counterbalanced a potential decrease resulting from this additional requirement.

Even though we found some instances of the strategic use of data, this type of behaviour does not appear to be related to the measures in the Dutch accountability system. We found no significant difference in the extent to which schools reshape their test pool before and after the introduction of risk-based school inspections; there is also no difference in strategic data use in schools that perform above and below the inspection threshold.

Theoretical and educational significance of the research

Across Europe, school inspections are instated to provide checks and balances to the decentralization of national policies and increases in autonomy of schools, and to provide national mechanisms of quality assurance to ensure high quality teaching for all. Growing evidence indicates that school inspections can be a key feature of school improvement. More recent studies, however, also point to unintended consequences such as excessive bureaucracy and teaching to the test. Good measures and methods of school inspections are therefore crucial in promoting quality within schools.

The impact of school inspection on school improvement – a quasi-experimental field study

Holger Gaertner, Freie Universitaet Berlin, Germany; Sebastian Wurster, Humboldt Universitaet zu Berlin, Germany

This study examines the impact of school inspections on the development of various aspects of school quality. During the phasing-in of school inspections in the federal states of Berlin and Brandenburg both inspected and uninspected schools were examined. School improvement was surveyed over a period of one year from the perspective of school principals and teachers. The main finding is that perceptions of school quality were highly stable, irrespective of the introduction of school inspections. The results show school inspections had a comparatively low impact on the aspects of school quality measured here. Some findings suggest that the main effect of school inspections concerns preparations for inspection. This would have implications for the way in which inspection processes are currently designed.

Aims

In contrast to previous studies the following uses a control group design to examine the effect of school inspection. A number of empirical studies, mostly from England and the Netherlands, deal with the question of the effect of school inspections on school and instruction improvement processes. One recent summary of the state of research is de Wolf and Janssens (2007). The following findings on the effect of school inspections are already known: studies on satisfaction suggest that the majority of school principals of inspected schools are satisfied with the inspection of their own school. Studies on behavioural effects normally confine themselves to statements about which measures will be introduced in future in response to the results of the inspection. Studies on student performance yield an uneven picture. While English studies tend to point out the negative effects of inspection on student performance, a Dutch study recently reported a positive effect in relation to student performance (Luginbuhl, Webbink & de Wolf, 2007). In their synthesis, de Wolf and Janssens (2007) conclude that previous research approaches are not robust enough. Research designs previously used are not in fact suited to deriving statements about causal relationships. For this reason experimental or quasi-experimental studies should be used more often to clarify such questions. This study does that.

This study took the implementation phase of school inspections in two federal states in Germany, Berlin and Brandenburg, as an opportunity to investigate the effects of school inspections. Inspections in Berlin and Brandenburg take place as follows. Schools receive a systematic, full inspection. School visits include observation of lessons, interviews, questionnaires and the study of school documents. Based on the findings of the inspection report, schools are then requested to define objectives to enhance their quality (action plan). These objectives are defined by the school and by the responsible school supervision authority. The next school inspection takes place after approximately five years, or after two years for schools below standard. Even when a school is underperforming significantly, the inspectorate itself has no legal authority to take direct action.

Methodology

The survey included school principals and teachers from schools that had not yet been inspected, so as to compare the improvement of these schools with those that had already been inspected within the years before. This was done by surveying the schools again after one year (first survey: October 2008; second survey: October 2009). The make-up of the schools was as follows (the sample size for both surveys is indicated in brackets):

Experimental Group 1: Schools that were inspected two years before the first survey (N=56 Principals (P); N=167 Teachers (T))

Experimental Group 2: Schools that were inspected a year before the first survey (N=94 P; N=279 T)

Experimental Group 3: Schools that were inspected within the survey period (N=102 P; N= 321 T)

Control Group: Schools that were not inspected either before or during the survey period, but will be inspected in future (N=59 P; N=173 T)

Response rates for the survey range between 13.7% and 30.2% according to the group surveyed. An analysis of non-participants revealed no differences between the schools taking part and those not taking part with respect to either student performance or their evaluation by inspectors.

The 15 dependent variables represented aspects of school quality that accord with the quality framework used by both federal states (teacher and student satisfaction; burnout of teachers; classroom management; participation of parents and teachers; cooperation with partners; leadership; organisation; professional development; co-operation among staff; monitoring of instruction and student achievement; school-self-evaluation; quality management). Independent variables are federal state (Berlin/Brandenburg), perspective (principals/teachers) and school group (experimental group 1 / 2 / 3 / control group).

Findings

A multivariate variance analysis, controlling for pre-test values, revealed significant effects for federal state ($F(15/610) = 4.04$; $\eta^2 = .09$), perspective ($F(15/610) = 5.14$; $\eta^2 = .11$), and school group ($F(45/1836) = 2.24$; $\eta^2 = .05$), as well as a significant three-way interaction between these factors ($F(45/1836) = 1.49$; $\eta^2 = .03$). This means that while there were significant changes over the survey period, these were perceived differently depending on the federal state and perspective. Changes of differing degrees were also observed for each of the school groups, although with low effect size. Considering the influence of the independent variables separately yields the following results:

Federal states: In both federal states, only few changes were statistically significant: in Brandenburg 9 of 120 – still less than in Berlin (15 of 120), though the inspection process in both states is comparable.

Perspective: Changes are perceived differently by school principals and teachers. For example, in Berlin, among principals it is those in the control group who see most changes, whereas among teachers, it is those who were inspected in the survey period who see most changes.

School group: The results show no systematic differences between the development of the inspected schools (experimental groups 1 - 3) and the control group. While there was not one significant change in the control group in Brandenburg, the control group in Berlin stood out as having the most changes (4 positive changes from the perspective of the principals).

Theoretical and educational significance

Taken together, the results suggest that school inspections have comparatively little influence on the variables measured here. The results suggest a high degree of stability for the aspects of school quality measured here, irrespective of the implementation of school inspections. However, the Berlin results suggest that the initial hypothesis (i.e. that the effect of a school inspection would be most noticeable after an inspection) may be incorrect. Instead, these results can be interpreted as indicating preparatory activities: that is, most effects occurred prior to an inspection.

If this hypothesis is confirmed by other studies, this would have implications for the way inspection processes are designed in future. For example, Baden-Württemberg already gives schools one or two years' advance notice of an inspection, so that they can (with support) specifically prepare themselves. This approach would strengthen the tendency towards specific preparations, and contrasts markedly with the notion of announcing inspections at short notice.

SYMPOSIUM

Differential effects of preschool education: Examples from England, Germany and Belgium

Chairperson: Pamela Sammons, University of Oxford, United Kingdom

Organiser: Yvonne Anders, University of Bamberg, Germany

Discussant: david reynolds, University of Southampton, United Kingdom

There is growing empirical evidence that high quality preschool education may have beneficial effects on young children's cognitive and non-cognitive development. But when looking at the body of research concerning the impact of preschool programs, there is less clear evidence concerning their differential effects on children's development. Can universal preschool programs protect children from the impact of developmental risks the same way Early Interventions can? Which groups of children benefit most from high quality preschool programs? Which pedagogical approaches serve best to promote young children's cognitive and non-cognitive development? This symposium seeks to draw light on these questions through three papers on large-scale longitudinal studies conducted in England, Germany and Belgium. The British study illustrates how high quality universal preschool has the potential to serve as an intervention to promote children's cognitive and social skills within normal populations. Results of a longitudinal secondary analysis are reported that examined the psychological development of preschoolers between the ages of 3 to 5 years. The German study focuses on the language development of young children while they move through preschool. This paper investigates the differential effects of various measures of preschool experience depending on children's migration background and their language competencies when they begin preschool. Finally, the Belgium study explores the impact of alternative schools on children's non-cognitive development and compares these results with children from traditional schools. Furthermore, the possibility of differential effects regarding students' social status and functional risk, are examined.

Can pre-school protect cognitive and social development? Variation by center quality and duration

James Hall, University of Oxford, United Kingdom; Kathy Sylva, University of Oxford, United Kingdom; Pamela Sammons, University of Oxford, United Kingdom; Edward Melhuish, Birkbeck, University of London, United Kingdom; Iram Siraj-Blatchford, Institute of Education - University of London, United Kingdom; Brenda Taggart, Institute of Education, University of London, United Kingdom

Aims:

Although it is well known that targeted Early Interventions can protect the development of young children from the impact of developmental risks, there remains less clear evidence concerning universal programs of pre-school.

Methodology: A longitudinal secondary analysis was conducted that examined the psychological development of 2,862 English pre-schoolers between the ages of 3 to 5 years.

Findings:

At age 5, instances of significantly protected development were more strongly evidenced when examining: 1) cognitive rather than social development, 2) child-level rather than family-level risks, and 3) the quality of the processes taking place within pre-schools rather than just the structures. For pre-schools that featured only high quality structures, any partial protection of development was limited to instances of longer duration of child-attendance.

Theoretical and educational significance:

That higher quality programs of universal pre-school have the potential to partially combat the effects of risks including social inequalities. Thus, programs of universal pre-school have the potential to serve as a type of intervention within normal populations by offering a form of primary prevention.

Aims:

This paper summarizes the results of a large-scale study that aimed to determine if the quality of pre-school programs (particularly high quality rather than low) could protect the cognitive and social development of a broadly representative sample of young English children. Aimed at addressing the limitations of previous research, this longitudinal secondary analysis adopted a broad remit with an examination of:

- (1) The cognitive and social skills of young children between 3-5 years
- (2) Child- (ecological) level and family-level risks
- (3) The quality of pre-school processes and structures
- (4) The varying lengths/duration that young children attended their pre-schools.

Methodology:

A reanalysis was conducted of the (anonymized) longitudinal data collected by the Effective Provision of Pre-School Education project (EPPE). This was a longitudinal English study that began in 1997 with the aim of investigating the effects of pre-school education and care on the development of young children between the ages of 3 and 7. Five geographical regions that were representative of England were sampled (covering urban, rural and sub-urban areas) and from these, 141 pre-schools were randomly selected. The qualities of the processes and structures within these 141 programs of universal pre-school were then assessed and the development of a random sample of children was

measured (after informed consent was obtained from parents). The final sample for this analysis consisted of 2,862 pre-school attendees.

Applying the terminology of 'developmental psychopathology', the young pre-school attending children had 21 recorded potential risks to their cognitive (measured via British Ability Scales; BAS) and social abilities (measured via Adaptive Social Behavior Inventory; ASBI) measured alongside their developmental skills when they were, on average, 38 months of age. Development was then measured again when these children were, on average, 58 months. Further to the aims of this study, a single global/overall measure (Early Childhood Environmental Rating Scale-Revised; ECERS-R) of the quality of the pre-schools that these children attended was assessed alongside 5 indicators of the quality of processes and 7 indicators assessing structures. To properly assess the impacts of the qualities of pre-school, the EPPE project also measured the duration that each child had attended their pre-school.

The 5 measures of process quality included the overall score from the Early Childhood Environmental Rating Scale-Extension, (ECERS-E) and the four subscales of Caregiver Interaction Scale, (CIS; Positive Relationships; Punitive Relationships; Permissive Relationships; and Detached Relationships). The 7 measures of structural quality included:

- Manager:
 1. Highest Academic Qualification
 2. Highest Childcare Qualification
- Staff:
 3. Mean Age
 4. Mean Highest Academic Qualification
 5. Mean Highest Childcare Qualification
- 6. Number of Staff
- 7. Number of Children

This study divided potential risks according to ecological levels that were either closely (proximal) or distantly (distal) related to the children. Seven of the measured risks in this study were hypothesized to be proximal to the child whilst fourteen were judged to be more distal and thereby more proximal to the family. Each of these two sets of risks (7 child-level, 14 family-level) were then hypothesised to have impacts on development that were best measured with all individual risks being considered in combination with one another (via Formative Confirmatory Factor Analysis; CFA).

The 21 recoded potential risks were composed as follows: 7 risks pertinent to the child included: Male child gender; English spoken as additional language; Birth weight; Number of siblings; Birth order; Ethnic Minority Background; Any Parent/Carer reported developmental salient event.

The 14 risks pertinent to the family included: Family salary; Mother's occupational status; Partner's occupational status; Highest status in the family; Mother's qualifications; Partner's qualifications; Mother working status; Partner working status; Whether either parent worked; Whether the child had a two parent family; Mother's age; Partner's age; Number of non-parental carers; Home Learning Environment.

Findings:

Figure 1 presents a stylized representation of the SEM that were specified to examine the relationships between latent combined risks, the development of children's cognitive and social abilities, and the quality and duration of children's attendance at pre-school. A series of analyses were conducted in which each measure of quality was independently examined to determine whether it could significantly moderate the effects of each of the combined risks as they impacted each measure of development that was assessed at entry to school (General Cognitive Ability, self regulation, antisocial/worried behavior). In addition, duration of attendance at pre-school was also tested alongside each measure of quality, both as an additional moderator of risks but also as a moderator of any of quality effects. As a result, when testing the hypotheses of risk-moderation, three multiplicative statistical interaction terms were used: 1) quality x risk; 2) duration x risk; and 3) (quality x duration) x risk.

The results of the analyses summarized in Figure 1 showed there to be many more instances of significantly protected cognitive (46% incidence) rather than social/behavioral development (15%). Further, perhaps the most important protective finding was that the global/overall quality of pre-school (incorporating assessments of both structures and processes) had the potential to protect the General Cognitive Abilities of young children from the significant impacts of family-level risk.

Theoretical and educational significance:

Given that the combined family-level risk measured in these analyses was broadly analogous to socioeconomic status, the findings of this study suggest that the attendance of young children at higher quality programs of universal pre-school has the potential to partially combat the effects of inequalities (including social) in a manner similar to Early Interventions such as the High/Scope Perry Pre-school Project (although not necessarily to the same extent). Moreover, it therefore becomes possible to conclude that programs of universal pre-school have the potential to serve as a type of intervention within normal populations by offering a form of primary prevention.

Internal and external influences on children's language development during preschool

Susanne Ebert, University Bamberg, Germany; Sabine Weinert, University of Bamberg, Germany; Kathrin Lockl, University of Bamberg, Germany; Yvonne Anders, University of Bamberg, Germany; Katharina Kluczniok, Otto-Friedrich-University of Bamberg, Germany; Hans Guenther Rossbach, University of Bamberg, Germany

International studies have pointed out significant disparities in educationally relevant competencies related to social background variables for German children. It is assumed that language - as a means supporting children's knowledge acquisition - plays an important role for the emergence of these disparities. Therefore the aim of the present study is to investigate language development and its predictors in the preschool years in groups with different verbal competencies at the beginning of preschool. In particular we ask, whether there are differential effects of various measures of preschool experience on language growth. The study draws on 547 children from 97 preschools followed from beginning of preschool until grade four of elementary school. The present investigation focuses on children's receptive vocabulary (PPVT) development using latent growth curve models. As predictors children's phonological working memory skills as well as indicators of preschool and home environment were included. Multiple group analyses differentiating between children with more or less advanced language competencies at first time of measurement were conducted to compare the effects of the various predictors. Results show strong impacts of phonological working memory on vocabulary development in all groups. However, we identified also differential effects, especially on the growth of vocabulary over preschool years. For example for children with background of migration growth in vocabulary is influenced by aspects of structural quality of kindergarten (e.g. children with background of migration-to-class size ratio). The results will be discussed with respect to their developmental and educational consequences.

Aims

Among other findings, international large-scale surveys like PISA or PIRLS have pointed out significant disparities in educationally relevant competencies related to social background variables for German children. In particular, severe disadvantages of children with a background of migration were found concerning their competence development and educational careers in the Germany (e.g. Baumert & Schýmer, 2001; Bos et al., 2003). Up to 40% of children with a background of migration have severe difficulties in German language when they start school. Therefore it is likely that these deficits hinder their successful start into the German school system (e.g. Mengerling, 2005; Schßler et al., 2004). However, also in the group of native German speaking children social disparities in language development in preschool years can be found and may explain later problems in school (Weinert et al., 2010). Language as a means to support children's acquisition of knowledge in various domains presumably plays an important role for the emergence of these disparities. Therefore we ask how and what factors influence language development in the preschool years in groups with different (German) verbal competencies at the beginning of preschool. In particular we ask, whether there are differential effects of various measures of preschool experience on language growth.

Methodology

The reported data are part of the more comprehensive longitudinal project BiKS (Bildungsprozesse, Kompetenzentwicklung und Selektionsentscheidungen im Vor- und Grundschulalter / Educational processes, competence development and selection decisions in pre- and elementary school age). In BiKS two longitudinal studies are conducted, whereas the present study is part of the study BiKS-3-10. In this study 547 children from 97 preschools are followed from beginning of preschool until end of grade four in elementary school. At first time of measurement children were about 3;8 years old.

The present investigation focuses on children's vocabulary development using latent growth curve models. Children were tested with a German Research Version of the Peabody Picture Vocabulary Test (PPVT) at three measurement points, separated by testing intervals of one year.

As predictors of children's vocabulary development various child characteristics, indicators of the preschool environment as well as variables concerning the child's home environment were included.

Multiple group analyses were conducted to compare the effects of the various predictors for (a) children with background of migration and children with no background of migration and (b) children with good German language competencies (grammar as well as vocabulary) at the first time of measurement and children who did not that good. For (b) only children without background of migration were considered.

As it is known that children's phonological working memory is a relevant predictor of children's language development we ask whether these child competencies have a different impact on children's vocabulary development. Furthermore we wanted to know whether there are differences in additional effects of preschool learning environment for the various groups. Therefore we looked at process quality, especially concerning literacy stimulation (as measured by ECERS-E), as well as structural quality (e.g. child-staff-ratio, class size). In addition family background variables (migration background, HISEI and mother's education) and a scale measuring the quality of the home environment in terms of promoting literacy skills (based on information from questionnaires, interviews and observations) as control variables were considered.

Findings

The results show that the average vocabulary grows significantly and steadily over the preschool years. Concerning our research question we identified different effects of various covariates for starting level and growth for children with and without background of migration as well as for children without background of migration but high vs. low language competencies at first time of measurement. Although there seems to be a strong impact of phonological working memory skills on vocabulary development for all investigated groups, an effect on growth shows up only for native German speaking children with worse language competencies at first time of measurement.

First analyses also demonstrate effects of structural quality of kindergarten on vocabulary growth for children with background of migration. Children with background of migration seem to profit from smaller class sizes as well as less children with background of migration in their class. There is an interrelation between children's language competencies on the one hand and support programs in kindergarten on the other showing that language problems are well noticed by the preschools. However, these programs as well as kindergarten quality as measured in this study do not seem to have significant impact on the growth of vocabulary.

Theoretical & educational significance

Summing up child's phonological memory skills, indicators of the preschool environment as well as variables concerning the child's home environment have an effect on children's language development in preschool year. However, effects can be different in accordance to children's language competencies at beginning of preschool. These results point to the importance of fostering language development in accordance to children's competencies. Further implication of results will be discussed with respect to their developmental and educational consequences.

The impact of alternative schools on children's early non-cognitive development

Jerissa de Bilde, University of Leuven, Belgium; Bieke De Fraine, K.U.Leuven, Belgium; Jan Van Damme, K.U.Leuven, Belgium

Alternative schools are often said to put more emphasis on supporting children's natural inclination to learn and promoting children's well-being. Surprisingly, the claims of these alternative schools have seldom been the subject of study. Present research aims at examining the impact of alternative schools on children's non-cognitive development and compares these results with children from traditional schools. Furthermore, the possibility of differential effects regarding students' social status and functional risk, are examined. Results revealed that, without controlling for student background characteristics, children from Freinet school have a higher teacher-rated school enjoyment and independent participation. However, these effects disappear after taking into account student background characteristics. Finally, the gap between at-risk and not-at-risk children is generally smaller in Freinet or Waldorf schools compared to traditional schools.

Aims.

Flemish (Belgium) schools are free to develop their own teaching methods, and there is a considerably amount of schools with alternative pedagogical beliefs. These alternative schools are often said to have an atmosphere that promotes well-being and motivation, more than is the case in traditional schools. Two of these alternative pedagogical methods are discussed in this paper: Freinet education and Waldorf education.

Schools modeled on the pedagogy of French educator Célestin Freinet (Acker, 2007) see the child's interest and natural curiosity as a starting point for learning and attempt to use real experiences of children as authentic opportunities for learning. Children are encouraged to learn by cooperatively making products or providing services. In Freinet schools, students are familiarized with democratic self-government to take responsibility for themselves and

for their community. Today, Freinet schools exist mostly in France, Belgium and Germany, often as alternative schools within the public school system. Waldorf schools, also known as Steiner schools, are based on the educational ideas of the philosopher Rudolf Steiner. Waldorf education is currently practiced in kindergartens and schools in 60 countries and is thus, together with Montessori education, the predominant form of alternative education around the globe. Waldorf schools emphasize that school should be a place where children can grow up in peace and harmony. Typical Waldorf education is the late onset of formal teaching (starting at age seven), offering structure and routines and offering artistic activities (Nicol, 2007).

Surprisingly, the claims of these alternative schools have seldom been the subject of study. Studies comparing traditional schools to alternative schools are very rare. The current paper intends to make such a comparison. Three questions are central in this research:

- First, what are the gross differences between traditional and alternative schools with regard to children's growth in school enjoyment and independent participation from kindergarten till third grade? (gross effect)
- Second, what are the differences between traditional and alternative schools with regard to children's non-cognitive development after controlling for student intake characteristics (e.g. gender, age, SES, initial achievement)? (controlled effects)
- Third, do the effects of pedagogical method differ between at-risk and not-at-risk students (differential effect)?

Methodology.

The study is based on data from the SiBO project (Maes, Ghesqui re, Onghena, & Van Damme, 2002), a longitudinal study in Flanders (Belgium) involving a cohort of about 6000 pupils followed through primary school. It provides us with teacher rated information about children's school enjoyment and independent participation in kindergarten, first, second and third grade (4 fixed measurement occasions).

We applied three level growth curve models (measurements within pupils within schools; Snijders & Bosker, 1999). Five series of analyses were executed. First, we modeled the development of school enjoyment and independent participation during these early years using quadratic functions. Second, interaction terms with a) Freinet schools and b) Waldorf schools were entered into the model, providing information about the gross effect of a method on the growth in school enjoyment and independent participation. Third, student predictors age, gender, SES, and initial language and arithmetic achievement were added into the model to create a corrected measure of the effect. Fourth, interaction terms with the at-risk variables SES and initial language achievement were entered, providing an answer to the question whether the effects are different for at-risk and not-at-risk children. In the fifth and last step, several simple slope analyses (Aiken & West, 1993) were conducted.

Findings.

The results suggest that gross differences between schools in children's enjoyment and independent functioning can be found. In general, children from Freinet schools have higher ratings in enjoyment and independent functioning. Children from Waldorf schools tend to score lower on enjoyment and independent functioning, although these differences are not significant due to the small sample size.

Second, it was examined whether these differences would change after taking into account pupil characteristics (gender, age, SES and initial achievement). First, after controlling for differences between schools in child intake characteristics, the positive effect of Freinet schools on children's enjoyment dropped to non-significance. Moreover, children from Freinet and Waldorf schools were rated as less independent in their school functioning, compared to their peers in traditional schools. This findings suggest that the positive effects of Freinet schools are due to the high amount of children with a high SES, children with high initial achievement, in their school and that intake characteristics.

Third, in traditional schools the gap between at-risk and not at-risk children with regard to SES and initial language achievement, is usually slightly increased. Although no significant differences were found in the slopes of Freinet and Waldorf schools, these schools tend to diminish, or even reverse, the gap. These results suggest, that alternative education may play a role in the promotion of at-risk children.

Theoretical and educational significance.

This study covers a field of educational effectiveness research that remains understudied, namely the effectiveness of alternative compared to traditional schools. The results could shed light on the effects of school's pedagogical approach on children's non-cognitive functioning and contribute to the field of educational effectiveness research.

SYMPOSIUM

Understanding emotional dynamics in collaboration and learning

Chairperson: Michael Baker, CNRS - Telecom ParisTech, France

Organiser: Sanna Jarvela, University of Oulu, Finland

Michael Baker, CNRS - Telecom ParisTech, France

Discussant: Charles Crook, LSRI, United Kingdom

Collaborative learning takes place as a result of group work on solving problems designed to promote learning, or more precisely as a result of collaboration. Such a coordinated, synchronous activity requires communicative interaction, in order to share and agree on ideas, strategies and solutions. When group of people collaborate emotional reactions can emerge endangering the emotional balance and optimal conditions for collaboration. While the impact of social dynamics on student learning can be partly inferred from the study of communicative interactions, understanding the development of emotional experiences related to social dynamics is still a challenge. The purpose of this symposium is to bring together researchers who have different empirical approaches to understanding emotional dynamics in collaboration and learning. The three papers will complement our understanding about emotional dynamics in collaboration. Baker, Andriessen and Pardijs focus on the nature of the collaborative working relationship between students, the regulation of tension and relaxation in collaborative interactions, and its interdependence with respect to progression of the learning task. Schwartz and Goldberg present a case study to inquire the role of emotions in learning a hot historical issue in argumentative activities. Järvenoja and Järvelä paper stresses a need for regulation of emotions to ensure a favorable affective atmosphere for collaboration. Their empirical study show that regulation of emotion can be scaffolded by increasing students' awareness of their situational emotions and by prompting them to plan their regulatory aptitude purposefully.

A developmental perspective on collaborative working relations and learning

Michael Baker, CNRS - Telecom ParisTech, France; Jerry Andriessen, Wise & Munro, Netherlands; Mirjam Pardijs, Wise and Munroe Learning Research, Netherlands

Students who work in groups in educational situations have to not only try to solve the problem that is set to them in order to learn, they also have to work on each others' problem solving, regulate their collaboration, and also maintain their interpersonal relationship. Within the framework of the "social turn" in human, social and educational sciences, that gives primacy to the social nature of human encounters, in this paper we focus on the nature of the collaborative working relationship between students, and its interdependence with respect to progression of the learning task. Building on previous work on the regulation of tension and relaxation in collaborative interactions (Andriessen, Baker & van der Puil, 2010), we adopt a developmental perspective, providing rich interpretations, or "thick descriptions", of a series of six working sessions, during which a group of three students designed a student area for a town. The students' interpersonal relationship was revealed as sufficiently resilient to be able to absorb or dissipate various tensions arising from the task, each other, and group-external aspects (such as the teacher's monitoring). We conclude that development is not only a matter of change, but also of actively remaining the same — in this case, as a group — in the face of an evolving task context.

In the continuation of the "cognitive revolution" of the end of the previous millenium, and the separation of reason from emotion (itself over two millenia old: Aristotle, c. 330 B.C.), the dominant vision of collaborative learning was that of knowledge co-construction. More recently, the emergence of what has been termed the "social turn" in human and social sciences (e.g. Foucault, 2001; Latour, 2010), and educational sciences in particular (Vygotsky, 1930/1978), has led to a view of collaborative learning situations as primarily social encounters, and secondarily, as joint attempts to solve problems and learn together. The common approach of constituting "friendship" groups in collaborative learning situations bears witness to the fact that in these cases, students have to solve at least three 'tasks' * i.e. solving a school problem, working together on that problem, and creating or maintaining a satisfactory "collaborative working relation" (Andriessen, Baker & van der Puil, 2010).

In the research presented in this paper, our aim is to extend previous work (op. cit.) that studied the collaborative relation in terms of the relation between the interplay of tension and its relaxation and deepening of a pedagogical debate, in a single interaction. Our approach was to develop a set of categories for the qualitative analysis of different dimensions of students' interactions. Tension and relaxation relate to the interactive circulation of affect. For example, making counter-arguments raises tension, and even more so if they are stated in an aggressive, ironic or sarcastic way. Tension can be relaxed, for example, by playful laughter, or by simply conceding, and showing consideration for others' views and feelings. We found that the pattern of tension rising and relaxation (by argumentation) was related to the depth of the argumentation, albeit in an indirect way. Tension-raising contributions by one party resulted in the other party producing new arguments and deepening previous ones, which resulted in the first party raising the tension by rejecting these arguments. Relaxation was produced by (sudden) changes of topic, especially going off-task. Our conclusion was that there is a relationship between the socio-emotional and the socio-cognitive aspects of collaboration, and in order to understand collaborative working relationships we have to look more closely at the patterns of tension and relaxation during collaborative interaction.

Here, we adopt a developmental perspective, studying how the collaborative working relationship changes and remains the same throughout a series of interactions between members of a single group of students. The students were engaged in an open-ended design task, specifically (on their own choice) that of designing a student area of a town. Given the innovative and exploratory nature of this research, we have not limited our approach by the pre-specification of a determinate set of analytical categories, for the design task, the collaborative working relation and the flux of tension-relaxation. Rather, we provide rich interpretations (Baker, 2010), or "thick descriptions" (Ryle, 1968; Geertz, 1973) of the students' activity, with a view to furthering theoretical insights into relations between cognitive, socio-relational and affective dimensions of interaction.

Across six working sessions of the students, we analysed the progression of the design task, from brainstorming general ideas, establishing constraints, genuinely collaborating to draw the town area plan, interacting with the teacher to explain their work, and concluding it. We related this progression to the flux of tension and relaxation in the group, and to off-task talk (about football) that served to cement the relationship. Overall, we found that the students' collaborative working relationship was remarkably stable across the various working sessions. When tensions did arise from the task (frustration with lack of advancement), from subtask allocation, or even from the teacher's probing questions, the students were able to quickly absorb this, and displayed group solidarity when faced with the teacher. It is an axiom of small group research (Arrow, McGrath & Berdahl, 2000) that there is a tradeoff between working on the task and working on the relation: when the relation is problematic or nascent, work on it will detract from work on the task. More prosaically, it might be thought that groups of good friends will tend to concentrate on 'having fun together' rather than on achieving the task. However, in this study we saw that a strong interpersonal relationship, and group identity and solidarity, enabled the relaxation of tensions, that will inevitably arise, and thus enabled the group to function effectively. Finally, from a developmental perspective, educational systems tend to emphasise the need for (positive) change, i.e. learning. But development also involves the active process of remaining the same (Hviid, 2010) remaining oneself, and preserving the group, in a changing task context and a changing world. This is what we have exemplified in the present study.

A case study to inquire the role of emotions in learning a hot historical issue in argumentative act

Baruch Schwarz, Hebrew University, Israel; Tsafrir Goldberg, University of Haifa, Israel

We report on the analysis of a series of activities designed to trigger productive argumentation in a history class. Students wrote an argumentative essay on a hot issue, read conflicting sources on this issue, evaluated the sources with the teacher, participated in a small group discussion to elaborate their views on the issue, and wrote again individual essays. We focus on one group of students to show that while their reasoning was very often biased, the interaction between students with different views on the hot issue led them to boost three historical disciplinary practices: (1) historical empathy, (2) the use of evidence in argumentation, and (3) evaluation of reliability. Theoretical considerations on the role of emotions in learning hot issues in history will be elaborated.

There is hardly a discipline in which emotional states are more pronounced than history. However, in spite of the centrality of emotion in history learning, this issue has been hardly studied. Researchers have recognized the impact of collective memories on individuals to show that students' attribution of significance to past events is mediated by family and ethnic collective memories (Seixas, 1994), by students' racial and social background (Epstein, 1998), or by media conveying a collective memory (Wineburg, Mosborg, & Porat, 2001). Also, educational research has paid growing attention to two practices that are quite prone to social and emotional influences: (1) the ways students evaluate and interpret historical evidence (Lee, 2005; Wineburg & Schneider, 2010); the learning with multiple historical sources (Hynd, 1999; Rouet, Britt, Mason, & Perfetti, 1996). The various biases that may rise in historical reasoning do not augur, a priori, occasions for learning gains in rich social interactions involving students with different views since the social interactions risk exacerbating these biases.

In a first study (Goldberg, Schwarz & Porat, 2008), we investigated the effect of the vitality of historical issues in collective memory on students' history learning processes and products. Sixty four 12th grade students of different ethnic background participated in two historical problem-solving learning tasks based on argumentative design (critical evaluation of sources and unguided group discussions). Vitality impinged on narrative and argumentative change, and on the relation of historical source evaluation with narrative change. An interaction was found between issue vitality and ethnicity in source evaluation: more vital collective memory narratives were more resistant to change and more prone to ethnic identity bias.

This first study suggests that collective memory and collective identity bias learning. However, a closer analysis of learning in the context of a vital collective memory issue, revealed effects for design and identity (Goldberg, Schwarz & Porat, in press). Even on the backdrop of a consensual collective memory narrative, argumentative condition produced improvement in the argumentative level of writing and promoted narrative change. Surprisingly, no evidence of confirmation bias was found in students' evaluation of sources and in final narratives. However, identity did seem to have strong impact, as the narratives of students from different ethnicities differed in the frequency, direction and degree of changes. Narrative change apparently bolstered in-group image. Argumentative design seemed to facilitate adoption of new perspectives, while social identity needs seemed to motivate it. In other words, emotional factors which could be thought as detrimental to historical learning seemed to boost it.

In the presentation, we will delve into interactions instead of relying solely on interpretations based on inferential statistics. We explore how emotions were intertwined in learning of an ethnicity relevant historical issue, heating up, but also promoting reasoning processes. The historical disciplinary practices to which we shall refer in our analysis to show the beneficial effects of emotions are (1) historical empathy, (2) the use of evidence in argumentation, and (3) evaluation of reliability. Historical empathy refers to the ability to put oneself in "the other's shoes", and to reconstruct historical agency in terms of mentality, context and intentionality. Empathy, or perspective taking, is one of the highly advocated and operationally under defined concepts in history education (Barton & Levstik, 2004).

Evidence use refers to reasoning on the basis of evidence. At its lowest level, evidence use is not deemed necessary to back historical claims. Higher up is the reference to generalized collective memory images. A more proficient use of evidence would be citation of a historical source relevant to the claim made. In the full disciplinary level a learner combines sources on the basis of relevance to claim and of evidence reliability. However, a learner may ignore the reliability of evidence, unintentionally or for a deliberate rhetoric reason (Rouet et al, 1998).

Evidence reliability evaluation is a dialectical process in which the learner determines in what way and to what degree the information contained in a source may be biased or flawed. At its lowest level all evidence is taken as true with no reference to reliability or bias. At higher levels, evidence reliability is evaluated through content and style cues, corroboration and contextualization ((Lee, Ashby & Dickinson, 1995; Wineburg & Fournier, 1994).

We will show that socially charged issues, and the "hot" cognition accompanying them, while fueled by biases, actually fostered cherished practices as evidence evaluation and perspective taking through one in-depth analysis of an unguided small group discussion on a "hot" issue. Students' "hot cognition" led from an egocentric to an "other oriented" or universal approach. Such a development could be seen as somewhat parallel to the courses of development outlined by Piaget, Erikson and Kohlberg, in the cognitive and moral realms. We will show that discussants progressed from solipsistic unsupported claims to reasoned argument addressing peer's challenge. They progressed from ignoring historical agents' consciousness to explaining it on the basis of historical context and human feelings' universality. We will show the complexity of the picture both practically and theoretically. Discussants' argumentative moves were fueled by ego and social belonging needs, not just by universal principles. They moved from universal to contextual explanations to individualized personal testimony based reasoning. We will suggest that although for most cognitive developmental theories the direction is from the individualized egocentric, to contextual and then to the universal reasoning, learners abandoned universalistic assumptions in favor of more contextual and even more individualized mental reconstruction.

Individuals' Situational Emotions and Regulation of Emotions in Collaborative Learning

Hanna Jarvenoja, University of Oulu, Finland; Sanna Jarvela, University of Oulu, Finland; Jonna Malmberg, University of Oulu, Finland

Successful collaboration involves regulation of emotions to ensure a favorable affective atmosphere for collaboration, but there is not much research on how these processes can be supported. Our hypothesis is that regulation of emotions can be scaffolded with emotion awareness tools. That is why the aim of this study is to investigate 1) How students' situational emotions can be characterized?, 2) How students plan their anticipated emotion regulation?, and 3) How students' anticipated and realized emotion regulation correspond with each others?

Participants included 14 adult graduate students working in teams in three collaborative learning phases over an 8-week period. The data is composed of the students' "emotion awareness tool" responses, which the students use to indicate their situational affective state and to plan anticipated emotion regulation as well as the students' "Adaptive Instrument for Regulation of Emotions" responses which they used to reflect realized regulation of emotions. The results show that students' reports on anticipated emotion regulation changed to be more strategic and realistic after using the Emotion Awareness tool. Also the students' anticipated and realized regulation converged. Especially estimations of the use of "positive" regulation of emotions increased along with estimations of the use of "social" regulation of emotions decreased and corresponded better with evaluations of realized regulation. The results suggest that the students utilized the Emotion Awareness tool as a strategic emotion regulation tool.

INTRODUCTION

The importance of optimum motivational and emotional conditions for collaboration is widely acknowledged (Järvelä, Volet, & Järvenoja, 2011). However, when group of people collaborate emotional reactions can emerge endangering the emotional balance and optimal conditions for collaboration. This means that successful collaboration involves regulation of emotions to ensure a favorable affective atmosphere for collaboration.

Although studies have shown the importance of motivation and emotion regulation in learning, there is not much research on how these processes can be supported (Boekaerts & Corno, 2005). Research has shown that cognitive regulation processes can be promoted with computer-based regulation tools (Winne & Hadwin, 2009). These types of tools can also be useful for supporting motivation and emotion regulation, given that they provide possibilities for example to increase students' awareness of these processes and can provide feedback and visualise their activities.

AIM

Our hypothesis is that regulation of emotions can be scaffolded with emotion awareness tools that (A) Increase students' awareness of their situational emotions, (B) Guide students' to explicate the reasons for their emotions, and (C) Prompt students' to think and plan strategically their regulation of emotions. To investigate the hypothesis the specific research questions are

1) How students' situational emotions can be characterized?,

- 2) How students plan their anticipated emotion regulation?, and
- 3) How students' anticipated and realized emotion regulation correspond with each others?

PARTICIPANT AND METHODS

Participants included 14 adult graduate students working in collaborative teams of 3 to 4 over an 8-week period that included three face-to-face meetings, and three virtual solo and collaborative learning periods. Collaborative tasks were constructed to be challenging and require multiple student perspectives. The nStudy (Winne & Hadwin, 2009) software was used for collaborative planning and work, as well as for collaboration between team members.

The data of this paper focus on virtual collaborative learning periods. Every time students logged in to the nStudy learning environment they were advised to fill in an EmA-sheet. This "emotion awareness tool" (EmA) was used to increase students' awareness of how their emotional state affect on their studying and prompt students to regulate their emotions if needed. The questions in the sheet were 1) How are you feeling right now (neg-pos), 2) Why? (open question), and 3) How do you aim to control your emotional state? (open question).

ANALYSIS

Analysis proceeded by first characterizing students situational emotions (RQ 1). Students' feelings during collaborative learning phase and the reasons for the situational affective states were decoded. The reasons for affective state were coded into three categories; studying or course, other aspects of life, and un/balance between studying and life. The reliability of the coding was checked by another coder, and inter-coder reliability was calculated (Cohens Kappa 0,87). Next in the analysis students' plans for anticipated emotion regulation (RQ 2) were coded from EmA data according to the focus or aim of students' descriptions for the open question. The coding included four different categories presented in Table 1. Again, the reliability of the coding was checked by another coder, and inter-coder reliability was calculated (Cohens Kappa 0,67).

Finally, students' anticipated emotion regulation from EmA data were contrasted with their evaluations of realized emotion regulation reported with AIRE (RQ 3). The emotion regulation reports from each three collaborative learning phase were compared with each other using the categorization presented in Table 1.

RESULTS

Regarding to the first research question the results show that all together students felt positive during the collaborative working even though they reported emotions throughout the scale from negative (8%) to positive (63%). The experienced emotions were related to categories studying and course (33%), other aspects of life (49%) and un/balance between studying and life (18%).

Regarding to the second research question the results indicate that students reported plans for anticipated emotion regulation increased after the first collaborative learning phase; 48% of the codings in category nothing and 42% of the codings in category emphasizing social were given during the first learning phase. Codings in neutral –category remain almost the same throughout the three phases. Conversely 42% of the codings in to the category increasing positive were given during the last learning phase.

CONCLUSION

The results of the study showed that the students' awareness of their situational affective state increased when they used EmA-tool regularly. Furthermore, the results suggested that the students can employ the EmA-tool for their regulatory purposes and that they can learn to plan realistically how to regulate emotion during learning. All together the results indicate that regulation of emotion can be scaffolded by increasing students' awareness of their situational emotions and by prompting them to plan their regulatory aptitude purposefully.

SYMPOSIUM

What, when, where? How extracurricular activities foster learning and social development

Chairperson: Natalie Fischer, German Institute for International Educational Research, Germany

Organiser: Natalie Fischer, German Institute for International Educational Research, Germany

Discussant: Falk Radisch, Bergische Universitat Wuppertal, Germany

Effects of participating in extracurricular activities on several cognitive and non-cognitive outcomes have so far been analyzed primarily in the USA. European results are rarely quoted in literature. Moreover research in the field has predominantly been outcome-oriented so far. Only recently researchers started to examine questions of quality and dosage of extracurricular activities. The studies presented in this symposium focus on conditions and characteristics of after-school programs that are relevant for their effectiveness on learning and social and motivational development. Longitudinal data from three different countries (i.e. Australia, USA, Germany), assessed with different

methodologies, are presented. The studies are innovative by examining moderators and mediators of the effects of extracurricular activities. Different measures of experiences in activities and student-perceived quality of the programs are used. Student engagement, challenge, adult support and autonomy in the activities are amongst the included predictors and mediators. Influences of dosage are examined as well. In summary, results show that quality of experiences is an important factor in predicting academic and non-cognitive outcomes of adolescents. Results concerning dosage assessed as quantity of participation are inconsistent. Participation profiles as another measure of dosage seem to be predictive of academic success. The symposium can add to international research by clarifying processes and mechanisms underlying the effects of extracurricular participation.

Quality and dosage of extracurricular activities: Effects on motivational and social development

Natalie Fischer, German Institute for International Educational Research, Germany; Hans Peter Kuhn, University of Kassel, Department of Education, Germany; Ivo Zuechner, Deutsches Institut für Internationale Pädagogische Forschung (DIPF), Germany; Desiree Theis, Deutsches Institut für Internationale Pädagogische Forschung, Germany

The "Study on the Development of all-day Schools" (StEG) evaluates effects of the introduction of all-day-schools in Germany using a multi-perspective and multi-criterial longitudinal design. All-day schools offer extracurricular activities which include academic and non-academic enrichment. The evaluation of quality and individual effects of the school-based extracurricular activities is one main focus of StEG. Based on results of international studies in the field it is assumed that extracurricular participation in German all-day schools leads to improved motivation as well as reduced misconduct in school. Student perceived process quality of the activity and dosage are examined as mediators of these effects. This paper is based on data of about 9.000 students in 370 schools. They were assessed three times from grade 5 to 9 (age: 10 to 14 years). Hypotheses are tested using hierarchical linear modelling and structural equation modelling. Results show that extracurricular participation is related to a decrease of misconduct in school. Duration of participation is crucial for a positive development. Student perceived process quality and relatedness in the activities affect the development of motivational and social outcomes. Altogether, quality features of the activities seem to be more important than attendance intensity.

Introduction

In Germany, school is traditionally associated with the academic curriculum. Typically leisure activities are offered by out-of-school organizations. Due to the results of PISA 2000, the introduction and enhancement of the so-called "all-day schools" have been major topics in educational debates in Germany. The conversion and equipment of schools are financially supported by the federal investment program "Future of Education and Care". The "Study on the Development of all-day Schools" (StEG) was designed to evaluate effects of this program and is funded by the German Federal Ministry of Education and Research.

To be considered an all-day school, a school has to offer supervision for at least seven hours a day, three days a week. Although their pedagogical concepts are very heterogeneous, all German all-day schools provide extracurricular activities which mostly include academic and non-academic enrichment. The evaluation of quality and individual effects of the school-based extracurricular activities is one main focus of StEG. In Germany this is a new field of research but there is a large body of US-Studies about the effects of extracurricular activity participation on several cognitive and non-cognitive outcomes. The aim of this paper is to link the German results from StEG to international research in the field.

Theoretical and Empirical Background

At the beginning of this century research on extracurricular participation was mostly product-oriented. Recently researchers started to examine questions of process quality, student's experiences and dosage of extracurricular activities. In summary, empirical results showed that extracurricular participation in all-day schools can have a positive influence on social learning and the development of school grades and motivation (cf. Durlak et al., 2010; Feldman & Matjasko, 2005). But what are the processes leading to these effects? Existing models of after-school program effectiveness often include either process-quality or dosage. To measure dosage Fiester et al. (2005) differentiated between „absolute attendance", which means joining an activity compared to not participating, „attendance intensity", which covers the amount of time per week/ month etc. and „duration", which refers to the length of participation over time. Another measure of dosage concerns "breadth of activities" or participation profile (cf. Barber et al., 2005). Concerning program quality up to now there are some hints of certain features linked with positive outcomes. Mahoney and Stattin (2000) found that a structured environment in adult-supervised programs leads to a decrease of antisocial behavior compared to participating in low-structure activities. Besides structure, adult supervision is an important indicator of program quality (cf. Vandell et al., 2007). Based on self-determination-theory (Ryan and Deci, 2000), it can be assumed that extracurricular activities predict a positive development because of their high potential in addressing students basic needs (Barber et al. 2005; Fischer et al. 2009). Miller (2003) described

features of effective programs including supportive relationships, opportunities for skill-building and structure. Comparing the influence of quality versus dosage Shernoff (2010) argued that the quality of experiences in after-school programs is more important than dosage for academic outcomes. Contrary, first analyses of the first two measurements of StEG showed that duration of participation was linked to academic outcomes, whereas student perceived quality could predict motivation (Fischer et al. 2009).

Research questions

This paper examines two questions: a) Does extracurricular participation in German all-day schools lead to improved motivation and performance as well as reduced misconduct in school? b) Can the effects be mediated by student-perceived process quality of the activity as well as by attendance duration and intensity?

Method

StEG is a multi-perspective and multi-criterial longitudinal study. The target groups (i.e. the schools' principals, teachers, other pedagogical staff, parents and students) filled out questionnaires at three measurement points (2005, 2007 and 2009). Analyses for this paper are based on data of about 9.000 students from grade 5 to 9 (age: 10 to 14 years) in 370 schools. All day schools differ in student level of obligation. At most schools participation in extracurricular activities is available but not mandatory. So students in all-day-schools who did not participate in extracurricular activities are included in the analyses as control group. Hypotheses are tested using hierarchical linear modelling and structural equation modelling (growth curves).

Results and implications

Results show that participation in extracurricular activities influences social behavior. Duration of participation (but not intensity) is crucial for a positive development. Student perceived process quality and relatedness in the activities affect the development of non-cognitive outcomes (and GPA). Altogether, quality features of the activities seem to be more important than attendance intensity. This leads to implications for extracurricular arrangements in all day schools.

Predicting Social Competence and Academic Performance with Engagement in After School Programs

David Shernoff, Northern Illinois University, United States

Using Experience Sampling Method (ESM), this study examined two questions related to outcomes associated with after-school programming. First, does the quality of experience in after-school programs mediate the effect of program participation on social competence and academic performance? Second, among program participants, is the difference in quality of experience when in programs versus other settings after school related to higher social competence and academic performance? Middle school students (N = 196) attending eight programs in three Midwestern states reported a total of 4,970 randomly sampled experiences in and out of after-school programs during one week in the fall and spring of the 2001-2002 academic year. Engagement during after-school hours partially mediated the relationship between participation in after-school programs and social competence. In addition, relative perceptions of engagement, challenge, and importance when in after-school programs compared to elsewhere after school predicted higher English and math grades. Results suggest that the quality of experiences in after-school programs may be a more important factor than quantity of experiences (i.e., dosage) in predicting positive academic outcomes.

The goal of the proposed study is to examine how middle-school students' experiences and perceptions in after-school programs are related to social competency and academic performance. Research suggests that adolescents report a higher quality of experience in structured after-school programs, including greater engagement and more positive emotions, than in less structured and supervised activities after school (Authors, 2005). Research also links participation in after-school programs and extracurricular activities to the development of social competence (Durlak & Weissberg, 2007; Fredricks & Eccles, 2006a, 2006b; Larson & Brown, 2007) and higher academic achievement (Darling, 2005; Durlak & Weissberg, 2007; Fredricks & Eccles, 2006b; Mahoney, Lord, & Carryl, 2005). Few studies, however, have examined whether engagement and related experiential factors in after-school programs help account for positive social and academic outcomes. Using flow theory (Csikszentmihalyi, 1990) as a theoretical base suggesting that optimal experiences combining high concentration and enjoyment can lead to skill development (Csikszentmihalyi, Rathunde, & Whalen, 1993), two hypotheses were examined testing the role that the quality of experiences after school played in the development of middle school students' social competence and academic performance. The first hypothesis tested a mediation model: Does the quality of students' experiences after school mediate the effect of program participation on social and academic outcomes? The second hypothesis tested a differential benefits model: Among after-school program participants, does quality of experience in -programs relative

to that encountered elsewhere after school (e.g., home or in public) predict greater benefits in social and academic outcomes?

Method.

Data were collected in eight after-school programs in two medium sized cities and one small town in three Midwestern states. All of the programs were based in middle schools. The sample consisted of middle school youth ($N = 191$). Fifty-two percent were male, 60% were children of color, and 47% reported an annual household income of less than \$40,000. One-hundred-sixty students were program participants who reported participating in an after-school program at least once during the study, and 31 were program nonparticipants who did not participate in any organized program. Students' experiences and emotions were measured with the Experience Sampling Method (or ESM; see Hektner, Schmidt, & Csikszentmihalyi, 2007) over the 2000 – 2001 school year. To carry out the ESM, participants were provided with digital wristwatches that were programmed to emit 35 signals over two 7-day periods (approximately 5 signals per day) – one in fall (wave 1) and one in spring (wave 2). When signaled, students recorded their location, activity, social partners, subjective experiences, and emotions (e.g., challenge, importance, engagement, etc.) into self-report logbooks which were collected, monitored, and checked by field staff each day. The Social Competence Scale was completed at baseline (beginning of fall 2001 semester), and at follow up (end of spring 2002 semester) for the outcome measure. It yielded a measure of social competence of satisfactory reliability ($\alpha = 0.79$), factorial validity, and internal consistency. Academic performance was operationalized as English and math grades received at the end of the academic year, with self-reported grades at the beginning of the year utilized as the baseline measure. Analyses and results. The sample responded, on average, to 33 of the 35 signals (94% response rate). Self-reports ($N = 4,970$) occurring after school on weekdays, between the time school was dismissed and 6 p.m., were selected for analysis in the study. A variety of experiential variables (e.g., engagement, challenge, skills, positive affect) were significantly correlated with two measures of program participation (program status and dosage), and with social competence. Based on these correlations, plausible models were identified for further testing of mediation in four steps according to the seminal work of Baron and Kenny (1986) and Frazier, Tix, & Barron (2004). First, engagement was tested as potentially mediating the effect of program status (i.e., program participant vs. nonparticipant) on social competence. All four conditions tested in the four steps were satisfied, supporting partial mediation after controlling for background characteristics (i.e., gender, ethnicity, and socioeconomic status). Secondly, flow (i.e., mean of challenge, skills, and positive affect) was tested as a mediator of dosage (percentage of time spent in after-school programs) on social competence.

While the direct effect of dosage on social competence was not significant, the indirect effect of dosage on flow, and flow on social competence, was significant after controlling for background characteristics. However, mediation was not significant in either mediation model after additionally controlling for the baseline measure of social competence. To test the differential benefits hypothesis, a series of General Linear Models (GLMs) were conducted predicting outcome variables with mean differences in each experiential variable when in programs versus elsewhere after school. Higher levels of challenge and importance in programs (versus elsewhere after school) predicted both higher English and math grades, and higher negative affect predicted higher English grades, after controlling for background and baseline characteristics. In addition, engagement in programs predicted higher English and math grades after controlling for background characteristics but not baseline measures.

Discussion and implications.

Engagement and flow after school predicted higher social competence, an effect found to account for a significant portion of the positive association between program participation and social competence. This finding is consistent with Larson's (2000) conception of positive youth development: when youth combine concentrated focus with positive emotions in the task at hand, a combination represented in the engagement and flow constructs, conditions are optimal for developing social competencies such as teamwork and conflict resolution. These conditions are reported most frequently in structured, voluntary programs such as school-based after-school programs.

Results testing differential benefits of program participation among participants suggested that relative perceptions of environmental challenge and meaningfulness during after-school programs may be especially related gains in academic achievement. This finding supports perspectives of situational challenge and relevance as integral to flow-producing, authentic engagement and achievement (Csikszentmihalyi, 1990; Newmann, 1992). Especially considering the lack of significant associations between dosage and academic outcomes, results suggest that relative quality of experience in programs may be stronger and more positive predictor of academic performance than the quantity of experience in programs.

Profiles of activity participation and academic engagement - the impact of positive adult leaders

This paper examines the role of patterns of extracurricular activity participation, positive adult leadership, and social class in academic engagement of Australian adolescents. The sample included 1,504 adolescents (56% female). Students from Year 8 ($n = 924$) and Year 10 ($n = 579$) participated in the study, with the mean age of participants being 13.8 years ($SD = 1.02$ years, range 12-16 years). Participants in lower SES schools had the least auspicious participation profiles, being overrepresented among those with no activities, or playing only sports. Students from high SES schools were more likely to combine sports with other types of activities such as debate or band. Positive adult experiences in both sport and non-sport activities significantly predicted academic self concept, school attachment, and university aspirations. There was a significant cross-level interaction between positive adult leader in non-sport activities and school SES in the models predicting academic self concept and school attachment. Specifically, the association between positive adult leader in non-sport activities and both academic self concept and school attachment was stronger for youth from lower SES schools. Coordinated efforts are needed to increase the range of available activities for youth, particularly in under-resourced areas.

Going to school involves much more than the formal academic curriculum. The broader school environment can offer a range of opportunities for students to find their niche and invest in endeavors such as sports, music, or student leadership activities. School-sponsored activities such as sports and performing arts are important contexts that can support or undermine academic developmental goals and link students to the larger society of the school. However, recent reviews have observed that the scientific research base pertaining to activity participation is limited. There has been far less research on the developmentally facilitative processes in constructive leisure activities than on those in other contexts such as family and school. Nevertheless, it is becoming clear that structured organised activities are important, with mounting evidence that activity participation facilitates healthy development. There has been a recent call for researchers to consider the patterns or profiles of participation, that is, ways that students combine multiple activities. For example, some students play on a sport team or two, while others spend their time in academic clubs, and still others participate in a combination of different activities. One mechanism through which these participation patterns of activities can influence positive development is through interpersonal supports. Structured extracurricular activities provide adolescents with access to caring non-familial adults. Coaches and club advisors often invest a great deal of time and attention in these young people. With the right adults, such contact is likely to have positive effects on development particularly during adolescence. This paper addresses this link. The moderating effect of socioeconomic status on the outcomes associated with activity participation has received surprisingly little attention. A consistent criticism of the majority of studies investigating adolescent activity participation is that they are based primarily on middle-class youth. However, the findings of studies that have assessed the role of socioeconomic status suggest that the benefits of extracurricular activity participation are particularly prominent for adolescents from more disadvantaged backgrounds. Our paper considers SES as a moderator of the impact of the adult leader on academic engagement.

Method

Participants were recruited from 26 high schools, selected to represent the four metropolitan school districts ($n = 14$) and five of the regional school districts ($n = 12$) across Western Australia. The questionnaire took approximately 40 minutes to complete, and was administered either via laptop computers connected to a wireless intranet, or in an equivalent paper and pencil format. The sample included 1,504 adolescents (56% female). Students from Year 8 ($n = 924$) and Year 10 ($n = 579$) participated in the study, with the mean age of participants being 13.8 years (range 12-16 years).

Measures.

Participants were provided with a list of 30 sports (e.g., basketball, netball, swimming) and 24 non-sport structured extracurricular activities (e.g., band, school council, drama club), and were asked to check off all their extracurricular activities. Participation types were then divided into 4 categories: those who did not participate in any structured extracurricular activities (no participation), those who participated only in sports (sports only), those who participated in only non-sport structured activities (activities only) and those who participated in at least one sport and one non-sport structured activity (mixed). Participants also responded to a series of questions concerning their experiences with the adult leader in the sport and/or non-sport they spent the most time in (positive adult-leader; 4 items, sport $\alpha = .85$, non-sport activity $\alpha = .91$). The survey also included scales measuring academic self-concept (3 items; $\alpha = .79$) school attachment (5 items; $\alpha = .73$), and university aspirations. To assess socio-economic status (SES), school-level data were obtained from the Department of Education and Training in Western Australia which computes the Index of Community Socio-Educational Advantage (ICSEA) for each school in Western Australia. From their ICSEA scores, each school was given a rank of 1-26, with 1 representing the lowest ICSEA school in the sample, and 26 representing the highest ICSEA school.

Results

Chi-squared analyses revealed that participation category was distributed significantly differently by SES group ($\chi^2(6, 1486) = 123.45, p < .001$). Given the hierarchically nested structure of the data and our hypotheses concerning the main and interactive effects of SES (a group-level variable) on individual-level relationships, a multilevel analytic strategy was appropriate. The analyses were conducted with the Mplus 5.21 program. In order to test the links between individual characteristics (activity participation, positive adult leadership), group characteristics (school SES), and interactions and academic engagement, a series of 2 Level models were estimated. The within-person associations were modelled at Level 1. Gender and year at school were included as covariates. The between-person variable, school SES, was modelled at Level 2. Cross-level interactions were also investigated. Positive adult experiences in sport and non-sport activities significantly predicted academic self concept, school attachment, and university aspirations. There was a significant cross-level interaction between positive adult leader in non-sport activities and school SES in the models predicting academic self concept and school attachment. Specifically, the association between positive adult leader in non-sport activities and both academic self concept and school attachment was stronger for youth from lower SES schools.

Discussion and Implications The past 2 decades have seen a growth of interest in the extracurriculum. Much of the research on extracurricular activities has been concerned with the outcomes or effects of participation. Although we now have a good understanding of the benefits of activity participation, less is known about the mechanisms responsible for these effects. Our results suggest that having a more positive adult leader in one's activity is one promising explanation. However, despite good opportunities for many youth, those in disadvantaged communities have quite limited access, especially to non-sport activities. In tight economic times, school budgets have been cut, and teachers are under pressure to focus on achievement rather than non-academic activities. Coordinated efforts are needed to increase the range of available activities for youth, particularly in under-resourced areas.

SYMPOSIUM

Multimedia Goes to School: Studying Learning from Text and Pictures Beyond the Lab

Chairperson: Katharina Scheiter, Knowledge Media Research Center, Germany

Organiser: Katharina Scheiter, Knowledge Media Research Center, Germany

Jennifer Cromley, Temple University, United States

Discussant: Roger Azevedo, McGill University, Canada

In the last years, various suggestions have been derived from tightly controlled laboratory experiments on how to create effective multimedia instruction (i.e., instruction involving verbal and visual representations like diagrams or animations). For practical reasons, these experiments are often limited to rather homogeneous subject samples, short instructional messages, system-controlled instruction, a narrow range of materials of little personal relevance to learners, and learning outcome assessments immediately after learning. Nevertheless, the derived design principles are claimed to also provide useful guidance for the design of multimedia lessons to be used in real-life learning situations. The aim of this symposium is to challenge this idea of a simple transfer from the lab to the field. Results from the contributions show that first under real-life learning conditions (e.g., longer instructional units, learner control, delayed assessment) well-established multimedia design effects cannot be confirmed or even reverse (Contributions 1 & 2). Second, multimedia design effects obtained in the field are relatively small and may easily be overridden by more influential factors such as learners' individual characteristics (e.g., motivation, preexisting cognitive abilities; Contributions 2 & 3). Third, as a consequence, a successful approach towards improving multimedia effectiveness under these conditions may be to focus on fostering learners' abilities in handling the materials (e.g., by training them how to study diagrams) rather than on optimizing only the materials' design (Contribution 3). These findings therefore imply that the generalizability of lab research needs to be empirically proven; moreover, they suggest new avenues for supporting multimedia learning.

Long-term modality effects of multimedia learning in children and adults

Eliane Segers, Behavioural Science Institute, Netherlands; Gesa van den Broek, Radboud Universiteit Nijmegen, Netherlands; Ludo Verhoeven, Radboud Universiteit Nijmegen, Netherlands

In this presentation, I will describe three studies that investigated modality effects in multimedia learning in children and adults. In all three studies, both quantity and quality of learning were assessed. In a first study with 128 fifth-graders, we compared four learning conditions (written text, written text & pictures, oral text, oral text & pictures) in a learner-paced learning situation. Modality effects were found directly after the intervention, but reversed for the quality of learning one week later. In a second study with 80 children in sixth grade, we found a reversed modality effect for quantity of learning directly after the intervention, and again a reversed modality effect on the long-term measurement. In a third study with 86 adults, this reversed modality effect at long-term was again replicated. In this

third study, we took study-time and modality of the questions into account, but these were not of influence on the modality effect. It was found that the participants in the two conditions spent the same amount of time studying, but those who received on-screen text went through the slides faster and repeated more slides than those who studied spoken narrations. Such study behaviors were not correlated with performance. In the discussion, I will relate the three studies to the ongoing research on multimedia learning and challenge the design principles that suggest oral text accompanied by pictures is the optimal learning situation. The effect does not seem to hold in more realistic school situations.

Instructional materials that combine verbal information, such as on-screen text or spoken narrations, with pictures or animations, have become more and more relevant for education since multimedia computers are increasingly available to students and teachers. However, a learner's capacity for cognitive processing is limited and designers of multimedia instructions must take into account the load that is imposed on the learner's cognitive system (Verhoeven, Schnotz, & Paas, 2009). As a result, design principles for multimedia materials have been investigated extensively (see Mayer, 2009). One important conclusion from previous studies is that learners better simultaneously process pictures and spoken narrations than pictures and on-screen text (see Ginns, 2005). This effect is known as the modality effect. According to the cognitive theory of multimedia learning (CTML) (Mayer, 2009), explanations lie in early levels of processing of sensory information in working memory. A second type of explanations of modality effects is based on the idea that it is easier for learners to divide their (visual) attention between pictures and spoken narrations than between pictures and printed text. This split-attention hypothesis became prominent when evidence accumulated that modality effects, though often found with system-paced presentations, seemed to disappear or reverse when learners controlled the presentation rate of the information (for a review, see Ginns, 2005).

Both the CTML and the Split-Attention hypothesis focus at early processing stages and make relatively few predictions about later meaningful processing of the materials. Differences between visual-only and audio-visual materials are explained in terms of the amount of information that a learner can process simultaneously, either the amount of visual and auditory input that the working memory can take up at one moment in time, or the amount of visual and auditory information that learners can look at or pay attention to at one moment in time. The implicit assumption behind these accounts is that materials, which allow the learners to process more information at the same time, are also more likely to later engage learners in meaningful cognitive processing of this information.

However, text modality does not only influence early sensory processes, but also the way in which learners can deal with the information (e.g. spoken text is "fleeting", and printed text typically remains visible on the screen). Consequently, learners can decide at which point in the printed text they want to start reading, can quickly scan the text to find out if it includes a specific piece of information, and can selectively re-read difficult parts of the text. It is therefore interesting to study long-term modality effects. The focus of this paper lies on the practical importance of modality effects. We believe that, in order to formulate multimedia design principles, there must be sufficient evidence for the generalizability and the permanence of text modality effects.

Study 1 was a within-subject experiment with elementary school children (N=128 fifth-graders), testing modality effects in a self-paced learning situation. Children read or heard four texts each, of 190–240 words, either or not accompanied by pictures. The children showed standard modality effects immediately after learning, but after one week, the effects disappeared for retention measures (i.e., the amount of information that the children could reproduce), and even reversed for transfer measures (i.e., the degree to which the children were able to apply the acquired knowledge to solve new problems): Postponed transfer scores were better for the visual-only than for the audio-visual materials. Study 2 used the Mayer material on the formation of lightning, and replicated this postponed reversed modality effect for transfer measures in a between-subject experiment after a delay of just one day with 80 sixth-grade children.

In both studies, the performance of the participants in the audio-visual and the visual-only condition changed differently over time. Performance in the audio-visual group decreased from the immediate to the delayed test. With regard to performance development in the visual-only condition, we found no change in the retention performance and an improvement on the transfer scores from the first to the second testing occasion in study 1. In study 2, we found a decline in retention performance, but again an improvement on transfer scores.

In study 3, with 86 adults, participants had more extensive study material. It consisted of 128 slides (2695 words) about physical processes in Magnetic Resonance Imaging. No modality effects were found directly after learning, but reversed modality effects appeared one day later when the participants who studied the visual-only presentation performed better than the participants who studied the audio-visual presentation. This effect did not depend on the modality of the questions, as it was found for oral and written retention questions and for oral, but not written,

transfer questions. We also found that the questions were consistently more difficult when presented in the oral form than in the written form. The students in the two experimental conditions both spent about half an hour studying, but the participants who received on-screen text went through the materials faster and repeated the slides more often than the participants who studied spoken narrations. These study behaviors were, however, not related to performance outcomes.

We can conclude that with respect to long-term outcomes, learner-paced multimedia presentations with pictures and on-screen text are superior to presentations with pictures and spoken narrations. This finding is in line with the claim that the presentation rate of multimedia instructions constitutes a boundary condition of modality effects (Mayer, 2009).

The relative importance of learner characteristics and instructional design in multimedia learning

Katharina Scheiter, Knowledge Media Research Center, Germany; Anne Schueler, Knowledge Media Research Center, Germany; Peter Gerjets, University of Tuebingen, Germany

The goals of the study were to test whether well-established multimedia design principles that have been derived from experimental studies conducted under strictly controlled laboratory conditions hold also in real-life learning situations as has been suggested. In particular, we investigated whether under more realistic conditions additional variables such as motivation or cognitive abilities come into play that may override the effects of improved multimedia design. Moreover, we were interested specifically in the relative contribution of reading comprehension skills to multimedia learning. In the study, 125 pupils from grades 9 and 10 of a German Gymnasium learned about cell reproduction during their regular Biology lessons in one of six conditions that resulted from cross-varying multimedia (text only vs. text plus visualizations) and text modality (spoken vs. written vs. spoken and written). Various learner characteristics were assessed prior to learning. A recall and a transfer test served as dependent variables. The results from several regression analyses support the assumption that under realistic learning conditions multimedia design manipulations become less important (in that there was no modality or redundancy effect and a limited multimedia effect only) than individual learner characteristics (e.g., motivation, representational abilities). The relevance of the latter was particularly evident when looking at performance measures that imposed higher cognitive demands such as transfer tasks or delayed tests. Moreover, the results suggest that text comprehension is highly important in learning irrespective of whether the text is accompanied by visualizations or not. Consequences for multimedia design theories will be discussed at the conference.

In the last years, various multimedia design principles have evolved from experimental studies conducted under strictly controlled laboratory conditions (Mayer, 2009). These principles are claimed to also provide useful guidance for the design of multimedia lessons to be used in real-life learning situations. So far only a few studies have investigated their applicability in real-life classrooms; however, they speak against a simple transfer from the lab to the field (e.g., De Westelinck, Valcke, De Craene & Kirschner, 2005; Tabbers, Martens & van Merriënboer, 2004). One reason may be that under more realistic conditions additional variables come into play that override the effects of improved multimedia design. For instance, motivation may be required to remain engaged during longer instructional sessions that may also build upon cognitive prerequisites to a larger extent than self-contained lab materials do. Moreover, because the content is taken from the regular curriculum and students have made prior experiences with similar contents, they bring specific attitudes towards the domain into the learning situation (e.g., domain-specific self-efficacy beliefs). In the current field study the relative importance of multimedia design manipulations compared to individual learner characteristics was investigated. Moreover, we were interested specifically in the relative contribution of reading comprehension skills as compared to skills related to the integration of verbal and pictorial information as well as related to handling computer-based materials in general (i.e., digital literacy). Given that the processing of multimedia materials has been shown to be largely text-driven (Hegarty & Just, 1993), reading comprehension was expected to be particularly influential in multimedia learning.

Method

In the study, 125 pupils from grades 9 and 10 of a German Gymnasium learned about cell reproduction during their regular Biology lessons. They had not received any prior instruction on this topic. Within each class, the pupils were randomly assigned to one of six conditions that resulted from cross-varying multimedia (text only vs. text plus visualizations) and text modality (spoken vs. written vs. spoken and written). Thereby the study allowed investigating

the multimedia principle, the modality principle, and the redundancy principle (Mayer, 2009). The learning environment comprised ca. 2,200 words that were either in written form or were spoken by a female voice. Depending on condition, the instructional explanations were or were not accompanied by static as well as animated visualizations that depicted cell structures and the process of cell reproduction.

With respect to learner characteristics, established measures assessed the pupils' biological literacy, their motivational orientation towards Biology (i.e., self concept, self-efficacy expectations, intrinsic motivation, extrinsic motivation, as well as pleasure and interest in science) as well as towards the task, reading speed and reading comprehension, digital literacy, and their ability to integrate text and pictures (self-constructed measure). Learning outcomes were assessed with a recall and transfer test that addressed students' memory for the presented information as well as their ability to draw inferences. Both tests were administered immediately and one week after the instructional lesson.

Results

A factor analysis of the learner characteristics data yielded three factors (explained variance: 56.43%). The first factor represented concepts addressing students' motivation towards Biology (domain-specific motivation). The second factor comprised concepts related to the ability to extract information from external representations and to use digital tools (representational abilities). The third factor represented more general motivational aspects as well as domain-specific prior knowledge (general motivation / scientific literacy).

The learners' factor scores, the two independent variables as well as the interaction terms were used as predictors in a regression to analyze recall and transfer performance; all reported results were significant at $p < .05$.

Both, the presence of visualizations as well as representational abilities contributed positively to immediate recall performance. Moreover, two interactions showed that adding visualizations aided learning especially if they were accompanied by spoken text and if learners possessed a high level of domain-specific motivation.

Immediate transfer performance was better the higher learners loaded on any of the three learner characteristics factors. Moreover, similar to recall performance, adding visualizations aided transfer performance only in the case of spoken text.

Multimedia design manipulations had no impact on either delayed recall or transfer performance, where either only domain-specific motivation served as a predictor (for recall) or a combination of domain-specific motivation and general motivation / scientific literacy (for transfer).

To test whether representational abilities related to either traditional media (i.e., reading speed, text comprehension) or to more advanced media (i.e., digital literacy, text-picture integration ability) are more influential for learning, the respective concepts were introduced separately as predictors together with the instructional design variables in a regression. This analysis revealed the overarching importance of text comprehension ability, which was the only significant predictor for delayed recall as well as immediate and delayed transfer. Immediate recall performance improved as a function of text comprehension as well as when visualizations were present.

Discussion

The results support the assumption that under realistic learning conditions multimedia design manipulations become less important - in that there was no modality or redundancy effect and a limited multimedia effect only - than individual learner characteristics. The relevance of the latter was particularly evident when looking at performance measures that imposed higher cognitive demands either because the knowledge had to be maintained over a longer time period or because inferences were required. Moreover, the results suggest that text comprehension is highly important in learning irrespective of whether the text is accompanied by visualizations or not. Therefore, multimedia cannot be used as a way of circumventing low text comprehension.

Can laboratory research on multimedia comprehension be implemented in 10th grade biology classes?

Jennifer Cromley, Temple University, United States; Bradley Bergey, Temple University, United States; Shannon Fitzhugh, Temple University, United States; Theodore Wills, Temple University, United States; Nora Newcombe, Temple University, United States; Thomas Shipley, Temple University, United States

In an attempt to improve student comprehension of multimedia in situ, we created two workbooks for high school biology students—Coordinating Text and Diagrams (CTD) and Self-explanation in diagrams (SelfExpl)—and compared

effects to teaching Conventions of Diagrams (COD) in two studies ($N = 100$ and $N = 113$). Teachers delivered their usual instruction, pausing for about 7 min for students to complete a worksheet in pairs, followed by whole-class discussion of about 3 min ($M = 1$ worksheet/class meeting). Each workbook was implemented over a 5-6 week period covering 3-4 chapters and 21-34 worksheets, with daily researcher checks for fidelity of implementation. Results showed equal, significant, growth in biology diagram scores from pre- to posttest for COD and CTD ($d = .29$ and $.44$). Biology topic knowledge at pretest and Embedded Figures (spatial ability) scores at T1 predicted the rate of growth in diagrammatic reasoning (biology), but there were no interactions with condition. By contrast, only the Self-explanation treatment showed significant effects only on a transfer measure in another domain, and there was a condition \times MRT (spatial ability) interaction favoring high-spatial students in the Self-explanation treatment. Results suggest that, with these younger students studied in situ, 1) diagram skills can be improved with little disruption of normal classroom routines, 2) diagram skills may be more domain-specific than the literature has recognized to date, 3) different measures of spatial ability relate differentially to diagram skills in different domains, and 4) there are relatively complex individual difference \times treatment interactions.

Most research on students' comprehension of multimedia has been conducted in laboratories, with undergraduate psychology majors as participants. As part of a program of applied research, we have been creating a series of classroom interventions in reasoning with diagrams and text. In the current paper, we report on an evaluation of two workbooks we created for high-school biology students—Coordinating Text and Diagrams (CTD) and Self-explanation in diagrams (SelfExpl).

People often have difficulty understanding diagrams (Hannus & Hyona, 1999; Mayer, 2005). In the context of high-school biology, diagrams illustrate key concepts and are ubiquitous in textbooks. Despite their prevalence and importance, students often ignore large portions of diagrams (Cromley, Snyder-Hogan, & Luciw-Dubas, 2010). When students do attend to diagrams, the meanings of diagrammatic conventions (e.g., arrows, color use, labels) are often misunderstood (Hegarty & Sims, 1994; Heiser & Tversky, 2006).

While understanding diagrammatic conventions is necessary for deep understanding, the act of making sense of diagrams requires students to make inferences as they try to relate diagrammatic representations with the concepts represented and with prior knowledge. The cognitive complexity of such tasks may be particularly challenging for students at different developmental stages (Ainsworth, 2006) and abilities (Mayer, 2005; Sweller, 2005). One promising approach for helping students understand diagrams is self-explanation (Chi, de Leeuw, Chiu, & Lavancher, 1994). While the body of research on multimedia learning continues to grow, only a small proportion of these are experimental intervention studies (e.g., Seufert, 2003).

The purpose of this study is to experimentally compare the effectiveness of two classroom interventions on students' ability to answer near transfer (uninstructed biology diagrams) and far transfer (geology diagrams) measures of diagrammatic reasoning. Because neither type of instruction has been previously implemented with high school students, we were not able to predict whether the CTD instruction might be more effective because it would not be too difficult for the students, or whether the SelfExpl instruction might be more effective because it was designed to foster high-level processing.

Method

Across two studies, participants were $N = 100$ and $N = 113$ ninth-grade (i.e., 14-year-old) students in intact biology classes at a medium-achieving school in a small city in the Eastern United States.

Materials

We created Self-Expl and CTD workbooks to accompany 3-4 chapters (21-34 worksheets) in the students' own textbook, and compared each to previously-developed COD workbooks. Each workbook included images of every diagram in the relevant chapters, together with explanations and a series of targeted questions, which students answered in writing. In the COD workbook, the uses of various conventions were explained, and students answered questions identifying and explaining conventions in figures from their own textbooks. In the CTD workbook, students were shown that they should look at diagrams whenever a figure reference was given or a part in a diagram was explained; they then practiced these skills on figures from their own textbook. In the SelfExpl workbook, self-explanation was modeled, and students were asked self-explanation questions.

Measures

Students completed researcher-developed measures of biology and geology (transfer domain) knowledge and biology and geology diagram reasoning, and the Mental Rotations Test (spatial ability) during one regular class meeting. Both diagram reasoning measures were given again at posttest.

Procedure

Teachers received a 2-hr training explaining how to integrate the workbooks, scaffold students as they completed workbooks, and lead a class-wide discussion. Teachers delivered their usual instruction over 5-6 weeks, pausing for about 7 min for students to complete a worksheet in pairs, followed by whole-class discussion of about 3 min. After obtaining parental informed consent and student assent, students were pretested, received the intervention, and were posttested.

Results

Results showed equal, significant, growth in biology diagram scores from pre- to posttest for COD and CTD ($N = 100$; from 10.02 at pretest to 10.98 at posttest and from 11.25 to 12.96, $d = .29$ and $.44$, respectively). Biology topic knowledge at pretest and Embedded Figures (spatial ability) scores at T1 predicted the rate of growth in diagrammatic reasoning (biology), but there were no interactions with condition.

By contrast, in our second study ($N = 113$), only the Self-explanation treatment showed effects and only on the geology (transfer domain) measure; COD was 3.26 at pretest to 3.55 at posttest, but SelfExpl students increased from 2.49 to 3.18 ($d = .40$). We found a condition \times MRT (spatial ability) interaction favoring high-spatial students in the Self-explanation treatment.

Discussion

Results suggest the following conclusions regarding teaching diagram skills in situ to younger students than have usually been studied:

- 1) diagram skills can be improved with little disruption of normal classroom routines.
- 2) diagram skills may be more domain-specific than the literature has recognized to date: results differed for (instructed) biology diagrams and (non-instructed) geology diagrams, and only growth in biology diagram scores depended in topic knowledge at pretest.
- 3) different measures of spatial ability relate differentially to diagram skills in different domains
- 4) there are relatively complex individual difference \times treatment interactions.

SYMPOSIUM

The impact of genre on reading processes, critical thinking and epistemological beliefs in science

Chairperson: Isabel Braun, University of Freiburg, Germany

Organiser: Isabel Braun, University of Freiburg, Germany

Matthias Nuckles, University of Freiburg, Germany

Discussant: Clark Chinn, Rutgers University, United States

Science communications and popularizations differ from research articles in their communicative function and socio-cultural context, content and surface features (e.g. source information, structure, rhetoric), with function and context being reflected in content and surface features. Articles in popular science magazines, for example, are characterized by a rhetoric that attributes certainty to the scientific evidence presented whereas the distinct rhetoric of research articles suggests ambiguity and complexity. Furthermore, the standard structure of the research article gives way to an engaging storyline when an original publication is popularized. Scientists process science communications and popularizations in a different way than research articles and other scientific genres. In distinguishing between these

genres, they rely on the distinctiveness of textual characteristics and their knowledge of text genres. Hence, genre informs scientists' reading practices. With students, however, the role of genre remains largely unexplored: How do students distinguish among genres? (Strömsö & Bråten) Do students pay attention to surface features indicating the genre of scientific texts? (Braun & Nyckles; Strömsö & Bråten) Do genres differ in their effects on students' reasoning about scientific texts, critical thinking skills and epistemological beliefs? (Braun & Nyckles; Norris, Phillips & Yarden; Strömsö & Bråten) How can texts written in a scientific genre be modified so as to facilitate student learning? (Braun & Nyckles; Norris et al.) These are the central questions the symposium will address. The unifying aim of those involved in the symposium is to clarify the impact of genre on students' reading processes and learning outcomes in science.

Sourcing and judgment of trustworthiness when reading scientific texts representing different genres

Helge Stromso, University of Oslo, Norway; Ivar Braten, University of Oslo, Norway

Sourcing refers to readers' attention to and use of source information while reading different kinds of documents. In this study we hypothesized that students' sourcing activity would vary with different documents representing different genres. We also assumed that students' sourcing activity would be related to how much they trusted the documents that they read. A group of undergraduates ($n = 51$) were instructed to think aloud while reading two different documents about the possible relationship between cell phone use and health risks. The first document was a public information text from a national agency, while the second document was a newspaper article. After having read both documents, participants were asked to judge their trustworthiness. Analyses of think-aloud protocols indicated that students were paying significantly more attention to source information when reading the public information text than when reading the newspaper article. The public information text was also judged to be significantly more trustworthy than the newspaper article. Results also showed that students' level of sourcing while reading the public information text was positively related to their trust in that document. Their level of sourcing while reading the newspaper article was negatively related to their trust in that article, but positively related to their trust in the public information text. The results from the present study indicate that students' on-line attention to differences in genres, as indicated by source information, is related to how they judge different documents' trustworthiness.

Aims

In the present study, we set out to explore whether undergraduates' sourcing activities would vary according to the genre of the document. Next, we investigated whether on-line sourcing was related to students' judgments of the documents' trustworthiness. Theoretical framework Sourcing refers to readers' attention to and use of source information while reading different kinds of documents. Such skills are of importance to readers' understanding and evaluation of documents concerning scientific issues (Strömsö, Bråten, & Britt, 2010). With source information being central indications of a document's genre, students' sourcing activity may enable them to contextualize the content of a document and thereby facilitate comprehension. An important premise for readers' possibilities to take advantage of source information in text processing is that they actually pay attention to such information. However, even readers at university level may ignore vital source information while reading and evaluating media reports on scientific research (Goldman & Bisanz, 2002; Kopran, Bisanz, Bisanz, & Henderson, 1997; Stadler & Bromme, 2007). Students' lack of source awareness could affect their understanding of the documents' content, and is possibly also related to how trustworthy students judge a document to be (Bråten, Strömsö, & Britt, 2009). In the present study, we also hypothesized that sourcing activity could be related to the document's genre, with an informational document from a public agency expected to elicit more sourcing than a newspaper article. The public agency document will probably represent a less familiar genre to the readers. In addition, we wanted to explore whether on-line sourcing was related to students trust in the documents.

Methodology

Fifty-one undergraduates read two documents presenting different views on cell phones and health risks while thinking aloud. Verbalizations were coded as representing different forms of attention to source information, including both explicit and implicit source verbalizations. Explicit verbalizations of source information would typically be references to the publication's or author's name, while implicit verbalizations could be pronouns (e.g. he, this, that) referring to source information. The first document was a 444-word public information text from the National Radiation protection Agency, and the second document was a 395-word newspaper article. Participants were informed that they could read the documents in any order they preferred. After having read both documents, participants were asked to judge their trustworthiness. Results Think-aloud protocols were segmented and coded according to whether and how participants referred to source information while reading the documents. Preliminary analyses, using Wilcoxon Signed Ranks test, indicated that students paid significantly more attention to source information while reading the public information document than while reading the newspaper article, $z = -2.53$, $p =$

.011. There was also a significant difference in students' ratings of the two documents' trustworthiness, $z = -5.54$, $p = .001$, $p = .30$, $p = -.33$. **Conclusions** The results from the present study indicate that students' on-line attention to source information varies according to what kind of document they read. Specifically, students may pay less attention to source information when they read an article from a well known newspaper in a well known format than when they read a more unfamiliar document type, although they represent related genres (Goldman & Bisanz, 2002). It was also found that students' on-line sourcing was related to the perceived trustworthiness of the documents. Trust in the public information document was positively related to students' on-line sourcing while they read both documents, while trust in the newspaper article was negatively related to students on-line sourcing while they read that article. These results indicate that the relationship between perceived trustworthiness and sourcing activity is dependent on the nature of the document. As the results are of a correlational nature, we suggest that more experimental studies should be carried out to examine whether on-line sourcing affects students' trust in the documents they read. With the specificity of genres possibly being less apparent in the wealth of digital documents on the web, we believe that students need to be even more aware of source information in order to contextualize and understand many documents and that educators should facilitate such awareness.

Students' interpretations of two scientific text genres: A tale of two countries

Stephen Norris, University of Alberta, Canada

Linda Phillips, University of Alberta, Canada

Anat Yarden, Weizmann Institute of Science, Israel

This paper reviews the results of two related studies, one conducted in Israel and the other in Canada, on the effects of Adapted Primary Literature (APL) on students' interpretations of scientific text. APL comprises articles written for high school students. It is based upon Primary Scientific Literature (PSL) and maintains its original structure by including introduction, methods, results, discussion, and conclusion sections, and by preserving the argumentative genre. Baram-Tsabari and Yarden compared the use of APL and Secondary Literature (SL) with two groups of high school biology students and found that the students using APL showed greater scientific inquiry and critical thinking skills in their interpretations of the text than did the students using SL. In addition, students comprehended the SL better and expressed more negative attitudes towards APL. Subsequently, Norris, Stelnicki, and De Vries conducted a similar study with two groups of high school mathematics students. They found a comparable effect on critical thinking in the interpretations of the APL group with an effect size almost identical to that found in the Baram-Tsabari and Yarden study. They also found APL to be more difficult to interpret than SL, but did not find differences in students' attitudes towards the two types of text. It appears from these studies that the use of APL might be an effective means to provoke students' critical thinking during the course of reading scientific text, as well as to present them with a more authentic scientific reading experience than afforded by SL and school textbooks.

Theoretical framework

This paper reviews the results of two related studies, one conducted in Israel and the other in Canada, on the effects of Adapted Primary Literature (APL) on students' interpretations of scientific text. Conceptually, APL is different from both Primary Scientific Literature (PSL) and Secondary Literature (SL) (Yarden, 2009). PSL comprises articles that appear in scientific journals written for scientists, while SL comprises articles that appear in the popular media written for non-scientific readers. The genre of PSL is mainly argumentative, while the genre of SL is a combination of narrative and expository. APL comprises articles written for high school students. It is based upon PSL and maintains its original structure by including introduction, methods, results, discussion, and conclusion sections, and by preserving the argumentative genre (Yarden, Brill & Falk, 2001). The rationale for using APL is that it introduces students to more authentic scientific texts than appears in SL and in their school textbooks and thus has an increased potential to teach students how to reason scientifically and to read the scientific genre (Yarden, 2009). In both studies

it was hypothesized that students would comprehend SL better than APL, because of their greater familiarity with the SL form, whereas students reading APL would gain greater insight into scientific inquiry and scientific thinking.

Study 1 – Methodology and Results

We shall describe two experimental studies and compare their results. In the first study, Baram-Tsabari and Yarden compared the use of APL and SL with two groups of 10th, 11th, and 12th grade high school biology students in Israel (N = 272). The students went to both urban and suburban schools, and were enrolled in a high school biology course. The PSL had appeared in Nature Biotechnology and reported an empirical study that designed a polyvalent inhibitor of anthrax toxin. The PSL was written in English, whereas the APL and SL adaptations were written in Hebrew, which was the language of instruction in the schools. After initial instruction in the underlying biological concepts given to all students, the APL and SL texts were assigned randomly to students to read and to answer a series of questionnaires. The questionnaires were validated by a team of six experts and measured comprehension, attitudes towards the texts, and scientific inquiry including critical thinking about the texts. It was found that the students reading the APL showed greater scientific inquiry and critical thinking skills in their interpretations of the text than did the students using SL

Study 2 – Methodology and Results

Subsequently, Norris, Stelnicki, and De Vries conducted a similar study with two groups of 12th grade mathematics students in Alberta, Canada (N = 211). The students were enrolled in an introductory calculus course, and were attending urban schools. The APL and the SL were based upon a PSL that appeared in the Proceedings of the Royal Society of London B and provided an epidemiological model for the spread of the West Nile virus. The study was a theoretical exercise in mathematical modelling. Both the APL and the SL were written in English. As in the Israeli study, after the basic mathematical modelling concepts were taught to all students, the APL and SL were assigned randomly to students to read and to respond to questionnaires. The questionnaires were either taken exactly from the Israeli study, or modified to accommodate the differences in content. The results showed a similar effect on critical thinking in the interpretations of the APL group compared to the SL group (p d, .34 v. .38 for critical thinking; .44 v. .39 for comprehension). The results also showed APL to be more difficult to interpret than SL, as was found in Israel (p ConclusionsIt appears from these studies that the use of APL might be an effective means to provoke students' critical thinking during the course of reading scientific text, as well as to present them with a more authentic scientific reading experience than afforded by SL and school textbooks. The findings from both studies highlight the contribution of APL in encouraging critical thinking and demonstrate that the structure of scientific texts can be useful in prompting students to think critically. In each study, exposure to different types of texts for portraying the same content was the treatment difference between the experimental and control groups. The content instruction in each study was identical for both groups and was not designed to assist with interpreting the texts. The findings are particularly encouraging given the difference between the Canadian and Israeli contexts. There were differences in the grade levels of the students, in the language of instruction, in the scientific content and nature of the scientific studies, in the urban and suburban composition of the schools, and in the school subject in which the students were registered. Despite these differences, the findings were largely the same. This is why we conclude that the results seem to suggest that exposure to texts that resemble canonical scientific form can provoke students to use critical thinking skills they already possess and that this result can occur across different cultures, languages, student ages, science topics, and other contextual differences. Nevertheless, although the studies mutually confirm the major findings on the size of comprehension and critical thinking effects, there are other results regarding student attitudes that appear might be influenced by context. A possible next step in this line of inquiry is to employ instruction that aims to teach students about the APL genre so that they are able more effectively to interpret it. It would be interesting to learn whether such instruction had positive effects on students' attitudes towards APL and on their ability to think critically about it.

How the rhetoric of science can improve beliefs about knowledge construction

Isabel Braun, University of Freiburg, Germany; Matthias Nuckles, University of Freiburg, Germany

Scholarly journals, popular magazines and textbooks have their own ways of "telling science" and, hence, differ in their portrayal of the nature of science (NOS). As their rhetoric conveys a more adequate epistemology of science, research articles may provide more effective support for the development of students' understanding of the NOS than popular and instructional genres. To test this hypothesis we had 81 high school juniors read one of four versions of a

biology text: (1) an original publication from a scholarly journal, (2) a text adapted from the original publication so as to represent adapted primary literature (APL), (3) an article from a popular science magazine, (4) a chapter from a biology textbook. We administered questionnaires to assess students' understanding of the NOS, epistemological reasoning and genre knowledge. Half of the participants were prompted to think aloud during reading. Analyses of the post-test data showed that students improved significantly in their beliefs about the argumentative nature of knowledge construction after reading in the scientific genre (APL or original publication) but not after reading in the popular and instructional genres. We observed a general lack of knowledge about the scientific genre and low engagement in epistemological reasoning during reading. Our results seem promising as they show that the "rhetoric of science" can improve students' understanding of the NOS. However, as the potential of research articles was only partially realized, we suggest extending the notion of APL to include modifications of deep-level text characteristics, prompting epistemological reasoning or providing genre instruction.

Aims

The aim of the research we will be presenting in the symposium is twofold: First, we investigated the effects of discourse genres differing in their rhetoric and underlying epistemological assumptions on students' understanding of the nature of science (NOS). Second, we aim at refining the APL approach (Yarden, Brill & Falk, 2001) to more fully realize the potential of research articles for science instruction. Background Cognitive models of text comprehension assert that reader characteristics and text characteristics form complex interactions when students learn from text. The effects of surface-level text characteristics on students' understanding are well understood. However, research on features that mark a text as belonging to a particular genre and reflect both conventions and shared understandings of a discourse community remains limited. In the case of scientific, popular and instructional genres this lack of research is striking as they convey different epistemological assumptions through rhetorical features and structure, i.e. the way they present and unfold arguments. For example, popularizations of research articles furnish scientific evidence with a degree of certainty not found in the original accounts (e.g., Fahnestock, 1986). A similar "rhetoric of conclusions" (McComas, Almazroa & Clough, 1998), which contrasts the "rhetoric of science" (Har   , 1990) characteristic of the research article, can be found in high school science textbooks (e.g., Penney, Norris, Phillips & Clark, 2003). As the rhetoric of scientific genres implies a more adequate epistemology of science we assume that research articles provide more effective support for the development of students' understanding of the NOS than popular and instructional genres. Empirical evidence lending support to our hypothesis comes from research on the effects of refutational texts on epistemological beliefs (Kienhues, Bromme & Stahl, 2008) and research on adapted primary literature (APL) (see paper by Norris, Phillips & Yarden, this proposal). APL refers to research articles which are modified so as to be comprehensible and accessible to high school students.

Method

In a randomized experiment, we had high school juniors (n=81) read one of four versions of a biology text: (1) an original publication from *Animal Cognition*, (2) a text adapted from the original publication so as to represent APL, (3) an article from a popular science magazine that reported on the original publication, (4) a chapter from a biology textbook. Questionnaires were administered before and after the learning phase to assess students' understanding of the NOS, epistemological reasoning and knowledge of key concepts addressed in the texts. Half of the students of each condition were prompted to think aloud during reading. After completing the reading activity, students were asked to indicate which genre they thought their text had been written in (multiple-choice item).

Results

Students who read texts written in the scientific genre (original publication or APL) improved in their understanding of the NOS whereas students in the popular and instructional genre conditions showed less adequate understandings of the NOS after the treatment. Planned contrasts following MANOVA ($F[21,219]=1.78$, pp Students' responses to the epistemological reasoning questionnaire (free-response items) were analyzed for implicit references to the NOS. Despite a low number of implicit references in all of the four conditions (as indicated by preliminary analyses), more references were observed in the APL condition ($M=2.70$, $SD=1.38$) than in the popular genre condition ($M=2.40$, $SD=.99$), the instructional genre condition ($M=2.29$, $SD=1.10$) and in the remaining scientific genre condition (original publication), $M=2.47$, $SD=.90$. However, analysis of variance did not yield a significant result. An inspection of the think-aloud protocols corroborated the overall result obtained with the epistemological reasoning questionnaire: Across conditions, very few students engaged in any reasoning about issues related to the NOS. More detailed results will be presented at the conference. Out of 76 students who indicated the genre of the text they had read, 47 were unable to identify the correct genre (observed/expected per genre: $\chi^2[4, n=76]=45010.53$, p

Conclusions

The results from our present study indicate that discourse genres featuring a "rhetoric of science" facilitate the development of an adequate understanding of the NOS whereas popular and instructional genres and their "rhetoric

of conclusions" do not. The beneficial effects of texts written in the scientific genre were limited, however, to a single aspect of the NOS. Given the findings from our study, three approaches might prove successful in increasing the effectiveness of reading texts written in scientific genres.

First, we suggest that the notion of APL be extended to include modifications of deep-level text characteristics. In particular, the epistemological assumptions encoded in rhetorical features should be elaborated and the salience of the overall line of argument (running from the introduction to the discussion section) should be increased. This might allow students access to the implicit epistemology of the research article which appears to have been limited in our study as we did not observe differences between APL and the original publication.

Second, prompting epistemological reasoning during reading seems necessary as we found hardly any evidence of epistemic processing in the think-aloud protocols and students' awareness of the NOS at post-test appeared low across conditions. This will be the approach taken in our second study, which we plan to conduct in the fall. In a 2x2 design, students will read APL or an article from a popular science magazine. Half of the students will be prompted to engage in epistemological reasoning. Third, students might benefit from explicit genre instruction before reading APL (cf. paper by Norris et al., this proposal) as the high number of incorrect genre categorizations we identified points toward deficiencies in students' knowledge of scientific genres. Taken together, our results seem promising but they show that students cannot gain a complete understanding of the NOS through reading in the scientific genre only even when the research article has been adapted to their level of prior knowledge. Hence, the approach of adapting research articles has to be refined or complemented by instructional support in order to realize its full potential for learning from text in science.

SYMPOSIUM

Social Interaction in Learning and Instruction

Chairperson: Gaye Williams, Deakin University, Australia

Organiser: David Clarke, University of Melbourne, Australia

Discussant: Helen Melander, Uppsala University, Sweden

The theme of this symposium is "coherence," which includes curricular links between different pieces of knowledge, narrative links between different ideas or events within a lesson or between lessons, and connections between pedagogical incidents, performatively realised by the classroom participants (the teacher or the students). The analyses were conducted within the Learner's Perspective Study, in which sequences of lessons were recorded, using a multi-camera approach supplemented by post-lesson video-stimulated interviews (see Clarke, 2006), in mathematics classrooms around the world. In this symposium, we consider two forms of coherence that were performatively realized in mathematics classrooms in Hong Kong, Melbourne and San Diego:

? Coherence of knowledge: The structural coherence inherent in mathematical knowledge was performed as a narrative constructed by the teacher (and possibly by the students) to link old knowledge (what the students have learned) to new knowledge (what the students are intended to learn).

? Pedagogical coherence: Consistent pedagogical strategies were used by the teacher in the lessons analysed, such that sociomathematical norms were well-established in the classroom and understood by all participants.

The combination of coherence of knowledge and pedagogical coherence can be portrayed as a form of classroom narrative, in which the logic and connectedness of the instruction reflect the connectedness of the mathematical concepts in a form of curricular storyline that is perceived as coherent by the students. It is not sufficient to argue for a coherence evident to the researcher, if no similar coherence was perceived by the participants.

The performative realization of coherence in one San Diego classroom: Scaffolding student mathematic

Carmel Mesiti, International Centre of Classroom Research, Australia; David Clarke, University of Melbourne, Australia

This study examined the management of instructional transitions in a year 8 mathematics class in San Diego (USA) with a view to revealing strategies used by the teacher to assist the students in making connections between these various activities and the conceptual content and associated mathematical practices that were the focus of each activity. The hypothesis underlying this research was that these transitions, from one type of instructional activity to another, facilitate or inhibit connection between mathematical concepts and activities. Ardoin, Martend and Wolfe (1999) reported that efficient transitions can lead to an increase in academic learning time and thus student achievement. We are investigating the notion of coherence in relation to the teacher's active construction of meaningful connections in the management of these transitions.

Our analysis of a San Diego classroom has helped to identify ten different categories of dialogue that are present in the moments identified as instructional transitions. These categories are not restricted to the organisational domain and indeed some statements are intended to make more explicit the cognitive connection from one type of task to another. Our analysis suggests that the transitions are integrated so well that the students appear to engage with the sequence of tasks as a seamless progression. Further analysis addresses whether this progression equates to productive conceptual connections and thereby to coherence of knowledge construction and mathematical practice by students. Student post-lesson interview data suggest a connection between such classroom coherence and the coherence of student-constructed mathematical narratives.

The connection of instructional activity to learning outcome remains an abiding challenge for classroom research. In this study, use was made of data generated by the research design employed in the Learner's Perspective Study (LPS) (Clarke, 2006) to study lesson sequences in geographically and culturally diverse classroom settings, where multi-camera video documentation of classroom practice was supplemented by post-lesson video-stimulated interviews with teacher and students. The study of mathematical talk by Clarke, Xu and Wan (in press,) suggested that student fluency with spoken mathematics provided a learning outcome capable of distinguishing one classroom from another in a fruitful and theoretically interesting way. Based on this analysis, it was the students of LPS San Diego classroom 2 that employed the most mathematical terms overall in their post-lesson interviews. In particular, in discussing the mathematical content and their learning, the students in this classroom made more frequent use of mathematical terms not actually employed in the particular lesson under discussion, thereby demonstrating a compelling form of connected knowing. This consistent use by students of both mathematical terms central to the lesson and other mathematical terms encountered in earlier lessons or other contexts can be interpreted as suggesting a form of interconnected mathematical knowledge or conceptual coherence arising from the instructional practices of the classroom.

This argument suggested that a case study of San Diego classroom 2 should be conducted with a particular focus on the teacher's strategies and success in developing this connected mathematical knowing among the students. In particular, it was hypothesised that this demonstrable connectedness might be associated with the teacher's actions during instructional transitions during the lesson sequence. On that basis, the teacher's management of instructional transitions was taken as an appropriate analytical entry point.

We identified the transitions as the moments between the periods of expected student engagement in academic activities, when the teacher actively seeks to direct students' attention and engagement with a discussion or task. The lesson transcript, with specific attention to the teacher dialogue, was used to categorise teacher attempts at connecting one task to another from two points of view: organisationally and conceptually.

Our analysis suggests that the transitions in this classroom were not always efficient, yet the engagement rate of students was still quite high. This is in conflict with Brophy (1988) who has previously reported that student engagement rates require, in addition to other elements, that transitions between academic activities are brief and orderly. From a related perspective, Stevenson and Stigler (1992) found that more time was spent in transition between instructional activities in American classrooms with respect to their Chinese and Japanese counterparts, and they suggested that this may have consequences for the instructional environment. In fact, the San Diego classroom that provided the focus of this study can be characterized by the manner in which the teacher seized every opportunity to create a teaching moment. As a consequence, what might appear to be a lengthy transition becomes an academic activity in its own right.

Our analysis of San Diego classroom 2 has identified ten different categories of dialogue that are present in the moments identified as instructional transitions. These categories are not restricted to the organisational domain and indeed some statements are intended to make more explicit the cognitive connection from one type of task to another. Our analysis suggests that the transitions are integrated so well that the students appear to engage with the sequence of tasks as a seamless progression. Further analysis addresses whether this progression equates to productive conceptual connections and thereby to coherence of knowledge construction and mathematical practice by students.

Our results suggest that analyses of classroom discursive practice that address both conceptual and pedagogical coherence offer new insights into the constitution of accomplished teaching practice in mathematics classrooms by shifting emphasis from connecting instructional task types to testable student performances to a more subtle and sophisticated reading in which students participate in the development of coherent mathematical narratives. The development of these narratives being facilitated by the teacher's management of the transitions between instructional activities, thereby scaffolding student construction of coherent mathematical narratives related to the

lesson's content, in which the student's mathematical vocabulary is inevitably invoked. The facility with mathematical language and the integration of diverse mathematical terms into student reconstructive accounts of lesson content, documented previously by Clarke, Xu and Wan (in press) would be entirely consistent with this hypothesis.

Seeking coherence in mathematics teaching: An example in Hong Kong lessons

Ida Ah Chee Mok, The University of Hong Kong, China

Many educators agree that coherence is important to support students to realize and appreciate the rich relationship between concepts and skills. By analysing a sequence of ten Hong Kong 8th Grade lessons on the topic of equations, this presentation reports how coherence could be established between lessons and within lessons. There are two research questions. First, how is new knowledge linked to old knowledge? That is, how links between knowledge in the past, knowledge in a different part of the lesson, knowledge in different lessons in the sequence of lessons or knowledge developed outside that classroom could be established in the teaching. Second, what are the pedagogical strategies that create a pedagogical coherence throughout the teaching?

The data used in the analysis is taken from the Hong Kong data set (the lesson data and the teacher interviews) in the Learner's Perspective study. In the analysis, coherence was identified in terms of similarity in content and pedagogy. Applying a Grounded Theory approach in the analysis, I present the storyline of "coherence" in terms of three categories that include: the curricular links between different subtopics within a topic; the narrative links between different ideas or events within a lesson or between lessons, and the consistent pedagogical features found in the teacher's pedagogical beliefs.

Understanding in mathematics is about the realization of the relationship between concepts and skills. Such a relationship is not a matter of socially emergent causal connections nor of random association, because the structure embedded in mathematical knowledge is often hierarchically or logically structured. For this reason, many educators agree that coherence is important to support students to realize and appreciate the rich relationship between concepts and skills. By the analysis of a sequence of 10 Hong Kong 8th Grade lessons on the topic of equations, this presentation describes how coherence could be established between lessons and within lessons. There are two research questions. First, how is new knowledge linked to old knowledge? That is, how links could be established in the teaching between knowledge in the past, knowledge in different parts of the lesson, and knowledge in different lessons in the sequence of lessons. What are the instructional strategies that create a pedagogical coherence throughout the teaching?

The data utilized in this analysis are taken from the Hong Kong data set in the Learner's Perspective study. The data set included: the video of the lessons; transcripts with English translation; lesson materials which included the textbook pages, the students' work, the teacher's handouts and powerpoint files; the transcripts of the teacher's interviews.

In the analysis, coherence was identified in terms of similarity in content or pedagogy. In the analysis, the framework by Chen and Li (2009) for instructional coherence was adapted. The possible relationship between segments in the lessons are classified into categories: (1) the segments had similar mathematical ideas; (2) the segment was dependent procedurally on an earlier segment; (3) the segment extended an earlier segment procedurally or conceptually in terms of level of complexity. At the same time, a Grounded Theory approach was used to allow synthesis and extension of theory.

In the paper, I present the storyline of "coherence" in terms of three categories that include: the curricular links between different subtopics within a topic; the narrative links between different ideas or events within a lesson or between lessons; and the consistent pedagogical features found in the teacher's pedagogical beliefs.

The first kind of coherence comes from the connection between the sub-topics under the topic of simultaneous equations. The sequence began with the meaning of simultaneous equations in two unknowns, followed by the method of substitution and the method of elimination, the graphical method, and finally word problems. The coherence is inherent in the relationship between the sub-topics that in turns supports the understanding of the topic and is embedded in the design of the curriculum.

The second kind of coherence is found within the lesson. In the analysis of the lessons, the word "narrative" was used. The narratives describe a sequence of connected events or episodes in the lesson, which are useful in creating coherence in the flow of teaching and in the presentation of knowledge during the lesson, which can appear in different functional form in the lessons. For example, in a lesson the teacher respectively used a review, a word problem and a worksheet to create a context in which he connected different objects together. In the review of an

earlier topic that took place at the beginning of the lesson, the teacher used the concept “a linear equation in one unknown and its solution” with which the students were familiar to remind the students of the meaning of unknown and degree; concepts that are canonical for building equations with more unknowns and higher degrees. Using the chicken-and-rabbit problem as a context the teacher created a context linking three methods of solving the problems that included both the old knowledge (linear equation of one unknown) and the new knowledge (simultaneous equations in two unknowns). A worksheet provided an exercise that let the students to explore the meaning of solutions first in the case of a single equation followed by the case of a system of two equations.

The third kind of coherence refers to the pedagogical consistency embedded in the teacher’s belief. Embedded in his actions and decision-making in his lessons, the teacher often took into pedagogical consideration the development of some generic aspects besides the explanation of the content. These were: building the new knowledge from the old, building confidence and treasuring each student’s contribution.

Should Areas of Parallelograms Be Taught Before Areas of Triangles? Is that the question?

Gaye Williams, Deakin University, Australia

In Victoria, Australia, curriculum documents do not prescribe the order of curriculum sequencing within a year level, and although broad guidelines on approaches to implementing the curriculum are provided, teachers in some schools are given considerable autonomy in sequencing and implementing the curriculum. This paper reports the activity of a teacher (Mrs Milano) who used such autonomy to develop a more coherent approach to the topic of ‘Areas of Triangles and Parallelograms’. It stimulates thinking about differences in pedagogical understandings developed by teachers who have responsibility for developing topic coherence, and teachers required to follow a prescribed curriculum that could vary in level of detail prescribed: order of sub-topic sequencing, tasks to be used, and / or how these tasks are implemented.

This study raises questions about whether teachers develop deeper pedagogical understandings when they struggle and work out ideas for themselves, or whether deeper pedagogical understandings develop through study of research literature. Mrs Milano’s experience suggests that studying research literature is not sufficient, on its own, to develop deep pedagogical understandings although this knowledge may have been important to her reflection process. Maybe the question should be “Is there an optimal balance between learning from experts and experimenting and reflecting to deepen pedagogical understandings? And, “What support structures could be developed to enhance such processes?” This case suggests we should have faith in teachers’ ability to develop topic coherence, and provide appropriate support structures to enable those teachers interested in doing so to develop curriculum coherence.

Coherence, for the purpose of this study, relates to the quality of student outcomes associated with a learning sequence. Coherence was considered to be present when students had opportunity to develop a deep and connected understanding of a mathematical topic. In Victoria, Australia, curriculum documents do not prescribe the order of curriculum sequencing within a year level, and although broad guidelines on approaches to implementing the curriculum are provided, teachers in some schools are given considerable autonomy in sequencing and implementing the curriculum.

This case reports the activity of a teacher (Mrs Milano) who used such autonomy to develop a more coherent approach to the topic of ‘Areas of Triangles and Parallelograms’. It stimulates thinking about differences in pedagogical understandings developed by teachers who have responsibility for developing topic coherence, and teachers required to follow a prescribed curriculum that could vary in level of detail prescribed: order of sub-topic sequencing, tasks to be used, and / or how these tasks are implemented. Mrs Milano progressively developed greater coherence for these topics by reflecting on difficulties students experienced, and what could help student learning in the future.

Mrs Milano had taught for more than five years and continued with postgraduate studies through that time. She has thus been exposed to research on the deeper understandings students develop when they build on their own ideas. Mrs Milano was described by many of her students as caring, easy to understand, willing to explain ideas, and available to speak to students and student pairs during student explorations. These students identified three ways in particular in which Mrs Milano assisted them: answering their mathematical questions; seeking out reticent students to be sure they understood; and affirming students’ mathematical pathways. Mrs Milano intentionally provided both ‘emotional and cognitive security’ for class members with actions including ‘telling’ and ‘affirming’. Such activity at

first appeared inconsistent with Mrs Milano's expressed goals of encouraging students to build ideas. During the research period, it became clear that in this topic at least, Milano interpreted 'students building ideas' to mean letting students develop ideas associated with a pathway she had pre-planned. Thus, Mrs Milano was identifying, and affirming ideas that progressed this direction, and gently deflecting ideas that did not. At the end of the sequence, Mrs Milano was concerned that the students had not developed the deep understanding she had expected: ability to recognise the relevant height of a triangle no matter its orientation.

After the lesson sequence, Mrs Milano's initially queried the order in which she had sequenced the subtopics because a student in another class she taught had just suggested using the area of a parallelogram to help find the area of a triangle. Mrs Milano had deflected this same suggestion during the lesson sequence because students had not learnt the formula for finding areas of parallelograms. Mrs Milano now realised it was not necessarily a change to topic sequencing that would enhance student learning: there were other possibilities. By retaining the sequence of lessons, and having faith in student ability to select and pursue their own mathematical directions, she now considered students could gain a more connected understanding. Mrs Milano's activity was increasing topic coherence.

There are parallels between exploratory student activity leading to deeper understanding of mathematics, and autonomous teacher activity leading to deeper pedagogical understandings. There are also parallels between the role of the teacher as listener and questioner eliciting further mathematical thinking from their students, and the role of the researcher as listener and questioner as the teacher reflected on pedagogical possibilities. This study raises questions about whether teachers develop deeper pedagogical understandings when they struggle and work out ideas for themselves, or whether deeper pedagogical understandings develop through study of research literature. Mrs Milano's experience suggests that studying research literature is not sufficient, on its own, to develop deep pedagogical understandings although this knowledge may have been important to her reflection process. Maybe the question should be "Is there an optimal balance between learning from experts and experimenting and reflecting to deepen pedagogical understandings? And, "What support structures could be developed to enhance such processes?" It could be productive to interrogate Japanese Lesson Study to identify whether, and if so how, it combines these different processes for developing pedagogical expertise. This case suggests we should have faith in teachers' ability to develop topic coherence, and provide appropriate support structures to enable those teachers interested in doing so to develop curriculum coherence.

SYMPOSIUM

Discussing complex "real world" issues at school: A space of dialogical tensions

Chairperson: Nathalie Muller-Mirza, Institut de Psychologie, Universite de Lausanne, Switzerland

Organiser: Michele Grossen, University of Lausanne, Switzerland

Discussant: Ed Elbers, Utrecht University, Netherlands

Over the last years, school curricula have given more and more importance to subject matters that deal with complex social issues and are closely related to the students' everyday experience. One general pedagogical purpose is to contribute to the development of responsible individuals and, eventually, of accountable citizens. However, the proximity of such topics with everyday experiences and highly polemical social discourses is challenging. Discussing "real world" issues may be extremely emotional and threaten the students' and teachers' identities. It may also be a source of misunderstanding between the school expectations and the students' experience, knowledge, opinions, etc., as well as between the school, the students and their families. Drawing on a socio-cultural and dialogical framework, this symposium aims at identifying the specificities of educational situations dealing with complex social issues and to understand how the teachers and the students make sense of them: What are the goals of these situations from the actors' perspective? How are "real world" issues discussed? In which communicative format and with what difficulties and misunderstandings? What mediational means can bring about change in student's commitment? More specifically, the aim is to examine the various dialogical tensions that arise when "real world" issues are discussed within the classroom. These research questions are examined through the analysis of actual teaching-learning practices dealing with topics that are of special relevance in the contemporary world and pertain to citizenship education: intercultural communication and racism, violence prevention through peer mediation, socio-scientific issues such as climatic change and environmental sustainability.

Access points to knowing: Arguing and learning about "real world" issues in the school context

Asa Makitalo, University of Gothenburg, Sweden

The aim of the reported project was to scrutinize how students approach socioscientific issues in a school context. In Sweden, the institutional response to the media development is that learning is more frequently organised in terms of extended projects where students work on real world dilemmas in groups using the internet, textbooks and other

resources. The extensive use of internet and other textual resources creates a learning context characterised by heteroglossia, which implies that the range of available voices and genres, potentially useful to frame an issue, are increasing. This implies that the "issues" students are working on must be transformed and framed in a specific discourse which makes local sense, i.e. it must be made relevant to the school setting and the task at hand. Three cases of such 5-7 week long project work arrangements were documented using video- and audio recordings and analyses of participants' interaction was conducted from a sociocultural and dialogical perspective. The results show the discursive complexity and argumentative challenges for both students and teachers as real world concerns and a set of different genres are brought into the school setting.

Taking a sociocultural and dialogical perspective on learning as the point of departure (Bakhtin, 1986; Rommetveit, 1992) the interest in the reported project was to study current attempts to organize teaching and learning activities in school. In particular, we studied activities arranged with the view to develop the communicative and literacy skills necessary to exert agency as citizens in a complex world mediated through digital media.

In Sweden, the institutional response to the media development is that learning is more frequently organised in terms of extended projects where students work on socioscientific issues and real world dilemmas in groups using the internet, textbooks and other resources. This kind of arrangement means that the complexity of what is to be learnt in school is increasing (Mäkitalo, Jakobsson & Säljö, 2009). The extensive use of internet and other textual resources creates a learning context characterised by heteroglossia, which implies that the range of available voices and genres, potentially useful to frame an issue, are increasing. As the different genres available on the internet 'hits' the classroom it becomes "populated -- overpopulated with the intentions of others" (Bakhtin, 1986, p. 294). Students are accordingly expected to learn how to come to an informed opinion from a myriad of possible ones. This implies that the "issues" students are working on must be framed in a specific discourse which makes local sense, i.e. it must be made relevant to the school setting and the task at hand. The aim of the project was to scrutinize how students approach such complex tasks.

The data consists of three cases of 5-7 week long project work arrangements on a) energy and sustainable development, b) genetically modified organisms, c) globalisation and international economy. These projects were initiated by teachers for 15-17 year old students (one class in secondary and two in upper secondary schools). The three data corpuses consists of video- and audio recordings of authentic classroom work, of students' interaction in groups as well as their interaction with teachers. The main research question was: How do students transform information from the Internet into knowing relevant in school?

In terms of results we can conclude that the students took on epistemic responsibility with regard to the accuracy of the information they retrieved from the Internet. However, gathering information was not sufficient to solve their tasks. In order to meet the local institutional expectations they also needed to address the issue of what was relevant when producing knowing. We could see the following pattern across cases:

First, students took an evaluative stance and the information from the Internet was sorted into what was considered "negative" or "positive" facts. This evaluative engagement was grounded either in a normative classroom discourse and/or in personal values. However, this evaluative stance was only a first step in organizing their work in a set of activities, which anticipated and responded to the upcoming assessment arranged by the teachers. In these settings the debate format was commonly used to report on their work.

Second, as both the positive and negative information were to be accounted for, an argumentative format was needed, which fitted the aim of the project work arrangement. The way the students approached the task was accordingly heavily influenced by the debate format. The retrieved information was arranged into descriptions, which took a narrative form i.e. the negative and positive facts were arranged according to time and a set of events. The set of events were then connected in ways that allowed students to argue that the real world issue (global warming, poverty or cloning) were either a consequence of human action or had natural or causal effects.

Third, when framing the complex issues the students used different communicative genres and social languages. Economic and scientific discourses were commonly used to frame the issues but also moral and political discourses were brought into the classroom. The students moved between these discourses without explicitly noticing that the premises for the arguments changed. Neither did the teachers make such shifts noticable. Teachers however supported the students when moving between general claims and specific examples in their argumentation.

From a sociocultural and dialogical perspective it is concluded that learning the relevant discourses in contemporary society is a demanding process in which students and teachers need to find relevant and comprehensible access

points into very complex issues. To appropriate the normatively preferred discourse at school is a challenging task in the new media ecology. "Expropriating it, forcing it to submit to one's own intentions and accents, is a difficult and complicated process." (Bakhtin, 1986, p. 294).

Learning to care for the environment through mediated experiences in natural places

Peter David Renshaw, The University of Queensland, Australia; Ron Tooth, University of Queensland, Australia

This paper takes a sociocultural perspective to investigate primary-school students' learning of a sense of civic responsibility for environmental sustainability. The site of the investigation is outdoors at an environmental education centre but the students' experience of the natural environment is mediated by specific tools and social scaffolds including: ocular devices such as magnifying glasses, cameras and recorders; narratives and story-telling related to real and fictional characters related to the place; and by thought experiments such as imagining the past and reflecting on possible futures for the natural environment. Data collection included observations of and interviews with students and teachers, and recording of teacher-student discussions and inquiry circles. Data analysis revealed changes in students' knowledge of the environment and growth in personal qualities such as confidence and attentiveness. Of particular interest were changes in their values and relationships to others and to place. Students reported changes in their sense of civic responsibility for family, peers at school and for future generations regarding sustaining the natural environment. The paper highlights the key role of mediational means such as narrative and deep listening in natural places to bring about significant change in students' civic commitments to ensure environmental sustainability.

This paper examines students' learning for environmental sustainability beyond the classroom where detachment and abstraction are privileged, to the affordances of the outdoors where engagement with nature is privileged along with the associated emotions and responses of the body to nature (Wattchow Burke & Cutter-Mackenzie, 2008). There is tension between the abstraction and detachment typical of classroom learning and the civic and personal commitments associated with learning to care for the environment in a natural setting. For example, Tooth found that experiences in natural places could provoke a heightened responsiveness and motivation for students to change their behaviour regarding environmental sustainability.

This paper builds on this earlier research by taking a sociocultural perspective to investigate primary-school students' learning during an excursion to a natural setting. Our focus in this paper is on their sense of civic responsibility regarding environmental sustainability and their subsequent commitments to try to change the behaviour of family members at home and peers at school. The site of the investigation is outdoors at an environmental education centre but the students' experience of the natural environment is mediated by specific sociocultural tools such as: ocular devices including magnifying glasses, cameras and recorders; narratives and story-telling related to real and fiction characters related to the natural place; and thought experiments such as imagining the past and reflecting on possible futures for the environment (Tooth, Wager, & Proellocks 1988). During the excursion the students are guided by teachers to participate in: (i) first-hand experience of a natural setting where deep listening to nature and close observation of small events in nature are scaffolded by the teacher; (ii) collecting, categorising and returning plants, insects and other animals; (iii) using scientific vocabulary and forms of argument to back up their suggestions regarding sustaining the natural environment; (iv) entering an imaginary space where they adopt the identity of characters in a drama involving the natural environment; (v) within the drama resolving a dilemma created for them as characters in the story. These activities are subsequently reviewed and revisited by teachers and students during the weeks that follow the excursion.

The research project involved students and teachers from nine classes (year 1 to year 7) drawn from different primary schools (N>200 students) in Brisbane, Australia. Across the year (2010) data was collected on a range of measures (prior and following the excursion) of student knowledge, values and changes in their sense of civic responsibility and commitments to environmental sustainability. Data collection methods included observations of and interviews with students and teachers, video- and audio-recording of teacher-student discussions and inquiry circles. For this paper we drawn upon data collected during: (i) the inquiry circle where students responded individually to the question, What changed for you as a result of going to the environmental education centre? (ii) in-depth small group interviews where a researcher asked the students to reflect on the changes that had occurred for them as a result of participating in the excursion.

In categorising their responses we searched the whole corpus of responses for consistent foci and themes expressed by students as the key changes that had occurred. We abstracted three key foci – (i) changes in self; (ii) changes in ones relationship to others and place; (iii) changes in learning at school. The changes to self were in terms of their personal qualities such as confidence and enthusiasm and an emerging new identity. The changes to their relationship with others were concerned especially with their sense of agency to influence others and do things to protect the environment, as well as in the realisation that even children have the power and responsibility to act for others and to protect the environment. The changes with regard to school learning were concerned primarily with more positive engagement and realising the relevance of school learning more. These changes were explicitly linked by some students to their realisation of the importance of direct experience of natural places for longer lasting and deeper change to occur.

We were surprised by the depth and eloquence of some responses from students. For example, one student (year 6 female) expressed herself as follows:

Before I did this program I just saw myself as someone who is passionate about nature and, yeah, someone who cares about wildlife but after I'd done this program I see myself as a wildlife warrior and I feel more confident in myself and I've become more alert and observant with my surroundings and it has given me a new confidence to go out and see the environment, instead of - just sitting and think oh I like the environment, I like nature, but not actually doing anything about what's happening.

In reflecting on the data from the project, we consider the affordances of different kinds of learning experiencing for transformational rather than simply incremental changes in students' thinking and civic sense of responsibility.

Dialogical tensions and learning processes in intercultural education and interpersonal communicatio

Nathalie Muller-Mirza, Institut de Psychologie, Universite de Lausanne, Switzerland; Michele Grossen, University of Lausanne, Switzerland; Julien Grand, University of Lausanne, Switzerland

Drawing upon a socio-cultural and dialogical framework, we assume that a teaching-learning situation is a place of dialogical tensions between the here and now of the teaching situation and the there and then of situations outside school. Our aim is to identify the dialogical tensions at work in pedagogical situations dealing with real world issues and to examine the conditions in which they enable secondarisation, that is, the transformation of everyday experience into a form of conceptualised knowledge. How do teachers and students make sense of these pedagogical situations? What difficulties and misunderstandings do they face? What semiotic tools do they elaborate to enable secondarisation?

Teacher-students interactions and interviews with the teachers were collected in two contexts: intercultural education lessons and sensitisation course concerning interpersonal communication. The analysis of the results showed misunderstandings that referred to various dialogical tensions: (1) tensions between objects, values and norms that are valorised by the school and those that are valorised outside school; (2) tensions between various discursive genres; (3) tensions between various semiotic tools that can be used to elaborate a personal experience.

The significance of these studies is twofold: on a theoretical level, they shed light on the relationships between identity, learning processes and semiotic tools; on an educational level, they show that the introduction of real world issues in school has to go beyond the mere expression of personal emotions and values in order to foster the development of self-reflection.

Drawing upon a socio-cultural and dialogical framework (Marková, Linell, Grossen & Salazar Orvig, 2007; Muller Mirza & Perret-Clermont, 2009), we assume that a teaching-learning situation at school is a place of dialogical tensions in which the "here and now" of classroom interactions meets various "there and then" referring to the participants' (the students' as well as the teacher's) personal and social life outside school. From this standpoint, a teaching-learning situation is in permanent dialogical tension with other situations (Grossen, Zittoun & Ros, in press). It involves the person as a participant in various "communities of practice" (Lave, 1993) and, therefore, is related to the person's identity.

In this paper, we shall focus upon pedagogical situations in which these dialogical tensions may be particularly intense: those dealing with delicate social issues that are explicitly related to the students' everyday experiences, emotions and shared social representations. How do the students make sense of these situations and deal with these dialogical tensions? Our hypothesis is that such issues may raise highly emotional reactions, threaten the person's identity and hinder a secondarisation process (Bautier & Goigaux, 2004), that is, a transformation of everyday experience into a form of conceptualised knowledge that places the personal experience within a broader framework and takes it as an object of reflection. In other words, our aim is to examine the conditions in which pedagogical situations dealing with "real world" issues lead the students to take a reflexive stance on their own experience and identities.

We shall present some results taken from two studies. The first concerned intercultural education, and the second interpersonal communication. Despite their differences, these two pedagogical situations had at least three points in common: (1) they required the students to draw upon their personal experiences, feelings and everyday behaviour in order to participate in the pedagogical situation; (2) the issues at stake referred to various bodies of knowledge or competence (for example, social and intercultural psychology, communication sciences, etc.) that were not based upon explicit learning theories or pedagogical methods; (3) they were explicitly related to personal and social values and, therefore, differed from usual curricular subject matters.

Six teachers, who were interested in using intercultural pedagogical material provided by a pedagogical centre of intercultural education and sustainable development, and 105 students aged 4 to 16 from 6 classrooms of primary and secondary schools, participated in the first study. The pedagogical material concerned the relationship to "Otherness" and/or migration. Classroom observations were made and pre- and post-interviews were carried out before and after these observations. The data were audio- and video-taped. The second study was part of a larger research project concerning peer-mediation in a lower secondary school (12-16 years old). One part of the complex training programme set up by this school was a "sensitisation course" that introduced the students to interpersonal communication and, more specifically, to peer-mediation. This course was given in four half-day sessions in which students worked in small groups moderated by two teachers. Two groups were observed and audio-taped during the four sessions.

The method of analysis consisted of analysing the dialogue between the teachers and the students in order to identify: (a) the misunderstandings, divergences or gaps between the teachers' pedagogical goals and the students' interpretation of the situation and task, as we assume that misunderstandings and gaps shed light on the implicit expectations of these pedagogical situations; (b) the place given by the teachers to the expression of personal experience, values and emotions; (c) the intermingling between the present dialogue between the teacher and the students, and the distant dialogues with other situations and third parties.

The results of our analyses enabled us to identify a series of divergences or misunderstandings that can be seen as the expression of various dialogical tensions: (1) tensions between objects, values and norms that are valorised by the school and those that are valorised in peer and social groups outside school ; (2) tensions between various discursive genres (academic genre vs. everyday conversation); (3) tensions between various semiotic tools that can be used to elaborate a personal experience.

The significance of these results is twofold: on a theoretical level, they shed light on the relationships between identity, learning processes and semiotic tools; on an educational level, they show that the introduction of 'real world' issues in school has to go beyond the mere expression of personal emotions and values in order to foster the development of self-reflection.

SYMPOSIUM

Measurement and cognitive structure of digital literacy skills

Chairperson: Johannes Naumann, German Institute for International Educational Research, Germany

Organiser: Johannes Naumann, German Institute for International Educational Research, Germany

Frank Goldhammer, DIPF - German Institute for International Educational Research, Germany

Discussant: Jean-Francois Rouet, Université de Poitiers, France

This symposium aims at exploring digital literacy skills both from a measurement and a cognitive perspective. Under digital literacy skills we subsume skills in accessing, integrating, and evaluating information, using information and communication technologies (ICT). We address this issue from three angles: First, we look at individual differences in the skills of using the ICTs to access and evaluate information, and new approaches to measure these skills taking into account efficiency of task engagement. Second, we look at students' skill in understanding digital reading materials, which can be assumed distinct from their skill in print reading, and also can be assumed to partly rest upon the skills discussed previously. We introduce a large scale assessment of these skills carried out in PISA 2009, the Electronic Reading Assessment (ERA) and show how success in ERA tasks depends on students' access of information, and the interaction of access processes with access demands. Third, we complement the large scale assessment perspective including cross-sectional data by an experimental psychology perspective towards strategies in accessing digital information. This study seeks at disentangling different cognitive strategies in hypertext selection. By these means, this symposium, besides its substantive aims, also seeks to bring together methodological perspectives and traditions in research on digital literacy (psychometric measurement/process analysis; large scale assessment/experiment) that often remain distinct, to complement each other in giving a comprehensive picture of students' digital literacy.

Measuring individual differences in ICT literacy: Accessing and Evaluating Information

Yvonne Pfaff, German Institute for International Educational Research, Germany; Frank Goldhammer, DIPF - German Institute for International Educational Research, Germany

The computer and the Internet have become essential and omnipresent parts of our daily life. Thus, computer-related skills are considered as an important condition for successful problem-solving in educational and workplace settings. A multi-faceted construct of Information and Communication Technology literacy (ICT literacy) is needed to address the competent, responsible and critical handling of information- and communication technology. This study focuses on the theoretical and empirical fundamentals of two major facets of ICT literacy, namely accessing information and evaluating information. The ICT literacy facet 'access' is defined as the skill and speed to use basic interaction functions of graphical user interfaces of computers to access, collect, and provide information. 'Evaluate' refers to the cognitive skill to efficiently make judgements about the quality of online-information using structural and message features of a website. We look at new approaches to measure these skills taking into account not only accuracy, but also efficiency of task engagement. The psychometric properties of the two scales are investigated as well as their validity following a nomological network approach.

During the past decades the competent and critical handling of information- and communication technology (Information and Communication Technology, or ICT literacy), has become a crucial skill in many educational areas. In the 21st century, no study programs, either vocational or academic, can be accomplished without basic ICT skills. Individuals lacking ICT skills will be left behind both in educational as well as in professional contexts. Moreover, the computer itself has become an important means of instruction, and to-be-learned materials are being delivered through the computer as hypertext, hypermedia, or simulations. This study focuses on the theoretical and empirical fundamentals of two major facets of ICT literacy, namely basic computer skills that enable to access electronic information and evaluation skills that allow to judge information retrieved from the Internet with respect to credibility. We define the competence of 'access' as the skill and speed to use basic interaction functions of graphical

user interfaces of computers to access, collect, and provide information (see Goldhammer, Naumann, & Pfaff, in preparation). We conceptualize the competence of 'evaluate' as the skill to efficiently judge the reliability and credibility of online-information, using structural and message features of a website (cf. Hong, 2006). Message features are defined according to five criteria originally developed for print-media, but being applicable also to the credibility of online-information. These are accuracy, authority, objectivity, currency, and coverage (see Alexander & Tate, 1999). Structural features are specifically related to the composition of websites and include domain names, the presence of site maps, online privacy policies, third-party seals of endorsement, and advertisements. A website is regarded to be a credible source of information on the basis of message-features primarily. Based on the assumption that structural features are predictive for message features, however, structural features can serve as valid heuristic cues to efficiently judge the quality and reliability of a website. Regarding measurement of digital skills, tests are often designed as knowledge tests, using multiple-choice-questions and short answer formats (e.g. Richter, Naumann & Groeben, 2001). Such atesting approach cannot provide an authentic interactive task as computer simulations can do. Thus, one major goal of this study was to design, scale and validate computer-based measures which indicate 'access' and 'evaluate' by means of interactive simulations of computer environments, allowing to estimate a person's efficiency and speed in task completion in addition to their accuracy.

The 'access' scale proposed here consists of 25 interactive items assessing the skill to operate mouse and keyboard, to open, save, delete and change texts and to handle menu bars, hyperlinks, scrollbars and hotkeys etc. The items include simulated environments representing standard programs, i.e., word processing, web browser and email client. For all items, response accuracy and response times are collected. The scale 'evaluate' comprises 24 interactive items simulating web-environments assessing the skill to efficiently judge online-information with respect to credibility. Online-information is presented in the form of link lists provided by a search engine, and forum entries. The informational context varies across items and includes health, craft, school and sports. Eight items consist of link lists, where the links cannot be clicked on. In this case the test taker needs to use structural features, and is not able to fully evaluate message features. Another eight items consist of link lists, where the links can be clicked on and the corresponding websites can be explored. Here the test taker can use both structural and message features. The last set of eight items comprises forum entries where the test taker needs to make a judgment on message features alone, and cannot rely on cue information provided by structural features. Again, for all items response accuracy and speed are collected.

A sample of 400 students in grade 9 from all educational tracks and 200 students in grade 12 completed the ICT scales 'evaluate' and 'access' as well as further computer-based tests for validation. We will present results pertaining to the measurement models for 'access' and 'evaluate'. In line with previous findings (Goldhammer et al., in preparation), for 'access', data proved unidimensional for each accuracy and speed, i.e., responses and response times were accounted for by one skill factor and one speed factor. Also in line with previous research as well as assumptions made in item development, 'access' item parameters were predicted by the number of steps required for task completion. For 'evaluate', two skill dimensions were identified, relating to whether structural or message features of a website had to be taken into account. The same pattern held for speed in the completion of 'evaluate' tasks. Analyses of 'evaluate' item characteristics predicting 'evaluate' item difficulties are currently under way. First results indicate that in line with item development rationales, the amount of information that has to be considered is predictive of item difficulty. Also, items that allow for the attendance to both structural and message features are harder if message and structural features in the to-be considered websites point to different directions in terms of reliability. In sum, the 'access' and 'evaluate' scales appear to provide a reliable measure of persons' ability and speed with respect to these two dimensions of ICT literacy.

To further investigate the construct validity of 'evaluate' and 'access' scales, the respective skill and speed dimensions will be embedded in a nomological network, including their relation to practical computer knowledge, general cognitive ability, attentional speed, word recognition, and computer usage.

Introducing the PISA 2009 Electronic Reading Assessment and explaining performance by process data

Johannes Naumann, German Institute for International Educational Research, Germany; Tom Lumley, Australian Council for Educational Research, Australia; Juliette Mendelovits, Australian Council for Educational Research, Australia

In the 2009 cycle of PISA, for the first time, an assessment of students' skill in reading and understanding digital texts was carried out, the Electronic Reading Assessment (ERA). In PISA 2009, the ERA option was an international option that was chosen by 19 countries and involved 24,000 students. In the present paper, we introduce the ERA framework, and present results speaking to both commonalities of electronic and print reading skill, and distinctive features of electronic reading. Results from the ERA indicate that while print reading and electronic reading share a substantial proportion of their variance, their latent correlation is also clearly different from one, indicating the presence of unique variance in electronic reading that print reading skill cannot account for. One factor specific to electronic reading is the use of navigation strategies in information access. Logistic regressions of success in responding to electronic reading tasks on navigation behaviour, navigation demands, and the interaction of navigation behaviour and navigation demands revealed an impact of navigation on the probability of succeeding in electronic reading tasks especially for tasks with high navigation demands. These relations prevailed when print reading skill on the student level was controlled for.

In the 21st century, a still increasing amount of students' reading activities is directed at electronic sources such as websites, e-mails, blogs or microblogs, or online discussion forums. On the one hand, the demands put on a reader when engaging with electronic reading materials are closely related to the comprehension of printed text, since all the basic processes of text comprehension, from word recognition to forming macropropositions, are the same in the printed and electronic medium. On the other hand, a number of reading processes take on a specific shape, and require specific knowledge and skills, when electronic reading materials are encountered (Rouet, 2006).

Referring to characteristics of the aspects of reading, as distinguished by the PISA 2009 assessment framework (OECD, 2009), first, accessing information in the electronic medium usually requires navigation of the text material, which includes the use of devices such as hyperlinks, menus, search boxes, etc. Second, integration of information from multiple documents is crucial in reading electronic sources, as most electronic documents come as hypertexts, which are intrinsically multiple documents. Because readers typically have more freedom in constructing hypertexts than they do when reading in the print medium, strategies for managing the reading process are likely to assume even greater importance in electronic reading than in print reading (e.g. Naumann, Richter, Christmann & Groeben, 2008). Third, the evaluation of electronic sources delivered via the internet requires the use of specific cues such as information contained in a website.

Given the distinctive features of electronic documents, and their distinctive processing requirements, a reading assessment not incorporating electronic texts will under-represent the domain of reading, and fail to measure an important part of students' reading skills. For these reasons, in the current cycle of PISA, a measure of students' skills in reading electronic texts was employed in addition to the PISA print reading assessment. In the present paper, we (1) introduce the PISA 2009 Electronic Reading Assessment (ERA), and discuss a selection of its basic outcomes (OECD, forthcoming), with a focus on the relationship between reading performance in the print and electronic environments; and (2) take the opportunity provided by a computer-delivered reading test to describe and investigate processes of information access in reading tasks. We use information provided through log files of students' navigation to determine the goal-directedness of their navigation behaviour to predict task success.

The Electronic Reading Assessment was an international option in PISA 2009, taken by 19 countries, involving a total of approximately 24,000 students. The ERA used a total of 29 computer-delivered reading tasks, covering a range of types of reading materials currently found on the Internet, encompassing both authored (e.g. Websites) and message-based (e.g. blogs, e-mails) texts. The 29 tasks were distributed across nine units, with each student responding to two-thirds of the tasks.

To investigate the relation of reading skill in the print and electronic medium, in a first step, ERA scores were regressed on print reading scores. Results indicate that, as expected, print reading and electronic reading share a major part of their variance. At the same time, however, their latent correlation was clearly different from one, indicating that parts of the variance in electronic reading are specific and cannot be accounted for by print reading skill. Therefore, in a second step, behavioural data was taken into account to depict students' navigation strategies as one factor specifically affecting electronic reading outcomes. For these analyses, a two-level logistic regression model was employed, with tasks being nested in students. Consideration of a task level was required as electronic reading tasks differ considerably from one another in the navigation demands posed by each task. Indices of navigational

behaviour such as the number of visits to task-relevant pages, however, will be more or less predictive of task performance conditional on task demands. Thus, on the task level, the log odds of task success were regressed on navigation behaviour (number of task-relevant page visits), navigation demands, and the interaction of navigation behaviour and navigation demands. In line with what was expected, goal-oriented navigation, as indicated by the number of visits to task-relevant pages, was positively predictive of the probability of succeeding in a task. This was, however, conditional on task characteristics: A positive relation of task success probability with number of task-relevant page visits was found only for tasks requiring a high degree of navigation both quantitatively (number of page visits required) and qualitatively (number of different navigational devices required to respond successfully to the task). Emphasizing the specific importance of navigation processes in electronic reading, these results held when print reading skill on the student level was controlled for. This means, in other words, that navigation predicts comprehension in electronic reading over and above print reading skill.

All in all, the analyses and results presented in this paper highlight both commonalities and distinctive features of print and electronic reading. On the student level, while already a substantial proportion of variance in electronic reading performance can be explained by print reading skill, their latent correlation is also clearly different from one. Analyses on the task level point to the importance of goal directed navigation in responding to electronic reading tasks. Taken together, these results imply that in future reading assessments, electronic reading tasks should be included to achieve a full coverage of the domain. From a methodological perspective, the task level analyses provided here also illustrate the potential that lies in process data that become increasingly available also in large scale assessment settings such as PISA, as computer-based assessment procedures become more common.

Hyperlink Selection strategies in a Wikipedia reading task: Literal versus semantic matching

LADISLAO SALMERON, UNIVERSITY OF VALENCIA, Spain; Pilar Garcia-Carrion, Universidad de Valencia, Spain; Raquel Cerdan, Faculty of Psychology. University of Valencia, Spain; Johannes Naumann, German Institute for International Educational Research, Germany

Current models of hyperlink navigation propose that students assess the semantically process hyperlinks before deciding to proceed. The matching heuristic model challenges this view, suggesting that as an alternative mechanism students may select links based on a matching heuristic: they may follow a link if it contains similar words as those included in their study goal (i.e. a particular question), independently of the semantic relevance of it. We studied students' selection of links in a task-oriented Wikipedia reading scenario. Results provide evidence favoring the predictions of the matching heuristic model, assuming a literal matching heuristic is used in addition to semantic matching. In addition, comprehension skill modulated the use of the matching heuristic. Proficient readers were more able to discard irrelevant semantic matches initially, and more able to recover the correct route after having selected an incorrect link.

Current models of hyperlink selection such as SNIF-ACT (Fu & Pirolli, 2007) propose that hyperlink selections are generally made on the basis of a semantic match between the person's goal and the link. Evidence for these models comes mostly from fact searching tasks (i.e. selecting a page to buy a flight ticket), with university students. An alternative strategy in contrast might rely not on a semantic, but a literal match between the question and the wording of a link, independently of the semantic relationship between them (Cerdán, Gilabert & Vidal-Abarca, in press). For example, imagine that while learning about the French Revolution, a reader encounters a question such as "Why did peasants benefit from the popular revolts during the French Revolution, after they took the Novelty castles around France?" A Wikipedia document may include two embedded links: "Live conditions in the country-side after the Revolution" and "The Novelty castles in France". Although only the first link would include relevant information to answer the question, some students may decide first to select the second link because it includes a positive word matching with parts of the question. Especially younger or less able students may be inclined to use this matching strategy (Rouet et al., in press). The aim of the present experiment was to investigate whether students in fact use a simple literal matching strategy to a substantial degree when selecting hyperlinks when both semantic and literal matching strategies can be applied, and lead to different choices. We used a Wikipedia reading task to investigate this issue. Fifty-five eight-grade students from a private school participated in the experiment (mean age 14.2 years).

Participants' task was to navigate through a Wikipedia document about 'The French Revolution' to answer a series of questions. The main document was an adapted version of an on-line document developed by a professional teacher, and distributed by the Spanish Minister of Education. The main document was composed of 1559 words, and was organized in three main sections (Causes, development and consequences of the Revolution), and 10 subsections. Eight sections included 3 embedded hyperlinks to additional 24 Wikipedia documents. A total of 12 retrieve and interpret questions were used. After being presented with a question (e.g. "Why did the King defeat the new revolutionary laws emerged in the National Assembly after the Storming of the Bastille?"), participants were told to go to a specific subsection of the main Wikipedia document to answer that question. In each subsection there were three links: (1) a relevant hyperlink that was signaled in the question. In one condition, this link was explicit in that it had a literal overlap with the question (e.g. "New revolutionary laws"). In a second condition, this link was a paraphrase of the question wording (e.g. "Novel legal order"). In both conditions, (2) an irrelevant-signaled link that was always explicitly signaled in the question (e.g. "Storming of the Bastille") was included that pointed to a document with irrelevant information for that question, and (3) an irrelevant and non signaled link with a wording that had no literal overlap with the question.

We performed two sets of analyses: first we explored students' initial hyperlink selection, and second we checked how students' comprehension skills related to hyperlink selection. With regard to students' initial selections, an ANOVA with type of hyperlink (relevant and irrelevant) and matching condition (explicit and paraphrase), showed an effect of type of hyperlink ($F(1,50)=19.37$, $p=.001$, $\eta^2=.28$). Participants accessed the relevant link more often ($M=30.63$; $SD=22.69$) than the irrelevant-signaled link ($M=19.44$; $SD=19.01$). This main effect of link relevance was however qualified by whether the relevant link also included a semantic match to the question, or a paraphrase, $F(1,50)=16.36$, $p=.001$. In addition, we regressed link selection (initial and rectification) on reading skill in both matching conditions. In the explicit condition, comprehension skill was not related to initial relevant link selection, $r(53)=.13$, $p=.32$, but proficient readers selected it more often after an initially incorrect selection, $r(32)=.32$, $p=.06$. In the paraphrase condition, proficient readers selected initially the relevant link more often, $r(53)=.50$, $p=.001$. Our results concur with a matching heuristic model. Although students clearly identified the relevant hyperlinks when there was a literal match in addition, they were equally inclined to select either a relevant or irrelevant hyperlink if the question included a word-match to the irrelevant link only. These results suggest that students may find it difficult to decide which link to select when the relevant one for a specific task requires a semantic conversion and there is simultaneously a competing link that shares superficial features with the original task. In such cases, the simple overlapping of words between the task and a specific link may be equally salient than performing a more demanding semantic analysis, at least for younger students. Data from the reading skill analyses go in the same direction. When the task was semantically demanding (paraphrase), proficient readers were able to discard the irrelevant match. In addition, they were able to recover the correct link route. Less proficient readers, in contrast, more heavily relied on literal matching even in the presence of a semantically plausible alternative when this alternative did not provide a semantic match. In further analyses we will explore the influence of individual differences and navigation behavior in students' performance.

SYMPOSIUM

Teacher learning in the context of educational innovation

Chairperson: Kurt Reusser, University of Zurich, Switzerland

Organiser: Jan Vermunt, Utrecht University, Netherlands

Monika Waldis, University of Applied Sciences, Switzerland

Discussant: Paul Conway, University College Cork, Ireland

Claims that teacher education programs have improved teaching very little and rest on a shallow knowledge base (e.g. Morris & Hiebert, 2009) have sparked controversy. Acknowledging diversity of opinion, we take the view that expanding our knowledge base about teacher learning in different learning environments and educational contexts does contribute to our understanding of processes and factors that influence teacher professional development. The aim of this symposia is to bring researchers from three different countries together who have been engaged in the study of teacher learning in a variety of contexts. These contexts include (1) the introduction of a national innovation programme in secondary education in the Netherlands, aimed at introducing more active and self-regulated pupil learning (SRL) in the classroom, (2) a quasi-experimental study to investigate the implementation and effects of collaborative pre-lesson conferences on assisting student teachers in practica in Switzerland and on the advancement

of student learning and (3) a professional development program in Teaching and Learning Mathematics in the USA, investigating the efficiency of learning materials developed for teacher learning including videocases and analyzes of teaching materials.

PAPER PRESENTATIONS will include the underlying theoretical notions of the research and intervention models chosen and display empirical data on effected teacher learning activities and learning outcomes. Preconditions for teacher learning in the context of educational innovation will be discussed.

Teacher professional learning in a time of educational change: a model

Jan Vermunt, Utrecht University, Netherlands; Theo Wubbels, Utrecht University, Netherlands; Mieke Brekelmans, University of Utrecht, Netherlands

This longitudinal study was aimed at increasing our understanding of how teachers learn. The central question was: What learning activities do teachers employ in different types of learning environments and what are the relations between these learning activities, type of learning environment, personal and contextual factors, and changes in their beliefs and teaching practices? More specifically, this study was aimed at testing a model of interrelations between these variables. During one year 94 teachers reported a learning experience every six weeks. Moreover, they completed a questionnaire on their beliefs about and their interpretations of the innovation twice. Personal factors included learning motivation, learning conception, professional identity and personality traits. Contextual variables included type of learning environment, dominant beliefs at the school, and perceptions of organizational climate. Teacher practices were measured in terms of student perceptions. Interrelations between variables in the model were tested. Results showed, among other things, that learning activities were associated significantly with all measures of learning outcomes. Moreover, personal factors were more important than contextual factors for explaining teachers beliefs and practices. However, for explaining learning outcomes and activities, contextual factors seemed to be more important. Especially type of learning environment turned out to matter. It is concluded that teachers respond to educational change with ways of learning. From the viewpoint of adopting innovative teaching methods, some of these approaches are more favourable than others. Implications for a scientific knowledge base needed to explain and foster teacher professional learning are discussed.

Aims

This longitudinal study was aimed at increasing our understanding of how teachers learn. The central question of this research project was: What learning activities do teachers employ in different types of learning environments and what are the relations between these learning activities, type of learning environment, personal and contextual factors, and changes in their beliefs and teaching practices? More specifically, this study was aimed at testing a model of interrelations between these variables. The context of the research project was a national innovation in Dutch secondary education aimed at fostering students' active and self-regulated learning, implying a fundamental change in the pedagogical role of the teacher.

Methodology

The study was characterised by a longitudinal design. During one year 94 teachers reported a learning experience every six school weeks by email. Moreover, they completed a questionnaire on their beliefs regarding the innovation and their interpretations of the innovation twice, at the beginning and end of the research year. Personal factors and contextual factors were measured twice with existing and newly developed questionnaires. Personal factors included learning motivation, learning conception, professional identity and personality traits. Contextual variables included type of learning environment (informal workplace learning, collaborative project groups, reciprocal peer coaching), dominant beliefs at the school, and perceptions of organizational climate and workplace conditions. Students of the teachers completed a questionnaire on their teacher's classroom practices twice.

The learning experiences were content-analysed in terms of learning activities and learning outcomes. Relations between personal and contextual variables and teacher beliefs, practices, and learning process and outcome variables were computed via regression analyses and related techniques.

Findings

Six main categories of learning activities were identified: experimenting, considering one's own practice, getting ideas from others, experiencing friction, struggling with behavioural tendencies, and avoiding learning, the first two being reported most frequently. Reported learning outcomes referred to changes in knowledge and beliefs, emotions, practices, and intentions for practice, with changes in knowledge and beliefs being reported most frequently and changes in teaching practices being reported rarely. Learning activities were associated significantly with all measures of learning outcomes.

Teachers turn out to learn predominantly through experimenting, but there are large differences between teachers in the extent to which they do these experiments, and conduct other learning activities, in a more meaning-oriented or performance oriented way. In the first instance they work at the development of their personal theory-of-practice, in the second they generate more isolated knowledge elements.

Analyses pertaining to the testing of the model are still in progress. Preliminary findings show, for example, that perceived workplace conditions are related to teachers' attitudes towards and interpretations of active and self-regulated student learning. Personal factors show to be more important than contextual factors for explaining teachers beliefs and practices. However, for explaining learning outcomes and activities, contextual factors seem to be more important. Especially type of learning environment turns out to matter, which is significantly associated with teachers' learning activities and learning outcomes.

Theoretical and educational significance

This study contributed to scientific knowledge about the way teachers learn in a period of educational change, the learning outcomes they attain, and the personal and contextual factors that influence these learning processes and outcomes. Evidence was generated that some ways of teacher learning are better than others with regard to the learning outcomes that are attained. The study has contributed to theory building about teacher professional learning. To our knowledge this study was one of the first that tried to relate teachers ways of learning to realised learning outcomes on a fairly large scale, using both qualitative and quantitative methodology. In our view, attempts to foster teacher learning should be based on a solid scientific knowledge base about how teachers learn in more or less natural settings.

It is concluded that teachers respond to educational change with different approaches to learning. From the viewpoint of adopting innovative teaching methods, some of these approaches are more favourable than others. The discussion of the findings focuses on implications for a scientific knowledge base needed to explain and foster teacher professional learning.

Teacher learning through videocase-based professional development

Nanette Seago, WestEd, United States; Hilda Borko, University of Stanford, United States; Jennifer Jacobs, University of Colorado at Boulder, United States

The main goal of the Learning and Teaching Geometry (LTG) project is to build professional development materials that provide opportunities for teachers to expand their mathematical knowledge for teaching. In particular, the LTG materials are designed to engage teachers in learning about mathematical similarity through the use of videocases, in which specific and increasingly complex mathematical ideas are presented within the dynamics of classroom practice. Videocases allow teachers a window into both classroom practice and mathematics. They offer great potential for teachers to gain a better understanding of the relationship between pedagogical decisions and practices, students' mathematical work, and the mathematical content.

The central component of the LTG materials is the Foundation Module, which is comprised of 10 3-hour workshops, and is intended to provide teachers with a thorough grounding in key mathematical and pedagogical issues related to similarity. The Foundation Module has been developed and piloted in 5 sites throughout the U.S (with different facilitators). Data were collected on the impact of these pilots on teachers' knowledge of mathematics for teaching (specifically in the domain of geometry), using three assessment instruments. In this presentation we discuss the results, focusing on the degree and nature of teachers' learning.

Learning and Teaching Geometry project's professional development (PD) materials are aimed at supporting middle grades teachers to meet the challenges of teaching mathematical similarity. LTG is premised on the idea that using artifacts of practice within a well-structured PD program can promote mathematical knowledge for teaching (Ball & Cohen, 1999). This idea is supported by a variety of learner-centered, inquiry-based theoretical traditions, including constructivist and situative perspectives on learning (Cobb, 1994). These perspectives share the notion that engaging in challenging, problem-based, collaborative, and socially shared activities is likely to promote an expanded knowledge base (Borko, et al., 2005).

We have chosen classroom video as the primary medium for teacher learning in the LTG project because of the opportunities it provides for teachers to consider issues related to their own practice through viewing and discussing the practice of others (Seago, 2004). By viewing real classroom video footage, the materials provide insight into (1) what an emerging understanding of similarity among middle school students looks like and (2) what instructional strategies can foster students' understanding of similarity. The LTG project is creating a Foundation Module and four extension modules. Throughout each module teachers (a) explore the mathematics, (b) view, analyze and discuss videocases, (c) compare and contrast issues across cases, and (d) make links to their own instructional practice. Some

of the video cases portray student thinking about particular concepts and tasks and some cases portray pedagogical issues and their impact on students' opportunities to learn (Seago, Driscoll & Jacobs, in press).

The Foundation Module is comprised of 10 3-hour workshops, and is intended to provide teachers with a thorough grounding in key mathematical and pedagogical issues related to similarity. To date, the Foundation Module has been piloted in 5 sites throughout the U.S., in order to generate both formative and summative evaluation data. The first pilot was facilitated by the Principal Investigator and lead materials developer (the first author of this presentation). Based on data collected from this initial pilot, the module was revised and the revised version was used by facilitators in diverse locations across the country. The facilitators of the 4 later pilots were known to the LTG staff and had extensive experience facilitating similar types of mathematics professional development. Altogether, 75 teachers participated in the pilots, which totaled 30 hours of PD for each group (10 sessions x 3 hours per session).

Three instruments were used to assess impacts of the PD on teachers' knowledge of mathematics for teaching: a content assessment and two sets of embedded assessments. All of the assessment items are situated in the work of teaching geometry, and specifically mathematical similarity, and all include pre- and post-measures. The content assessment is a 25-item multiple choice test that covers properties of similarity, ratio and proportion, scaling, dilations, and transformation. The embedded assessments are tasks that exist within the Foundation Module as part of the PD; they include an open-ended mathematics task (administered during sessions 2 and 9) and a video analysis task (administered during sessions 3 and 10). In addition, data were collected on the fidelity of implementation by the 4 pilot facilitators who were not part of the materials development process. Instruments to measure fidelity of implementation include facilitator session logs, a professional development observation protocol, and a facilitator interview protocol.

In this presentation, we will discuss the results of the three pre-post assessments (the content assessment and two embedded assessments), including sample items, scoring rubrics, and differences across the pilot sites. Preliminary results suggest trends in teacher learning that are aligned with the goals of the Foundation Module. In addition, we will present data on the fidelity of implementation, focusing on the extent to which facilitators adhered to and focused on the intended mathematical and pedagogical storylines, and the philosophy of teaching and learning that undergirds the LTG materials. Finally, we will note next steps in the research and development of the LTG materials as well as implications of this work for the broader field of teacher learning.

Advancing Student Teacher Learning through Collaborative Pre-Lesson Conferences

Fritz C. Staub, University of Fribourg, Switzerland; Monika Waldis, University of Applied Sciences, Switzerland

There is much evidence from student teachers that classroom-based practica are considered to be highly useful for professional learning (e.g. Hascher et al., 2004). Very little is known, however, on the effects of different ways of assisting, mentoring or coaching student teachers on the advancement of their learning (Hobson et al., 2009). In contrast to the predominant approach of assisting student teacher learning through reflection after lessons, Content-Focused-Coaching (West & Staub, 2003) is a new model that suggests a more active role for cooperating teachers or mentors. One of its pivotal features is that cooperating teachers assist student teachers through content-specific collaborative lesson planning in pre-lesson conferences. In an intervention study, 30 cooperating teachers were randomly assigned to either an innovative setting introducing them to lead collaborative pre-lesson planning conferences to assist student teachers in 7th and 8th grade mathematics classrooms or to a traditional setting. The study looks at the extent to which pre- and post-lesson conferences are implemented and at the quality of assistance as perceived by student teachers. Results provide evidence that the professional development with the innovative element lead cooperating teachers to implement content-specific collaborative pre-lesson conferences in significant ways. Considering the fact that the professional development sessions were of short duration only, this is very

promising. Further analyses will focus on effects of pre-lesson conferences on student teachers' quality of teaching as viewed by the pupils in the 30 classrooms involved in the study.

Theoretical Framework and Aims

Classroom-based practica are pivotal elements of teacher education. There is much evidence that student teachers view practica to be highly useful for their professional learning (e.g. Hascher et al., 2004). There is, however, little research on the effects of different ways of assisting, mentoring or coaching student teachers on the advancement of their learning (Hobson et al., 2009; Wolf, 2003; Zanting et al., 2003). The predominant practices strongly focus on reflecting lessons. Content-Focused-Coaching (West & Staub, 2003) is an innovative model that suggests a more active role for cooperating teachers. One of its pivotal features is that cooperating teachers assist student teachers through collaborative content-focused lesson planning in pre-lesson conferences. There is already some evidence that student teachers working with cooperating teachers who make use of pre-lesson conferences reported more learning gains and enacted lessons of higher quality than student teachers assisted in traditional ways (Futter & Staub, 2008; Kreis & Staub, submitted). However, the intervention workload in these studies was quite demanding, including up to 120 hours within 15 months. Building upon this research, the goal of the new intervention study reported in this paper is to introduce cooperating teachers in professional development sessions of a shorter format (2-3 hours only), in how to conduct productive pre-lesson conferences. Research interest focuses on the kind of assistance these teacher subsequently provide and on the question how different ways of assisting student teachers (with or without collaborative pre-conferences for lesson planning) impact student teachers' self-reported learning and their quality of teaching.

Method

Cooperating teachers are randomly assigned to one of two types of professional development offered in collaboration with three Swiss teacher colleges. In the innovative setting teachers were introduced to lead productive pre-lesson conferences, in the traditional setting the focus was on the reflection in post-lesson conferences. So far, a total of 98 dyads of cooperating teachers and student teachers participated. In this paper we focus on those 30 dyads, who documented their teaching of mathematics classes in 7th or 8th grade.

Data collection during practica took place on days when mathematics lessons had been taught. Student teachers reported by means of an on-line questionnaire on the occurrence, duration and quality of pre- and post-lesson conferences. They also provided written statements on their learning. Quality of assistance in lesson conferences was assessed with two scales: Interaction Atmosphere (4 items on a 4-point-Likert-scale, e.g. "In the pre-lesson conference our discussion took place in a friendly atmosphere"; $\alpha = .79$) and Collaborative Assistance in Lesson Planning (5 items; e.g. "In the pre-lesson conference we discussed different options of a lesson plan"; $\alpha = .71$). Student teachers were asked to indicate the degree of detail in which topics such as lesson content, learning goals, etc. were discussed in each conference (single items, 5-point Likert-scale). To adequately deal with the nested data including various numbers of entries belonging to one person, data analyses are based on hierarchical linear modelling with level 1 representing the collected online-reports and level 2 representing person's allocation to the innovative or traditional intervention group.

Once a week during practica, pupils in the mathematics classes taught by the student teachers answered a short questionnaire aiming to assess pupils' perception of aspects of quality of teaching like cognitive activation, clarity, and classroom management (Cronbach's $\alpha > .65$; rit $> .30$).

Findings

From the 30 student teachers a total of 251 online-reports were collected. On average, student teachers answered 8.5 times ($SD = 2.50$). Pre-lesson conferences were held more often in the dyads ($n = 14$) guided by a cooperating teacher who attended the professional development session with the innovative focus on collaborative pre-conferences than in dyads ($n = 16$) collaborating in traditional ways ($b = .32$, $SE = .11$, p and the use of didactical materials. For the traditional dyads, however, there is a preference to discuss aspects of classroom management (all HLM Beta-coefficients). Pupils' ratings of the quality of teaching provide an additional perspective on how the assistance of cooperating teachers affects the performance of student teachers. Preliminary analyses of the first 14 dyads show significant differences in terms of classroom management between the two intervention groups with an advantage for student teachers being assisted by cooperating teachers.

Theoretical and Educational Significance

The differences found between the dyads with innovative and traditional professional development with respect to the occurrence, duration and quality of pre- and post-lesson conferences provide evidence that the innovative professional development sessions did lead cooperating teachers to implement content-specific collaborative pre-

conferences in significant ways. This is encouraging, considering the fact that the professional development sessions were of short duration only. Further analyses looking at student teachers quality of teaching from pupils point of view and content analyses of student teachers answers to what they have learned from lesson-conferences will allow to further assess and understand the effects of collaborative lesson planning for the advancement of teacher learning.

SYMPOSIUM

Self-regulated learning at school

Chairperson: Jasmin Warwas, German Institute for International Educational Research (DIPF), Germany

Organiser: Gerhard Buettner, University of Frankfurt, Germany

Discussant: David Whitebread, University of Cambridge, United Kingdom

Self-regulation is assumed to be closely related to academic achievement. Empirical evidence shows that self-regulatory competencies are crucial in the prediction of students' academic performance. Moreover, a number of studies reveal that training on self-regulated learning enhance students' academic performance. The symposium brings together recent studies aimed at investigating several aspects of instructing self-regulation in classrooms. Otto, Olyai, Buettner & Krajewski (Frankfurt, Germany) developed an intervention in order to enhance self-regulated learning in primary students. The intervention was conducted during regular school lessons by teachers. The authors examined the effects of this self-regulated learning training, a math specific training, and a combined training (both math specific training and self-regulated learning training) on first graders' self-regulated learning. Kistner, Rakoczy, Buettner & Klieme (Frankfurt, Germany) present a study intended to identify possible influencing factors on teachers' instruction of strategies. Analysing three lessons on the Pythagorean Theorem and two lessons on word problems they investigated the significance of both didactic context and teacher beliefs for the amount and pattern of strategies that teachers instruct. The purpose of Kramarski and Weisbart's (Israel) study was to investigate the mathematical literacy (i.e., problem solving in a context) of low-achieving students who were exposed either to hypermedia with self-regulated learning support or hypermedia with no self-regulated learning support. In addition, the ability of self-regulated learning among low-achieving students in both hypermedia groups was examined. The presentations are discussed by David Whitebread (Cambridge, UK).

Effects of a teacher intervention on first graders' self-regulated learning

Barbara Otto, Institut of Psychology, Germany; Nadja Olyai, Goethe-University Frankfurt, Germany; Gerhard Buettner, University of Frankfurt, Germany; Kristin Krajewski, University of Giessen, Germany

This study examined the effects of a teacher training program on first graders' self-regulated learning (SRL). The study theoretically based on a process model of SRL. Data of 47 first grade classes of German primary schools were collected. All together, 660 students voluntarily participated in the study. The classes were randomly assigned to one of four conditions: (1) control group without training (CG); (2) math specific training (MZZ); (3) self-regulated learning training (SRL); and (4) combined training (MZZ + SRL). The teachers of the training classes were instructed in applying the eight week training program during regular school lessons. The post-test was conducted ten weeks after teacher instruction. SRL was assessed by two measures: (1) students filled in a questionnaire (25 items; $\alpha=.86$); (2) teachers rated their students' self-regulated learning behavior (13 items, $\alpha=.91$). In order to examine the effects of the training program on self-regulated learning multivariate analyses of variance were conducted. The results reveal that according to students' self-report compared to the control group SRL could significantly be enhanced by SRL training and combined training but not by MZZ training. With regard to teacher ratings of students' SRL no significant difference to the development of the control group could be found for all three training conditions. These findings lead to several theoretical and practical conclusions which will be discussed at the end of the presentation.

Objectives

Even though a large number of recent studies on self-regulated learning (SRL) show that high self-regulation is accompanied by high academic performance (e.g. Hidi & Ainley, 2008), most of these studies are purely correlative. However, single empirical studies using regression analyses also revealed that self-regulatory competencies truly are crucial in the prediction of students' academic performance (e.g. Otto, Kistner, Perels & Býttner, submitted). If self-regulatory competencies are indeed that important for students' academic achievement, it appears necessary to foster these competencies already at the beginning of students' school career in order to prevent learning difficulties. Although interventions to enhance SRL are more effective if they are conducted by researchers than by teachers (Dignath, Býttner, & Langfeldt, 2008), pure researcher interventions seem not to be practicable for different reasons (e.g. costs) in real school life. It is rather of interest to develop an effective intervention which can be conducted by primary teachers. Thus, the present empirical study addressed this imperative by developing and evaluating an appropriate intervention which is supposed to be conducted during regular school lessons by first graders' teachers in order to enhance the students' SRL.

Theory

The present study is based on a process model of SRL, which is basically consistent with the theoretical assumptions of Schmitz and Wiese (2006). According to Zimmerman (2000) the learning process is divided into three consecutive phases: The pre-action phase, the action phase, and the post-action phase. The learning process begins with the pre-action phase which refers to the preparation of the learning. The given assignment and the particular conditions in the learning environment initiate the beginning of the SRL processes by evoking certain motivational and emotional tendencies within the learner. If the learner is not intrinsically motivated or shows low self-efficacy he needs to apply self-motivating strategies. Under these affective-motivational conditions the student has to set goals for his learning. Moreover, the learner will have to plan the application of learning strategies as well as the time he will invest for finishing the task. Afterwards, the learner starts with learning (action phase). In order to complete his assignment he will apply different learning strategies. Moreover, he has to apply volitional strategies in order to avoid internal or external distraction and maintain concentration, effort, and motivation while performing academic tasks (Corno, 2001). In case the learner deviates from his planned learning behavior it is beneficial if he self-monitors his actual behavior. Finally, a learning outcome results. In the post-action phase the student has to compare his actual final result with his prior set goal (ideal result). Hereby, he also has to evaluate whether the final result can be interpreted as success or failure. Furthermore, he will also reflect how he approached the given task. As a consequence of comparing, evaluating, and reflecting, certain emotions (e.g. satisfaction) will arise depending on whether the task was successfully solved or failed. These subsequent emotions and evaluations have an impact on future learning, as they can lead to modifications in planning strategies and time or in setting goals.

Method

In order to answer the research question data of 47 first grade classes of German primary schools were collected. All together, 660 students voluntarily participated in the study. As different studies already proved interventions to foster SRL are particularly effective if self-regulatory contents are combined with the instruction of domain-specific contents (e.g. Perels, Gyrtler & Schmitz, 2005). Therefore, the classes were randomly assigned to one of four conditions: (1) control group without training (CG); (2) math specific training (MZZ); (3) self-regulated learning training (SRL); and (4) combined training (MZZ + SRL). The teachers of the three training conditions participated in a one day workshop by which they were instructed in applying the training program during regular school lessons. All three training programs were designed to be applied during eight weeks (90 min per week). The teachers of the control group did not participate in any workshop and did not receive any material. The math specific training MZZ is an effective program in order to enhance basic mathematical quantity-number competencies. Teachers of this condition received the original training program (Krajewski, Nieding & Schneider, 2007) with all materials. The SRL training based on the above mentioned process model of SRL and consisted of eight units addressing the enhancement of self-efficacy, realistic goal-setting, motivation to learn, time management, concentration, stress relief, positive dealing with mistakes, and the application of the individual reference norm. Teachers of this condition also received all required materials. Teacher of the condition with combined training (MZZ+SRL) received a selection of the original training program MZZ which was supposed to be applied during the first four weeks of the training period. Furthermore, they also received the material of a shortened version of the SRL training which was supposed to be applied during week five to eight. Data were collected with a pre-test post-test design. The first assessment took place right before teacher instruction. The post-test was conducted ten weeks after teacher instruction. SRL was assessed by two measures: (1) students filled in a questionnaire (25 items; $\alpha=.86$); (2) teachers rated their students' self-regulated learning behavior (13 items, $\alpha=.91$). Both measures based on the above mentioned process model of SRL. The students' questionnaire was newly developed whereas the teachers' instrument was basically compiled by combining existing scales.

Results

In order to examine the effects of the training program on SRL multivariate analyses of variance were conducted. The preliminary results reveal that according to students' self-report compared to the control group SRL could significantly be enhanced by SRL training and combined training but not by pure MZZ training. With regard to teacher ratings of students' SRL no significant difference to the development of the control group could be found for all three training conditions. These findings lead to several theoretical, methodical, and practical conclusions which will be discussed at the end of the presentation.

Instruction of learning strategies in classrooms: the role of didactic context and teacher beliefs

Saskia Kistner, , Germany; Katrin Rakoczy, German Institute for International Educational Res, Germany; Gerhard Buettner, University of Frankfurt, Germany; Eckhard Klieme, Deutsches Institut fur Intern. Padagogische Forschung, Germany

Instructional learning strategies is one important aspect of the consistently claimed promotion of self-regulated learning in classrooms. This study intended to identify possible influencing factors on teachers' instruction of strategies. We investigated the roles of (1) didactic context and (2) teacher beliefs for the amount and pattern of strategies that teachers instruct. 20 mathematics teachers were videotaped for 5 lessons in the ninth grade. 3 lessons on the Pythagorean Theorem (PT, introductory unit including a mathematical proof) and 2 lessons on word problems (WP, practice unit including a phase of cooperative learning) represented the two different didactic contexts. A low-inferent observation instrument was used to code the teachers' instruction of cognitive strategies (e.g., organisation), metacognitive strategies (e.g., planning), and motivational strategies (e.g., resource management). Different aspects of teacher beliefs were captured by a teacher questionnaire in the beginning of the school year. Results show differences between didactic contexts only for the instruction of planning strategies. Strategy instruction correlated highly between the two kinds of lessons, for organisation and resource management strategies as well as overall. Regarding teacher beliefs, the emphasis of an individual reference norm was related to the instruction of several kinds of strategies. Other aspects of teacher beliefs were associated more specifically with single types of strategies. Thus, teacher beliefs seem to play a role for strategy instruction, which makes them a possible starting point for enhancing the promotion of self-regulated learning.

Theoretical Background and Aim of the Study

In current research on learning and instruction there is a strong agreement that self-regulation is important for successful learning and that self-regulated learning should be promoted in schools. A central aspect of the promotion of self-regulated learning in classrooms is the instruction of learning strategies. Following Boekaerts (1999), self-regulated learning strategies can be grouped into cognitive, metacognitive, and motivational strategies. Studies that observe teachers' strategy instruction in classrooms indicate that this kind of instruction is rather rare, but also show that teachers highly differ in their amount of strategy instruction (e.g., Kistner et al., 2010). The present study aims at identifying possible influences on the amount and pattern of strategies instructed by teachers in regular classroom settings. It is assumable that didactic features of a specific lesson such as the instructional aim or the amount of cooperation are related to teachers' strategy instruction. For example, there is some evidence that the number of suggested strategies varies depending on the subject matter (Moely et al., 1992). Research on teachers' professional competence suggests that teachers' beliefs about the nature of teaching and learning influence their daily practice in classrooms. Indeed, various studies report associations between teachers' beliefs and their activities in the classroom, for example their emphasis on student autonomy (e.g., Stipek et al., 2001). Thus, teacher beliefs could also play a role for teachers' instruction of strategies.

This study investigates the roles of didactic context and teacher beliefs for the instruction of learning strategies in classrooms by addressing the following research questions: (1) Does the amount and pattern of instructed learning strategies differ according to the didactic context? and (2) Is the amount and pattern of instructed learning strategies related to teacher beliefs?

Research Methods

We analysed a subsample from the video study "Quality of Instruction, Learning, and Mathematical Understanding" (Klieme et al., 2009). Twenty teachers and their overall 538 secondary school students (grade 9) were videotaped for five mathematics lessons. A low-inferent observation instrument (Dignath & Býtner, 2010), based on Boekaerts' (1999) self-regulation model, was used to assess the instruction of specified learning strategies. Minute by minute, the instruction of cognitive strategies (elaboration, organisation), metacognitive strategies (planning, monitoring and evaluation), and motivational strategies (resource management, feedback) was coded. Interrater reliability (Cohen's Kappa) was high. The didactic context was varied by videotaping each teacher for three lessons on the Pythagorean Theorem (PT) and for two lessons on word problems (WP). The three lessons on the Theorem of Pythagoras were the beginning of an introductory unit on this topic. Here, a new mathematical concept was introduced to students and teachers were advised to carry out one proof for the Pythagorean Theorem during the videotaped lessons. The two lessons on word problems were part of a practice unit on this theme and the focus was on the application of linear equations. Teachers were advised to implement a form of cooperative learning within the two lessons. Teacher beliefs were assessed using a teacher questionnaire in the beginning of the school year. The questionnaire covered world views of the subject mathematics with the two scales "formalism" ($\alpha = .80$) and "application" ($\alpha = .66$). It included a scale that measured a constructivist view of learning and teaching mathematics ($\alpha = .78$). Furthermore it included a single item on the relevance of extrinsic motivation and a scale on assessing students according to an individual reference norm ($\alpha = .85$).

Results and Implications

Concerning the didactic context, the total number of instructed strategies did not differ between PT lessons and WP lessons ($t = -.08$, $p = .93$). This was also true for most of the specific kinds of strategies. Only for the instruction of

planning strategies, we found a significant difference between the two kinds of lessons. More planning strategies were instructed in WP lessons compared to PT lessons ($t = -2.67$, $p = .01$). We also looked at the stability of strategy instructions between the two kinds of lessons by computing correlations. For the total number of strategy instructions we found a significant correlation between PT lessons and WP lessons ($r = .50$, $p = .02$), as well as for organisation strategies ($r = .46$, $p = .03$) and resource management strategies ($r = .66$, $p = .001$). As for teacher beliefs, the scale on individual reference norms correlated significantly with the total number of instructed strategies ($r = .57$, $p = .001$) and monitoring and evaluation strategies ($r = .60$, $p = .001$). The results contribute to the understanding of teacher activities in classrooms and stress the importance of teachers' beliefs for their daily practice regarding the promotion of self-regulated learning. Thus, when we intend to foster self-regulatory skills in students, we should consider trying to shape teacher beliefs as a possible starting point.

Investigating the benefits of stimulating SRL with hypermedia

Bracha Kramarski, Bar-Ilan University, Israel

The present study investigated the benefits of stimulating self-regulated learning (SRL) in hypermedia environment for fostering students' (low and high achievers) mathematical literacy and SRL. The study compares 64 seventh-grade students who were exposed to a self-directed hypermedia either supported by SRL with IMPROVE questions (the H_SRL group) or receiving no direct SRL support (the H_NS group). We investigated mathematical literacy with: (a) authentic problem solving performance on basic, routine and complex tasks (PISA, 2003); and (b) online discussion for SRL processes (cognitive, metacognitive, motivation and social feedback). Findings indicated that the H_SRL intervention led to more significant gains than the H_NS group in mathematical literacy for students of varying ability levels (low and high-achieving students). In addition, the benefits of H_SRL persisted in online discussion feedback. These effects were particularly beneficial for the low-achieving students. This study offers potential contributions to theoretical research examining the role of SRL support in hypermedia for enhancing mathematical literacy and SRL of low-achieving students.

Introduction

The goal of the present study was to design an instructional intervention based on stimulating SRL in a self-directed hypermedia environment geared toward low-achieving students. Hypermedia is a powerful cognitive tool that provides students with dynamic, interactive nonlinear access to a wide range of links to information and online interactions. However, research has indicated that very few students (i.e., low and high achievers) are skilled at regulating their learning to optimize self-directed learning in such an environment (e.g. Azevedo & Cromley, 2004; Kramarski, in press; Kramarski & Dudai, 2009; Kramarski & Mizrachi, 2006). Hence, providing support and guidance to facilitate learning for the low-achieving students should help them access and interact with the content productively and allow them to think about the deeper concepts and structure of disciplinary relations. In our study SRL support was based on the IMPROVE self-questioning prompts, which are effective for fostering domain knowledge and self-regulatory cognitive strategies (e.g., Kramarski & Mevarech, 2003). The IMPROVE model aims to support key aspects of self-regulation by using four generic self-questioning prompts: comprehension (e.g., "What is the task/problem?"), connection (e.g., "What is the difference/similarity?" and "How do I justify my conclusion?"), strategy (e.g., "What is the strategy?" and "Why?"), and reflection (e.g., "Does the solution make sense?"; "Can the task be solved otherwise?". The purpose of the present study is twofold: (a) to investigate the mathematical literacy (i.e., problem solving in a context) of low-achieving students who were exposed either to the hypermedia with SRL support (H_SRL) or hypermedia with no SRL support (H_NS); (b) to examine the ability of SRL among low-achieving students in both hypermedia groups (H_SRL and H_NS). Mathematical literacy is determined by different task complexity, and SRL is observed in forum discussions related to online feedback. Furthermore, to achieve a more comprehensive understanding of the low-achievers' performance, we compared these outcomes to those of the high-achievers.

Method

Our study investigated 64 Israeli seventh graders attending two heterogeneous classes within one junior high school. At the outset of the study, there were no significant differences between the two groups in their prior knowledge of mathematics. The low-achieving students were selected according their scores (below the median score-55.4) on the Ministry of Education's standardized test administered in the beginning of the year. Instructional programs: H_SRL vs. H_NS group. Students from both groups were exposed to distance learning with hypermedia self-directed course (eight weeks) based on the Moodle (Modular Object-Oriented Dynamic Learning Environment) open e-learning software platform. Participants practiced varying complexity dealing with mathematical literacy. They could click onscreen links for clarifying "Terms" (e.g., variable, mean), using "Resources" (i.e., internet, guided prompts), viewing video "Lessons" (i.e., authentic classroom events of teachers' explanations and instructions), and accessing additional "Help" (e.g., worked-out examples). Finally the link to "Forum" enabled discussing solutions and providing/receiving feedback. Students in the H_SRL group received SRL support for problem solving, based on the IMPROVE self-

questioning approach (Kramarski & Mevarech, 2003). The metacognitive questions were presented and explained on the "metacognitive screen" in the link of Resources; question prompts were embedded in students' tasks. The students were encouraged to answer these questions while solving their tasks and to use them when providing explanations and peer feedback in the forum. The aim of the H_NS Group was to improve students' mathematical literacy by sharing knowledge in the forum.

Measures

Mathematical literacy. A 46-item pre/post test included items assessing procedural tasks demanding basic skills of one-step calculations, problem solving in routine tasks demanding several manipulation steps and justifications of the solution, and problem solving in complex tasks demanding high-level skills (i.e., justifications and conclusions). Cronbach alpha reliability coefficient was .81.

Online forum discussion.

Online discussion was assessed on the SRL process scheme index (low-1 to high-3; Kramarski, in press) related to cognitive (i.e., mathematical-solution accuracy, knowledge, strategy use and explanations), metacognitive (i.e., planning, monitoring and evaluation) motivational (investment of effort and interest), and social categories (interaction style as help seeking). Inter-rater reliability, calculated with Cohen's kappa coded by both raters, yielded high reliability coefficients for the feedback (cognitive- .93; metacognitive- .89; motivational and social - .92). Results of a two-way MANOVA test followed by univariate ANOVAs and Cohen's *d* effect sizes for the posttest indicated a significant interaction between groups and levels of achievement on the procedural, routine and complex tasks (p d = 1.19; 0.80, respectively for the low and high achievers), routine (d = 0.75; 0.48) and complex tasks (d = 1.38; 0.56). A MANOVA test followed by univariate ANOVAs and Cohen's *d* effect sizes for online feedback discussion criteria indicated a significant difference between the groups along the four criteria for cognitive (d = 0.61), metacognitive (d = 0.70); motivation (d = 1.9), and social feedback (d = 0.67). Furthermore, a significant interaction between groups and levels of achievement was found only on cognitive and metacognitive feedback (p d = 1.0; 0.37) and metacognitive feedback (d = 0.89; 0.61).

Discussion and Conclusions

In conclusion, making disciplinary strategies explicit in technology tools can help low-achieving students think about the steps of the solution process and monitor strategies that they need to adopt. H_SRL probably guided subjects to look for all the relevant information, to combine all types of knowledge (i.e., linguistic, mathematical and strategic) and so construct a correct mental representation of the problem. The study extends previous findings in regular learning environments regarding the effects of IMROVE support on mathematical problem solving among young (grade 3) low-achieving students (Kramarski, Weiss, & Kololshi-Minsker, 2010). The present study calls for further scrutiny of how low-achieving students' SRL in hypermedia emerges in the context of mathematical literacy.

SYMPOSIUM

Developing expertise development in the classroom: An utopia or reality?

Chairperson: Mien Segers, Maastricht University, Netherlands

Organiser: Quincy Elvira, Radboud University, Netherlands

Discussant: Jeroen Van Merriënboer, Maastricht University, Netherlands

It is argued that reconceptualization of school learning based on expertise development literature is needed (e.g. Hatano & Oura, 2003). The results of expertise development research offer valuable insights on how to design classroom learning environments in order to enhance students' expertise development. However, to date, there is no comprehensive overview of the instructional implications of expertise development research. The members of the expert panel have extensively built on the theory of expertise development from various perspectives. Their research has indicated various implications for designing (classroom) learning environments focused on fostering expertise development in different domains (e.g. medicine, management, counselling and law). The aim of this expert panel discussion is threefold; (1) to bring together current insights on the instructional/educational implications of expertise development research in terms of design principles for learning environments; (2) to further explore and debate on the design principles (3) to enhance the cross-fertilization between expertise research and studies on school learning. Particularly, the following issues and questions will be addressed by the panel: 1) How to define expertise development? 2) Can expertise development be enhanced in school settings? If yes, when to start? 3) Which learning and teaching activities are powerful to foster expertise development? 4) Which specific design principles can be formulated for the developers of learning environments and learning materials, taking into account the results of expertise development research?

Task, Learner, Context, and Time: The Interactive Elements of Competence Development

While addressing the theoretical, conceptual, and operational questions posed for panelists about expertise development and learning environments that contribute to expertise, this presentation will seek to raise several critical issues for consideration. First, what is the fundamental relation between expertise development, in particular, and learning, in general? Second, to what degree is it within the purview of secondary and tertiary education to "develop" experts? Third, what should be the academic mission of K-16 education regarding expertise development? And, what emphases and what transformations are required of academic learning environment to support students in their journeys toward expertise?

Task, Learner, Context, and Time: The Interactive Elements of Competence Development

The stated goal of this panel is to explore the features of learning environments that contribute to expertise development. This exploration will unfold around four interrelated questions:

- How do I define expertise development?
- Can expertise be fostered through formal education?
- What activities or features of the environment are likely to contribute to expertise development?
- What principles should developers of learning environments take into consideration if their intention is to foster expertise development?

In the broadest sense, expertise can be understood as a special form of learning marked by the exceptional level of performance or achievement for a given task or within a particular domain or discipline. Thus, considerations of expertise development must begin with a careful examination of learning. For instance, Alexander, Schallert, and Reynolds (2009) have argued that the topography of learning at any stage entails the continual and critical interaction between four foundational dimensions: the task (the what), learner (the who), the context (where), and time (when). Certainly, any discussion of expertise development must pay homage to these dimensions of learning, and the changes in knowledge, strategies, beliefs, and motivations associated with learning (Alexander, 1997, 2003; Alexander & the Disciplined Reading and Learning Research Laboratory, 2010).

Drawing on the topography of learning forwarded by Alexander et al. (2009), it is impossible to regard the nature of expertise development by isolating the features of the learning environment (the where) from the what, who, and when dimensions. First, there is always a "what" that is being learned; where the what represents the objects or foci of that learning system (Giussani, 1995; Spiro, Feltovich, Jacobson, & Coulson, 1992). These objects of learning can be distinguished and classified along dimensions that matter to expertise development. Second, the "where" of learning refers to the ecological context where that learning unfolds—a context that entails both the physical environment as well as the social and cultural milieu. Third, learning is inevitably influenced by the biological, cognitive, experiential (including individual and cultural experience), and affective (motivation/emotion) characteristics of the learners who populate any instructional environment. Finally, just as learning does not occur in a vacuum but unfolds in a physical and social context, there is always a temporal nature to learning. The time scale for learning can be measured in seconds or can be gauged over many years. If we are to consider expertise development then time ultimately must be considered.

Moreover, because this discussion panel has been asked to focus on learners within secondary and tertiary education, it is my contention that it is more relevant to consider the optimal combination of task, learner, context, and time that should give rise to competence within an academic setting rather than expertise (e.g., Fox, Dinsmore, & Alexander, in press). Educational systems at the secondary and tertiary levels are not expressly configured to develop experts in any academic domain. Instead, secondary and tertiary systems have been devised to lay the foundations for expertise; that is, to move students into the stage of competence in foundational domains and disciplines.

Based on the aforementioned grounding and building on over a decade of research that my colleagues and I have undertaken (Alexander, 2005; Alexander, Jetton, & Kulikowich, 1995; Fox et al., in press), I would forward the following principles to guide the development of learning environments that can move students into competence and toward expertise:

- Seek Principled Understanding
- Teach More About Less
- Allow Students to Appreciate the Complexity, Sophistication, and Uncertainty of Knowledge
- Aim for Rooted Relevance
- Incorporate an Array of Social Interaction Patterns
- Attend to Individual Strengths and Needs
- Build in Opportunities for Student Choice and the Pursuit of Individual Interest
- Explicitly Teach Domain-General and Domain-Specific Strategies

- Work toward Self-Regulation and Self-Assessment
- Appreciate that Expertise Development Comes from Effort and Sacrifice

This consideration of the optimization of competence will be informed not only by the decades of research in expertise, but also by the theoretical and empirical work in individual differences, learning, instruction, development, motivation, epistemic beliefs, higher-order thinking, and problem solving.

Developing expertise in the classroom requires an understanding of cognitive AND social adaptations!

Hans Gruber, University of Regensburg, Germany

Research on expertise has delivered many arguments that domain-specific cognitive adaptations result from extended deliberate practice – in virtually every serious domain. Some findings confirm that in the classroom similar processes as in many other domains can be observed. On the other side, (conservative) political interests and some myths about the nature of teaching and learning in the classroom (e.g. "born as a teacher") make a different issue of the "domain classroom". In the panel, I will argue that there is no intrinsic distinctiveness to the domain. Nevertheless, understanding the development of expertise in the classroom requires more than understanding cognitive adaptations. A research focus should be directed towards social adaptations, for example the growth of social networks. The analysis of social adaptations has to take into account particular features of the domain and of prominent kinds of workplaces. Simultaneously taking into consideration both cognitive adaptations and social adaptations, helps to predict how subjects master critical changes or transitional periods in their professional careers. I will outline some research projects, in which such joint analyses of individual and social aspects of expertise have been conducted.

Research on expertise and expert performance has become a promising approach to investigate high level performance in many domains (Ericsson, Roring, & Nandagopal, 2007). In particular, individual cognitive components of expertise, such as memory and knowledge, are focused. There is convincing evidence that inter-individual differences in such components are acquired rather than innate (Ericsson, 1996). But although expert performance often is individual in nature, expertise is situated within a social context. Individual strength and group acknowledgment are intrinsically related: Skillful people "become" experts through translating and integrating their knowledge into popular meaning systems (Walter, 2004). Other members of the social system guide them during (and often are the driving force behind) the acquisition of expertise. In the panel, I will argue that research on expertise should take into account both processes of cognitive adaptation and processes of social adaptation during the development of complex (professional) performance.

A close look at professional learning processes reveals, that subjects have to practice a lot AND the right issues in order to develop expert level. Superior reproducible performance of experts generally emerges after extended periods of deliberate practice, which aims to develop one's performance level beyond the current level (Ericsson, Krampe, & Tesch-Römer, 1993). The improvement of specific components is addressed in order to refine the related activities. Such experience is neither mindless drilling nor joyful and is not conformable with definitions of intrinsically motivating activities. It is not trivial to decide which (parts of) components are candidates for forthcoming deliberate practice, and individuals rarely spontaneously engage in deliberate practice. Usually there are persons who define the direction of practice and who guide (and enforce) subjects during practice.

It is this description which reveals that the development of expertise is based on cognitive adaptations (within individuals), which are triggered and directed by significant other persons (Gruber, Lehtinen, Palonen, & Degner, 2008, call these persons "persons in the shadow"). Social adaptations thus play an important role in the development of expertise, because the individual has to get opportunities (and she/he has to make use of them) to grow into relevant social networks and to build up professional relations with significant "persons in the shadow".

Such persons in the shadow play a critical role in designing practice activities, setting the goals for practice, motivating (often: forcing) individuals to engage in practice, breaking down complex performance into smaller units to be practiced, etc. They bear different names in different domains: trainers, coaches, teachers, mentors, parents, etc. So far only few studies have pointed to the important role of particular social contacts for the long term development of individuals in expertise research (Mieg, 2006).

In the panel I will argue that the acknowledgment of the presence of such persons has to be an integral part of the assessment and of the prediction of future expertise development. I concede that this argument makes the definition of "expertise" even more difficult, which seems to be particularly problematic in the teaching domain (Berliner, 2001). Most current approaches to investigate teacher expertise include measures which are based on peer nomination. Such measures have been criticised (Ericsson et al., 2007). An explicit analysis of professional social networks and of those characteristics of networks, which are used as indicators for the definition of "expertise", might help to better understand different notions of "teacher expertise". It might thus contribute to raise our awareness of what we are talking about when we are talking about "expertise development in the classroom".

Expertise development in the professions; Implications for teaching and assessment
Els Boshuizen, Open University, Netherlands

In this contribution the implications of a theory on expertise development in professional domains is worked out in terms of implications for education and instruction, and for assessment. Next this is taken one step further by extrapolation the theory and empirical findings developed in domains with a common body of knowledge, domain-specific skills, agreed upon best practices, and shared professional values, to labour markets that put more emphasis on fundamental knowledge and generic skills in graduates. This does not only apply to the standard professional domains, but also to domains –the 'new' professions– that so far do not have developed a shared body of knowledge and set of best practices. Competences to set standards and find feedback on performance seem key competences here.

Investigating expertise and expertise development from the perspective of the professions implies a specific goal, i.e. that the student develops into the direction of the standards set by the specific professional community this person is training for.

Professions set standards for the kind and level of competencies that are expected of a practitioner in that field, the body of knowledge shared by its members, or the practices performed. From that perspective, expertise is relative to the standards set for the quality of the services provided both to the clients of the profession and to the profession itself. Services to clients are medical care, contract writing, or teaching lessons; similarly, services to the profession can be improvements of care practices, guidelines for certain contracts, or evidence-based improvement of a teaching method. This means that expertise level can be defined according to set standards, but also to performance of peers. The expert in a certain field is characterised by better performance on critical tasks than his or her peers, while experts in general are better than intermediates.

From the perspective of formal education, standards set for expert levels of performance are not very informative. More interesting and informative is the answer to the question how experts came to that level. How was the trajectory that brought them so far? Which educational and instructional measures and formats can help novices and intermediates take the next step in their development toward expertise? These measures depend on the level of expertise.

In our research efforts we have taken the latter perspective using a cognitive view on knowledge and skill development; it has led to a theory of expertise development including two major processes: knowledge extension and validation and problem-oriented knowledge restructuring – consisting of knowledge encapsulation, and illness script formation and enrichment (see Boshuizen & Schmidt, 2009; Boshuizen, Van de Wiel & Schmidt, submitted). It was also found that skilful use of knowledge in practical settings requires that knowledge can be used dynamically and is automatically and readily available (Wagenaar, 2008). The role of biomedical and clinical knowledge (in the medical professions, which is comparable to the fundamental and applied sciences in other fields) turned out to have two dimensions: 1) it lays and structures the scientific grounds for development of the whole domain, and 2) through the same structure it helps students to learn and remember the less principled and less coherent knowledge of the applied sciences (Woods, et al., 2007). Intermediates and experts use this basic science knowledge in different ways: Intermediates use it to solve cases, unless they are very easy; experts hardly use biomedical knowledge, unless they deal with very complex cases.

Such findings have several implications for teaching both at the novice and the intermediate levels of expertise.

- 1) Selection of topics and subject matter to be included in a curriculum must depend on the body of knowledge shared by professionals;
- 2) Selection of the basic science knowledge should also serve the goal to improve understanding of clinical knowledge;
- 3) Tasks set for students should help them to evaluate and validate their knowledge;
- 4) Solution of misconceptions should be supported;
- 5) Students should be trained in all competences required of a beginning professional;
- 6) As the role of well-structured knowledge permeates all competences, knowledge development should come first but not in isolation from the competences;
- 7) Authentic problems should be used to guide problem-oriented knowledge reconstruction;
- 8) These problems should be chosen such that they best serve integration and validation of knowledge, support knowledge restructuring in the 'right direction', demonstrate the variations within problem themes prevalent in the field, and cover the kind and complexity of tasks of beginning professionals.

Assessment formats should match the levels of expertise reached and be in accordance with the aim of a specific curriculum part. That might mean the following:

- 1) Whole-task assessment should be the norm in an assessment programme though part-task assessment may play a role; a backwashing effect of the latter might have detrimental effects of the intended learning outcome
- 2) At the lower levels students should demonstrate the validity and extent of their knowledge in the context of authentic cases.
- 3) At higher levels students should show their competences in the context of cases that gradually become more complex both in the sense that the cases themselves become more complex and that the circumstances in which action is required become more demanding.
- 4) Task complexity can involve co-ordination, speed, timing and time-management.

All this is relatively 'easily' done when the relation between education and expertise domain is clear, which is the case in medicine, but less in law or language or mathematics.

An extra complication results from differences in the structure of labour markets in different countries and continents. Some countries and labour market expect more generic skills in graduates while other countries expect that graduates have a mix of generic and domain specific skills.

So far no good models of generic skills exist. In much literature, problem solving, social and communication and lifelong learning have been identified as important skills. However, there is no common understanding of what lifelong learning skills are. Especially in domains where no set practices and no common body of knowledge exist –the 'new' professions– lifelong learning skills should entail generating and setting standards for practice and finding sources for feedback on performance to be compared with these standards.

Building the pillars of expertise: self-regulated learning, knowledge, and high-quality performance

Margje W.J. van de Wiel, Faculty of Psychology and Neuroscience, Maastricht University, Belgium

Development of professional expertise is characterised by a developmental process that stretches over many years. Formal education lays the foundation of a person's expertise development, and should create prerequisites for successful progress in further studies and professional life. Research on expertise development has to meet the challenge of providing tools how to design a learning environment in these formal educational settings focused on that progress. Although we cannot raise experts in secondary and higher education, we can build the pillars of expertise based on guiding principles and strategies, derived from expertise development research. In this discussion panel, I will first critically examine what is meant with expertise from three dominant perspectives. Second, I will discuss the deliberate attempts at developing expertise in various domains, including the workplace. Lastly, I will answer the question whether and how learning environments can be designed that would foster expertise by formulating seven guiding principles.

To answer the question whether and how learning environments can be designed that would foster expertise development already in secondary and higher education, I will first critically examine what is meant with expertise from three dominant perspectives. From an expert-performance perspective, Ericsson (2009) characterizes expertise as the capability to demonstrate reproducible superior performance in a specific domain. The highest expertise level is obtained when individuals are able to go beyond mastery and contribute creative ideas and innovations. Although years of practice and experience are needed to become an expert, skilled performance and experience are not enough. Routine behavior and full automaticity should be counteracted by gaining high-level control of performance that allows further improvements to be made. From an adaptive expertise perspective, researchers (Hatano & Oura, 2003) argue that real expertise is characterized by flexible, innovative, and creative competencies within a domain that are used to adjust procedures to task constraints and solve new problems. This is contrasted to routine expertise, in which experts can only solve familiar problems with high speed, accuracy, and automaticity. Finally, from an expert-novice research perspective (Chi et al., 1989), expertise has been characterized by differences in performance and underlying knowledge between groups with increasing levels of experience in a domain. Experts have a large and well-developed knowledge-base, that is tuned to the tasks performed and the problems encountered, and allows fast and accurate performance in routine situations. In more complex situations, they can flexibly apply their knowledge in trying to understand the situation and decide upon further actions.

The obvious similarity in these characterizations of expertise is that they all emphasize routine, automatic versus controlled performance. For the development of expertise this means that challenging situations and tasks in which further thinking is required can contribute most to the building of knowledge and skills. According to Ericsson (2009) experience with such situations must be enhanced by specifically designing tasks to develop performance aspects that need improvement, i.e. deliberate practice. In our own research we have applied the expert-novice approach (Van de Wiel, Boshuizen, & Schmidt, 2000), but also deliberate practice theory (Van de Wiel, Szegedi, & Weggeman, 2004; Van de Wiel, Van den Bossche, Janssen, Jossberger, 2010), as we wanted to move beyond implicit learning from

experience and examine deliberate attempts at developing expertise. We investigated engagement in work-related activities that might further professional development including preparation, problem-solving, asking for feedback and advice, performance evaluation, reflection and updating activities. For both organizational consultants and physicians we found that these activities were mostly engaged in with the professional goal of high-quality performance and to a much lesser extent to improve competence. This suggests that much could be gained from managing learning opportunities in the workplace more explicitly. Therefore, we deduced from the descriptions of deliberate practice recommendations to design learning environments that promote the acquisition of expertise formulated in seven guiding principles (Van de Wiel, Van den Bossche, & Koopmans, in press):

Principle 1: Informative and immediate feedback is fundamental to refine knowledge and skills.

Principle 2: Measuring and analyzing current performance is the cornerstone to improve it.

Principle 3: Practice activities need to be specifically designed to improve performance aspects that need improvement.

Principle 4: Practice activities need to be repetitive but also allow for reflection on outcomes and processes.

Principle 5: The motivation to improve performance is prerequisite to achieve expertise.

Principle 6: Time and effort need to be invested.

Principle 7. Teachers and coaches play a crucial role in guiding individual development.

In these principles we can clearly recognize, the importance of self-regulated learning for deliberate practice as the control of learning by planning, monitoring and evaluating performance plays a key role (Van de Wiel et al., 2004; Zimmerman, 2006). Enhancing the ability of self-regulated learning, and creating work environments in which learning is facilitated, incorporated in work procedures (e.g., exchanging knowledge and experience around difficult problems), and set as a norm will foster expertise development.

In secondary and higher education we cannot raise experts, but we can build the pillars of expertise based on these principles and strategies. Thus, motivation for learning should be encouraged, self-regulated learning need to be practiced, and knowledge and understanding of a domain must be acquired that enable flexible and high-quality performance. Very important is the pursuit for further improvements if the goal is to make all professionals perform at top-level (think of your own physician).

SYMPOSIUM

Invited SIG

The role of refutational texts in achieving conceptual change

Chairperson: Wim Van Dooren, K.U. Leuven, Belgium

Organiser: Wim Van Dooren, K.U. Leuven, Belgium

Michael Schneider, ETH Zurich, Switzerland

Discussant: Clark Chinn, Rutgers University, United States

The development of instructional interventions and learning environments aimed at promoting conceptual change has been a central concern for the conceptual change community over the past years. Nevertheless, there is a general feeling that more research is needed in this domain.

This invited symposium focuses on the role that refutational texts may play in achieving conceptual change, therefore addressing not only issues related to conceptual change, but also themes that are of more general interest to the EARLI community, such as text comprehension or instructional design. Refutational texts are considered a powerful resource when a learner's inaccurate ideas about scientific phenomena need to be revised.

The three contributions in this symposium will provide a review of important research findings in this domain. Sinatra and Broughton will set the stage by reviewing multiple perspectives on the role of refutational texts in promoting conceptual change. Next, the contributions by Ariasi and Mason and by Kendeou will focus on how the underlying subprocesses that take place in processing refutational texts can be revealed by relying on eye-tracking data, reading times and thinking aloud data. The findings will not only point at the characteristics of texts that may elicit conceptual change in learners; they also contribute to our theoretical understanding of conceptual change.

Understanding the Refutation Text Effect in Conceptual Change Research: Multiple perspectives

Gale Sinatra, University of Nevada, Las Vegas, United States; Suzanne Broughton, University of Nevada, Las Vegas, United States

In this presentation, we present an overview of multiple perspectives on the role of refutational text in promoting conceptual change. Perspectives from text processing such as Kintch's Construction Integration Model, and van den Broek and colleagues Landscape Model, and Broughton and colleagues' perspective on attention allocation will be reviewed for their contributions to our understanding of the effect of text structure on processing. Perspectives from conceptual change learning such as that offered by the CRKM (Dole & Sinatra, 1998), Hynd (2001), Mason (Mason & Gava, 2005), Skopeliti and Vosnidou, (2008) and Chi (2009) will also be discussed. These perspectives will be contrasted to provide a framework for the symposium and a summation of where theory and research is to date in exploring the nature of the refutational text effect.

The inquiry movement in science education has focused interest on hands-on learning, problem-based learning, and the design of inquiry projects. As inquiry has been foregrounded in researchers' attention, text has been backgrounded. Recently, however there has been a renewal of interest in text in science classrooms (see Broughton & Sinatra, 2009). In particular, the resurgence of research on refutational text has led to a renewed interest in the potentially positive role text can play in the science classroom to promote conceptual change.

In this presentation, we will overview recent perspectives from text processing research and conceptual change research on the role of refutational text in promoting conceptual change, providing a framework for the symposium. One text processing perspective is from Kendeou, Van den Broek and their colleagues. They proposed a model of reading comprehension that may help explain the nature of the refutation text effect called the Landscape Model (see van den Broek, Young, Tzeng, & Linderholm, 1999). According to the Landscape Model, readers balance their limited attentional resources while at the same time maintain standards of coherence. Readers integrate four sources of information in each cycle of processing in working memory: the text information in the present cycle; residual text information from the previous cycle; the memory representation constructed thus far; and the reader's prior knowledge, which can include misconceptions. Van den Broek and Kendeou (2008) explained, "As the reader proceeds through the text, concepts fluctuate in activation: with each new cycle some concepts continue to be active, others decline in activation and yet others become newly reactivated" (p. 338).

The key for conceptual change according to this model is that only information that is coactivated – that is active in the same processing cycle– can be compared and integrated with the reader's developing text representation. The Landscape model predicts that the misconception must be activated at the same time as the accurate scientific information is activated for conceptual change to occur. Van den Broek and Kendeou postulated that coactivation is essential if the reader is to engage in the deeper cognitive processes needed for conceptual change.

In a related view, Kintsch's (1988) Construction Integration Model hypothesizes that reading comprehension occurs in two phases. In the construction phase a network of associations of the readers' propositions and concepts are automatically activated. In the integration phase associations that do not fit with the text's meaning are discarded. In relation to conceptual change, as learners read a refutation text they integrate their prior knowledge with the new

information in the text. This often results in the formation of a new mental model of the phenomenon under study (deLeeuw & Chi, 2003; Mikkila-Erdmann, 2002). Readers may assimilate elements of the scientific explanation into their existing mental models, distorting the scientific concepts, while at the same time adding or deleting beliefs from their existing mental model, resulting in a synthetic model (Hynd, Alvermann, & Qian, 1997; Vosniadou, 2002). Gradually, with repeated exposure to the scientific information, the synthetic model can be revised to align with the scientific explanation (Mikkila-Erdmann, 2002).

A processing perspective offered by Broughton, Sinatra, and Reynolds (2010) is that readers may devote more attentional resources to processing the refutation text segments than other comparable segments of the text if they find the information to be important or salient. In a recent study, Broughton et al. (2010) showed that readers spent less time processing the refutational text segment, a finding consistent with the literature on attention and interest showing that readers who find a text segment interesting, actually spend less time processing that text segment. Broughton et al. (2010) did not have crucial "look back" data that can only be obtained through eye-tracking. Others who have used eye tracking have shown that while readers may spend less time processing the refutational text segment, they also often look back, or make a regression, to previous text perhaps in an attempt to reconcile the discrepancy between their prior knowledge and the new text information which contradicts that knowledge.

Hynd (2001) offers yet an alternative perspective based on text structure. She claims that it is the structure of refutational texts that contributes to their effectiveness. She claims that because refutational texts are structured to concretely and explicitly tell the reader what to think and why, text content is better learned and recalled due to the concrete and explicit format.

Researchers such as Vosniadou, Chi, Sinatra, and Mason offer alternative perspectives based on conceptual change research and theory. Skopeliti and Vosniadou (2008) have explored the effectiveness of refutational text based on the type of information that is refuted in the text (categorical or non-categorical). Similarly, Chi (2009) has explored whether the type of learning failures (under-developed schemas, misconceptions, incomplete activation of relevant schema) is the key factor. Mason and her colleagues (Mason, Gava, & Boldrin, 2008) have explored how learner characteristics interact with text features to support or hinder conceptual change.

Yet another perspective comes from models of conceptual change learning. Conceptual change from refutational text may be the result of increased learner engagement with the ideas in the text (Dole & Sinatra, 1998). For example, a reader might find the refutation information to be personally relevant because the misconception in the text is similar to the conceptions held by the reader. In addition, the refutation sentence may lead the reader to thoughtfully and critically weigh the scientific explanation because it explicitly rejects their idea. A large body of research supports the notion that refutation texts may exert their effect through inducing deep engagement and critical thinking as the result of the cognitive conflict that arises when readers have the opportunity to juxtapose their misconceptions against the new information (Guzzetti et al., 1993; Hynd et al., 1997; Mason, et al., 2008).

These multiple perspectives will provide a context for the empirical studies presented in the symposium.

Eye-Movement Analysis for a Process Approach to the Refutation Text Effect

Nicola Ariasi, University of Padova, Italy, Italy; Lucia Mason, University of Padova, Italy

In academic contexts, texts are the primary medium for acquiring disciplinary knowledge. The effects of a particular text structure, the refutational, were examined in this study. A refutation text is one that acknowledges students' alternative conceptions about a topic, directly refutes them, and introduces scientific conceptions as viable alternatives. Refutation texts are considered a powerful resource for science learning, which very often implies the revision of inaccurate ideas about scientific phenomena. Using the methodology of eye movement, we have addressed the open issue of whether the refutation text effect encompasses a series of sub-processes with different time courses, which take place on different parts of the text and at different stages of the reading process. Forty undergraduates were randomly assigned to different reading conditions, according to a 2 (text: refutation, non-refutation) x 2 (topic: tides, Darwinian theory of evolution) within-subject design. As hypothesized, results show that, regardless of the topic, participants made shorter first-pass fixations while reading the refutation text. Concurrently, they made longer looks-back and looks-from the whole refutation text than the non-refutation text. In addition, readers devoted shorter first-pass fixations to the metatexts in the refutation text. At the same time, refutation metatexts were backtracked (looks-back) for longer. In addition, the information provided by scientific segments was re-fixated more while reading the metatexts in the refutation text (looks-from). Finally, refutation-text readers outperformed non-refutation text readers in learning the new scientific concepts.

Theoretical Framework and Aims

Conceptual change is shaped by the interplay of multiple factors, especially as related to the characteristics of students and instructional materials (Murphy & Mason, 2006; Sinatra & Mason, 2008). In academic contexts, the latter mainly regard written texts, as they are the primary medium for acquiring disciplinary knowledge. This study focused on the effects of a particular text structure, the refutational. A refutation text is one that acknowledges students' alternative conceptions about a topic, directly refutes them, and introduces scientific conceptions as viable alternatives (Alvermann & Hague, 1989; Hynd, 2003). Refutation text is considered powerful for science learning, which very often implies revising inaccurate ideas (Chi, 1992; Vosniadou, 1994). Research has documented that a refutation text is more effective than a standard text in learning physics (Hynd, 1998) and biology concepts (Mikkilä-Erdman, 2002), for students of elementary (Diakidoy, Kendeou, & Ioannides, 2003; Mason, Gava, & Boldrin, 2008), middle (Mason & Gava, 2007), high school (Qian & Pan, 2002), and college (Chambers & Andre, 1997). As these studies were mainly focused on the end product of refutation text reading, we adopted a process approach (Kendeou & van den Broek, 2007) to reveal what underlies the refutation text effect. Its greater effectiveness may be due to a peculiar type of global text processing (Hyßnä, Lorch, & Rinck, 2003) that it promotes. Recent studies have documented that refutation text facilitates reading the parts which challenge the reader's alternative conceptions (Broughton, Sinatra, & Reynolds, 2010) and sustains the co-activation of inaccurate and scientific conceptions (van den Broek & Kendeou, 2008). To extend current research, both theoretically and methodologically, we sought to go beyond these process data by examining eye movements, which have been proved useful in investigating the cognitive processing of text segments that are larger than a single sentence and span relatively long distances (Ariasi & Mason, 2010). In addition, eye movement analysis makes it possible to tap into the time course of cognitive processing during reading (Kaakinen, Hyßnä, & Keenan, 2003). Using this methodology, we have addressed the open issue of whether the refutation text effect encompasses a series of sub-processes with different time courses, taking place on different parts of the text and at different stages of reading. Assuming the superiority of refutation text, the following research questions guided our study: (1) What is the time course of the facilitation effect while reading the refutation text?; (2) What parts of the text are concerned with such a facilitation?; (3) Is the co-activation of inaccurate ideas and scientific conceptions actually greater during the reading of a refutation text? The related hypotheses were: (1) The effect of facilitation would take place during the initial processing of refutation text reading; (2) This facilitating effect would regard the refutation parts; (3) The refutation parts and those introducing the scientific conceptions would be co-activated more strongly, and the former would be used more as anchor points to integrate new information.

Method

Forty ($F=25$) undergraduates (age: $M=25.1$, $SD=4.7$) participated. Each participant was randomly assigned to a different reading condition according to a 2 (text: refutation, non-refutation) \times 2 (topic: tides, Darwinian theory of evolution) within-subject design. Both texts introduced four new concepts, each presented on a different page. For each concept the texts included metatexts (refutation, non-refutation) and scientific parts. Following Hyßnä and Lorch (2004), the scientific parts were further divided into three segments: introducing, medial, and end. Readers' conceptions about the topics were assessed through open-ended questions, before and after each reading. Five eye-movement measures were computed by ratio-per-character: first-pass forward, first-pass rereading, and first-pass fixation time, all reflecting the early processing of a text segment; look-back fixation time revealing the strategic behavior during reading; look-from fixation time unveiling the simultaneous processing of different text segments. These eye-movement indices were used as different levels of a variable named "processing". Data about 6,400 segment-level eye-movement durations were collected. These durations were log-transformed to control for the great inter-individual variability.

Results

Differences for prior-knowledge in the four conditions were not significant ($ps>.05$). Thus, prior-knowledge was not considered in the analyses. As assumed, the end product of reading showed that refutation text was more effective than the non-refutation, $F(1, 65)= 6.166$, $p=.016$, $n2p=.09$. To test our hypotheses, a within-subject ANOVA with text (refutation, non-refutation), topic (tides, evolution), concept (first, second, third, fourth), segment (metatext, introducing, medial, end), and processing (eye-movement measures) was performed. Log-transformed eye-movement durations represented the dependent variable. Results showed a significant text \times processing interaction, $F(4,5600)=2.976$, $p=.018$, $n2p=.12$. Participants made shorter first-pass fixations while reading the refutation text. Concurrently, they made longer looks-back and looks-from on the whole refutation text than on the non-refutation text (Figure 1). Furthermore, the text \times segment \times processing interaction was significant, $F(12,5600)=2.400$, $p=.004$, $n2p=.15$. Specifically, readers devoted shorter first-pass fixations to the metatexts in the refutation text. At the same time, refutation metatexts were backtracked (looks-back) for longer (Figure 2), and the information provided by the scientific segments was re-fixated more while reading the metatexts in the refutation text (looks-from).

In sum, as hypothesized, the facilitation effect produced by refutation text takes place during initial processing, regardless of the topic (Broughton et al., 2010). Readers are therefore able to save resources in the earliest stage of processing and invest them to re-read and integrate the new information to be learned. Additionally, inaccurate ideas and scientific conceptions are co-activated more while reading the refutation text (van den Broek & Kendeou, 2008). The former are also used more to integrate the new information.

Theoretical and Educational Significance

The study makes a scientific contribution to research by providing objective evidence that the refutation text effect takes place in different parts of the text and at different stages of reading.

From an educational point of view, the study indicates that the structure of an expository text for learning disciplinary knowledge plays an essential role. Although not all learning texts can have a refutation structure, it may be especially useful when complex phenomena must be understood by changing previous representations.

Situating conceptual change in the process of reading comprehension

Panayiota Kendeou, Neapolis University Pafos, Cyprus

Refutation texts have been found to have considerable potential for changing students' misconceptions. Most of prior research has observed such effects after reading is complete. The aim of the present study is to understand the mechanism by which refutation texts exert their influence during reading comprehension. To do so, we follow a three-pronged approach (cf. Magliano & Graesser, 1991). First, we form hypotheses with respect to readers' processing of scientific texts drawing on recent research in cognitive psychology and discourse processing. In particular, we use the conceptual framework of the Landscape model, in which many of the comprehension processes identified in cognitive research are integrated. Second, we perform simulations to test our hypotheses using the computational implementation of the Landscape Model (Tzeng, van den Broek, Kendeou, & Lee, 2005). Third, we collect empirical data using think-aloud, reading time, and eye-tracking methodologies on the reading process to compare with the computational data (Kendeou, 2010; Kendeou, Muis, & Fulton, in press; Kendeou & van den Broek, 2007; van den Broek & Kendeou, 2008).

The results show that texts that promote co-activation of misconception and correct information (i.e., refutation text) elicit fundamentally different comprehension processes in readers with misconceptions than do texts that do not promote co-activation (non-refutation text). The findings provide new insights in the underlying mechanisms that support change during reading and how situating the study of these change processes in current theories of reading comprehension can contribute to our theoretical understanding of conceptual change.

The aim of the present set of studies is to understand the mechanism by which refutation texts exert their influence during reading comprehension by situating their investigation in the context of current theories of reading comprehension. To do so, we follow a three-pronged approach (cf. Magliano & Graesser, 1991). First, we form hypotheses with respect to readers' processing of refutation texts drawing on recent research in cognitive psychology and discourse processing. In particular, we use the conceptual framework of the Landscape model, in which many of the comprehension processes identified in cognitive research are integrated. Second, we perform simulations to test our hypotheses using the computational implementation of the Landscape Model (Tzeng, van den Broek, Kendeou, & Lee, 2005). Third, in a series of studies we collect empirical data using think-aloud, reading time, and eye-tracking methodologies (Kendeou, 2010; Kendeou, Muis, & Fulton, in press; Kendeou & van den Broek, 2007; McCrudden & Kendeou, 2010; van den Broek & Kendeou, 2008).

Step 1: Forming Hypothesis within the Landscape Model Framework

The Landscape model was developed to capture the comprehension processes that take place during reading and their relation to the gradually emerging memory representation of a text. In the Landscape model, the various processes that take place at each point during reading reflect a balancing of the reader's limited attentional resources with the standard of coherence and comprehension that the reader –implicitly or explicitly– sets. As a result, as the reader proceeds through the text, concepts (propositions, informational units) fluctuate in activation: With each new cycle (e.g., sentence) some concepts continue to be active, others decline in activation, and yet others become newly (re)activated.

Step 2: Computational Simulations

In two sets of simulations we investigated the availability of information critical to comprehension during reading of refutation and non-refutation scientific texts. Two texts were used, each describing a common problem in Newtonian Mechanics. The texts were adapted from McCloskey (1982). These simulations revealed that refutation texts create optimal circumstances for co-activation of the misconceptions and correct conceptualizations (van den Broek & Kendeou, 2008).

Step 3: Empirical Evidence

The description of cognitive processes during reading comprehension and the simulations outlined above suggest that refutation texts may be effective because they create optimal circumstances for co-activation of the misconceptions and correct conceptualizations and, thereby, provide the foundation for further processing that differs fundamentally from the processing that takes place during reading of traditional, non-refutation texts. To determine whether such differences in processing indeed occur, we conducted four empirical studies on the on-line processing of refutation and non-refutation science texts by readers with and without misconceptions related to the topics of the text.

In Study 1, readers read the same texts as were used in the simulations, while performing a think-aloud task (Kendeou & van den Broek, 2007). In Study 2, readers read the refutation text or the non-refutation text on the computer, one sentence at a time in a self-paced manner (Kendeou et al., in press). In Study 3, readers read the refutation text or the non-refutation text while their eye-movements were recorded (Kendeou, 2010). In Study 4, a younger group of readers read the refutation text, and following a case-based approach, the time course of conceptual change was investigated (McCrudden & Kendeou, 2010).

The results from Study 1 showed that, for both refutation and non-refutation texts, readers with misconceptions generated more incorrect (difference in average number of inferences per text = 3.8, pp For refutation texts readers with misconceptions engaged in more conceptual change behaviors. The reading times for the sentences with the correct information (which conflicted with the prior knowledge of readers with misconceptions) in Study 2 showed that readers with misconceptions spent more time reading those sentences than did readers with no misconceptions but only when these sentences were included in a refutation text (difference = 104 ms, $p = .05$). For the non-refutation text the reading times of target sentences by readers with and without misconceptions did not differ (difference = 30 ms, $p > .05$). The results of Study 3 showed that readers made significantly more $F(1, 95) = 8.15$, $p = .005$ and longer $F(1, 95) = 10.12$, $p = .002$ forward fixations during reading the refutation sentence in the refutation than the non-refutation text. Also, readers made significantly more $F(1, 95) = 6.42$, $p = .013$ and longer $F(1, 95) = 7.28$, $p = .008$ look back fixations in explanation sentences in the non-refutation text version. These findings show that readers experience initial difficulty during reading of refutation sentences most likely due to the conflict between their misconception and the refutation (due to co-activation). This initial difficulty, though, assists readers in subsequent integration of the explanations of the misconception. Finally, in Study 4 the results of the case-based analysis showed that readers can undergo conceptual change during reading of refutation text and that these changes appear to be influenced by the degree of similarity between readers' conceptions and scientific conceptions.

Discussion

These results indicate that texts that promote co-activation of misconception and correct information (refutation text) elicit fundamentally different comprehension processes in readers with misconceptions than do texts that do not promote co-activation (non-refutation text). When reading the refutation texts, readers with misconceptions read the sentences with correct information more slowly (Study 2 & Study 3) and engaged in more conceptual change behaviors (Study 1 & Study 4) than when reading the non-refutation texts. Thus, the co-activation of misconceptions and correct information led readers with misconceptions to experience conflict (i.e., they detected the inconsistency between their prior knowledge and the textual information) and allowed them to engage in efforts to repair the conflict and create coherence. In contrast, readers with misconceptions who read text versions that do not promote co-activation did not slow down or engage in conceptual change behaviors anymore than did readers without misconceptions.

Reflections on the interpretation of collective interactions in learning and instruction

Chairperson: Patrick Sins, Leiden University, Netherlands

Organiser: Patrick Sins, Leiden University, Netherlands

Michaela Glaeser-Zikuda, University of Jena, Germany

Discussant: Petra Grell, University of Potsdam, Germany

Although the learning sciences still lack standard methods for analyzing learning and instruction, most studies comply with a traditional approach. This approach involves that particular relevant learning processes are deconstructed into analyzable units that are coded and subsequently correlated with other relevant (outcome) variables in a nomological network. The rationales underlying the substantial preference for this approach are cultivated by respectively a positivistic and a reductionist epistemological view that can be considered problematic. Firstly, it presumes that what people explicate in questionnaires, interviews or in dialogues provides a straightforward view into the nature of their learning. However, we need to consider that there is a two-way interaction between the nature of learning and the nature of what is represented in these measures and that the mechanisms and configurations of elements involved may differ structurally. Secondly, learning is a process that can be characterized as a dynamic system where interactions between its elements emerge, unfold, accumulate and refer back. This view is incommensurate with decomposing learning into isolated units of analysis. Consequently, there is an emerging need for alternative methodological approaches toward interpreting and analyzing learning. We have gathered three distinct scholars – from Germany, France and The Netherlands – who have all confronted the same challenge. We invited each of them to present their reflections on alternative approaches for interpreting learning. Our discussant, Petra Grell, who is not affiliated with any of these research programs, will synthesize the ideas and advances in this work and leads the discussion amongst the symposium's participants.

Potentials of qualitative content analysis for research on learning and instruction

Michaela Glaeser-Zikuda, University of Jena, Germany

Conducting empirical research in the field of learning and instruction is a highly complex task. It requires first, to find the most appropriate research methods to address our theoretically framed research questions. Second, those research methods and strategies need to be identified, designed, and applied to ensure that results produce reliable and valid answers to these questions. This presentation is focusing on a specific method for analysis of qualitative data. This method, called qualitative content analysis, has been widely applied in the field of research on learning and instruction, especially in studies focusing learning strategies, instructional quality, learning motivation and emotion, teaching competencies, and school effectiveness. Based on several examples from research on students' learning strategies and emotions, and instructional quality the ways in which data can be analyzed and interpreted by qualitative content analysis is illustrated. Finally, implications for how this approach may contribute to a better and deeper understanding of learning and instruction are discussed.

Levels of analysis in the interpretation of dialogues

Patrick Sins, Leiden University, Netherlands

This contribution attempts to engender and to illustrate an alternative approach to the interpretation of dialogues in collaborative learning settings, taking into account the movements across timescales as an additional dimension to the analysis of dialogues. Based on a critical reflection of quantitative content analysis, the argument is made that in order to understand how dialogue may contribute to collaborative learning, researchers need to understand how interactions occurring at different timescales connect. Based on the works of Lemke (2000; 2001), semiotic artefacts are proposed as the carriers of information that enable us to create coherence between distal interactions. Three levels of analysis are proposed that focus on respectively: (a) trajectories of the development of interactions over time (macro level), (b) patterns in artefact-mediated interactions (meso level) and (c) the ways in which concepts articulated become materialized in semiotic artefacts (micro level).

Many authors in the field of educational research have advocated quantitative content analysis for investigating collaborative learning (cf. Chi, 1997). This approach roughly involves that researchers interpret set of codes that have been assigned to segments identified in the verbatim transcripts of verbal interactions between people who had been engaged in achieving a particular collaborative learning task. The segment constitutes the unit of analysis and may vary from small to large, e.g. a word, an utterance, an episode or a thematic unit. The basic tenet of this approach is to generate models explaining how specific configurations of processes identified in the interactions between learners affect a particular outcome measure of what has been learned. In other words, this means that the analytic focus is on relating the systemic relations between forms of interaction at the one hand and qualities of learning outcome on the other (cf. Arnseth & Ludvigsen, 2006).

What is problematic in this method is the underlying reductionist view that considers the act of speech as a process that can be decomposed into isolated units of analysis. The meaning and functions of a coded segment cannot,

however, be treated as distinct and separable from other discursive acts that have occurred in the interaction. In contrast, communicative acts are by nature responsive to each other and at the same time they project possible responses in the future (Linell, 1998). Moreover, contributions to dialogue are made coherent by being related to some issue of current relevance that may be related back to something that had been explicated somewhere in the past. Thus, in order to understand how interactions between learners may contribute to collaborative learning, we as analysts need to carefully investigate the sequential unfolding of dialogues along different timescales (Lemke, 2000).

Every discursive act occurs on some timescale (Lemke, 2001). What is articulated here and now is constrained, facilitated and afforded by the discourse that has been typically taking place on longer timescales. In addition, the kinds of interactions that can happen depend on the kinds of processes occurring on shorter timescales. This means that a particular meaningful segment in the interaction that has been assigned with a code, is not only constituted by configurations of words articulated, but they are also constrained by being themselves part of longer timescale processes, such as talking about a specific topic or theme or participating in a particular discourse genre (cf. Bakhtin, 1986). Moreover, to make sense of how concepts introduced earlier in the interaction between learners are taken up and advanced later on, we need to zoom out to include interactions occurring on other timescales. Local coherence is achieved when interactions occurring on shorter timescales are constrained by these higher level processes occurring on longer timescales in such a way that patterns consistent with the constraints become manifest. Learning is an aspect of development on a longer timescale, which means that it is essential to investigate dialogues both in relation to articulations on the shorter timescale as well as in relation to patterns and trajectories in the discourse taking place on longer timescales.

How do articulations that occur on short timescales become embedded in and contribute to discourse on longer timescales? How can we investigate interactions between processes occurring on different timescales? Lemke (2000; 2001) proposed the concepts of heterochrony and semiotic artefacts to address these questions. Heterochrony involves the exchange of knowledge between timescales through the indirect means of people interpreting and making use of semiotic artefacts during interactions. These artefacts, such as notebooks, research reports or wiki-pages materialize knowledge that can subsequently be carried across several timescales serving to create coherences between distal events (Lemke, 2001, p.21). An implication for the analysis of dialogues of this stance, is that we need to focus on the role of these artifacts in order to move between timescales to make claims about collaborative learning.

This contribution will illustrate an alternative approach to the investigation of dialogues employing three levels of analysis that correspond to idiosyncratic timescales (i.e., macro, meso and micro). The data consists of the interactions between researchers and teacher-trainers that had occurred in a one-year project that focused on the collaborative development of curricular artefacts for advancing existing teaching practices. On the macro level, trajectories and developments in the interactions between project team members over time are described as well as the extent to which artefacts are taken up in subsequent meetings is investigated. On the meso level, collaborative learning was discerned in emerging patterns in the artefact-mediated interaction taking place over several episodes. These patterns were consisted of sequences of moves in the interaction that were found to be significantly higher than may be expected on the basis of the distribution of moves. The micro level analyses focused on particular concepts that were explicated during particular moves in the project team's interactions and that had been materialized into their artefacts. The contribution concludes with contemplating how qualitative with quantitative measures can be integrated to investigate the relation between interactions and object progression taking into account differences in timescales.

A significant area of research in the Learning Sciences involves studying collective activities in educational situations, and thus the attempt to analyse how meaning is co-created in and by communicative interactions. In this paper I want to deconstruct the very notion of such "analysis", taking as a point of departure the etymology of the term, as 'unloosening the bonds that hold together discrete elements'. My critique bears principally on difficulties involved in identifying the unit of analysis of collaboration, in ascribing univocal speaker-meanings and in studying fossilised thinking. Drawing on theoretical perspectives from sociology and anthropology (Geertz, Latour), I argue that in the human and social sciences, the relation between researcher and object of study is rather one of interpretation, i.e. an empathetic interactive encounter allowing the creation of meanings (rather than explanations). This leads on to a critique of the very paradigm of which interaction analysis is a part, from the point of view of complexity theory. In the second part of the presentation, I illustrate an approach to interpreting students' argumentation dialogues, based on articulating seven alternative perspectives. The paper concludes with remarks on the nature of dialogue as collective thinking and how it can be known scientifically.

A significant area of research in the Learning Sciences involves studying collective activities in educational situations. In the absence of perfect mutual knowledge in evolving situations, people have to communicate and to interact with each other, in order to work and learn together. It follows that the study of how meaning is co-created in and by communicative interactions is a central focus of research.

Within what has been termed the "interactions paradigm" in collaborative learning research (Dillenbourg, Baker, Blaye & O'Malley, 1996), the study of communicative interactions produced in educational situations has been conceived in terms of analysing different types of categories of interactions and correlating frequencies of categories with learning effects, as a means of identifying productive types of interactions.

I will argue that the study of communicative interactions occurring in educational situations should be conceived of as a process of articulating multiple interpretations and meanings, within a dialogue involving social actors, of which participants in those situations, and members of the relevant research community.

In the first section of this paper, my argument begins with a critical perspective on the interactions paradigm and the very notion of analysis of interactions that it incorporates. From the perspective of cognitive theories of dialogue (Allwood, Clark, Trognon), certain 'technical' problems arise with analysis of dialogue into discrete units. These include, firstly, segmentation into units, which from the very outset requires definition of the unit of analysis and the object of study. I shall argue, on methodological grounds, that the unit can not be individual thoughts expressed in dialogue (to paraphrase Edwards, 2003, dialogue is not a "window on the mind"), but can only be collective thinking, the set of elaborations of others' thoughts. This leads to the exchange being identified as the fundamental unit of collaboration and thinking. Further technical problems relate to multifunctionality (Bunt) and strategic indeterminacy (Edmondson, 1981), that should erode belief in the possibility of univocal analysis of units, however defined. Finally, on this level of technicity in interaction analysis, the very status of the corpus as a finished textual object, to be perused by the analyst, can be called into question, with respect to the idea of dialogue as a kind of processual "palimpseste" (Bouchard, 1988) that is continually overwritten. In the conclusion of this first section, I move to the level of the paradigm within which interaction analysis is situated. It involves an assumption of linearity: learning conditions engender (relate to, are correlated with, cause, etc.) specific types of interactions that in turn engender specific types of learning effects (conditions > interactions > effects). Such linearity is not tenable; and I shall explore the diverse ways in which "effects" exert influence on their "causes" (knowledge emerging from interaction transforms the nature of interaction; interaction is the locus of the transformation of the meaning of "conditions", etc.). This amounts to a view of context as interactively constituted rather than 'given', that has been magisterially elaborated by researchers such as Perret-Clermont and Grossen. At the end of this critical analysis of the interactions paradigm, I want to elaborate an alternative view, which amounts to saying that we should embrace interpretation rather than analysis; recognise that researchers, as human beings, have a privileged way of interpreting other human beings, that is different from the analysis (or separation into components) of inanimate objects such as sand and salty water. Scientific truth in this domain may well be what emerges, in a constructivist sense (Brouwer), from the scientific debate between interpretations (Latour), leading to some kind of 'thickening' of descriptions (Geertz), tending towards a limit. Validation of scientific interpretations is a matter of confronting explicit and publicly available views within a research community (pace "intercoder reliability ratings"). In a sense, this amounts to a restatement,

specifically anchored in a fundamental problem for the Learning Sciences, of the old debate between sciences of nature and sciences of the mind, between explanation and understanding (Dilthey, Weber; Naturwissenschaften vs. Geisteswissenschaften vs. Kulturwissenschaften).

In the second section of this paper, I shall try to give an illustration — albeit, a necessarily monological one — of what a dialogue between interpretations might be like, for the case of the study of students' argumentation dialogues occurring in collaborative problem solving situations in both natural and social sciences (cf. Baker 1996, 1999, 2002, 2010). Here, the dialogical proponents are not necessarily individuals (although proponents of certain theories will be referred to here), but rather interpretative viewpoints. The list is not closed; but I shall try to sketch out a general integrative vision of how students create meanings for the educational situations in which they find themselves and which they co-create, where they confront disagreements and controversies whilst confronting each other, drawing on the following viewpoints: dialectical, rhetorical, dialogical, epistemological, discursive, socio-relational, affective. What seems to be beginning to emerge from this epistemological dialogue is a vision of such educational interactions as a kind of tension-relaxation process (Andriessen, Baker & van der Puil, 2010), operating conjointly with respect to the plasticity of concepts, modes of reasoning and ways of relating to each other.

In conclusion to this critical and comparative analysis of interaction analysis and interaction interpretation, I shall try to sketch out a vision of what collective thinking in dialogue is, — or rather of dialogue as collective thinking — and to examine prospects for the elaboration of publicly expressed and evaluable, teachable, research methods for interpretation of students' dialogues.

SYMPOSIUM

Invited SIG

Education for a Global Networked Society: Online Collaborative Learning in Higher Education

Chairperson: Velda McCune, University of Glasgow, United Kingdom

Organiser: Anne Nevgi, University of Helsinki, Finland

Velda McCune, University of Glasgow, United Kingdom

Discussant: Jeroen Van Merriënboer, Maastricht University, Netherlands

This symposium aims to explore the relevance of online and blended collaborative learning as a means of educating students such that they will be able to participate effectively in a global networked society. The symposium will involve consideration of online collaboration across a range of subject areas and different international contexts. The papers which will be presented in this symposium offer both rich empirical findings and considered theoretical perspectives on students' experiences of collaboration. This provides a sound basis for discussion of how collaborative learning may contribute to students' development in ways which meet the particular demands of the 21st century.

Knowledge creating inquiry in customer projects

Hanni Muukkonen, University of Helsinki, Finland; Kari Kosonen, University of Helsinki, Finland

The study examines two higher education courses which involved students, teachers, and customers in multifaceted experiences of knowledge creation. Participants engaged in online collaborative knowledge creation within a blended learning environment. The knowledge creation approach to learning (Paavola et al., 2004; Hakkarainen et al., 2004) provides a theoretical tool to address learning and teaching organized around authentic problems and the development of shared knowledge objects, such as reports, products, and new practices. This approach directs attention to those aspects of social interaction and artifact-mediated activities which focus on the development of shared objects and the pursuit of novelty. To create an authentic mirroring of professional work practices, it appears necessary to design sufficient open-endedness and complexity for students' teamwork to generate unpredictable and both practically and epistemologically challenging situations. The investigation addresses the roles of technology-mediation, customer involvement, and guidance in developing effective knowledge creating inquiry practices.

The aim of the present study was to explore the kinds of knowledge creating inquiry processes higher education students take forward in course settings focused on complex customer projects. The pedagogical design, actual practices, and technology-use of two courses were investigated. The theoretical background of the study, the Trialogical learning approach (Paavola et al., 2004; Hakkarainen et al., 2004) places particular value on the development of various shared knowledge objects and artifacts as a central mechanism for fostering collaborative

knowledge-creation. It emphasises the interaction between collective and individual efforts on shared objects as well as pragmatic, epistemic, social, and reflective mediation (Rabardel & Bourmaud, 2003) for these processes. A virtual collaboration tool, the Knowledge Practice Environment (KPE) developed in Knowledge Practice Laboratory Project (see <http://www.knowledgepractices.info/>) was used as the virtual environment of the courses. The KPE has been designed to support collaborative knowledge creation: it provides various tools and functionalities for reflective and "object-centred" knowledge practices, such as planning and brainstorming about epistemic processes, producing texts, organising collaboration around knowledge objects as well as planning and reflecting on processes. The design of the tool is based on the design principles of the dialogical learning approach.

Two research questions are addressed: What kind of knowledge creation processes did the participants engage in during the investigated courses? How did the KPE-environment and its integrated analytical tools enable the participants to organize their work and artifacts as well as reflect on their working activities? The first setting which was investigated was the "Application development project" course organized at the Metropolia University of Applied Sciences. It aimed at promoting the learning of various professional practices featuring the development of business ideas, services and multimedia products taking place in professional practice. From the 11 teams taking part, 5 were included in the data-analysis. Representatives of 4 customer organizations were intensively involved in the process. In the second course which was investigated, "Humans, organizations and technology", students from the University of Helsinki and the Aalto University, School of Economics were organised into multidisciplinary teams. The teams worked on a project related to the psychology of economic behaviour for a customer organization, the Finnish Tax Administration.

Thirty students participated in the course, composing 6 project teams, a research team, and a coordination team. Data collected included the database materials from the KPE environment, students' answers to pre- and post course reflective questions, selected team interviews including stimulated recall of the use of the learning environment as well as teacher and customer interviews. In the first course selected teams' steering group meetings were video-recorded, as were both courses' lectures and customer feedback. A qualitative content analysis of the items created in the virtual working space of the teams was conducted to find out what kind of functions these items served. The answers to the reflective questions and interview data were analyzed. In the first course, students participated from 3 training programs, media engineering, industrial management and media and communications. The 5 multidisciplinary teams of 3-6 were observed to develop business plans, user stories, marketing strategies, prototypes, sales pitches, weekly team progress reports and software architecture to come up with an application and business in operation. During lectures students were introduced to the practices and methods used in business and application development. A proportion of the lectures were held by visiting experts coming from business settings. Working documents (templates) pre-structured with domain specific conceptualizations were provided by the teachers. The "steering group" for each team consisted of 1-2 teachers and 1-2 company representatives. They were held weekly in the first two periods, and every second week in the last period. The goal of the steering groups was to support the teams to address all relevant aspects of business planning, software development and acquiring users (and business revenue) for their application. In the second course, the project teams had members with business and psychology backgrounds. The teams worked jointly to produce research plans for the customer, including, for instance, data collection about initial attitudes towards tax-paying and interventional approaches for transforming these attitudes. Teams developed team flyers and rules, projects plans, presentations for the customer and final reports.

In their answers to the reflective questions, the vast majority of respondents described their experiences from the course in mainly positive terms pointing out that the course setting provided them with a window into real working life. The involvement of the company representatives in the first course was perceived to bring a particularly valuable perspective to the steering sessions that supplemented the teachers' guidance and positions. The working document templates mediated the participants' work on their projects, business ideas and products and the analysis of related problem spaces. The use of the KPE facilitated student teams to jointly develop their working ideas, organize related sub-tasks visually, explicate interdependencies of the produced knowledge artefacts, and to define and negotiate on roles, deadlines, milestones, and responsibilities. As the teams were relatively free to select their collaboration tools, we observed a large variation in the tools used. Although in both courses the teachers were able to follow team activities and artefacts in the KPE, nearly every second team in effect adopted other, often more familiar tools in their collaboration and only posted the necessary reports and outcomes in KPE. However, with the teams that did carry out their processes in the KPE environment, the teachers expressed that they would have valued and benefited from a similar overview of activities from all teams.

The use of these working document templates reflecting real professional practices and the company representatives' participation brought a strong cross-fertilization mechanism into the pedagogical setting of the courses. Overall, the investigated courses presented very demanding collaboration tasks for the students. They encountered epistemic and

pragmatic challenge related to the analysis and development of business ideas and applications or the research plans, and the management of workflow in teams. The outcomes were valued by the customers, suggesting potential of the knowledge creating inquiry practices in bridging between expectations of workplace practices and higher education.

Knowledge development and problem solving in practice: what students value in collaborative aspect

Samuel Edelbring, Karolinska Institutet, Sweden; Nabil Zary, Karolinska Institutet, Sweden; Lars-Ove Dahlgren, Linköping university, Sweden

The Dublin descriptors ("The joint quality initiative," 2010) emphasise sharing understanding with others. Professional work is also based on collaboration in knowledge use (Hutchins, 1995). Recently there has been increased interest in collaborative aspects of studying with computers (Koschmann, 1996). New ICT allows for more flexible use and educational practices change accordingly. We need knowledge on students' strategies regarding collaboration and to what extent we should encourage this formally in higher education. Col[®]lab[®]orating in the small group setting using computer applications is beneficial in most, but not all settings (de Leng, Muijtjens, & van der Vleuten, 2009; Lou, Abrami, & d'Apollonia, 2001). What reasons do students see for collaboration and how does collaboration contribute to student learning? We have been investigating two course contexts where students use computerised virtual patients (VPs) with the aim of understanding the functions of this technology for student learning. One context where collaborative work was designed into a clinical practice setting, another where collaboration was left to free choice in a course. Results from these studies will be presented and discussed from a collaborative learning perspective. Collaboration does not necessarily occur naturally among medical students. The relevance of collaboration in knowledge development and problem solving are identified by students when having worked in that setting. However, when given a free choice in "everyday study" the students opted for individual work. Motives for collaborative work need to be explicitly expressed and supported in course settings.

Introduction

There are political, societal and educational reasons for stimulating collaborative student work in higher education (HE). The Dublin descriptors ("The joint quality initiative," 2010) unite the different European countries in a common focus on learning outcomes in HE. For each of the three cycles within these descriptors there is an emphasis on students sharing their understanding with others with different perspectives. For example, in the 1st cycle it says: "can communicate about their understanding, skills and activities, with peers, supervisors and clients". The social dimensions of knowledge development and knowledge use in professional practice have also been pointed out (Hutchins, 1995). Work in the Computer Supported Collaborative Learning (CSCL) tradition has emphasised the social aspect of learning in educational research on the use of new technology for learning (Koschmann, 1996).

Changed practices

New technology is not only passively mediating information, but shapes our practices and the way we think (McLuhan & Fiore, 1967). We see this in society at large but also in HE. The technology we bring to education has consequences for educational practices. The formal education community is a driver in creating innovations; much of the ICT that we use has its embryonic start at universities. However, apart from innovators themselves and technology enthusiasts, the large majority of teachers seem reluctant to adopt new technology and innovations for learning until they are more commonly used. Everett Rogers (2003) describes uncertainty and perceived benefits as important to address in the integration of new practices within organisations. From Cuban's (1988) historical analysis of IT integration in schools in the USA we learn how important it is to involve teachers in the integration process of innovations. Students as well as teachers need to know "what's in it for them". A meta analysis of col[®]lab[®]orative learning when using computer applications, shows that the small group setting is beneficial for learning (Lou, Abrami, & d'Apollonia, 2001). We also need studies which clarify the benefits of new practices in ways which go beyond performance measures designed to suit previous practices. What reasons do today's students see for collaboration and how does collaboration contribute to student learning? Two empirical studies: technology resources allowing for student collaboration in medical education In medical education, as in many other disciplines, students' reasoning and elaboration around specific cases is of concern for educators. The collaborative aspect seems natural to use to bring in other perspectives into the elaboration or problem solving. However, our experience is that this collaboration does not occur naturally among students. We have been investigating two course contexts where students use computerised virtual patients (VPs) as learning tools for working with patient cases. The aims were to understand the functions of this technology for student learning. In the first context the collaborative work was designed into the course. In the other context students were left to choose whether to work individually or in collaboration. The first setting was a rheumatology clinic where medical students get early clinical experience during a stay of two weeks. A mandatory part of their stay was to work through 4 VP rheumatology cases. The 31 students were placed at the clinic in pairs and were encouraged also to work with the VPs in pairs which most of them did. When interviewed about the

VP experience, the pair-wise work, distinct from individual, but also from settings of 3 and 4 students working together, was highlighted as increasing their learning experience (Edelbring et al. submitted). Students expressed that case data was more elaborated and that they took different standpoints and argued for them in solving and managing the case when working in pairs. However, when comparing triad versus individual student computerised case work De Leng et al. (2009) found no difference between the two contexts regarding case elaboration. We intend to follow the collaborative work in this first setting more closely focusing on what happens in the interaction between students and VPs by using video observations and questions about the collaborative setting.

Research questions guiding that work are: What happens in the collaborative situation regarding knowledge development and reasoning? Is there an added value working with a peer in this activity? How do students describe that value? A case from that setting will be used to highlight these aspects. In the other setting medical students (n=247) were given VPs to work with in a clinical preparatory course. A web based login made it open to students to choose to work individually or collaboratively. Seventy-nine per cent of the respondents (161, rr=65%) chose to work individually. When asked for their preference on this 56% of the students preferred to work on their own (Edelbring et al., in preparation). The flexibility of this and many new learning tools allows for using them at any place, any time. In our investigation 65% used the tool at home, 19% at campus/hospital, 15% both at home and campus/hospital and two students (1%) at a café. The high numbers using the activity alone at home raises questions whether it is optimal use of this resource. Surely this depends on the kind of learning activity and its goal. The VP activity intends to enhance clinical reasoning and help to contextualise declarative biomedical knowledge. In case reasoning, collaboration seems, at least in pair-work, to stimulate case elaboration and enhancing the reasoning process. As future professionals students will also need to interact and collaborate not only with same discipline professionals, but also with other categories possibly taking different perspectives on their topic.

Conclusion

The relevance and benefits of collaborative aspects of knowledge development and problem solving are identified by students when having worked in that setting. However, when given a free choice in "everyday study" they opt for individual work. Motives for collaborative work need to be explicitly expressed and supported in course settings.

International Student Learning and Avatar Collaboration in an Immersive World

Howard Ramsay, University of Strathclyde, United Kingdom; Catherine Demangeot, University of Strathclyde, United Kingdom; Ray Land, University of Strathclyde, United Kingdom

This project brought together online, within the immersive world of Second Life, a small group of MBA students from 8 different locales in Europe, the Middle East and Asia (and from distinctively different cultures) to collaborate on various questions of International Marketing. The research aimed to ascertain how students and their facilitator felt about their avatar and about mediating their interaction through an avatar. Did it help or impede communication, involvement and collaboration? The facilitator was not aware of the real identity of the avatars at any point during the research. The avatars' relative genderlessness and culturelessness meant that the communication with each avatar was not affected by awareness of differences between high? and low?context cultures (Hall, 1973). A related issue was whether trust could flow through avatars in the same manner that it does between students. The virtual environment appeared to change the 'rules of engagement' between avatars, primarily as a result of the absence of body language cues, and the contextlessness and culturelessness of the avatars. The resulting findings from this project are now informing the design of a follow-up study in collaboration with the Canadian Civil Service.

Introduction

The idea of immersive learning environments is seductive for higher learning institutions whose co?producers of learning (students, academics and tutors) may be spread around the world. Such immersive worlds as Second Life offer the opportunity of bringing together, in one – virtual – world, people residing in different locales, achieving increased student interaction and enabling them to network internationally, at a very low cost. In immersive worlds students might also experiment and play, comforted by the anonymity afforded by the mediation of an avatar. This can enhance the social interaction of a virtual community, while avoiding the mainstreaming and inhibiting aspects of real learning communities. The project aimed to investigate the potential of immersive environments in bringing together students from different centres or cultures. It entailed the development of a pilot learning environment on Second Life and its deployment in two different learning situations. The research project was supported by a Teaching Research and Development Grant from the Academy of Marketing and the UK Higher Education Academy Subject Centre for Business Management Accountancy and Finance.

Principal objectives

The project's principal objectives were: To research and test the practical requirements of setting up immersive learning environments; To develop an immersive environment and customise it to the needs of two learning events; To investigate how students of a different culture react to learning in an immersive environment; To investigate how student avatars negotiate collaboration in an immersive learning environment. Theoretical background The project explored interaction in an immersive environment and the effect of being given freedom to experiment and play? While in reality people are at their desk, in front of a computer screen, telepresence, facilitated by both the interactivity and the vividness of the medium (Steuer, 1992), enables them to feel part of a remote environment. Websites can also convey social presence, or a feeling of warmth and sociability (Gefen and Straub, 2003). Therefore, immersive learning environments could be propitious to student involvement and student collaboration. Educators have also noted that virtual learning communities lead to greater collaboration and more even participation (Falloon, 2010; Hansen, 2008). This may happen through the sense of belonging to a virtual community (Peltier, Drago and Schibrowsky, 2003). Virtual worlds deprive their visitors of cues as to the reality behind the world represented on their screen, thus potentially confusing their sense of the real and the virtual (Bayne, 2008). However, the 'non?real' nature of immersive learning worlds may also facilitate learning in new ways. In particular, anonymity may prevent emotions such as shyness, self?consciousness or fear of embarrassment from inhibiting student participation. Learners can make mistakes safely (Tambone et al, 2009). For these reasons, in spite of the absence of important cues and the uncertainties associated with participation in a non?real environment, the co?production of knowledge may be made easier in an immersive world: students may feel freer to ask for help or provide help since their behaviour will not have consequences on their permanent identity.

Method

Two virtual seminars were organised, to which the University's executive offshore MBA students, residing in 8 different locales in Europe, the Middle East and Asia, were invited on a volunteer basis. Interested students contacted the technologist (they remained anonymous to the facilitator). They were matched to an avatar whose first name was the name of a Scottish town – so as to avoid revealing students' gender or ethnicity. Students were offered a short one?on?one initiation session to Second Life, during which they could test audio and navigation. A total of seven students participated in the study: three in the first seminar, four in the second. Issues investigated The research aimed to ascertain how students and facilitator feel about their avatar and mediating their interaction through an avatar ?? does it help or impede communication, involvement and collaboration? The facilitator was not aware of the real identity of the avatars at any point during the research. The avatars' relative genderlessness and culturelessness meant that the communication with each avatar was not affected by awareness of differences between high- and low-context cultures (Hall, 1973). A related issue was whether trust can flow through avatars in the same manner that it does between students. The virtual environment appeared to change the 'rules of engagement' between avatars, primarily as a result of the absence of body language cues, and the contextlessness and culturelessness of the avatars.

Conclusion

The presentation will explore the methodology in further depth and then report on the project's findings regarding students reactions to participating in this multicultural initiative. It will explore the opportunities offered by this manner of online collaboration as well as its distinct constraints. Future research could consider whether avatars in immersive environments are particularly suited to learning situations dealing with controversial topics. While several students stated that the anonymity of their avatar did not make a difference to what they said, social desirability may have affected their response. A follow up project is currently being organised in collaboration with Dalhousie University and the Canadian Civil Service to explore the matters further.

SYMPOSIUM

Invited SIG

Learning and Development in Early Childhood

Chairperson: Marja-Kristiina Lerkkanen, University of Jyväskylä, Finland

Organiser: Marja-Kristiina Lerkkanen, University of Jyväskylä, Finland

Miriam Leuchter, University of Munster, Germany

Discussant: Paul Leseman, Utrecht University, Netherlands

Number of previous studies has shown that the high quality home and pre-school environments in early years provide children's later learning and development. Drawing on the recent research in several countries using a range of methodologies, contributors of this symposium will present and discuss evidence for the importance of home environment, teacher support and classroom quality and child's own engagement with teachers, peers, and tasks in relation to child outcomes. This symposium seeks to address these questions through three papers on large-scale

early childhood studies conducted in England, Finland and US. The British study investigates whether high quality home environment at early years enhance children's later development and learning. The Finnish study focuses on the effect of classroom quality (i.e., emotional, instructional and organizational support) in preschool for children's motivation and academic and social skills development. Finally, the study from US explores preschool children's engagement with teachers, peers, and tasks in relation to language and literacy gains over time. The discussion will highlight the need for triadic perspective on child's learning and development in early childhood and why improving the quality of parenthood, classroom practices and teacher-child interaction in classroom should be a priority in early childhood.

The Effects of Parents and the Home Learning Environment on Children's Development and Learning

Iram Siraj-Blatchford, Institute of Education - University of London, United Kingdom; Pamela Sammons, University of Oxford, United Kingdom; Edward Melhuish, University of London, United Kingdom; Kathy Sylva, University of Oxford, United Kingdom; Brenda Taggart, University of London, United Kingdom; Aziza Mayo, University of London, United Kingdom

This paper examines quantitative (N = 3000+ children) and qualitative data for the Effective Provision of Preschool Education (EPPE) project during the first five years of this longitudinal study, supplemented with some in-depth case studies conducted five years later (N=50 cases) with some of the children and families with interesting learner trajectories. The early HLE as reported by parents in the pre-school period was found to exert a strong and significant net impact on intellectual development and a weaker positive impact on aspects of social behaviour at earlier time points, even when parental education, SES and income are controlled. Aspects of the HLE experienced by children as reported at age 3 continue to show significant positive effects on attainment and social behaviour at age 7 years plus, net of the influence of child and parental background influences such as family SES and mothers' qualification levels. For example, parents reading to their child, teaching/playing letters and numbers, visiting the library, and teaching songs and nursery rhymes continues to be related to better outcomes at age 6 and 7 years. Our quantitative and qualitative data show that boys and girls have significant differences in the early HLE they experience, with boys tending to have lower scores on HLE and less educational and self-regulation experiences at home. Such differences in parenting may account for gender differences in cognitive attainment and social behaviour. The results on HLE confirm that such experiences remain statistically significant predictors of later educational outcomes at age 7 years.

The Aims

Learning happens in social contexts and is often contingent and embedded in the child's earliest experiences. The contribution of parents and families is well recognised as a driver for children's development and learning, yet many studies focus on only the effects of pre-school and later stages of education. Other papers in this symposium look at the impact of pre-schools and teacher interactions. The Effective Provision of Pre-School Education (EPPE) project is the first major European longitudinal study of a national sample of young children's development between the ages of 3 and 7 years. We asked:1. What is the impact of pre-school on children's intellectual and social/behavioural development?2. Are some pre-schools more effective in promoting children's development?3. What are the characteristics of an effective pre-school setting?4. What is the impact of the home on children's development?5. Do the effects of home and pre-school continue through Key Stage 1 (age 7 years)?This paper will only focus on aim 4, the contribution of the early home learning environment (HLE).The qualitative case studies gave us information to the question of why parents choose to provide their children with a strong or weak early HLE. This makes the study unique in answering some of the what, how and why HLEs contribute or not to children's learning and whether the impact is lasting.

Methods

The impact of the early home learning environment at age 3+ on children's development to age 7Interviews were conducted with 3000+ parents when their child entered the study at 3+ (with follow-up questionnaires when the children were in school). These were used to collect detailed information about childcare histories, characteristics of children, their families and home education environments. In addition we collected teacher and psychometric child assessments and pre-school and school information. This wealth of information has enabled the research study to investigate some of the influences affecting young children that have a significant relationship with their later intellectual and social/behavioural development. These factors clustered around demographic influences, the home learning environment and patterns of childcare before entering the study. EPPE uses statistical techniques (multilevel modelling) to measure the influence of different background factors on young children's attainments at the start, middle and end of primary school. Qualitative interviews were conducted with 50 carefully sampled children and their parents when children were in secondary school to get behind some of the reasons why parents offered strong or

weak early and later HLEs and how these experiences persisted and influenced later learning. These qualitative data were analysed using NVivo software.

Findings

The EPPE research points to the importance of a young child's HLE. Although other family factors such as mother's qualification level and family SES are also highly significant, the 'Home Learning Environment' exerts a significant and independent influence on attainment at both age 3 years plus and later at the start of primary school (rising 5 and 7 years) and progress during this pre-school period. Aspects of self-reported parental involvement in activities (such as reading to their child, teaching songs and nursery rhymes, playing with letters and numbers, visiting the library, painting and drawing, etc.) remain significant positive influences which account for differences in attainment and also influence young children's cognitive progress over the pre-school and early primary period. The study also shows that the HLE index we created (measuring the extent of different activities involving the child at home) is only moderately correlated ($r = 0.3$) with family SES or mother's qualification levels. EPPE demonstrated a strong relationship between children's outcomes and parental factors but this was somewhat weaker for their social/behavioural development than for cognitive. Research has consistently indicated that there are strong associations between certain factors related to disadvantage (such as low socio-economic status or SES, low income, mother's educational levels etc.) and children's poor intellectual attainment at school. However, few large-scale research studies have been able to explore the very wide range of background factors considered in the EPPE study, especially daily activities in the home. The qualitative follow-up case studies showed that for children from low SES families who academically succeeded against the odds, these early HLE experiences were often strong, particularly for boys. Even in those cases where frequency was low due to parent's need to work long hours outside the home, need to care for relatives and limited financial resources, we found that the quality of interactions was still high, i.e. providing children with informal learning experiences that prepare them for classroom interactions and academic learning. Parents and children felt strongly that these early HLE experiences had helped them bond and had provided children with a sense of awareness of the value for school and learning at a young age. Our quantitative and qualitative data show that boys and girls have significant differences in the early HLE they experience, with boys tending to have lower scores on HLE and less educational and self-regulation experiences at home. Such differences in parenting may account for gender differences in cognitive attainment and social behaviour.

Theoretical and educational significance

What parents and carers do makes a real difference to young children's development. The EPPE project developed an index to measure the quality of the home learning environment (HLE). There are a range of activities that parents undertake (outlined above) with pre-school children that are related to a positive effect on their development. These activities could also be viewed as 'protective' factors in reducing the incidence of SEN because children whose parents engaged regularly in home learning activities were less likely to be at risk for special educational needs. Poor families/parents with few qualifications can improve their children's progress and give them a better start at school by engaging in activities at home that engage and stretch the child's mind. This has important implications for programmes in England and beyond for such programmes as Local Sure Start and Children's Centres that target areas of high social disadvantage.

The Effects of Classroom Quality on the Development of Motivation and Pre-Skills in Preschool

Anna-Maija Poikkeus, University of Jyväskylä, Finland; Marja-Kristiina Lerkkanen, University of Jyväskylä, Finland; Helena Rasku-Puttonen, University of Jyväskylä, Finland; Eija Pakarinen, University of Jyväskylä, Finland; Martti Siekkinen, University of Eastern Finland, Finland

This paper reports findings from a large scale longitudinal follow-up conducted in Finland. Preschool year data on motivation, mathematics, pre-reading, and social skills were available for approximately 1300 6-year-old children. Observation data were collected from 49 preschool classrooms using the Classroom Assessment Scoring System (CLASS; Pianta, La Paro, & Hamre, 2008). In the present analyses we report on the predictive relationships between indicators of classroom quality (i.e., emotional, instructional and organizational support) as assessed by the CLASS, and children's early motivation and skill development. The results of the multilevel modeling at the classroom level showed, first, that the higher the level of instructional support observed in a particular classroom, the less children were rated as showing task-avoidant behavior, and the lesser the level of children's task-avoidant behavior in a particular classroom, the higher were their math skills. Second, the higher the level of classroom organizational support observed in a particular classroom, the higher the children's learning motivation shared among the class members, and, further, the higher the level of learning motivation in a particular classroom, the higher were children's pre-reading skills. Finally, the higher the level of instructional support observed in the classroom, the more empathy and less disruptiveness the children displayed in that particular classroom. These predictive links suggest that

children's learning motivation is sensitive to classroom quality, and motivational factors may have a mediating role between classroom practices and skill development.

The Aims

Three domains of classroom quality, i.e., emotional support, classroom organization, and instructional support (Pianta, La Paro, & Hamre, 2008) have been differentiated as having documented links with children's developmental outcomes in early year education. High instructional quality, for instance, has been found to be associated with the children's classroom engagement (Downer, Rimm-Kaufman & Pianta, 2007), academic outcomes (Hamre & Pianta, 2005; Mashburn et al., 2008), as well as more positive interactions with teachers and peers (NICHD, 2002). Although motivational factors are known to form cumulative cycles with academic skills and school performance the effects of classroom quality have thus far rarely been examined with respect to children's motivation. Task-focused versus task-avoidant behavior and children's interest in subjects, tasks and activities are among the motivational constructs that have an important role in children's academic achievement and performance. Task motivation has been found to predict the development of math and reading skills among children (e.g. Aunola, Nurmi, Lerkkanen, & Rasku-Puttonen, 2003). The three substudies reported in the present paper aimed to add to the understanding of the effects of classroom quality as assessed by the CLASS (Pianta et al., 2008) on the preschool-age children's motivation (task-avoidance, and preschool learning motivation) and skill development (mathematics, pre-reading, and social skills). Research questions were: Study 1: To what extent do observed preschool classroom quality dimensions predict children's task-avoidant behavior and math skills in preschool? Study 2: To what extent do observed preschool classroom quality dimensions predict children's learning motivation and pre-reading skills in preschool? Study 3: To what extent do observed preschool classroom quality dimensions predict classroom differences in children's social competence?

Methods

Participants.

The children represent a whole age-cohort from three municipalities, two of them located in Central Finland and one in Eastern Finland. Children's data was available for 1,268 (613 girls, 655 boys) preschoolers ($M = 73.58$ months old, $SD = 3.40$ months). Of the altogether 137 preschool teachers, a subsample of 49 preschool teachers participated in the classroom observations.

Children's motivation.

The measure of task-avoidant behavior was based on teacher ratings (5 items rated on a 5-point scale) of the behavior of each child in their class using the Behavior Strategy Rating Scale. The measure of children's preschool learning motivation was based on the Content Interest Rating Scale for Children (7 items rated on a 5-point scale) which was individually presented to the children.

Children's skills.

Children's math skills in the preschool Fall were assessed by using a Number Sequences test, and in the preschool Spring by using a Number Concept test and an Arithmetic test. Children's pre-skills in reading were assessed in the preschool Fall by using two subtests, Initial Phoneme Identification and Letter Knowledge. Phonological awareness in the preschool Spring was assessed using the same Initial Phoneme Identification test. The teachers rated each child's social competence using the Multisource Assessment of Social Competence Scale which consists of 15 items assessed on a 4-point rating scale and provides the following four sub-scale scores: Cooperation, Empathy, Impulsivity, and Disruptiveness.

Classroom observations.

The classrooms were observed using the Classroom Assessment Scoring System (Pianta et al., 2008). The CLASS consists of ten dimensions measuring three components of classroom quality: Emotional Support (4 dimensions), Classroom Organization (3 dimensions), and Instructional Support (3 dimensions). Each dimension was rated on a 7-point scale: low (1, 2), moderate (3-5), and high (6, 7) quality. Observation was carried out in 30-minute cycles in two separate days in each classroom (total number of the cycles was 10-12 per classroom).

Analysis.

Multilevel modeling was used which enables the variance in the observed variables to be divided into variation due to differences between different classrooms (between class variation) and variation due to individual differences after taking into account class membership (within- class variation). Since the missing data proved to be missing-at-random, statistical analyses were carried out using the full-information maximum likelihood estimation (FIML), which allows all the information available to be used without imputing data. In all studies, intraclass correlation coefficients were first calculated to determine the between-classroom variation in the skill and motivation measures. After that separate

multilevel models were run for the three CLASS domains to determine whether the observed classroom quality indicators would predict classroom differences in children's motivation and skills, after controlling for factors such as maternal education, child's gender, child's age, and pre-skills.

Findings

Study 1: Instructional support in the classroom was found to be associated with children's task-avoidant behavior: the more instructional support the teacher provided in a classroom, the less task-avoidant behavior children were showing. Furthermore, the lesser the level of children's task-avoidant behavior in a particular classroom, the higher were their math skills, even after controlling for entry level math skills. Emotional support and classroom organization correlated also negatively with teacher-rated task-avoidance, but the modeling failed to find statistically significant associations. Study 2: The results of multilevel modeling showed that high classroom organization predicted high learning motivation in children, and that children's learning motivation contributed to their level of phonological awareness in preschool. Study 3: High quality of instructional support was found to predict high levels of empathy and low levels of disruptiveness among children.

Theoretical and educational significance

The results of the present study add to the previous research by showing that children's achievement-related behaviours are sensitive to the quality of teacher-child interactions in the preschool classrooms. Support for the development of children's motivation and learning strategies clearly deserves more attention already in preschool. In our recent analyses we have used a microanalysis on a subset of videorecorded classroom learning sessions selected based on CLASS ratings of high instructional support. These analyses have identified patterns of teacher-student interaction with dialogical exchanges, and provided understanding of the means through which the preschool teachers foster educational dialogue (e.g., encourage children's participation and diverse contributions, and allow space for child-initiated sharing of ideas).

Language and Literacy Development in Preschool: Children's Engagement with Teachers, Peers, & Tasks

Jason Downer, University of Virginia, United States; Virginia Vitiello, University of Virginia, United States; Amanda Williford, University of Virginia, United States; Natalie Bohlmann, University of Virginia, United States

This study examined preschool children's positive and negative engagement with teachers, peers, and tasks in relation to language and literacy gains over time. During the fall, 381 diverse preschoolers (3 - 5 years old) were observed and rated on their classroom-based positive and negative engagement with teachers, peers, and tasks. Assessments of receptive vocabulary and expressive vocabulary, as well as teacher ratings of language and literacy and classroom communication were collected in the fall, spring, and fall of the following year (preschool or kindergarten). Positive engagement with teachers and tasks were associated with higher initial receptive vocabulary, language and literacy, and classroom communication, while negative engagement with teachers and peers was associated with lower initial classroom communication. Positive engagement with peers was associated with greater gains in teacher-rated language and literacy across the study period. Implications for fostering language and literacy through classroom engagement will be discussed.

The Aims

Studies have shown that supportive classroom-based interactions are important for fostering children's school readiness outcomes, including early language and literacy (Burchinal et al., 2008; Connor, Son, Hindman, & Morrison, 2005). However, research on classroom processes has focused primarily on understanding how teachers promote positive engagement in classrooms, de-emphasizing the role that children have in creating their own learning environments. According to ecological systems theory, children are active in shaping their own experiences; children's unique approaches to engaging with other people and with learning materials contribute significantly to their classroom experiences and to the acquisition of skills across both academic and social-emotional domains (Bronfenbrenner, 1979; Ladd, Birch, & Buhs, 1999). Thus, examining how individual children engage with classroom experiences is important to understanding how preschool contributes to early learning. The current study examined how individual children's classroom engagement in four domains (positive engagement with teachers, peers, and tasks, as well as negative classroom engagement) was related to the development of early language and literacy skills in an economically and linguistically diverse sample of preschoolers. Specifically, this study considered whether positive and negative engagement observed in the fall could forecast the development of language and literacy skills into the following school year.

Methods

Participants. Participants were 381 children enrolled in 103 preschool classrooms within a large urban area in the southwestern US. Children were largely Hispanic (66%), with the second largest group being white (14%). Fifty percent of the children were girls. Children's ages at the start of the study ranged from 25 - 61 months, with an average of 46.8 months ($SD = 6.7$). The average income-to-needs ratio, calculated by dividing each household income by the federal poverty level for households of the same size, was 1.7 ($SD = 1.5$); 48% of households had ratios lower than one, indicating that they lived below the poverty line. English was spoken in the majority of homes (61%), but Spanish was also a common home language (65%).

Measures and Procedure.

Children were observed in the fall of preschool using the Individualized Classroom Assessment Scoring System (inCLASS; Downer et al., 2010), an observational measure that yields scores of children's positive engagement with teachers, positive engagement with peers, positive engagement with tasks, and negative classroom engagement (including conflict with teachers and peers as well as difficulty matching classroom expectations in terms of activity level and noise). Each child was observed for an average of four, 10-minute cycles across a morning. Scoring was completed after each observation cycle, and summary scores were created by averaging across the observation cycles. Inter-rater reliability data were collected in 22% of classrooms and yielded an average intra-class correlation of .85. Children were administered two direct assessments of language: The Picture Vocabulary subtest of the Woodcock-Johnson III Tests of Achievement (Woodcock et al., 2001) for expressive language, and the Peabody Picture Vocabulary Test (Dunn et al., 1997) for receptive vocabulary. Teachers rated children's language and literacy skills using the Academic Rating Scale (NCES, 2000); and their classroom communication skills using the California Preschool Social Competency Scales (CPSCS; Levine, Elzey, & Lewis, 1970), which assesses children's ability to follow instructions and communicate verbally. Children's language and literacy were assessed in the fall and spring of a single year of preschool as well in the fall of the following year, which was the start of kindergarten for 66% of the children and the second year of preschool for the remainder. Findings Growth models were used to determine whether aspects of children's classroom engagement were related to initial levels and growth in the language and literacy outcomes. Results indicated that positive engagement with teachers was positively associated with initial levels of teacher-rated language and literacy ($b = .21$, $SE = .09$, $p = .04$, $SE = .02$, $p = 3.02$, $SE = 1.44$, $p = .11$, $SE = .05$, $p = -.18$, $SE = .08$, p

Theoretical and educational significance

The study provided preliminary evidence that child-level learning processes are associated with language and literacy development among diverse preschool children. Children who were observed to engage more positively with teachers and tasks, as well as those who refrained from engaging negatively with teachers and peers, had higher initial levels of receptive vocabulary, language and literacy ratings, and classroom communication ratings, and maintained their advantage across the study period. Additionally, children who engaged more positively with peers made greater gains in language and literacy ratings across the study period. These results underscore how important it is for teachers, and for individuals who support teachers' work (e.g., mental health consultants, program directors), to recognize that providing opportunities for children to engage in a variety of high quality interactions daily can contribute to the development of children's school readiness. Carefully observing how a child interacts with other children, adults, and learning opportunities in the preschool classroom can potentially help teachers determine how to best support an individual child's development within the early education classroom environment. Future research is needed that further examines the variability of children's engagement in preschool and how this variability is related to children's learning.

SYMPOSIUM

Educational Effectiveness

Networks and education in resource-scarce schools

Chairperson: Susan Jones, Exeter University, United Kingdom

Organiser: Debra Myhill, Exeter University, United Kingdom

Discussant: Judy M. Parr, University of Auckland, Faculty of Education, New Zealand

The aim of this symposium is to illustrate how teachers establish, access and maintain social networks as ways of addressing adversity in resource-scarce school-environments to buoy resilience. Social capital is used as overarching theoretical lens. Whereas the first two presentations share knowledge co-constructed during intervention-based research with teachers in school-settings, the last paper presents an overview of existing knowledge on teachers' own resilience as outcome of supportive networks. Insights contribute to scholarship related to education in developing

contexts, and the way networks can serve as resources to mediate adversity and scaffold education-related resilience in resource-scarce settings.

A web of resilience: teachers promoting resilience in schools

Liesel Ebersohn, Unit for Education Research in AIDS, South Africa

Schools can serve as access points for the delivery of care and support to vulnerable members of communities. I explain how teachers in schools function as resources to buoy resilience in the face of cumulative adversities by drawing on participatory reflection and action data from a longitudinal study with teachers (n=57, 5 male, 52 female) from six schools in three South African provinces. The study tracks teachers' psychosocial support following their participation in STAR (Supportive Teachers, Assets and Resilience).

Schools can serve as access points for the delivery of care and support to vulnerable members of communities. I explain how teachers in schools function as resources to buoy resilience in the face of cumulative adversities by drawing on participatory reflection and action data from a longitudinal study with teachers (n=57, 5 male, 52 female) from six schools in three South African provinces. The study tracks teachers' psychosocial support following their participation in STAR (Supportive Teachers, Assets and Resilience). Following thematic analysis of verbatim interview transcriptions three themes (as well as sub-themes and categories) emerged: firstly teachers use resources to promote resilience in schools (teachers use: (a) systems to identify and refer vulnerable cases, and (b) neighbourhood health and social development services), secondly teachers form partnerships to promote resilience in schools (teacher-partnerships include: (a) children and families, (b) community volunteers, and (c) community organisations, businesses and government), and lastly vulnerable individuals using offered school-based support (using (a) vegetable gardens, (b) emotional and health support, and (c) capacity development opportunities). Teachers can promote resilience in schools by establishing networks with service providers functioning across systems to support vulnerable groups. The core of systemic networks is relationships, relationship-driven support networks mediate the effects of cumulative risk and school-based networks enable schools to function as resilience-promoting resources.

From baseline data in a longitudinal study intervention (STAR, Supportive Teachers, Assets and Resilience) it was apparent that teachers had not identified and used community resources prior to STAR. Teachers expressed concern about levels of poverty, illness, absenteeism and fear related to HIV&AIDS in the respective school-communities. Even more apparent however was a sense of teachers being overwhelmed by the magnitude of needs. I provide evidence of how teachers accessed social capital to mediate the effects of adversity and promote resilience in schools. The guiding question is: How do teachers in cumulative risk school-settings promote resilience by implementing what they have learned from a strength-based intervention?

I report on the initial four schools (40 teacher participants) involved in the development/pilot phase (2003-2006), as well as the first two schools (17 teacher participants) involved in determining the fidelity of STAR (2007-2009) - totalling six schools (57 teacher participants).

Data collection and analysis was participatory and iterative with data sources for this paper limited to verbatim transcriptions (focus groups, interviews). We combined focus groups and individual interviews with PRA-interactive activities. Research activities focused on: (1) obtaining baseline data in each school (observation and focus group on first site visit), (2) implementing STAR, (3) data collection to explore the promotion of resilience, (4) member checking of data analysis, and (5) monitoring and evaluation. Focus groups, interviews and observations were guided by the following questions: (1) Which risks can be identified in the school/community?; (2) Which resources can be identified in the school/community?; (3) How do teachers mediate risks by relying on identified resources?; and (4) How and by whom is teacher-initiated school-based support used?

Teachers opted to establish mechanisms and processes that function to modify the effect of a cumulative risk. Protective processes teachers instituted to ameliorate adversity, on the one hand, assessed risk that increased children's response to adversities (rendering them more vulnerable), and on the other hand assessed available resources (structures to mediate). Teachers' modus operandi post-intervention was to (1) identify available assets and relevant risks; (2) initiate partnerships with people related to these assets in order to provide psychosocial support; (3) establish school-based community systems to identify vulnerability; (4) refer children and families for support to pertinent partners in the community systems, and (5) maintain and monitor partnerships.

Neighbourhoods have been identified as influential environmental resource, and the current study supports the role teachers can play in identifying, mobilising and linking resources to promote resilience through networks.

Characteristic of ecological perspectives on resilience the networks were systemically integrated, collaborative and referred vulnerable individuals to either community systems or on-site networks at schools.

Teachers expanded the framework of resilience using partnerships to link individual-level resources (e.g. teacher compassion and commitment), social-level resources (e.g. parents' willingness to cultivate gardens) and societal-level resources (e.g. school leadership, small businessmen, clinics and social workers). This finding corresponds with other development studies signifying networks, collaboration and partnerships as central to strength-based interventions. Significantly networks 'liberated' teachers to function in their primary roles as facilitators of teaching and learning, with teachers continuing to support resilience in collaboration with partners, via networks.

Relationships were central in teacher support. Teachers used relationships to: access and mobilise identified resources for addressing identified needs, and to establish and maintain networks. I contend that relationships are resilience-promoting resources that teachers use when promoting resilience. This finding echoes that of other studies indicating relationships as essential for strength-based capacity development. Partnerships, networks and relationships signal social capital.

Teachers and schools can mediate risk in resource-stretched environments. Amongst other factors (including teacher disposition, available resources), teachers' provision of psychosocial support is one catalyst for schools to potentially function as resilience-promoting resources. Significantly children, youth and families made use of tendered support demonstrating reciprocity and the value of protective resources. This finding support studies showing that available resources can be mobilised and accessed to promote resilience.

Like others I found that school-community collaboration significantly promotes resilience. Teachers used schools (as a social environment-resource) to direct the establishment of supportive communities, through partnerships. In cumulative risk school-contexts, teachers used partnerships to establish school-linked services and situate social and health services for children and their families in school-sites. In this way teachers and school-level resources were expanded as resilience experiences to thrive beyond supportive peers, positive teacher influences and success experiences as previously found. Teachers promote resilience by making the most of social capital to identify and harness community resources, thereby buoying vulnerable children. These relationship-driven support networks mediate the effects of cumulative risk. Relationships constitute the core of such systemic networks. School-based networks by teachers in partnership with others enable schools to function as resilience-promoting resources. A strength-based approach can enable teachers to establish and sustain networks across systems.

Portraits of care and hope: How teachers perform support in vulnerable school communities.

Estelle Swart, Stellenbosch University, South Africa

The time-honoured conventions of schools and classrooms are becoming obsolete as the political, economic, social and educational needs of society rapidly change. These changes challenge teachers and schools to not only alter their instructional methods but to also respond effectively to the diverse learning and social needs of the whole child. The international movement of inclusive education promotes the idea that school communities grounded in democratic principles and the values of equity and social justice serve as a vehicle to address these challenges. The foundations of such communities are caring, diversity and community and the assumption is that the school is responsible for the support needs of all its members.

The time-honoured conventions of schools and classrooms are becoming obsolete as the political, economic, social and educational needs of society rapidly change. These changes challenge teachers and schools to not only alter their instructional methods but to also respond effectively to the diverse learning and social needs of the whole child. The international movement of inclusive education promotes the idea that school communities grounded in democratic principles and the values of equity and social justice serve as a vehicle to address these challenges. The foundations of such communities are caring, diversity and community and the assumption is that the school is responsible for the support needs of all its members.

We contend that teachers are often the only sources of support in a community and play an important role in promoting pupils' well-being and development. Within the context of the contextual challenges of global and local change, and the adversities that children and families face in vulnerable contexts, this responsibility does not only refer to intellectual well-being and the teaching of basic academic skills. It also includes psychological, emotional and social well-being. The literature is clear that this will take a combined effort of not only teachers but also of pupils, families, educational professionals and communities which in itself is a new way of thinking and doing for teachers.

Teachers' roles therefore become increasingly demanding, complex and multifaceted. In addition, as a result of the demands of accountability measures and negative perceptions of teachers' work, they often experience feelings of hopelessness, decreased job satisfaction, demotivation and lack of confidence in their own knowledge and skills. The supporter therefore also needs support.

The concern of this paper is that education policies assume schools' and teachers' responsibility to create inclusive, caring communities that support all its members. This particular role represents the pastoral, citizenship and community work of teachers. In the adverse circumstances where our participants teach, they must be able to respond to socioeconomic and educational problems related to amongst others poverty, abuse, violence, illiteracy, unemployment and consequences of illnesses like HIV/AIDS. Teachers are consequently expected to counsel children with social and emotional problems, demonstrate caring and develop them as whole persons. However, this can only be done effectively if they work in partnership with the communities, families and professional services and redefine their roles as teachers.

This paper presents the findings of an ethnographic study that aimed to understand teachers' psycho-social support practices in the context of educational change and socio-economic challenges in two schools in the Western Cape province of South Africa. Our unit of analysis was therefore teachers' organic support and care practices and how they transcend their traditional roles to deal with the vulnerabilities that impact children's learning. As part of an intervention-based design, we move away from problem-saturated stories to a focus on what teachers already do and have to develop networks of support and care. Although we identified teachers who 'perform' support to fulfil the performance criteria, this presentation focuses on those teachers with a caring identity that practice support with care and hope to share counter-narratives and strengthen protective factors in these contexts.

The feminist perspective of 'ethic of care' framed our understanding which places the role of relationships at the heart of support and caring practice (See the work of both Noddings and Gilligan). This perspective highlights caring and support as a moral purpose and commitment to enter into caring-for relationships with others. From a health promotive perspective there is conclusive evidence that children can develop resilience within schools with a strong ethos of care and concern, showing protective factors of caring relationships, high expectations and opportunities to participate. This brings hope for those who have been marginalised before. Accordingly we believe that hopefulness is the glue that holds a caring relationship together.

The main question of the broader study was: What are teachers' prevailing practices of support in vulnerable school communities? The design type of the inquiry was ethnography. In participation with the teachers we designed ethnographic casebooks of support and care practices in the schools and communities in two different schools. The volunteer teachers worked in vulnerable school communities in the Western Cape Province in South Africa. Together we generated data over a period of two years through observation and composed field texts, different types of interviews (semi-structured, informal conversations, narrative), school artefacts and visual data. The data were transformed by various methods, including content analysis in constructivist grounded theory mode and narrative analysis. Bronfenbrenner's bio-ecological theory (2005) informed our scope of analysis. We limited our data generation and analysis to the immediate systems in which the individual's interpersonal relationships occur namely the microsystems and the mesosystems. Microsystems include basic relationships between individuals and parents, teachers, peers or siblings. Mesosystems refer to an individual's accumulated microsystems. The strengthening of what Bronfenbrenner calls proximal processes can bolster the protective influences.

Based on the themes we constructed two portraits to illustrate teachers' support practices. The portraits focus on the distinct characteristics of the participating teachers, whom they support and collaborate with, how they support and the conditions that sustain support. We therefore bring into focus how teachers work intuitively and use their practical wisdom to support not only the children, but also the parents, one another and members of the community. They develop networks and use resources in the school and community to provide the support. The nature of their support practices and networks is characterised by caring relationships and hope. Their support practices focused on the whole person including emotional, social, learning, physical and spiritual support. In this paper we maintain that individual teachers cannot support effectively unless they have a moral purpose to care, develop and nurture caring relationships, access and use relevant resources and practice within a supportive school culture that acknowledge and value their efforts. In conclusion we maintain that teachers, who share a common concern for humanity and also get the support they sometimes require, can learn together how to be a functioning community of concern and care.

Teacher career resilience and supportive networks - what do we know?

Sonja Coetzee, University of Pretoria, South Africa

The aim of this paper is to explore existing knowledge about career resilience as it relates to teachers. A time-line of theoretical development on career resilience and teacher career resilience will be presented signifying the advances made in career resilience literature. Age-old questions plague the minds of many careerists: Are you happy with your career choice? If you do not like what you do, why not change? Do you enjoy your job? Are you career-happy? Questions like these may consume some careerists more than others but certainly at least once or twice in a career life.

The aim of this paper is to explore existing knowledge about career resilience as it relates to teachers. A time-line of theoretical development on career resilience and teacher career resilience will be presented signifying the advances made in career resilience literature. Age-old questions plague the minds of many careerists: Are you happy with your career choice? If you do not like what you do, why not change? Do you enjoy your job? Are you career-happy? Questions like these may consume some careerists more than others but certainly at least once or twice in a career life.

The changing world of work requires modern day workers to adapt more frequently to working conditions (Coetzee, 2005). Portfolio careerists are qualified, skills orientated individuals who are contracted in different organizations and who are not part of the core long term employee-team (Templer and Cawsey, 1999:70). It can be argued that these individuals are career resilient since they do not depend on others, they take risks by not having a stable long term defined income and they strive to be autonomous in their career path. The question that arises is: what about the "other" group of workers that stays in a particular career, who still works efficiently without relying too much on others and who, despite job uncertainty and less than optimal working conditions take the risk of staying and coping? This group of workers somehow stay motivated enough to continue on their chosen career path. It can be argued that they exhibit a high level of what London (1983) called career motivation.

London (1983) based his theory of career motivation on the results of assessments of personality and individuals done by several researchers viz Bray (1982), Bray, Campbell and Grant (1974) and Murray (1938). The participants of the studies mainly consisted of managerial level workers or workers with the perceived potential to reach managerial levels. London (1983:621) deduced that career motivation consists of three domains: career identity (what career direction are you following?); career insight (how realistic or unrealistic are your perceptions of yourself or the organization?) and career resilience (can you function during career disruptions or despite unfavourable work contexts?). He (London, 1983:621) further explains career resilience as the ability to cope or function effectively even though working conditions are negative (career uncertainty; poor interpersonal relationships; discrimination or favouritism etc.). Furthermore, career resilience consists of three sub-domains: self-efficacy, risk-taking and dependency (London, 1983:621). A person with a high career resilience profile is more self-reliant and risk taking than a person with a lower career resilience that is more dependent on others and avoids taking risks (London, 1983:621). So, career resilience can be conceptualised in different ways: you can think of career resilience in terms of the portfolio careerist that adapt quickly to new and challenging career environments or the long-term careerist that adapt despite an unfavourable career environment. In returning to the question of career happiness, perhaps to understand career resilience one should investigate career satisfaction since both conceptualisations or career resilience mentioned above could include a level of satisfaction.

Job satisfaction and dissatisfaction depends on various factors. More than 30 years ago researchers already established that factors such as career values and rewards influence employees' feelings of job satisfaction (Kalleberg, 1977:124). Bretz and Judge (1994) concluded that a good fit between person and organization leads to a high level of job satisfaction. Job dissatisfaction, however, can be caused by how environmental stressors such as working conditions and organizational policies or practices are appraised by the individual (Greenhaus, Callanan and Godshalk, 2000) or certain personality traits such as a high degree of neuroticism (Judge, Heller and Mount, 2002). Greenhaus, Callanan and Godshalk (2000:265) also note that "economic dependency can breed attachment to a job that one otherwise despises." Thus, job satisfaction has a role to play in people deciding to stay in or leave a particular career and it can be argued that there is a link between job satisfaction and career resilience.

Teaching may be one of the more controversial careers when one considers satisfaction and resilience. Some declare teaching as the most rewarding job in the world whilst others will tell you that it is the last thing on earth they would do. Day, Stobart, Sammons, Kington, Gu, Smees and Mujtaba (2006:50) conceptualise resilience in teachers as the teacher's degree of commitment to the teaching profession. Johnson, Down, Le Cornu, Peters, Sullivan, Pearce, & Hunter (2010) asserts that relationships, school culture, teacher identity, teachers' work, and policy and practices are conditions for supporting early career teacher resilience. Johnson et al (2010) maintains amongst others that social and professional networks, professional learning communities, economic and political understanding of unpredictable

nature of teachers' work, social justice and community engagement are conditions that support early career teacher resilience. These conditions are closely related to some of the advantages and key characteristics of the asset-based approach which are shared responsibility, mutual support and caring environment, creating networks and building relationships, collaboration, dynamic partnerships and participation (Ebersöhn and Eloff, 2006). There is a link between resilience and the asset-based approach in that resilience follows the "glass-half full" approach whereby strengths and assets of an individual are emphasized and mobilized amidst a process of struggle or change (Ebersöhn and Eloff, 2006; Henderson and Milstein, 2003:3). In the face of change or disparity one may draw from your social networks albeit professional or personal to cope. As such it is evident that supportive networks are pivotal in facilitating resilience in teachers.

SYMPOSIUM

Initial Teacher Education (Pre service)

Effectiveness of Primary and Lower Secondary Teacher Education in 16 countries

Chairperson: Sigrid Blomeke, Humboldt University of Berlin, Germany

Organiser: Sigrid Blomeke, Humboldt University of Berlin, Germany

Fritz Oser, Universität Freiburg, Switzerland

Discussant: Eckhard Klieme, Deutsches Institut für Intern. Pädagogische Forschung, Germany

With the publication of many international comparative studies on student achievement, the competencies of their teachers and the education of these teachers have become areas of considerable interest. This interest is reflected by IEA's "Teacher Education and Development Study in Mathematics (TEDS-M)" carried out in 16 countries with representative samples of primary and lower secondary teachers in their final year of teacher preparation. Based on data from this study, the relationship between future teachers' background, their opportunities to learn in teacher education, and outcomes of teacher education in terms of knowledge and beliefs will be examined in this symposium using advanced multi-level modeling. With reference to the conference theme, there will be a special focus on similarities and disparities in the results across countries.

From a research point of view as well as from a policy point of view, it is of high relevance to learn how teacher education contributes to teacher competencies. TEDS-M offers a unique chance to do so because data was gathered about teacher education policies, programs and practices on the national level; about curricula and practices of teacher education on the institutional level; and about mathematics teachers' knowledge, skills and dispositions at the end of teacher education on the individual level. From Europe, Germany, Norway, Poland, Russia, Spain, and Switzerland participated in TEDS-M. The study was the first comparative large-scale assessment of higher education with standardized testing of outcomes.

What matters for outcomes of teacher education: background, selection or opportunities to learn?

Sigrid Blomeke, Humboldt University of Berlin, Germany; Gabriele Kaiser, University of Hamburg, Germany; Rainer Lehmann, Humboldt University of Berlin, Germany; Martina Dohrmann, University of Vechta, Germany; Anja Felbrich, Humboldt University Berlin, Germany; Johannes König, University of Cologne, Germany; Christiane Schmotz, Humboldt University of Berlin, Germany

First findings of TEDS-M had revealed significant differences in future teachers' background, their opportunities to learn (OTL) in teacher education, and outcomes at the end of their training between countries. It had to remain an open question to what extent future teachers' background had influenced the acquisition of mathematics content knowledge (MCK) and mathematics pedagogical content knowledge (MPCK) in relationship to OTL factors.

In this paper, we examine the hypothesis that – besides OTL – background characteristics known as powerful predictors on the school level are significant predictors of outcomes at the end of lower-secondary mathematics teacher education as well. In addition, we examine the hypothesis that effects of teacher education programs are mediated by differential amounts of OTL and differential teacher intake. The hypotheses are examined by applying three-level models.

The data mainly support our hypotheses. However, the background effects are generally larger with respect to MCK compared to MPCK. We interpret this result as a consequence of a long history of differential school success. Background effects vary substantially across countries. Such cultural differences may show ways for other countries how to improve their equity efforts in education. The effects of differential teacher background point to a selection

bias – either formally implemented by the teacher education institutions or caused by self-selectivity of future teachers.

Confusing relationships: teacher beliefs about training quality and their professional knowledge

Fritz Oser, Universität Freiburg, Switzerland; Horst Biedermann, University of Fribourg, Liechtenstein; Sibylle Steinmann, PHZ Luzern, Switzerland; Margit Kopp, University of Teacher Education in Lucerne, Switzerland; Christian Bruehwiler, University of Teacher Education St. Gallen, Switzerland; Samuel Krattenmacher, University of Teacher Education in St. Gallen, Switzerland

Despite enormous research efforts we still do not know how teachers' beliefs and knowledge are correlated, mainly because most studies only include beliefs or knowledge measures. The rich TEDS-M data sets provides for the first time the opportunity to examine the relationship of mathematics content knowledge (MCK) and mathematics pedagogical content knowledge (MPCK), on the one hand, and beliefs about program quality, program coherence and personal preparedness for teaching, on the other. About 14,000 future teachers for primary and 8,000 future teachers for lower secondary schools from 16 countries were surveyed in their last year of teacher education. On the country level, we found a couple of surprising results. E.g. for lower secondary teachers the manifest correlation between their beliefs about "preparedness for teaching" and their PCK was strongly negative ($r = -.59$; p

A rich research tradition addresses the question of how teachers' beliefs relate to their mathematics content knowledge (MCK) and their mathematics pedagogical content knowledge (MPCK). Despite these research efforts we still do not know how beliefs and knowledge are correlated, e.g. regarding MCK and PMCK, on the one hand, and beliefs about program success, program coherence and personal preparedness for teaching, on the other. The justification to examine this research question stems from three perspectives: (a) primarily from the curriculum of teacher training. Decision makers often assume that those studying to become teachers already possess enough knowledge about the subject matter they will be teaching in the future. (b) A second justification comes from the design of the IEA study TEDS-M. In addition to MCK and PMCK, the two main elements of the study were beliefs and opportunities to learn (OTL). Thus, when viewed from the perspective of the study design, it is reasonable to examine the relationship between MCK, MPCK and beliefs. (c) A final justification stems from the general state of research of the relationship between teacher knowledge and beliefs. The relationship of teacher beliefs to their knowledge is still unclear.

Method

Data basis and random sample

The data basis for the analyses is the IEA-Study TEDS-M. In the last year of their teacher education program, 13,479 students for primary and 7,829 students for lower secondary school from 15 countries each participated in the study.

Measures

The TEDS-M research team used the Rasch model (Rasch, 1960) to derive the scales presented in this paper. To facilitate interpretation all beliefs were scaled across primary and secondary future teachers.

The scale "Beliefs about preparedness for teaching" is based on 13 items scored on a 4-point Likert rating scale ("not at all" to "a major extent"). The students had to evaluate the extent to which they think their teacher education program has prepared them to do their job well. The beliefs about preparedness for teaching indicate a mean of 11.69 ($SD = 1.20$) for future primary school teachers and a mean of 11.80 ($SD = 1.79$) for future lower secondary school teachers.

To rate the "Beliefs about program quality" students had to score 6 items on a 6-point Likert rating scale ("strongly disagree" to "strongly agree"). For primary, this scale has a mean of 12.58 ($SD = 2.54$) and for lower secondary 12.49 ($SD = 2.43$).

Two individual scales were modelled to measure mathematics content knowledge (MCK) and mathematics pedagogical content knowledge (MPCK). Each scale has a mean of 500 points and a standard deviation of 100.

Data analysis

To show how the correlations look like between different beliefs about the teacher training program and knowledge we estimated as a first step Person's r on the country level. For the presentation, we also will check the results with multi-level analysis. Since for primary and secondary we have only 15 countries, it should be mentioned that the results need to be handled carefully. However, despite the relatively low number of countries available, surprisingly

high correlations were observed. This opens the door to some interesting interpretations both on the primary and the lower secondary levels.

First results

With respect to the scale "preparedness for teaching mathematics", all countries have scores above the value 10; thus, on average the teachers in all countries expressed agreement with the belief that they are well prepared. The United States (in addition to the Philippines, Botswana, Malaysia and Chile) rank very high on this survey. The students in these countries feel especially well-prepared to teach mathematics. The bottom third of the ranking is represented by Switzerland accompanied by Chinese Taipei, Poland, Norway and Germany.

Interesting are also the correlations between the beliefs "preparedness for teaching mathematics" and "quality of the program". Here we see that countries with a high estimation of their teachers' preparedness also highly agree with the quality of the program ($n=15$ countries; $r=.79$). The Philippines, Chinese Taipei, USA, Malaysia, Russia and Singapore rate the program quality especially highly whereas Norway, Germany, Spain and Switzerland are more critical.

With regard to correlations of beliefs with knowledge, we found a couple of very surprising results on the country level. E.g. for the lower secondary teachers the manifest correlation between "preparedness for teaching" and MPCK is strongly negative ($r= -.59$; p

Discussion

When discussing and interpreting these results, attention should be paid to the fact that we analyzed correlations at a country-specific level, not at an individual or at a school level. We hypothesize that our results reflect more or less a cultural effect. If a person intends to assess his/her own education, he/she orients him or herself by the context he/she knows best. Thus, one possible answer to the surprising result is that future teachers may be satisfied with their education in relationship to other well-known aspects within their learning environment, e.g. curriculum expectations. So, we see that students from Chile feel quite well-prepared even if they have low scores on MCK and MPCK. In contrast, Swiss teachers are the most sceptical.

However, even if this is a plausible explanation, in a next step we will analyze the data in a multilevel model. It seems that we have to look at the variance explained on each level. Maybe the correlation then becomes a different meaning.

Public or private – Does it make a difference in teacher education effectiveness?

William Schmidt, Michigan State University, United States

Over 1,300 institutions of higher education in the U.S. have approved teacher preparation programs. Roughly one-third of these are publically funded and administered with the other two-thirds privately funded and controlled. However, available records indicate that public institutions are responsible for more than 60 percent of teacher preparation program graduates each year. The U.S. Teacher Education Study – Mathematics (TEDS-M) surveyed nearly 3,300 future teachers from over 80 randomly selected public and private colleges and universities in 39 states. These data provide a unique opportunity to explore the learning opportunities the potential future teachers experienced in their programs and what they knew about mathematics and mathematics pedagogy at the end of their preparation program.

This paper examines the variation in these measures among U.S. institutions. It turns out that it was among the largest found in any of the TEDS-M countries but that it was only weakly related to administrative control (public vs. private) of teacher education. No statistically significant differences between the public and private institutions existed at the lower secondary level when controlling for OTL. For elementary programs the differences between public and private institutions when controlling for OTL were only statistically significant for the mathematics assessment. This surprising result was true in spite of the private institutions' more selective admission policies. It invites for discussions whether the administrative control matters for outcome of tertiary education.

Conclusion

The lack of statistically significant differences in mathematics content knowledge or mathematics pedagogy knowledge between public and private universities and colleges at the secondary level seems surprising given that institution characteristics do vary. The 25th and 75th percentile of matriculating students' ACT mathematics scores were higher in the private than in the public institutions as was the Barron rating associated with the prestige of those

institutions. The selection bias associated with the private schools would suggest that their knowledge of mathematics would likely be greater at the outset, however, at the end, controlling for learning opportunities, there were no significant differences between the public and private colleges and universities. This was true in spite of the private institutions' more selective admission policies. It invites for discussions whether the administrative control matters for outcome of tertiary education.

Mathematics Education

Sixty-four or four-and-sixty? Number transcoding in primary school children

Chairperson: Ineke Imbo, Department Experimental Psychology, Belgium

Organiser: Ineke Imbo, Department Experimental Psychology, Belgium

Discussant: Liane Kaufmann, UMIT-Private University for Health Sciences, Medical Informatics and Technology, Austria

Transcoding Arabic numbers (e.g., 64) from and into verbal number words ('sixty-four') is one of the most basic tasks in the domain of number processing and serves as a cognitive building block for the development of more complex arithmetic skills. Although transcoding is very simple for adults, it is often a great challenge for children – and especially so in inversed number languages such as Dutch and German ('four-and-sixty'). This symposium brings together three empirical studies focusing on primary school children's transcoding performance. The first study tested the effects of inversion in children from France, Wallonia, Flanders, Germany, and Austria, and showed that not only differences in the number language, but also cross-cultural differences in math curricula are an important reason for performance differences. The second study longitudinally tested German-speaking children, and showed that performance on basic numerical tasks (such as transcoding and number magnitude comparison) assessed in first grade predicted performance on a complex addition task in third grade. The third study showed that both Dutch- and French-speaking children relied on executive functions when transcoding; however, only Dutch-speaking children relied on phonological working-memory resources. To conclude, although mastery of specific basic numerical principles (such as transcoding) during early school years is essential for successful numerical development, it is not self-evident for many children. It is of great importance to know the underlying processes in order to foster children's mathematical competencies.

Differential inversion effects on numerical skills in second grade

Helga Krinzing, RWTH Aachen University Hospital, Germany; Jacques Gregoire, Universite catholique de Louvain, Belgium; Annemie Desoete, Ghent University, Belgium; Liane Kaufmann, UMIT - University for Health Sciences, Medical Informatics and Technology, Austria; Hans-Christoph Nuerk, Eberhard Karls University Tübingen, Germany; Klaus Willmes - von Hinckeldey, Medical Faculty RWTH Aachen University, Germany

Little is known about the causes of cross-cultural specifics of numerical development. We examined effects of inversion (a linguistic effect) on three different numerical tasks in 220 second graders from France, Wallonia, Flanders, Germany, and Austria tested for the standardization of the dyscalculia test TEDI-MATH.

Results revealed that performance differences between countries are only partly attributable to language effects, but group differences in recognition of unit- and decade-digits and subtraction are more likely due to curricular effects. As expected, language effects due to the inversion principle could be observed in writing Arabic numbers to dictation affecting performance both specifically as well as in a generalized way being present in other error types. These results clearly show that numerical skills do not develop in a unitary fashion and that cross-cultural differences can be due to several factors.

Aims of the study

In our modern society, numeracy is becoming even more important than literacy for employment rates and wages (Dowker, 2005). In all modern societies, having sufficient numeracy means at least mastery of the Arabic number system and basic arithmetic operations. These numerical skills are taught in primary schools of all countries. Yet, this does not imply that the development of numeracy, which is a comparably young cultural invention (see: Dehaene, 1997), is the same in all cultures.

Furthermore, if performance differences in specific numerical skills are found between children of two different countries, these differences are often not unambiguously attributable to one cross-cultural distinction such as differences in the number word systems like inversion (e.g., 21 is spoken as "einundzwanzig", literally "one-and-

twenty", in German). Rather, other cross-cultural differences (e.g. in math curricula) may be an important reason for performance differences as well. This means that if one wants to study the impact of a cultural difference like language effects on the development of numerical skills, possible confounding factors like curricular effects either have to be ruled out, or more than two different cultural groups have to be tested.

The aim of our study was therefore to investigate cross-cultural differences in the development of different numerical skills and to analyse whether eventual differences are due to linguistic or curricular effects.

Methodology

We compared the performance of parts of the standardization samples of the dyscalculia test TEDI-MATH (Van Nieuwenhoven et al., 2001; Grégoire, Noël, & Van Nieuwenhoven, 2004; Kaufmann et al., 2009) from France (49 children, 51% girls), Wallonia (French speaking part of Belgium; 21 children, 57% girls), Flanders (Flemish speaking part of Belgium; 46 children, 57% girls), Austria (38 children, 58% girls), and Germany (66 children, 55% girls). These 220 children were tested in the middle of second grade with three different tasks: recognition of unit- and decade-digits (pointing to the unit- or decade-digit in three two- and two three-digit numbers, respectively), writing Arabic numbers, and subtraction. For all tasks and groups, the numbers of correctly solved items were used as dependent variables.

To unambiguously test an effect of inversion, we used a family of tests to analyze this specific research hypothesis: First, a one-way ANOVA on means from independent samples between all children speaking a language with (Flemish, German, and Austrian children) vs. all children speaking a language without inversion (French and Walloon children) had to be significant. Second, a two-sided independent samples t-test between the French and the Walloon as well as a univariate ANOVA between the Flemish, German, and Austrian children had to be non-significant. Only then an unambiguous inversion effect can be assumed.

Results

In the current study, we found a negative inversion effect on one out of three mathematical skills of second graders by comparing the standardization samples of the dyscalculia test TEDI-MATH from France, Wallonia, Flanders, Austria, and Germany.

In summary, the hypothesis of an inversion effect on multi-digit number processing could be clearly confirmed for writing Arabic numbers to dictation, but not for recognition of unit- and decade-digits.

Concerning the unexpected performance pattern we found for the task recognition of unit- and decade-digits, the group differences can not be clearly interpreted as being indicative of an inversion effect. We did not find the expected advantage of all French speaking children over the others, as Walloon children scored not only lower than expected but even worse than German and Austrian children. If inversion would impair performance on this task, we would expect Walloon children to be better than German speaking children. Furthermore, teen numbers and simple decade numbers were also affected by the group factor, which is not expected if performance is influenced by inversion.

Alternatively, these results may suggest differences in the focus of math curricula in the different countries, with the strongest emphasis on understanding the value of digits in multi-digit numbers in France, followed by Germany and Austria, and the lowest in Belgium (Wallonia and Flanders).

Surprisingly, we also found a positive (i.e. error-reducing) effect of inversion on two items of Subtraction, namely "16-4" and "27-6". These two items have in common that a single-digit number has to be subtracted from a two-digit number. Therefore, we speculate that naming the unit-digit first in the minuend may enhance attention to the digit from which the second number should be subtracted, at least during a short time window in children's numerical development. This may be interpreted as a positive effect of the inversion property in a number word system for learning how to subtract.

Theoretical significance of this study

In general, the results of our study show that numerical skills do not develop in a unitary fashion. Rather, individual performance on specific mathematical skills can be differentially influenced by linguistic properties of the number word system. This means that for a promising investigation of cross-cultural differences in mathematical development, it seems fruitful to study the performance patterns of children from multiple countries, as it is very likely that cultural factors are confounded if only two countries are compared. For example, if we would have examined only German and French children, we would have misinterpreted all group differences as linguistic effects

on numerical achievement of these two groups. Furthermore, our results showed that two tasks tapping multi-digit number processing (recognition of unit- and decade digits and writing of Arabic numbers to dictation) were differentially affected by the existence of the inversion property in the respective number word systems. This calls for a multi-task approach in cross-cultural comparisons – in many instances only one or very few tasks have been used so far. Our results show that cross-cultural differences in one task are not readily transferable to another task.

Early place-value understanding as a precursor for later arithmetic performance

Korbinian Moeller, Knowledge Media Research Center, Germany; Silvia Pixner, University of Health Sciences, Medical Informatics and Technology, Austria; Liane Kaufmann, University of Health Sciences, Medical Informatics and Technology, Austria; Hans-Christoph Nuerk, Eberhard Karls University Tübingen, Germany

Recent research suggests that basic numerical competencies such as transcoding, this means the ability to transfer a number from one notation to another serve as a cognitive building block for the development of more complex arithmetic skills. However, in numerical cognition, there is a lack of longitudinal studies examining this issue. In a sample of 94 typically developing children we investigated longitudinally whether performance in basic numerical tasks (such as transcoding and number magnitude comparison) assessed in first grade predicted performance in a complex addition task in third grade. It was observed that early successful understanding the place-value structure as reflected in transcoding and magnitude comparison tasks was a reliable predictor for later successful application of place-value knowledge as indicated by the processing of carry addition problems - even when controlling for non-numerical concepts like IQ and working memory. These findings are important for two reasons as they (i) lend support to developmental accounts emphasizing the importance of basic number representations as well as they (ii) underline that mastery of specific basic numerical principles (such as the place-value structure) during early school years seems to be essential for successful numerical development of more complex but nevertheless related competencies.

Aims

The aim of the current study was to investigate the influence of early basic numerical competencies such as transcoding or number comparison on later arithmetic capabilities in typically developing children. Therein, we set out to resolve several limitations in the hitherto investigation of this developmental trajectory: (i) most recent studies employed a simple task approach in which one particular representation is indexed by an overall performance measure of one particular task. (ii) The stimulus sets used to assess basic numerical competencies mostly comprised one-digit numbers only, preventing an examination of the influence of place-value understanding on later arithmetic ability.

Method

We aimed at addressing these issues in a longitudinal investigation involving 94 typically developing children (German native speakers, 48 girls) assessed at the end of grade 1 and 3 (mean age grade 1: 7;4 years, SD = 7.1 months, range: 6 years 5 months to 8 years 7 months). Following the research question at hand our proceeding was three-staged: (i) We were interested whether overall performance as reflected by error rates for number comparison and/or transcoding assessed in first grade was a reliable predictor of overall addition accuracy in third grade. (ii) More specifically, attention was paid to whether mastery of place-value understanding in first grade as indexed by related numerical effects (e.g., inversion related transcoding errors) predicts overall addition performance two years later. (iii) Most specifically, we aimed at evaluating whether such specific basic numerical effects (e.g., percentage of inversion errors) predict specific effects in later addition (e.g., carry effect) that can be attributed to the same underlying concept of place-value understanding. Please note that in the latter case predictor and criterion are specific numerical effects. Yet, due to the fact that for transcoding performance no reaction times were measured all of these interrelations were evaluated for error data using stepwise multiple regression analyses.

Results

Our results were straightforward on each of these questions:

- (i) We clearly identified overall number comparison performance in first grade to be the only reliable predictor [$b = .25$, $t = 2.48$, $p = .02$, adjusted $R^2 = .05$, $F(2, 92) = 6.13$, $p = .003$]
- (ii) Following the approach suggested by Holloway and Ansari (2009) we took a successful next step in identifying precursors of arithmetic capability. The final model [$R = .44$, adjusted $R^2 = .16$, $F(4, 90) = 6.99$, $p = .001$, $b = -.18$, $t = 1.93$, $p = .06$, $b = .18$, $t = 1.87$, $p = .07$, $b = .33$, $t = 3.47$, $p = .001$]
- (iii) Finally, examining the influence of specific numerical effects in first grade (e.g., compatibility effect, pure inversion errors) on the corresponding carry effects in third grade addition revealed a meaningful interrelation when operationalizing both predictor and criterion by specific numerical effects rather than by an overall performance

measure [$R = .29$, adjusted $R^2 = .06$; $F(3, 91) = 4.08$, p carry effect in third grade addition was predicted reliably by the number of pure inversion transcoding errors committed in first grade: A higher number of pure inversion errors in first grade transcoding [$b = .21$, $t = 2.00$, p

Discussion

Taken together, the results of the present longitudinal evaluation indicated that if the place-value concept is not mastered in early schooling difficulties in the successful application of this concept will evolve in later numerical development, in particular, regarding the capability to integrate tens and units into the Arabic place-value system as required in basic arithmetic operations such as addition problems requiring a carry. To our knowledge, these are the first longitudinal data which directly evidence the importance of early place-value understanding.

The conclusions for future research are then straightforward. Multi-digit number processing and in particular, the importance of place-value understanding should receive greater attention as the development of place-value knowledge poses a major challenge for elementary school children (especially for those that have to struggle with an intransparent name- and place-value system). Moreover, the unproblematic acquisition of the base-10 place-value system cannot be taken for granted in all children (e.g., Gervasoni et al., 2003). Instead, early deficits in place-value understanding may still exert their influence on later more complex arithmetic processes. Hence, future research should not only focus on single-digit number processing but should also incorporate representations and concepts necessary to successfully process multi-digit numbers. Beyond being confined to basic research, the systematic investigation of the processes and mechanisms underlying the development of the base-10 place-value system and its interrelation to other aspects of multi-digit arithmetic should be considered a major interest in the applied sciences as well. To summarize, the present data suggest that more specific teaching and training of place-value understanding in education contexts may endorse children's numerical development.

The Influence of Language and Working Memory on Children's Number Transcoding

Charlotte Vanden Bulcke, Ghent University, Belgium; Jolien De Brauwier, Lessius University College, Belgium; Ineke Imbo, Department Experimental Psychology, Belgium

Two studies are reported in which the transcoding abilities of Dutch- and French-speaking children (e.g., writing 64 when hearing 'sixty-four') are tested. French is, like English, a non-inversed number language, which means that the tens are pronounced before the units ('sixty four'). Dutch, in contrast, is an inversed number language, which means that the ten-unit order is inversed when number words are pronounced (e.g., 64 is pronounced as 'four-and-sixty'), which gives rise to inversion errors (e.g., writing 46 when hearing 64). In the first study, we show that 7- and 8-year old Dutch-speaking children make significantly more inversion errors than do 7- and 8-year old French-speaking children. In the second study we show that both Dutch- and French-speaking 8-year-old children rely on their executive working memory when transcoding numbers, but that only Dutch-speaking children rely on their phonological working memory when transcoding numbers. For the Dutch-speaking children only, gender effects (bad transcoders are more often girls) and effects of intelligence (bad transcoders are more often less intelligent) were also observed. Implications for elementary school education as well as ideas for further research are discussed.

Aims

Transcoding Arabic numbers (e.g., 64) from and into verbal number words (e.g., 'sixty-four') is one of the most basic tasks in the domain of number processing. Although transcoding is very simple for adults, it is often a great challenge for children – and especially so in inversed number languages. In inversed number languages, such as Dutch and German, the ten-unit order is inversed when number words are pronounced or written down (e.g., 64 is pronounced as 'four-and-sixty'). This gives rise to inversion errors (e.g., writing 46 when hearing 64).

In a recent study, 7-year-old German-speaking children were asked to write down dictated Arabic numbers (Zuber et al., 2009). The error rate was very high (47%) and inversion errors were very frequent (50% of overall error rate). The children's transcoding performance was best predicted by executive working memory (WM), and – in a lesser degree – by visuospatial WM.

We conducted two studies in which we pursued the results of Zuber et al. (2009). As transcoding may be a rather difficult task for 7-year old children, we decided to run a first study in which we tested 7-, 8-, and 9-year-old children. We did not only look at the transcoding competencies of children speaking an inversed language (Dutch) – we also tested children speaking a non-inversed language (French). Based on the results of this study, a second study was run in which we compared 8-year-old Dutch- and French-speaking children's WM involvement in transcoding tasks.

Method

In Study 1, we tested 57 Dutch-speaking and 60 French-speaking children between 7 and 9 years old. All children completed a group-administered dictation of Arabic numbers. In Study 2, we tested 49 Dutch-speaking and 38 French-speaking children of 8 years old. They all completed a group-administered dictation of Arabic numbers. For each language group, we selected the 10 worst and 10 best transcoders (based on the amount of transcoding errors) of whom we further tested intelligence and WM. The intelligence measure was based on four tasks of the WISC-III: Picture arrangement, Block Design, Similarities and Vocabulary. Based on these four tasks, an estimate of total IQ was made (Grégoire, 2001). WM was tested by means of two phonological tasks (Digit span forwards and Letter span forwards), two visuospatial tasks (Corsi Blocks forwards and Mazes Memory), and four executive tasks (Digit span backwards, Letter span backwards, Corsi Blocks backwards, and Sun Moon Stroop). For each WM component, a compound score was calculated as the mean of the z-scores.

Results

The first study was meant to look at age differences in transcoding abilities. At 9 years old, children barely made transcoding errors. The amount of transcoding errors at 7 and 8 years old, in contrast, was reasonably high (around 15%). Although the total error rate was equally large in Dutch- and French-speaking children, the percentage of inversion errors differed significantly. As can be seen in Figure 1, Dutch-speaking children made more inversion errors than did French-speaking children, $t(35) = 5.48$ ($p < .001$) for the 7-year-olds and $t(37) = 1.71$ ($p = 0.07$) for the 8-year-olds. Based on the results of this first study, a second study was set up. Because the dictation task seemed somewhat too difficult for the 7-year-olds (cf. around 25% non-responses) and too easy for the 9-year-olds, we decided to look further into the transcoding abilities of 8-year-old children.

Hence, in Study 2, we tested the transcoding abilities of 8-year-old children only. The intelligence and WM of the 10 worst and 10 best transcoders in each language group (Dutch and French) was tested as well. A stepwise logistic regression analysis was performed on transcoding performance (bad vs. good) with intelligence, age, gender, and WM (phonological, visuospatial, and executive) as predictors. As can be seen in Table 1, executive WM was a significant predictor for both language groups, indicating that children with high executive WM resources are more likely to be good transcoders than are children with low executive WM resources. Intelligence, gender, and phonological WM, in contrast, were significant predictors for Dutch-speaking children only. Since boys were coded as 0 and girls were coded as 1, the negative B value indicates that Dutch-speaking girls are more likely to be bad transcoders than are Dutch-speaking boys. Further, Dutch-speaking children who are more intelligent and have higher phonological WM resources are more likely to be good transcoders than are Dutch-speaking children who are less intelligent and have lower phonological WM resources.

A test of the final model versus a model with intercept only was statistically significant, $\chi^2(4, N=20) = 27.73$ ($p < .001$), $N=20$) = 5.04 ($p = .03$) for French-speaking children. The final model was able to classify all Dutch-speaking children (100%) correctly as being good or bad transcoders, whereas the overall success rate for the French-speaking children was 65%.

Theoretical and educational significance

Children speaking a language with inversed number words experience great difficulties when transcoding numbers. They make many inversion errors (e.g., writing 46 when they hear 64) and rely to a great degree on their WM. Elementary school teachers should be aware of this, and may have to give extra attention to children with lower intelligence and/or lower WM scores. They may, for example, try to avoid redundant WM load as much as possible when young children are transcoding. Further research is also needed in order to test the effectiveness of possible interventions (such as training phonological working memory) for children bad in number transcoding.

It is important to note that the inversion property is not only present in Dutch and German, but also in many other languages such as Arabic, Danish, Maltese, Czech, and Norwegian. The results of the present study are thus relevant for elementary school teachers all over Europe. Although children speaking a non-inversed number language make very few inversion errors and rely to a lesser degree on their WM, they do make as many transcoding errors as children speaking an inversed number language. Hence, further research on the underlying processes of the transcoding competence of these children is also needed.

SYMPOSIUM

Assessment and Evaluation

Theoretical Issues in Measuring Interactive Problem Solving and in Defining the Domain for PISA 2012

Chairperson: Samuel Greiff, University of Heidelberg, Germany

Organiser: Samuel Greiff, University of Heidelberg, Germany

Joachim Funke, Psychology Department, Germany

Discussant: Jean-Paul Reeß, DIPF, Germany

Problem Solving has largely been an area of experimental research and much less an issue in the field of diagnostics during the last decades. However, one might consider problem solving competency as an important skill in our increasingly technology-rich and thus, technically demanding environment of the 21st century. Not surprisingly, there is a newly emerged focus on dynamic problem solving in the PISA-2012 assessment. There, it will be measured fully computer-based under the term Interactive Problem Solving emphasising the importance of active interaction between problem and problem solver.

This symposium's aim is to present and critically discuss theoretical and practical issues when introducing a new domain in an educational large-scale assessment. More specifically, it gives an overview on the theoretical rationale behind the assessment of problem solving considering scientific and political points of view (paper 1), describes the formalism behind the item pool and its conceptual, theoretical and psychometric advantages over traditional measurement approaches (paper 2) and closes with an in-depth discussion of challenges that are to be met and overcome when dealing with such a diverse domain as interactive problem solving and when administering it computer-based (paper 3).

In the general absence of appropriate empirical data on interactive problem solving, theoretical issues and practical obstacles have to be discussed even more thoroughly. This symposium wants to enhance the debate on advantages and disadvantages of capturing interactive problem solving competency in PISA 2012.

New Aspects Related to the Theoretical Framework of Problem Solving in PISA 2012

Romain Martin, University of Luxembourg, Luxembourg; Beno Csapo, University of Szeged, Hungary

Problem solving is a highly relevant skill for success in a modern society as it can be viewed as a transversal skill implying processes that can be applied in very different contexts and that contribute to the successful adaptation to novel and changing situations. In a study based on broad literacy concepts such as PISA, the definition of a theoretical framework for problem solving will not only have to address the question of the relevance of results from a scientific point of view, but also the question of their relevance for political and other stakeholders in the educational field in general. We will show how the theoretical framework which has been adopted for problem solving in PISA 2012 tries to fulfill all the requirements related to the definition of the construct, the relevance for participation in society, the delimitation against other theoretical constructs and the added-value compared to classical content-related assessments.

PISA is a large-scale comparative assessment aiming to "assess how far students near the end of compulsory education have acquired some of the knowledge and skills that are essential for full participation in society" (OECD, 2007). Thus PISA goes beyond the assessment of particular curricular knowledge, as it aims at assessing competencies that are necessary for an active participation in a modern society. Essentially such a modern society is characterized by continuous changes in the working environments and their technologies. PISA studies made a great progress towards measuring knowledge relevant in these societies by introducing and elaborating a very broad literacy concept for the main domains (reading, mathematics and science). However, for assessing how well schools prepare their students for unknown future challenges, to solve problems which cannot be solved on the basis of domain-specific knowledge mastered at today's schools, new types of instruments are required. These new instruments should be able to assess how efficiently students act in novel situations, in unknown environments, how they are able to gain new knowledge and organize it according to the requirements of the actual demands of a given problem situation. Problem solving is a construct offering the possibilities of developing a framework satisfying the needs of these new

aims of PISA. On the other hand, problem solving is a very broad concept with many different facets, so developing a framework for this construct requires to choose theoretical approaches which fit the particular aims and characteristics of PISA, namely, that certain types of problem solving skills are already included in the main literacy domains.

Problem solving has been measured in the past in PISA 2003 and will again be measured in the context of PISA 2012. In light of the general objectives of the PISA study, it becomes clear that the elaboration of a theoretical framework for PISA will not only have to address the question of the relevance of results from a scientific point of view, but also the question of their relevance for political and other stakeholders in the educational field in general. It is thus important that the theoretical framework can respond to different constraints: (1) it should be rooted in existing theoretical frameworks about problem solving that have been proposed through research in the field; (2) the adopted definition should show the link with cognitive or motivational processes that are necessary for a successful participation in a modern society; (3) it should permit to delimit problem solving against other theoretical constructs such as intelligence; and (4) it should be possible to show the added value that can be expected from the measurement of problem solving as a separate domain in addition to the partial measurement of problem solving that is already included in the main domains. Finally, although the type of problem solving skills to be assessed cannot be directly taught, it should be amenable to education and be an indicator of the quality of schooling.

We will show how the theoretical framework which has been adopted for problem solving in PISA 2012 tries to fulfill all these requirements. Basically, the elaboration of the theoretical framework for PISA 2012 will be rooted in the research on problem solving done in the field of cognitive psychology (Mayer, 1992; Funke, 2009; Wang & Chiew, 2010). Based on a basic definition of problem solving coming from this field of research, it will be shown in which type of real-world situations these problem-solving skills will be needed. This analysis will open the possibility to define different types of problem solving situations according to the context in which they occur and according to the nature of the problem that has to be solved. Research about the link between intelligence and problem solving skills will be reviewed in order to show that the two constructs seem to be related, but not overlapping. A major importance in the theoretical definition of problem solving for PISA 2012 has to be attributed to the central cognitive (and motivational) processes that have to be used to various degrees in different problem solving situations. Being able to describe and assess these processes will be a core element in the theoretical framework of problem solving. One of the major goals of the problem solving assessment based on this theoretical framework will be to design measurement instruments which will maximize the variance that is attributable to these problem solving processes while at the same time minimizing the variance which is due to domain-specific knowledge unrelated to the problem-solving processes themselves. This effort to target the problem solving processes directly is the major difference between the assessment of “general” problem solving and the assessment of domain-specific problem solving such as mathematical problem solving. Being able to provide a “pure” measurement of problem solving skills seems to be very important in order to disentangle skills that can be considered to be truly transversal from skills that are bound to a specific content domain.

Dynamic Systems and Their Importance in Competence Assessment of Problem Solving

Joachim Funke, Psychology Department, Germany; Samuel Greiff, University of Heidelberg, Germany; Sascha Wustenberg, University of Heidelberg, Germany

In PISA 2012, dynamic problem solving will receive special attention for at least three reasons: (a) It is an additional option for the participating countries (46 out of 68 voted for it), (b) it is measured for the first time computer-based, and (c) problem solving is understood as Interactive Problem Solving and uses dynamic systems. In our presentation, we focus on the dynamic systems approach for competence assessment. Interactive problem solving requires from participants to explore and control minimal but sufficient complex systems like remote control, mobile phone, or home appliances. To model such systems, we use the formalisms of structural equation systems and finite state automata. With both approaches, a psychometrically sound assessment of the three theoretically derived facets “information retrieval”, “model building”, and “forecasting” is possible and useful for the description of interactive problem solving.

In PISA 2012, dynamic problem solving will take special attention for at least three reasons: (a) It is an additional option for the participating countries (46 out of 68 voted for it), (b) it is for the first time computer-based, and (c) problem solving is understood as Interactive Problem Solving and uses dynamic systems. What the 2012 assessment of problem solving differentiates from the 2003 assessment is mainly the mode of delivery (computer-based) and the inclusion of problems that cannot be solved without interacting with the problem situation.

What is interactive problem solving? How can it be measured? In concentrating on interactive problem solving, we focus on a 21st century skill that is not easily captured by paper-and-pencil tests. The 21st century offers a technology-rich environment to its citizens. It is taken for granted that a person is able to use mobile communication, use household devices, use public transportation, and use technology at work place, shortly put: to use technologies that show a broad range of applications, are rapidly changing, and often introduce new features and services to their users. These require interaction with mostly automated environments (e.g., using credit cards for public transport; pay-via-phone) that are in principle similar to each other but at the same time very context specific and changing from region to region. For example, when travelling around the world one experiences a lot of different paying systems for public transport even if in principle the systems are the same.

Our definition of interactive problem solving is as follows: "interactive problem solving is the ability to explore and identify the unknown structure of devices in dynamic, technology-rich environments by means of interaction, and to reach certain goals with such devices." Let us comment on the different components of this definition.

- (1) The term "ability" refers to the fact that interactive problem solving develops over the life span and that it can be learned and fostered, e.g., by training.
- (2) The two mentioned tasks (to identify structure; to reach goals) refer to the abstract requirements of (a) system identification and exploration (knowledge acquisition) as well as (b) system control and steering (Funke, 1991). System identification simply means to find out how a given device (e.g., a new mobile phone) works, how it reacts to certain inputs. System control simply means to know how to get what you want.
- (3) The notion of "unknown structure" points to the fact that dynamic problem solving deals with new situations for which a routine solution is not at hand.
- (4) The term "dynamic, technology-rich environments" characterizes a prerequisite for interaction between a user and the device, namely the dynamics of the system. This interaction implies that during the course of interaction the state of the device changes depending on the type of intervention. The resulting dynamics stand in strong contrast to simple problems that are static in nature (like a chess problem situation).
- (5) The term "devices" contrasts the objects for interactive problem solving to natural objects, (social) events, and so on. It specifies for example, that interactive problem solving does not deal with problems resulting from social interaction, problems which might require another ability that could be called "emotional intelligence".
- (6) "By means of interacting" characterizes the mode of exploration and refers to the most important aspect of this type of problems, namely the active process of exchanging information with a system; this is done not by reading a text but by actively dealing with the system.

Not explicitly included in the definition is the aspect of metacognition, i.e. monitoring and reflecting one's own problem solving activities. But because problem solving is not only an ability but also a process, it needs some feedback and control structures which guide the activities.

How could dynamic problem solving be measured? Recently, Greiff and Funke (2009) proposed the MicroDYN and MicroFIN approach. This approach was developed under a psychometric perspective for the use in large-scale assessments (like PISA) with computer-based test administration (Reeff & Martin, 2008) and has compared to other approaches advantages in terms of (a) time used for testing, (b) realism, (c) measurement model, (d) available data on reliability and validity, (e) comparability between different scenarios, (f) scalability overall and with respect to difficulty levels. Actually, it consists of a set of "items" which each consists of a small system of causal relations that have to be explored within 3-4 minutes and afterwards controlled for given goal states. The main feature of MicroDYN is the use of minimal but sufficiently complex systems, that is, systems which at the same time contain all of the features of a complex system (complexity, dynamics, politely, intransparency; see Funke, 1991) and do have low values on these parameters. From a psychometricians' point of view, this approach has some advantages for test developers that can be characterized by the following points: (1) the time spent for a single scenario is not measured in hours but in minutes, thereby increasing the economics of test application; (2) due to the short time for item application, a series of items can be presented instead of one-item-testing, thereby increasing reliability; (3) because of our use of formalisms, arbitrary semantic embeddings could be chosen, thereby increasing ecological validity; and, (4) a broad range of difficulty levels can be addressed, thereby increasing conceptual validity.

Computer-Based Assessment of Problem Solving in PISA 2012: Opportunities and Challenges

Barry McCrae, Australian Council for Educational Research (ACER), Australia; Dara Ramalingam, Australian Council for Educational Research, Australia

The PISA 2012 assessment of problem solving competency of 15-year-olds is entirely computer based. This provides the first-time opportunity in a large-scale international survey to concentrate on problems that cannot be solved without the solver interacting with the problem situation. Examples of problems administered include the difficulties encountered in using a new remote control or vending machine when instructions are missing or inadequate. The 68 countries participating in PISA 2012 are spread geographically across the globe, range widely in their level of economic development, and form a very diverse cultural and linguistic mix. This paper discusses the challenges that this presents to test developers in devising appropriate examples and illustrates how these challenges were met. Other opportunities and challenges, such as those afforded by the computer's capability to capture the strategies employed by the problem solver, are also discussed.

PISA (Programme for International Student Assessment) is an international standardised assessment of 15-year-olds in educational programmes that takes place every three years in participating countries. Since PISA's inception in 2000, it has been conducted on behalf of the OECD by the Australian Council for Educational Research (ACER).

Problem solving was previously assessed in PISA in 2003, by means of a conventional pen-and-paper test (OECD, 2003, 2004). The 2012 assessment of problem solving is computer-based and so, for the first time in a large-scale international survey, problems that cannot be solved without the solver interacting with the problem situation can be included. Indeed, so-called "interactive problems", are the main feature of the assessment.

A consistent research finding is that problem solving is dependent on domain-specific knowledge and strategies (e.g. Mayer, 1992; Funke & Frensch, 2007). PISA avoids the need for expert prior knowledge as much as possible in order to focus on measuring the cognitive processes fundamental to problem solving. This also distinguishes the assessment from problem solving tasks in the core PISA literacy domains of reading, mathematics and science, which can call on expert knowledge in these areas.

68 countries and economies are participating in PISA 2012 and each of them could opt to undertake the problem solving assessment. They are spread geographically across the globe, range widely in their level of economic development, and form a very diverse cultural and linguistic mix. A PISA assessment task needs to satisfy the following conditions:

- meet the PISA criterion of measuring how well students, at age 15, are prepared to meet the challenges they may encounter in future life;
- be regarded, by the students, as interesting and authentic;
- maintain its level of difficulty when translated into the various PISA languages;
- be culturally acceptable throughout the PISA countries and economies; and
- be accompanied by a coding guide that enables student responses to be reliably coded (marked).

PISA problem solving tasks are mainly based around authentic, everyday situations which should be familiar to most students. Examples include the problems commonly faced when encountering devices such as remote controls, mobile phones, home appliances and vending machines for the first time, especially if a user guide is not available or not easily understood. Prior knowledge is often not sufficient to solve such problems and must be enhanced with new knowledge gained from observing and exploring (i.e. interacting with) the situation.

Interactive problems can be built on underlying mathematical models whose parameters can be varied systematically to achieve differing degrees of difficulty. There are two well-known paradigms: finite state automata and models based on linear structural equations.

Greiff and Funke (2008) use the term MicroDYN to describe the latter systems in which the problem solver must manipulate one or more input variables and consider the effect this has on one or more output variables. An example is controlling the volume and tone of a sound system. In more complex examples, the output variables may also influence themselves (i.e. the system is in itself dynamic).

A finite state machine is a system with a finite number of states, input signals and output signals (Buchner & Funke 1993). The system's next state (and output signal) is uniquely determined by its current state and the specific input signal. The problem solver must supply input signals (usually in the form of a sequence of button presses) to determine the effect on the system's states in an effort to understand its underlying structure and move it towards a goal state. Examples are digital watches and ticket vending machines.

Both paradigms have been implemented in the PISA 2012 problem solving assessment, primarily involving a range of technological devices. This raises the question of differential student familiarity and a challenge faced by item developers has been to devise strategies to minimise this potential inequality, including constructing non-technological and artificial examples. Other challenges include avoiding situations where trial-and-error is consistently necessary and varying the presentation of MicroDYN units to make them more interesting and authentic.

This paper discusses the political, scientific and technical issues mentioned above and provides an insight into the benefit of computer-based assessment that allow a much wider range of possible answers and behaviours than constructed responses in a paper-and-pencil environment.

SYMPOSIUM

Social Aspects of Learning

Individual and social factors underlying school cheating on graded assignments

Chairperson: DORIT ALT, Zefat Academic College, Israel

Organiser: DORIT ALT, Zefat Academic College, Israel

Discussant: Roni Reingold, Achva-College of Education, Israel

This symposium aimed at empirically exploring the underlying factors of moral decisions regarding school cheating on graded assignments. Academic integrity is an important issue. Its absence may undermine the fundamental values and goals of education. Students who cheat bypass learning in an effort to obtain higher marks. Thus they are not engaged in a constructive learning process, and do not obtain academic skills. Moreover, cheating undermines equity, disorients teachers' feedback on the teaching effects, decreases the validity of measures on students' learning, increases damage to morale and threatens the integrity of school assessment. Therefore, it is important to examine individual and social factors which could dissuade students from this deviant behavior, thus developing strategies of dealing with the increasing problem. While academic cheating related studies suggest theoretical models of the phenomenon, this symposium provides empirical and practical contribution to the realm of moral rule breaking attitudes and behavior among students.

Motivational and cultural aspects related to students' academic dishonesty

DORIT ALT, Zefat Academic College, Israel

This study aimed at empirically examining the set of theoretical connections between several factors that may predict tendency towards neutralizing cheating among Jewish and Arab undergraduate students. The factors are: goal orientations, motivations and self-efficacy toward learning. Students who cheat bypass learning in an effort to obtain higher marks. Thus they are not engaged in a constructive learning process. Therefore, it is important to examine the factors which could affect academic cheating, and to develop strategies of dealing with the problem. Another aspect of the present study relates to social aspects and academic adjustment difficulties of Arab students that could lead to academic dishonesty. The present study seeks to empirically explore this assumption. In order to achieve these goals, three scales were administered to 122 undergraduate students, from three academic colleges, measuring the different variables. Findings suggest an empirical model in which performance goal orientations and extrinsic motivations - increase tendency to neutralize cheating; whereas mastery goal orientations, intrinsic motivations and self-efficacy towards learning - decrease this tendency. Arab students scored higher results than Jews students at: performance goal orientations, extrinsic motivations and tendency towards neutralizing cheating. Arab students appear to accept rule breaking if they can be justified by learning challenges, rather than instructional or social circumstances. This explorative study may lead to the development of different mechanisms suitable for each social group aimed at confronting academic cheating. These mechanisms could yield more effective learning and vocational training thus reducing the gaps between the Arab and Jewish populations.

This explorative study aimed at empirically examining the set of theoretical connections between several factors that may predict tendency towards neutralizing cheating among Jewish and Arab undergraduate students. The factors are: goal orientations (Urdu, 1997), motivations (Ryan & Deci, 2000) and self-efficacy toward learning (Bandura, 1997). Students who cheat bypass learning in an effort to obtain higher marks. Thus they are not engaged in a constructive learning process, and do not obtain professional skills (Whitley & Keith-Spiegel, 2002). Therefore, it is important to examine the factors which could affect academic cheating, and to develop strategies of dealing with the problem. Another aspect of the present study relates to academic adjustment difficulties of Arab students that may influence their goals, motivations, and self-efficacy toward learning (Benziman, 2002), therefore could be connected to academic dishonesty. The present study seeks to empirically explore this assumption.

Research questions

1. What are the empirical connections between purposes, motivations and self-efficacy towards learning, and tendency towards neutralizing cheating?
2. What are the differences between Jewish and Arab students (independent variable), regarding purposes, motivations and self-efficacy towards learning (mediating variables), and tendency towards neutralizing cheating (dependent variable)?

METHOD

Participants

The sample included 122 second year undergraduate students, from three academic colleges in north Israel, 63 Jewish, 59 Arabs. Mean age ranges from 21 to 25 years.

Data collection- Procedure and instruments

The following instruments were handed to the participants, who had the right to withdraw from the study at any time. All details regarding the participants' personal identity were kept anonymous. Data were collected during one academic year.

Instrument 1 – included three sub-scales measuring goal orientations from Patterns of Adaptive Learning Scales collection (Midgley et al., 2000):

- (1) Performance goal orientation: students' goal is to demonstrate their competence to other people within the academic institution sphere, namely, teachers or other students (9-item sub-scale, $\alpha=0.83$).
- (2) Parental Performance Goal: students' goal is to demonstrate their competence to their parents (5-item sub-scale, $\alpha=0.89$).
- (3) Mastery goal orientation: students' goal in an achievement setting is to develop their competence. Attention is focused on the task (4-item sub-scale $\alpha=0.72$).

Instrument 2 - included three sub-scales evaluating college student learning motivation and self-efficacy from Motivated Strategies for Learning Questionnaire (Pintrich, Smith, Garcia, & McKeachie, 1993):

(1) Intrinsic motivation, measuring the student motivation for learning and understanding the courses' materials (9-item sub-scale $\alpha=0.77$).

(2) Extrinsic motivation, measuring the student motivation for achieving high grades (4-item sub-scale $\alpha=0.76$).

(3) Self-efficacy for learning, designed to measure the extent to which students believe that they have the competence and skills necessary for successful learning of the studied materials (4-item sub-scale $\alpha=0.70$).

All items in instruments 1 and 2 were arranged in Likert-style response format on a four-point scale ranging from (1) not at all true to (4) very true. Structural validity of the each questionnaire was examined using Principal Component Analysis with Varimax Rotation.

Instrument 3- Neutralization scale (Haines et al., 1986). The scale consists of 18-items, designed to measure respondents' tendency to neutralize cheating regarding three aspects:

- (1) Teacher's behavior, for example: doesn't care if the students study or not (6 items, $\alpha=0.87$).
- (2) Studied material, for example: too much material to study, the language is too difficult to understand (6 items, $\alpha=0.88$).
- (3) Social causes, such as: helping other student if he is in danger of losing his scholarship due to low grades (6 items, $\alpha=0.86$).

Respondents were asked to indicate their level of agreement with the items in a 4-point Likert type scale, ranging from (1) strongly disagree to (4) strongly agrees. Structural validity of the scale was examined using Structural Equation Modeling (SEM).

FINDINGS

First question was examined using SEM. Second question was examined by Multivariate analysis and Step-Wise Discriminant Function analysis.

The empirical model suggests parental oriented purposes (extrinsic) to be positively contributive to motivation towards scoring high grades (extrinsic) which increases tendency to neutralize cheating. Whereas, learning oriented purposes (intrinsic) positively contributes to motivation towards learning and understanding the material (intrinsic). This intrinsic motivation positively connected to self-efficacy perceptions regarding the studied materials, both these factors were found negatively connected to neutralizing cheating tendency (Chi-square = 23.34, $df = 18$, $p = .178$; RMSEA = 0.49; CFI = .989). Findings showed that Arab students, compared with the Jewish students: are more motivated towards grades, are aimed at showing their parents their performance, and tend to neutralize cheating when the studied material is perceived to be hard to understand.

DISCUSSION

This explorative study empirically tested several predictors of academic cheating with relation to cultural aspects. The study has theoretical as well as educational implications. For theory, the results suggests goal orientations to be indirectly connected to neutralizing cheating, namely, student's tendency to justify cheating will not be directly affected by his extrinsic purposes, as suggested by theory, unless he is motivated towards achieving them. Consistent with theory (Finn & Frone, 2004), self-efficacy was found connected to intrinsic motivation, both negatively connected to neutralizing cheating.

Regarding cultural aspects, findings indicate that Arab students consider their parents expectations while formulating their academic goals and are extrinsically motivated towards these goals. This could be explained by other studies indicating that minority parents are aimed at raising their children chances for successful integration, therefore put pressure on them to achieve high grades (Karipidis, 2002). Following this study results, this kind of pressure could lead to increased tendency to neutralize cheating once the student confronts academic challenges related to the studied materials.

The educational implications of the results could relate to the necessity for establishing frameworks aimed at first, identifying the Arab students academic needs, such as: language mastering skills. Second, equipping the Arab students with the tools they need to successfully cope with academic requirements.

Students' reasoning about cheating:

Lars-Erik Nilsson, Kristianstad University, Sweden; Henrik Svensson, Kristianstad University College, Sweden; Henrik Larsson, Kristianstad University College, Sweden

This study empirically investigates students' reasoning about right and duties in examinations. Student cheating on graded assignments has become a common research topic. Cheating on assessed work is often presented as endemic to suggest that it is present in all assessment and epidemic to suggest that cheating is increasing. Activities cited as

cheating in reports are for example using crib notes, plagiarizing, fabricating, impersonating and colluding. These activities are considered to threaten the integrity of assessment. Our aim is to contribute to research on cheating from the perspective of students' management of meaning as they are confronted with moral dilemmas that may occur when doing graded work. Four focus group discussions about two moral dilemmas have been videotaped and analyzed using positioning theory. The results indicate that students' categorization of actions as acts are not stable. Consequently we take issue with studies that constitute students actions as cheating based on presumptions of what these actions are to students. Some categorization such as for example to use crib notes or to impersonate appear less problematic while text-borrowing needs to be situated. Students appear to apply situational ethics as well as neutralizing techniques as they categorize actions. Actions can be treated as acceptable rule breaks if they can be justified by mitigating circumstances. The analysis of the results is discussed in relation to theories of neutralization and situational ethics. One conclusion is that situational factors appear to be important to determine subject positions such as honest or cheater.

Student cheating on graded assignments has become a common research topic. Activities cited as cheating in reports are for example using crib notes, plagiarizing, fabricating, impersonating, colluding and changing results (se e.g. Haines, et.al., 1986; Franklyn-Stokes & Newstead, 1995; McCabe & Trevino, 1996). By large there is an agreement in these studies that such activities should be categorized as forms of deception. Our aim is to contribute to this research from the perspective of students' management of meaning as they are confronted with moral dilemmas that may occur when doing graded work. Consequently we take issue with studies that constitute students actions as cheating based on presumptions of what these actions are to students.

The study

The data presented here are derived from four focus group discussions where students from upper secondary school talk about cases that have been designed to introduce moral dilemmas to them (Larsson & Svensson, 2010). The cases have been designed from investigations into academic misconduct in higher education (Nilsson, Lßnn-Svensson & Orlenius 2009). They have been revised, so that upper secondary students can more easily relate to the material. The students have been asked to discuss two cases. In the first a student has placed a crib note in the toilette to help another student. When caught the student refuses to give the name of the other student. The second case concerns a student who gets top grades on an assignment. He has compiled his text from web sources, and his fellow students composed their own texts to receive the same grades. The students were first introduced to the cases and discussed these. They were then exposed to other teacher and student voices commenting on the cases. These voices were introduced to elicit further comments from the participants.

The video recordings were transcribed and analyzed using positioning theory. (Harr   and van Langenhove 1999). Positioning is a dynamic process. Subject positions become available to people as episodes (called storylines) unfold. Positions such as cheater and honest student for example are being made available for participants through the way in which a particular action is talked about. Positioning theory posits a distinction between actions and acts hence allow persons to see actions as confirming to the rules and yet under particular circumstances to break the same rules constituting different acts. Storylines are considered to provide clues as to how actions should be constituted as acts hence what positions are being made available to participants in talk. Nilsson (2008) has argued that the distinction between actions and acts can be important particularly for positioning of students accused of cheating. We use positioning theory to engage in a discussion about the importance of such a distinction.

Results

The results indicate that students' categorization of actions are not stable. Some categorization such as for example to use crib notes or to impersonate appear less problematic. How a person that borrows text from another person should be positioned appears to be contingent on the students intentions. Collaboration may be construed as collusion depending on the situation.

Situational factors appear to be important to determine subject positions. Cheating in this sense does not appear as a stigmatizing, rather as an alternative to other actions dependant on considerations such as whether future learning can be impaired, whether the assignment invites taking short cuts and whether someone else may be harmed by the action.

Students appear to apply situational ethics as well as neutralizing techniques as they categorize actions. Actions can be treated as acceptable rule breaks if they can be justified by mitigating circumstances. The same actions can be treated as in compliance with rules depending on circumstances surrounding the situation in which they are carried out.

Concluding discussion

Michaels and Miethe (1989, 870) asserts that "studies of academic cheating often are not theoretically driven". A similar critique has been directed at research methodology. Ashworth and Bannister (1997) for example consider studies based on survey methods to be curbed by "the presupposition that the meaning of cheating is relatively univocal". We take the critique from Michaels and Miethe primarily to concern a lack of debate about theories and methodologies respective contributions to research.

Many theories of deviance are based on the assumption that deviant behaviors are learned. Sykes and Matza (1957) confront the problem of "why men violate the laws in which they believe" (p. 666). They argue that delinquency is often preceded by defenses to the crime. These defenses referred to as neutralizations are applied before a deviant action "in the form of justifications for deviance that are seen as valid by the delinquent but not by the legal system or the society at large" (p. 666). Seen this way, students' that willingly violate rules for examinations do not do so because they disagree with the norms, but because they are able to find favorable definitions that neutralize the norm. Students in our study do present rules they agree with and show evidence that there are ways to justify breaking these rules. Helping a friend may under some circumstances serve as such a justification, a technique called "appeal to higher loyalties" by Sykes and Mazda. However, in some cases these students do not consider such actions to be rules breaks and to warrant a position as cheater.

In many cases it appears as if rules are unclear instead of agreed with. Students need to engage in talk about the rules that apply to a certain action. Norris and Dodder (1979) argue that neutralization theory provides a narrow view on how people orient to norms and suggest four norm orientations; moral absolutes, situational ethics, neutralizations, and rebellious absolutes (pp. 546-547). While neutralizations can be considered as defenses for socially unacceptable actions situational ethics can be seen as legally acceptable albeit sometimes slightly wayward guidelines (p. 547). Positioning theory allows us to look beyond a treatment of students actions as simply a question of rule-following and rule-breaking. The distinction made between actions and acts reflects the uncertainty present in moral reasoning.

Adolescents' beliefs on the inhibiting factors of cheating in school exams

Catherine Dimitriadou, University of Western Macedonia, Greece

This study aims to identify certain reasons which could dissuade students from deviant behaviour, namely from cheating in school exams. Premised on the fact that students' decision to cheat or not to cheat is influenced by a variety of individual and social factors, we examined students' attitudes to cheating, possible reasons which could cause them to behave 'honestly' in exam situations, as well as how these factors correlate to each other. With these considerations, we addressed two groups of early and late adolescents aged 12 and 18 years old in a primary and a secondary school. In accordance with a scheduled scenario both groups, since their supervision was interrupted, had the opportunity to carry out deviant behavior whilst sitting a science and a math test. The development of a discussion and the application of a questionnaire followed the episode, thus providing data concerning the factors that could probably discourage students to cheat. Comparative results indicated that early adolescents consider normative aspects as more important reasons to avoid cheating, whereas the older ones give priority to grades and respect for their teacher. The results can possibly facilitate initiatives toward limiting deviant behaviour in the classroom.

Cheating in the classroom is considered immoral behaviour, since it^{*****} undermines equity, disorients teachers' feedback on the teaching effects, decreases the validity of measures on students' learning, increases damage to morale and degrades confidence to school as an assessing institution. Students' beliefs on this phenomenon are influenced by a variety of individual and social factors, whereupon students consider whether the benefits of the act outweigh the costs (Eisenberg, 2004; Passow et al., 2006). These benefit/cost tradeoffs may concern both students' beliefs and attitudes, and they may additionally refer to their intention to perform this behaviour and to their perception of control over it (Ajzen, 2002).

AIM

This study aims to investigate school students' beliefs about the possible reasons that could dissuade them from cheating in classroom-based exams, as well as the differences existing in these beliefs with regard to students' age.

Research questions

Premised on the hypothesis that there are some factors which could inhibit students' cheating with regard to their age and psychological development, the following research questions were posed:

- What is the attitude of early and late adolescents to cheating?
- Which individual and social factors could influence early and late adolescents' opinions on the acceptability of rule breaking concerning cheating?
- Are there any factors that could cause them to alter their unobserved behaviour and behave 'honestly' in exam situations?
- How do these factors correlate to each other among early and late adolescents?

METHOD

Participants

The study was held in a rural primary school and an urban senior high school, with student populations from medium socio-economic classes. A total of thirty two @@@@@@@@@@@@@@@@@@students took part. In the primary school classroom there were eleven (11) boys and eight (8) girls aged twelve (12). Eight (8) boys and five (5) girls, all eighteen (18) years old, constituted the secondary school class. Two experienced state-school teachers participated: a male primary school teacher and a female mathematics secondary education teacher.

Procedure

The study was built on a teaching episode which acted to assist the students to respond effectively to the main question posed: 'What kind of factors could prevent them from deciding to cheat during a test?' A three-phase procedure was organized in both classrooms:

- The students were invited to provide answers in a test, when an 'incidental' matter obligated the teacher to depart.
- The teacher returned shortly and instigated a discussion among peer-students concerning their cheating efforts while escaping detection.
- The students responded to a questionnaire intended to investigate the possible reasons which could reduce the probability of cheating in a particular situation.

Data collection

The research was conducted in actual classroom-based exam conditions. Qualitative and quantitative data were collected with the use of two instruments: (a) journals wherein the teachers kept notes of the students' answers during the discussion held in the classroom, (b) student questionnaires which were filled in after the end of the discussion. In the latter case, the students were asked to indicate on a 5-point scale the degree to which they agreed with seventeen statements ('I would not cheat if...') related to academic motivation and relationship variables (Murdock et al., 2001). The statements referred to a series of possible situations that would inhibit cheating.

FINDINGS

A 2 (school type) x 2 (sex) x 3 factors repeated measures ANOVA, with the last factor as within factor, did not reveal any significant main effect. Although the reasons to avoid cheating did not differ within the two school types ($F(2,54) = 1.748$, $p = .184$, $\eta^2_p = .061$), there was a trend according to which younger children ($M = 3.03$, $SD = 1.86$) perceived the reason to avoid cheating as being less important because of the grades than the older children ($M = 3.21$, $SD = .907$). Similarly, the older children ($M = 3.3$, $SD = 1.03$) perceived the reason to avoid cheating because of respect for their teachers as being more important than the younger children ($M = 3.01$, $SD = 1.02$). Contrarily, the older children ($M = 3.06$, $SD = 1.03$) perceived the social norms as being a more important reason to avoid cheating in comparison with the younger ones ($M = 3.5$, $SD = 1.18$).

These data appear to confirm the findings resulting from the discussion. According to the teachers' diary entries, primary school students do not consider cheating an immoral action, whereas secondary school students view it as a socially accepted practice pertaining to the competitiveness in a particularly demanding examination system (De Palma et al., 1995). The reasons that the participants acknowledged as discouraging them from cheating can be grouped into three main factors: (i) the social norms involving their fellow students and schooling as a system of behaviour rules, (ii) the grades as criteria which determine the students' progress, and (iii) the teacher as a key factor who is able to develop honourable relationships with the students and also persuade them to respect exams. More precisely, the early adolescents seem to consider the normative aspects (fear of punishment, peers' attitudes and school regulations) as more important reasons to avoid cheating, whereas the older ones give priority to grades and their relationship with the teacher (persuasion, agreement and respect).

THEORETICAL AND EDUCATIONAL SIGNIFICANCE

The results indicate that cheating in exams pertains both to morality and social norms, since it appears as a cultural construct. The classroom environment, the examination system and the teacher's individual personality impact the

likelihood of cheating in various ways, depending on the students' age. Early and late adolescents' differences in their disposition to avoid cheating can be explained according to the influence the identified factors have on the two student groups' developmental characteristics pertaining to their interests and the school community (Hutton, 2006). Educational settings characterized by the acknowledgement and the functional support 'for' or 'against' these factors are expected to have an impact on students' decisions not to cheat.

SYMPOSIUM

Beliefs

Self-concept development in the early school years

Chairperson: Karl-Heinz Arnold, Universität Hildesheim, Germany

Organiser: Karl-Heinz Arnold, Universität Hildesheim, Germany

Claudia Kastens, university of Kassel, Germany

Discussant: Kathy Sylva, University of Oxford, United Kingdom

Family education, schooling, and peer interaction provide three major sources of building and developing children's views on their abilities. As self-appraisals, these views have been conceptualized in the multifaceted framework of Shavelson, Hubner and Stunter (1976). Whilst there is a lot of research on the structure of academic self-concepts, less is known on impact factors other than achievement feedback on the development of the academic self-concept. Further on, research on non-academic self-concepts is scarce although it is clear that both family and school education intend to foster children's social skills. The symposium presents three studies analyzing the development of self-concepts in the primary schools years. Longitudinal design allows for answering the crucial question of decrease, increase and stability of self-concepts as well as of causal relationships regarding factors that are supposed to influence self-concept. The first study investigates how beliefs of significant adults—i.e. parents who closely interact with the children and thereby are likely to communicate their views on their children's abilities—influence self-concept development. In the second study, the development of the self-concept of social competence is analyzed over four points of measurement during the first four years of primary education considering the influence of and impact on the sociometric status of the child in its class. The third study takes a differential perspective by answering the question of gender differences not only at the level of group means but also at the individual level by analyzing self-concept growth curves.

Importance of parental beliefs for the development of children's self-concept: Effects and mediation

Alex Buff, University of Teacher Education, Switzerland; Iris Dinkelmann, Zurich University of Teacher Education (PHZH), Switzerland

Students' competence and value beliefs are seen as central to the quality of learning and achievements. Accordingly, the question of conditions or influences under which students' competence and value beliefs develop more or less favourably is by no means trivial in terms of educational practice. The contribution focuses on parental child-related competence and value beliefs, and addresses the importance thereof for children's own competence and value beliefs. Based on the model of parents' influence on children's achievement-related self-perceptions, values, and behaviors, and on the expectancy-value model of achievement choices (cf. Eccles, 2007), both direct and indirect effects – mediated by two aspects of parental behaviour (exercising control and providing structure) and by the children's perception of this behaviour – will be cross-sectionally and longitudinally examined.

Data were analysed from approximately 450 children and their parents who participated in the two longitudinal studies "TRANSITION" (Buff & Reusser, 2008) and the "State of Learning" (Moser & Hollenweger, 2008). As theoretically assumed, first results show that parental child-related competence and value beliefs directly influence the children's own corresponding beliefs. Moreover, it is indicated that a part of the effect of parental child-related competence beliefs on the children's competence beliefs is mediated by parental control and / or the children's perception thereof. In the case of value beliefs, parents' provision of structure and / or children's perception thereof appear to serve as mediating variables.

Method

The sample consists of approximately 450 children and their parents who are participated in the study "TRANSITION: Parental support and motivational-affective development in the transition to lower secondary level" (Buff & Reusser, 2008). The concern here is with a subsample of the "State of Learning Surveys at elementary schools in the Canton of

Zurich" (Moser & Hollenweger, 2008). Data collection took place in November 2008, March 2009 (TRANSITION) and June 2009 (state of learning surveys) during the sixth school year.

In the two data collection rounds in November 2008 and March 2009, the parents received their questionnaires first, and once these were returned, the children received their questionnaires. Thus, there is a clear temporal sequence between the information provided by the parents and the children in each case. Within the respective data collection rounds, the information given by parents and children provided cross-sectional data; thus, for the data collection in November 2008 and March 2009, the model checking is rather cross-sectional in nature. By considering the data collected in June 2009, however, the model depicted in figure 1 can also be longitudinally tested: parental child-related beliefs (November 2008), parental behaviour and perceived parental behaviour (March 2009), children's self-related beliefs (June 2009).

The data analysis ensues either through path models with manifest variables or – provided it is feasible based on the sample size (which still needs to be checked in detail) – through structural equation modelling with latent variables.

Results

First path analyses show that parents' child-related competence and value beliefs prove to be relevant predictors of children's own corresponding beliefs: the higher the better. Parental control appears to be primarily influenced by parents' child-related competence beliefs, while providing structure is primarily influenced by value beliefs. The higher the child-related competence beliefs of the parents, the less control is reported, whereas higher value beliefs are associated with more structure. Equally, it is indicated that parental control and structure do not influence the competence and value beliefs of the children directly, but rather indirectly via their perception by the children. Exercising control appears to negatively affect competence beliefs, while providing structure seems to positively affect value beliefs. Altogether, the results of the analyses conducted so far are very encouraging, firstly confirming available empirical findings, and secondly, supporting theoretical assumptions.

Self-concept of social competence and social preference: Development during the primary school years

Carsten John, University of Hildesheim, Institute of Educational Science, Germany; Frank Lipowsky, University of Kassel, Institute of Educational Science, Germany; Karl-Heinz Arnold, Universität Hildesheim, Germany

Schooling can be seen as a major developmental and learning opportunity for social competence because both interacting in classrooms and receiving feedback on social behavior foster not only students' development of social skills but also the acquisition of social knowledge and the development of self concept of their respective abilities. The longitudinal research project "Development of academic and social competence of primary school pupils in classrooms differing by their multilingual composition" (KEIMS-plus) supported by the German Research Foundation (DFG) investigates the development of social, academic and linguistic competencies and their interrelations during the early school years of nearly thousand students.

The study intends to work out the construct of social competence by analyzing the relationship between the self-perception of social skills and abilities (self-concept of social competence) and sociometric status as a major impact variable of social behavior and vice versa, i.e., the social position in the class group is supposed to influence the self-concept of social competence. The longitudinal design (four points of measurement, ca. 1000 students) of the study allows for cross-lagged panel modeling. Results show considerable structural and level stability; normative stability is found moderate for self-concept and high for social preference which in turn is supposed to be the cause of no significant impact of self-concept on social preference whereas a slight influence of social preference on social self-concept is revealed.

Major educational goals like maturity and social as well as professional responsibility refer to social competence (see overview by Brohm, 2009, for international and German educational guidelines concerning social competence). Schooling opens a variety of learning opportunities for social competence, e.g., interacting in classrooms and receiving feedback on social behavior might foster students' development of social skills, acquisition of social knowledge, and the development of self-concept of their respective abilities (for the latter see Berndt & Burgoyne, 1996). In this respect, social competence can be seen as an outcome variable.

Social competence is also conceivable as an input variable predicting school readiness (e.g. Hasselhorn & Lohaus, 2006) or academic achievement (see Welsh, Parke, Widaman & O'Neil, 2001). Hence, it seems of major interest to have a closer look on relevant facets of social competence in the early school years, their measurement, and development.

According to Rose-Krasnor (1997, p. 112) most definitions of social competence share the aspect of "effectiveness in social interaction", but measurement demands for criteria on more concrete levels of definition. In this respect, four central approaches to social competence are distinguishable: (1) social skill approaches, (2) peer status approaches, (3) relationship approaches, and (4) functional approaches.

The social self-concept refers to peer status as well as social skills; it is defined alternatively as (a) perception of social acceptance of one's own person or (b) perception of one's own social competence or social skills—usually social self-concept scales refer to the first definition (Berndt & Burgoyne, 1996, p. 171, 173).

Significant relations between social self-concept of acceptance and actual social acceptance are reported but turned out to be weaker for the early school years in some studies (see overview by Berndt & Burgoyne, 1996, p.195). They comment that there is much variation between perceived and actual acceptance depending on sample and measure whereby regular effects of age could not be detected and various sources of inaccuracy of self-evaluations have to be taken into account. In principle, correlational analyses of relations between social self-concept of acceptance and actual social acceptance investigate the correspondence between self and other perspective, more information is available by longitudinal data for investigating reciprocal effects.

Sociometric measures assess the social position (status) of individuals in their respective peer group and could be defined as an indirect measure of social competence; correlations between social status and behavior are mostly moderate because further characteristics of the person are influential (e.g. Bursuck & Asher, 1986, p. 41). In this respect it has to be noted that peer status can be defined by different patterns of association between acceptance and rejection (e.g. "social impact" is represented by the sum of a child's liking and disliking score, "social preference" by the difference of a child's liking and disliking score; Coie, Dodge, & Coppotelli, 1982, p. 559).

Investigating longitudinally the linkage between self-concept of social competence and peer status could help to understand whether self-perception of one's own skills in social situations has an effect on peer status (presumably mediated by one's own behavior) and / or whether peer status functions as a kind of social feedback for one's own perceived social skills.

Method

The study assessed the developmental period of grade 1 through 4 comprising four times of measurement. The first measurement started at grade 1 in April 2007; the last measurement at grade 4 was in spring 2010. Twenty-six schools, respectively fifty-four classes, took part in the study. The sample consists of 1003 children (at time 1; day 3 of assessment); for 188 children no parental permission was available. The measurements of the entire study include (1) central aspects of social competence like self-concept of social competence, social information processing (response generation), ratings of prosocial behavior, and sociometric indices, (2) cognitive and linguistic abilities and (3) academic achievement in reading, writing and mathematics (assessed by standardized instruments). Self-concept of social competence was measured by 15 items assessing contact, empathy, and emotion regulation (Arnold & Lindner-Mueller, 2004, rev. 2007). At grades 1 to 3 the self-concept questionnaire was administered as an individual interview, at grade 4 the children filled in the questionnaire by themselves. Sociometric status was assessed by asking the children to name those children they mostly favor to work together and those they like to work together least. Liking and disliking indices according to Pettit (1980) were calculated.

Complementary stability-indices ("structural stability", "level stability" and "normative stability") could be taken as a basis for analyzing the social self-concept (see Möller & Trautwein, 2009, referring to Mortimer, Finch, & Kumka, 1982). Reciprocal effects between social self-concept and sociometric status are analyzed investigating origins and effects of social self-concept over time. Structural equation modeling was employed using the software package Mplus.

Results

Referring to the first three points of measurement (1) structural stability for a two factor-model including only the contact- and empathy-items is indicated by good fit indices for each measurement point and a global measurement model over the three times. (2) Level stability could be found. In contrast to some other studies, no decrease of average scores of social self-concept shows up. (3) Stability of interindividual differences (normative stability) is substantial for social-preference and lower but even large for the social self-concept. (4) Only a slight influence of social preference on social self-concept is found. Further results will be presented testing whether this holds for the fourth point of measurement.

Gender differences in primary school students' domain specific self-concept development

Claudia Kastens, university of Kassel, Germany; Frank Lipowsky, University of Kassel, Institute of Educational Science, Germany

Within the PERLE-Study (Personality and learning development of primary school children) we reliably assessed primary school students' self-concept in three domains (numeracy, reading, and writing) from school enrollment to the end of fourth grade, which marks the end of primary school in most German states. Research on self-concept development in elementary school often reports a decline in self-concept over the school years. We applied Latent-Growth-Curve-Models to our longitudinal data to analyze self-concept development in all three domains by considering interindividual differences in initial level and trajectories over time. We also analyzed whether gender differences in self-concept development (change trajectories) exist for all three domains and if gender differences in level can already be seen when students enter primary school. The results of the LGCM (considering data from school enrollment to the end of third grade) undermine the importance of a domain specific perspective on self-concept development. A decline in self-concept cannot be shown for all domains. After controlling for achievement we only found significant gender differences for self-concept level for numeracy and for self-concept development for writing.

SYMPOSIUM

Computer-supported Learning Environments

From concept to implementation: social presence in networked learning scenarios

Chairperson: Helga Dorner, Central European University, Hungary

Organiser: Ana Remesal-Ortiz, Universidad de Barcelona, Spain

Discussant: Jan-Willem Strijbos, Ludwig-Maximilians-Universitat, Germany

In a networked society, learners and also their teachers are increasingly using ICT tools to learn collaboratively and work together. Research has shown that establishing social presence is a prerequisite for interaction. This symposium gathers three different perspectives on the concept of social presence. The main purpose of the symposium is to generate debate, and challenge the current understanding of social presence in various contexts of computer supported education. In terms of theoretical background, the papers share different assumptions in different combinatorial pairs. While all of them depart from the original model of the Community of Inquiry, one paper proposes a revision of the concept. Two papers depart from a socio-constructivist conceptualization of the teaching and learning process, while a third paper takes a cognitive-constructivist perspective. Two of the papers purposefully link the object of study with motivation, from a Self-Determination Theory perspective, while the third does not this link. These differences at a theoretical level lead each of the authors to the search of the phenomenon in different interactional contexts, both with and without the instructors' intervention. The papers use a range of quantitative and qualitative methods in order to enhance the understanding of social presence. All authors agree with recognising social presence as a key factor for the successful development of online and blended courses. Nevertheless, each of the papers offers different arguments in favour of this point. In that sense, the contributors to the symposium expect to create a fruitful context for discussion with the audience.

The role of motivation and learning style on usage of ICT with low and high social presence

Bas Giesbers, Maastricht University, Netherlands; Bart Rienties, University of Surrey, United Kingdom

In recent years, the possibilities of Information and Communication Technology to support synchronous interaction in online learning have increased considerably. Web-videoconference systems offer several tools (like chat, audio, webcam) varying in the extent to which learners can display social and emotional information (social presence) when collaborating with others. In this study among 98 students in an online course on foundations of economics we examined whether the number of web-videoconferences a student participated in and the choice to use a range of communication tools was influenced by the individual characteristics motivation and learning style. We found a tendency toward intrinsic motivation and a disposition for stepwise learning in web-videoconference participants. Also, students participating more often tend to do so by using more rich communication tools. A challenge for future courses will be to find which students will benefit the most from the videoconferences and how they can be engaged more.

Conceptual Rationale Synchronous communication (like chat and videoconferencing) is superior to asynchronous communication (like discussion forums) in establishing discourse due to the ability to express immediate feedback (chat), ability to use voice and intonation and to show body language (videoconferencing) (Beers, Boshuizen, Kirschner, & Gijssels, 2007; Derks, Bos, & Grumbkow, 2007; Haythornthwaite, 2000; Tu, 2002; Tu & McIsaac, 2002). In terms of the Community of Inquiry model (Garrison, Anderson & Archer, 2000), synchronous communication fosters higher levels of social presence because there are more ways in which a person can project their personal characteristics to others. It is generally assumed that synchronous communication might reduce meaning barriers the obstruction of mutual construction of meaning of information from sender to receiver, when learners are working and learning together in an online classroom (Bromme, Hesse, & Spada, 2005; Rummel & Spada, 2005).

Research problem, aims and hypotheses

Adding web-videoconference to the course does not automatically lead to an increase in perceived usefulness of the course. Since students have the choice to participate and the means to project their identity, we want to know if there are individual characteristics that influence this choice. A large amount of research has found an influence of motivation, that is, the drive to learn, on contributions to discourse in a-synchronous discussion groups (Järvelä, Järvenoja, & Veermans, 2008; Veermans & Lalimo, 2008; Yang, 2006; Martens, Gulikers & Bastiaans, 2004). Intrinsically motivated students contribute more to task-related discourse, to planning and technical issues than extrinsically motivated students who contribute less actively, also in terms of social contributions. This leads us to expect that motivation also plays a role in a students' choice to participate in synchronous online communication which, to our knowledge, has not been addressed yet. We expect to find that students participating more often are more intrinsically motivated. In addition, we expect that intrinsically motivated students choose more rich communication tools. We expect that students who participate more actively, defined by the number of web-videoconferences attended and the richness of communication tools used, to have a strong disposition for stepwise learning and cooperation.

Research methodology

Participants were students in an online preparatory course for prospective bachelor students of an International Business degree programme of a Dutch university (N=98; age M = 19.5, SD = 1.28; 41% was female). For the purpose of this study, participants were divided into groups based on the number of times they participated in a web-videoconference: No participation (n = 15), participating once (n = 24), twice (n = 25), three times (n = 16), or four times (n = 18). Participation in the videoconferences was voluntary and to encourage students to do so, 1a participation score was calculated that constituted 10% of the final grade.

Results

Results indicate that the use of rich communication tools may be influenced by a more intrinsically directed motivation. Also, results show that students choosing to participate more often show a preference for a stepwise oriented learning style. With respect to performance measures we found the average score on the progress tests to be higher for students participating in all videoconferences compared to students participating once or twice. No significant result was found with respect to scores on the final test. Finally, the use of rich communication tools was found to be higher for students participating in all videoconferences compared to students participating once or twice. Discussion and conclusions When students can choose which ICT tools to use in an online classroom exercise, students do not automatically choose the richest ICT tools in terms of social presence. The use of rich ICT tools in our study is related to the type of motivation, whereby students with intrinsic motivation and stepwise oriented learning style were more inclined to use all web-videoconference facilities. Furthermore, these students were more inclined to continue with the online course and reach higher study success. In other words, differences in students' personal traits influence the selection, use and intensity of ICT tools. This implies that teachers should design online courses whereby students can choose a range of ICT tools that fit with their perception of social presence, learning style and motivation.

Training the trainers: Social and teaching presence in online mentoring

Helga Dorner, Central European University, Hungary

This study examines how Hungarian in-service teachers' social presence and their instructors' teaching presence are created and supported through online mentoring in the context of social interaction in an online collaborative professional development exercise. Transcripts of interactions among two groups of in-service teachers ($n = 23$, $n = 20$) and their instructors were analysed at the macro and micro level: at the macro level by Social Network Analysis; at the micro level by content analysis (Garrison, Anderson & Archer, 2001). When coding the interactions, we relied on numeric values indicating the agreement between two independent coders (Holsti's coefficient of reliability). Additionally to the above, we surveyed participants' satisfaction with the instructor's role and perceived social presence.

We found evidence of the effect of online interactions on the success of mentoring events i.e. participants' satisfaction with the experience. We also found that facilitator's activity and perceived social presence had significant influence on the participating in-service teachers' online communication. With the content analysis, we detected relations between facilitation approach and network interaction structures and strength of network ties. Accordingly, evidence of the effect of online mentoring on social presence was limited. We observed course characteristics (course structure, pragmatic and functional ways of instruction, scaffolding etc.) that can influence the creation of socially active communities. We intend to discuss the limitations of the applied research tools and suggest further research methodologies applicable in innovative mentoring models.

Conceptual rationale

Theories of social learning argue for the social aspects of learning and propose that cognition is a situated activity rooted in social, cultural contexts and interactions. From this perspective, learning is not the plain assimilation and accommodation of new knowledge, but it is the process by which learners become part of a knowledge community (Scardamalia & Bereiter, 1994; Vygotsky, 1978). The emergence of the new communication technologies enables new ways of designing and delivering education to learners. However, instructors are inadequately trained and not prepared for teaching and learning in an online environment (Harasim, 1991). Integrating the usage of computer-supported collaborative learning (CSCL) environments in in-service teacher training mentoring scenarios is one possible way to bring about change in communities where the intellectual traditions are merely based on individual knowledge creation processes. Accordingly, teachers' professional development has broadened to include learning communities that enable supportive interpersonal relationships and enhance professional growth. The success of such pedagogical scenarios is deeply impacted by the participants' experience of social presence, that is the degree to which a person is perceived as "real" in a mediated communication scenario (Short, Williams and Christie, 1976), and that is dependent on the extent to which the "illusion of nonmediation" (Lombard & Ditton, 1997) is maintained.

Research problem, aims and hypotheses

In such communities, the mistake of taking social interaction for granted often leads to „serial monologues" (Henri, 1991), which resemble the so-called IRE form of classroom discussion where the teacher initiates (I) the interaction,

learners respond (R), and the teacher evaluates (E) the responses (Lipponen, Rahikainen, Lallimo, & Hakkarainen, 2001). Since interaction does not simply occur but must be designed into the activities, the role of online instructors offering guidance and moderation in discussion is vital (Berge, 1999). Consequently, we focused on defining the online instructor's position within the ICT-based retooled mentoring scenarios. According to our hypothesis, online interaction facilitated by the instructor connected to creative collaborative activities is central to the success of mentoring events, and that instructors' teaching presence has an impact on participants' experience of social presence. We hypothesise that perceived social presence and online communication are interrelated phenomena and mutually impact each other in the mentoring process in the CSCL environment. We also address the questions whether the course structure and the facilitator approach provide adequate scaffolding to nurture development of social presence, if yes, then what pragmatic and functional ways of instruction can be designed to support these processes.

Research methodology

In order to be able to describe the underlying processes and the interrelatedness of social and teaching presence, transcripts of interactions among two groups of Hungarian in-service teachers ($n = 23$, $n = 20$) and their facilitators were analysed by two independent coders at the macro and micro level: at the macro level by carrying out Social Network Analysis; at the micro level by using content analysis, (Rourke, Anderson, Garrison & Archer, 1999; Anderson, Rourke, Garrison & Archer, 2001;) focusing on instructors' teaching presence and participants' social presence. Holsti's kappa was used for measuring interrater reliability. Additionally to the above methods, we surveyed participants' satisfaction with the online communication, instructor's role and perceived social presence.

Results

We found evidence of the effect of online interactions on the success of mentoring events i.e. participants' satisfaction with the experience, (p which could also imply that teaching and social presence are not interrelated phenomena. This provides for fruit for thought on challenging the concept of social presence, which is more frequently interpreted as a mediating variable between teaching and cognitive presence. However, with the content analysis we identified relations between facilitation approach and network interaction structures and strength of network ties. Additionally, we observed course characteristics that can influence the creation of socially active communities. We intend to discuss the limitations of the applied research tools and suggest further research methodologies applicable in innovative mentoring models.

Social Presence in small group work: it's all in the process

Rosa Colomina, Universidad de Barcelona, Spain; Ana Remesal-Ortiz, Universidad de Barcelona, Spain

In this study, the construct of social presence is approached from a socio-cultural perspective and thus recognised as an essential component of the virtual and blended collaborative learning process. Socio-cultural and social identity theory give support to interpret the development of a small group collaborative learning activity within a blended program at a bachelor program. Social presence is understood as the result of participants' enacted strategies to create and maintain a group identity and a shared goal, that is, social presence is seen as the sum of individuals' actions that contribute to the creation of a community feeling in such a way that the learning process is motivationally and emotionally supported. Participants of this study were 15 student-teachers who performed a collaborative writing activity during seven weeks, working in small groups of 3 and 4 members. They were expected to write a collaborative argumentative text by means of a non-specific asynchronous device (a forum space). Qualitative content analysis was carried out to classify the participants' interventions along two dimensions with each two opposite values: individual-oriented versus group-oriented, task-oriented versus people-oriented. Each of these dimensions holds three categories that contribute to draw an interaction map of each of the four groups in terms of their enacted social presence, highlighting different motivational aspects that appear to be playing a key role in their learning process.

Conceptual rationale

The importance of social presence was underlined in the late 1990s by the Community of Inquiry model (Rourke, Anderson, Garrison, & Archer, 1999). Social presence has been often equalled with students' satisfaction and learning post-hoc perception. Today, social presence is considered to be a mediating variable between teaching presence and cognitive presence.

In early studies, social presence has been mostly identified with off-task communication (Tu & McIsaac, 2002). However, recent research contributions highlight the importance of on-task figurative language in the process of creating a shared feeling of community, as a resource used by the participants to express their emotions along the learning process. Most of the previous studies have focused on online whole class discussions with no other expected shared result than the discussion itself. A quite different situation emerges when considering small group collaborative learning with different sorts of complex activities expected as group products. In that case, it seems necessary to rethink the concept of social presence from a different perspective. In this study social presence is understood as the result of participants' enacted strategies to create and maintain a group identity and a shared goal, that is, social presence is seen as the sum of individuals' actions that contribute to the creation of a community feeling in such a way that the learning process is motivationally and emotionally supported. From this perspective, there is a clear connection between the creation and maintenance of social presence and the regulation of motivational processes within the group, usually studied from a different perspective (Järvelä, Järvenoja, & Veermans, 2008). We also clame for a change of perspective in online learning that considers the contributions of social psychology and the notion of represented group, that is: the group is not an objective entity, but exists in the individuals' minds. The group members do act and react to the representation they have of the group and, in that sense, the group is continuously dynamically recreated (Rogers & Lea, 2005).

Research problem, aim, research questions

We approach social presence from a socio-cultural perspective and put the following research questions: How do the participants contribute to the creation and maintenance of social presence along the collaborative learning activity?

Design and analysis

We carried out a qualitative case study (Flick, 2002; Yin, 2009). Four small groups of student-teachers participated. The students worked together for a whole academic year in a blended program. Data were gathered during the realization of the last course assignment under complete on-line conditions, during seven weeks. The writing work was performed by means of a particular e-learning platform which offered asynchronous instruments (Moodle). Qualitative content analysis of the forum contributions (274 postings) was carried out. Two units of analysis were taken into account. First, the basic unit of meaning was the fragment of discourse in any posting. Second, the postings per se, and the historical development of the threads was taken as a contextual unit of meaning. The categories and indicators were initially defined based on the literature review. Progressively, they were revised and readjusted in an iterative analysis searching for inter-judges agreement.

Results

Categories were defined along two dimensions concerning the self-positioning of the individuals' in front of the task and in front of the other collaborators. The categories collect the individuals' positioning in terms of their explicit communication of positive or negative perceptions and expectations of the group performance. Results show, first of all, a great amount of social presence. This stands in contrast with previous studies, where only off-task conversation was considered to be 'social'. Results point, too, to certain gender-based differences in the process of social presence

management along the collaborative activity. Different emergent roles can be identified as well among the participants, pointing to power relations.

Discussion and conclusions

These results are important as far as they permit to rethink the concept of social presence within the field of collaborative computer supported learning in situations in which a real shared goal and product is expected from the participants, in contrast with previous studies, where social presence is considered a post-facto satisfaction measure of big-group debate situations. Thus, now it is possible to identify poor motivational situations and intervene appropriately as a teacher in order to enhance e-learning processes. For example, it is possible to identify groups focusing just on group-identity but forgetting about the task, or groups too much on the task and on the individual participation but not building a sense of group identity. Ideally, there should be a balance between all categories for a sound social presence leading to an enhanced learning.

Certainly, the fact that only four groups were analysed poses important limitations to the results. Nevertheless, the explorative purpose of this first study allows such a qualitative small-sample approach. Another shortcoming of the study is its relatively short duration. The fact that this learning activity took place at the end of course, with all group members knowing each other already for months, definitely must have an impact. Different results ought to be expected at the beginning of a course, when group members first meet. A definitive open issue pointed out by this study is the gender composition of the groups and its influence on social presence.

SYMPOSIUM

Teacher Education

Studying Effectiveness of TPD at the Level of Individual Teachers and Local Communities

Chairperson: Alexander Groeschner, Technische University Munchen, Germany

Organiser: Alexander Groeschner, Technische University Munchen, Germany

Tina Seidel, Technische Universität München, Germany

Discussant: Manfred Prenzel, TUM School of Education, Germany

Aims of the symposium.

Recent research on teacher professional development (TPD) emphasizes a number of factors influencing the effectiveness of such programs for promoting teacher learning. So far, emphasis has been placed especially on the relationship between characteristics of TPD (duration, active learning, cooperative learning) and individual teacher factors (knowledge in a domain, motivation for professional development). In addition, TPD characteristics in relation to factors at the level of schools and the local school community have been pointed out. The aim of this symposium is to present research findings investigating the relationship between TPD and individual and local community factors, as well as to provide a systematic overview of recent approaches to studying effective TPD. In order to achieve this aim, the symposium includes both a meta-analysis and review summarizing the state-of-art and identifying fields of future research, as well as two papers which provide an in-depth look at particular aspects of TPD. Scientific and educational relevance. Research on TPD suggests that there is still a range of professional development formats that either have been shown to lead to different effects or have not yet been studied in detail. This symposium provides both a broad perspective, considering broadly applicable findings with respect to TPD, as well as detailed consideration of factors at both the individual and school community levels. In this way, the symposium contributes examples of evidence for effective factors in TPD and points to directions for future research.

Effective Interventions for Professional Development of Teachers: A Review Study

Klaas van Veen, Leiden University, Netherlands; Rosanne Zwart, VU University, Netherlands; Jacobiene Meirink, ICLON Graduate School of Teaching, Leiden University, Netherlands; Nico Verloop, ICLON Graduate School of Teaching, Leiden University, Netherlands

This review study aims to explore what is currently known about the effectiveness of teachers' professional development programs or PD interventions on the quality of teachers, their teaching, and student learning. The review brings together 11 major reviews and texts on effective PD, and 37 recent empirical studies from the last ten years. Next to reviewing the effective characteristics of PD interventions, it also explores the often neglected domain in PD literature of the school organizational conditions necessary to implement and sustain successfully PD in the school. One major conclusion and point of discussion is that reviewing the field of effective PD is actually mapping out the terrain of research that still needs to be done.

Aims

Teacher professional development in this review is referred to as those processes and activities designed to enhance the professional knowledge, skills, and attitudes of educators so that they might, in turn, improve the learning of students (Guskey, 2000). The focus of the review is on those activities explicitly designed for professional development of teachers, which are described as interventions for PD. The review refers to four main problems in this field: 1) The state of the art of research on effective PD is problematic because most research only refers to the effects of one PD program, and still little is known about effective PD when a program is delivered in a range of typical settings and by multiple trainers. Furthermore, the evidence on features of effective PD is weak (Borko, 2004; Wayne, Yoon, Zhu, Cronen & Garet, 2008); 2) Different theoretical frames are (often implicitly) used to explore and develop effective PD (Desimone, 2009); 3) There are more empirical studies on traditional PD interventions than on the more current progressive ones (Wayne et al., 2008); 4) Research on effective PD hardly explores the school organizational conditions necessary to implement and sustain successfully PD in schools (Imants & van Veen, 2010). So, this review aims first to bring together what is the state of the art of research on effective PD and what is known about the features and conditions of effective PD. Second, the review uses the findings to discuss these four problems. Considering that most of these problems are well known for the last ten years (cf. Kennedy, 1998; Borko, 2004), the nature and implications of these problems are discussed, and directions for further research suggested.

Methodology

Literature searches were conducted with the use of ERIC, PsychINFO, Dissertation Abstracts, Sociological Collection, PiCarta en Google Scholar. Furthermore, references of previous reviews were examined, and various international experts in the field were consulted (including well-known researchers in the US, and Europe). The review focuses explicitly on the effects of PD interventions, so activities deliberately designed for teachers' professional development. This implies that related fields as informal learning has been excluded. Furthermore, in line with Desimone's (2009) conceptual frame, the studies should refer to effects of PD interventions on teachers and/or students. The review first brings together 11 major reviews and texts on effective PD that cover the last 25 years of research on PD interventions. Furthermore, 37 empirical studies are included from the last 10 years. Together they provide an impressive collection of theoretical and empirical body of research of the last 25 years.

Findings

Regarding the nature of research on effective PD, the review summarizes and discusses the problems found. The problems refer to teacher knowledge and skills as the major outcome measure (studies that include teaching behavior or student outcomes are relatively rare); the most common measure is teachers' perceptions (more quasi-objective measures are hardly used); general measures instead of PD specific ones; most effect research is on traditional PD; and Borko's (2004) observation of the lack of studies exploring PD programs in a range of typical settings and by multiple trainers. Considering these problems, some prefer to speak of a consensus on features for effective PD, some argue for improved and more rigid research designs. The review summarizes the empirical evidence on effective features. Despite the current tendency to favor more progressive PD interventions, the type of interventions in terms of traditional versus progressive does not seem to matter significantly: in both cases evidence is found that it is effective or not effective. Other features are more relevant for effective PD, such as a focus on subject content, subject pedagogy, active learning, coherence, duration, collective participation, and an explicit theory of change and instruction. However, the problem remains these effective features lack sufficient specificity to guide practice. Often it is too general, or the study is too context-specific. And most studies refer to math and science, and hardly to other subject areas. A last set of conclusions refers to the school organizational conditions for PD interventions to be successfully implemented and sustained. Only a few PD studies pay attention to this topic. In related bodies of literature, such as workplace learning, more relevant insights can be found about the conditions for learning in the workplace. However, hardly any empirical studies can be found exploring PD interventions in relation to those

conditions. Still, a relevant overview of potential relevant factors can be given. In general it can be stated that schools and classrooms are mainly designed for student to learn and for teachers to work, and hardly for teachers to learn.

Educational and theoretical relevance

A first contribution of this review is that it brings together a collection of relevant reviews and texts, and adding new empirical studies, trying to synthesize the different findings and perspectives. Secondly, Desimone's conceptual frame is used for this review, supporting her proposal to use one general frame in this largely fragmented field of research. Lastly, an attempt is made to combine insights from literature on PD with literature on workplace learning to gain more insights in how to successfully implement and sustain effective PD in schools.

Learning Processes in a Video-based Learning-Environment

Marc Kleinknecht, TU Munchen, Germany

Currently, there is a growing interest in using video as a reflective tool for professional teacher development. However, there is still little evidence for the specific effects that different types of video-based learning environments may have on teacher's learning processes. This study focuses on cognitive, motivational, and emotional processes that teachers experience during the analysis of videos of their own teaching compared to a group commenting videos of other teachers. For answering this question, a sample of ten eighth-grade experienced mathematics teachers analyzed 10 to 15 minute segments of videos of their own or external classroom situations in a newly developed computer-based learning environment. During their work on the videos, the teachers answered either open questions or structured questions with regard to 'cognitive activation'-focused observation tasks. Content analysis of the teachers' answers revealed strong differences between the teachers who commented their 'own teaching' versus teachers who commented 'other's teaching'. Particularly, the findings indicate that teachers who analyzed their own videos are more intensively emotionally involved than others. This emotional involvement has a detrimental impact on cognitive aspects of analyzing the videos because it draws away resources that are necessary to describe teaching situations in a neutral manner. The study emphasizes that different learning objectives need to be addressed before using videos of teachers' own teaching or that of others. The applied learning environment is used primarily for the process-orientated future research on teachers' differential learning processes.

Aims

Currently, two different learning arrangements are used widely in video-based teacher trainings: an individual reflection on the video or a discussion and joint reflection in groups (Brophy, 2004). These two settings allow both the usage of own videos and videos of others' teaching. This study focuses on the one hand the individual observation of own versus other teaching and on the other hand two different structured instructions for observation. The study refers to three main research questions:

- 1) What cognitive learning processes are activated when teachers observe video clips of their own teaching or that of others?
- 2) What emotional and motivational learning processes are initiated when teachers observe clips of their own teaching or that of others?
- 3) To what extent do cognitive and motivational-affective processes influence each other while commenting on video?

According to the findings of Seidel et al. (2011) we expected positive motivational effects derived by teachers who have analyzed videos of their own classrooms. The observation of others' classroom situations should lead to viewer's deeper reflection on critical incidents.

Methodology

Ten grade 8 mathematic teachers took part in this study. For the five teachers in the group 'own video' we selected 10-15 minutes videoclips from previously videotaped lessons. The clips show classroom dialogues before and after student seatwork phases. Teachers were matched to the two groups taking gender and the duration of teaching experience into account. Five pairs of teachers were grouped together with one person commenting the own video and one person commenting the same clip as 'other video'.

The videos were implemented in a computer-based learning environment. All teachers observed their video clip on their own and two times. First, no specific instructions were given. Afterwards teachers were able to pause and comment the clip whenever a scene of interest occurred. In the second stage, teachers were supposed to identify situations in which the teachers in the videos demonstrated behavior that cognitively activates the students. Before completing this task, the learning environment prompted an explanation of the concept of cognitive activation. As before the participants were asked to answer open-ended questions on their emotion and motivation. Additionally fixed questions with rating format items were used to evaluate the trait emotions and motivations after the two stages of observation (cf. Seidel et al., 2011).

Teachers' written comments were analyzed using a category system that focused on noticing classroom situations and knowledge-based reasoning processes which is based on the works by Sherin (2007) and Seidel et al. (2011).

Findings

In cognitive terms, the two groups differ in the perception of events ('noticing') and the knowledge-based reasoning process. Teachers of the 'own video'-group stopped the video especially in the first stage of observation more often. They frequently commented more scenes than teachers of the 'other video' group. An opposite picture emerged in different categories of the knowledge-based reasoning process. Teachers of the 'other video'-group named more alternatives with regard to teachers' ability of behavior in observed situations. Moreover, they discussed the filmed classroom situations more critically.

In terms of emotion and motivation the results also show a disparity between the groups. Teachers of the 'own video'-group reported more likely to be emotionally involved in the observed scenes. In particular, they account their perceived anger and disappointments. Furthermore, their comments contained evidence of a higher degree of involvement in observed situations and more reported connections to own teaching.

Educational and theoretical relevance

The findings of this study show substantial differences between the two groups. The observation of videos of others' teaching enables deeper reflection processes, while observing videos of own teaching leads to a higher degree of emotional and motivational involvement. Results suggest that video-clips of 'others teaching' are valuable to initiate emotionally distant and theoretically oriented systematic reflection in teacher professional development closely connected to classroom practice. In contrast, observing of video-clips of 'own teaching' should be guided more by teachers' experienced situations. Questions or tasks of reflection should be induced selectively and carefully. Through the conclusiveness of the study is limited by the small sample size. A follow-up study with a larger sample should prove evidence of this research. For this purpose the developed video-based learning-environment could be used for the process-oriented, introspective analysis of teacher cognition, motivation and emotion.

Practicing Teachers' Engagement with Video Clips Designed to Support PCK Development

Alicia Alonzo, Michigan State University, United States; Jiwon Kim, Michigan State University, United States

Video can be a powerful tool for teacher development (e.g., Borko, Jacobs, Eiteljorg, & Pittman, 2008; Sherin & van Es, 2009), offering a common classroom context for discussion. However, the interplay between work in professional development and classroom settings is influenced by the way in which artifacts of practice are used in professional development and, thus, depends, in part, upon the types of videos selected for discussion (Sherin, Linsenmeier, & van Es, 2009; van Es & Sherin, 2008). In this study, we sought to explore the types of conversations elicited by video clips selected to support beginning physics teachers' pedagogical content knowledge (PCK; Shulman, 1986) for teaching force and motion concepts. Video clips from experienced teachers' classrooms were used in a short, relatively unstructured professional development workshop. Teachers' conversations were analyzed both broadly – using a framework developed by Alonzo and Sato (2010) and by Sherin et al. (2009) – and more specifically – making comparisons to researchers' expectations for the specific discussions the video clips would elicit. Teachers' conversations were generally of high quality (according to the Sherin et al. framework) and broadly covered the three areas predicted by researchers – student thinking, pedagogical potential of instructional representations, and physics content. However, the specific foci of these conversations differed in important ways from researchers' expectations. These results have important implications, both for the selection of video clips and for the support for teachers' discussions of video evidence in professional development settings.

Aims

Video can be a powerful tool for teacher development (e.g., Borko et al., 2008), offering a common classroom context for discussion. However, we know too little about the interplay between teachers' work in professional development and classroom settings (Kazemi & Hubbard, 2008). This interplay is influenced by how artifacts of practice are used in professional development and, thus, depends, in part, upon the videos selected for discussion (Sherin et al., 2009). We are interested in identifying video clips that can be used to support beginning physics teachers' pedagogical content knowledge (PCK; Shulman, 1986) for teaching force and motion concepts. Therefore, we focus upon video clips that highlight student thinking and hope to elicit conversations about students' ideas, pedagogical responses to those ideas, and puzzling aspects of physics content. In this study, we sought to explore the types of conversations elicited by such video clips.

Methodology

Using the coding and selection procedures described in Alonzo and Sato (2010), we created video clips from video-taped observations (3-4 per teacher) in three experienced teachers' classrooms. Ten video clips with potential to elicit conversations about student thinking, pedagogical potential of instructional representations, and/or physics content were organized into five "video cases", each containing 1-3 video clips and associated classroom artifacts (e.g., a lab worksheet). A researcher not involved in the creation of the video clips rated each according to Sherin et al.'s (2009) criteria for evidence of student thinking – windows into student thinking, depth of student thinking, and clarity of student thinking. Eight physics teachers with a range of experiences engaged with the video cases as part of a relatively short (2-hour) professional development workshop. In groups of 2-3, teachers discussed 1-2 video cases during the workshop. The facilitator posed two questions designed to focus attention on student thinking and pedagogical responses to that thinking, but provided little additional guidance. Cameras recorded each group's conversation; transcripts were created to aid the analysis, which proceeded in two stages. First, teachers' conversations about each video clip were rated according to Sherin et al.'s (2009) criteria for discussions of student thinking – focus on student thinking, substance of discussion, and joint sense making. Second, an exploration of teachers' conversations was undertaken to examine the match to researchers' predictions – both broadly, in terms of whether teachers discussed student thinking, pedagogical potential, or physics content, and specifically, in terms of whether teachers noticed (van Es & Sherin, 2002) the same aspects of student thinking as the researchers did.

Findings

Researchers predicted that all ten video clips would elicit discussions of student thinking. About half of the video clips were thought to raise interesting issues with respect to the pedagogical potential of an instructional representation, and only a few were predicted to seed conversations about physics content. The 10 video clips rated highly on Sherin et al.'s criteria; 22 of the 30 ratings were medium-high or high, and none were below medium. Broadly, the nature of teachers' discussions was consistent with that predicted by the researchers. Student thinking (the nature of students' ideas and/or pedagogical responses to that thinking) was discussed most often, followed by consideration of instructional representations depicted in the videos; only a few conversations focused on physics content. The video clips elicited conversations which rated highly on Sherin et al.'s criteria. Discussions about all clips were consistent with a rating of high for joint sense-making. Ratings for the focus on student thinking tended to be slightly lower (typically, medium-high); although student ideas were identified and oriented teachers' conversations, they were not consistently treated as objects of inquiry. The lowest ratings (typically medium) were awarded in "substance of discussion" category; consideration of students' ideas was not always linked to the underlying physics content. While teachers' conversations were generally of high quality and broadly covered the three areas predicted by researchers,

their specific foci differed in important ways from researchers' expectations. This was often simply a matter of teachers and researchers noticing different aspects of the video. In addition, while researchers tended to view the videos as providing evidence of a general class of student idea, the teachers focused on specific students and classroom contexts; their pedagogical responses tended to be more contextualized and less focused on specific features of the content.

Theoretical and educational significance

Much of the work examining teachers' interactions with video evidence has taken place in mathematics (e.g., Borko et al., 2008; Sherin et al., 2009); this study provides an extension to science education. In addition, while much of the work in mathematics has focused broadly on the nature and quality of teachers' discussions, this study more specifically explores the substance of teachers' conversations and, thus, has implications for both the selection of video clips and needed support for teachers' discussions of video in professional development settings. Theoretically, as part of a larger program of research, this study contributes to a greater understanding of the ways in which teachers engage with video and the relationship between these discussions and classroom practice.

SYMPOSIUM

Social Interaction in Learning and Instruction

A less partial vision: Multi-theoretic research into science classrooms

Chairperson: Ida Ah Chee Mok, The University of Hong Kong, China

Organiser: David Clarke, University of Melbourne, Australia

Discussant: Neil Mercer, University of Cambridge, United Kingdom

A key aspiration of classroom research is the generation of empirically-grounded instructional advocacy. Since different research studies undertake data generation and analysis using different theories, the warrant that might be claimed for the consequent advocacy of any particular instructional action is contingent on the chosen theory, among other considerations. In the analyses that provide the focus of this symposium, multi-camera on-site video technology and post-lesson video stimulated interviews were used in a purposefully inclusive research design to generate a complex data set amenable to parallel analyses from several complementary theoretical perspectives. This symposium reports the results of parallel analyses employing distributed cognition, systemic functional linguistics, and positioning theory of the same nine-lesson sequence in a single science classroom during the teaching of a single topic. While each analysis is demonstrably valuable in itself, in combination, these results demonstrate the inadequacy of any single theory or theoretically-driven analysis to capture the complexity of the science classroom and the corresponding need for inclusive multi-theoretic research designs. In this symposium, while also addressing other goals, each of the three presentations examines student meaning making in relation to the concept of expansion in the same lesson sequence using the different theoretical lenses already identified.

The research design employed multiple, synchronised recordings of classroom interaction in order to maximize the sensitivity of the parallel analyses to a wide range of classroom actions and learning outcomes. This symposium specifically addresses the challenge of generating evidence-based instructional advocacy from multiple analyses drawing on different theoretical perspectives, even where the focus of analysis is the same setting and relates to the learning of the same science content.

The Challenges of Making Sense of the Microscopic World in a Secondary Science Classroom

Despite its importance, many studies have found that students experienced great difficulties in understanding the ideas behind the particulate nature of matter and its associated concepts (Driver, et al., 1985; Driver & Project, 1994). Based on the perspective of Distributed Cognition (Hutchins, 1995), our analysis focused on social interactions between classroom participants and their interactions with physical, conceptual and symbolic artefacts. Student understanding was examined as performed in their actions and displayed in their written work. This paper examines a group of students' attempt to make sense of the particulate ideas and to explain several phenomena such as melting, boiling, expansion, and contraction in their classroom. It appears that even though the Particle Theory had been introduced as a model in the classroom that can be used to explain many changes undergone by matter, the students tended to use the macroscopic properties to explain the microscopic ones, rather than the opposite. We propose that substance could be the key to unlock the macroscopic-microscopic relationship, and an explicit introduction to the idea of substance in particulate terms could have provided the students with a mechanism to generate the connection between the macroscopic phenomena and the microscopic model, and could have helped the students to see how the particle model could be applied in a variety of situations.

The particulate nature of matter is one of the most important ideas in science, particularly in chemistry, it is believed to be fundamental to every topic (Harrison & Treagust, 2002). Despite its importance, many studies have found that students experienced great difficulties in understanding the ideas behind the particulate nature of matter and its associated concepts (Driver, et al., 1985; Driver & Project, 1994). In this paper, we explore a group of students' attempts to make sense of the particulate ideas presented in their classroom. Based on the perspective of Distributed Cognition (Hutchins, 1995), the analysis focuses on social interactions between participants and their interactions with physical, conceptual and symbolic artefacts. Student understanding was examined as performed in their actions and displayed in their written work. The analysis identified similar student difficulties found in the literature, but the detailed analysis of the learning process revealed the potential sources of student difficulties and suggests a possible way forward.

In the classroom studied, the Particle Theory was formally introduced in Lessons 5 and 6 as an explanatory framework for why changes of state occurred. It was presented in the form of five statements (see table 1).

Table 1 Particle Theory of Matter (notes from the board)

See Appendix 1

Using the Particle Theory to explain expansion

One of the examples in which the students were expected to use the Particle Theory was found in Lesson 9, in which the class discussed several physical phenomena such as diffusion, contraction, expansion, and air pressure. To illustrate the phenomenon of expansion, the teacher gave a demonstration of activity C (see table 2). Two other activities (A and B) were assigned to be completed by each student group. For each activity, the students were asked to provide their predictions, observations, and explanations.

Table 2 Practical Activities in Lesson Nine (instructions from the prac worksheet)

See Appendix 2

For all three activities, the students were expected to make connections between the macroscopic world (e.g. the inflating of the balloon) and the microscopic world (the movement and the arrangement of particles). The analysis of student interactions showed that the students had different ideas about expansion, and their explanations also differed depending on the state of the object. While it is easier for the students to conceive the expansion of the balloon in terms of an increase in the amount of gas (Sydney) or the movement of gas particles (Lionel and Keith), the expansion of the metal ball appear to be less comprehensible in terms of conceiving what was happening at the microscopic level. The comprehending process is not the same as the process of understanding the expansion of the balloon because the expansion of the metal ball was not embodied graphically to be visible to the students, instead it has to be inferred from the action of fitting the ball through the ring. Furthermore, although the students frequently employed the word "particles" in their explanations of the inflation of a balloon, a careful scrutiny revealed that the students were thinking of particles based on their observations of what was happening at the macroscopic level without giving much attention to the microscopic events.

It appears that even though the Particle Theory had been introduced as a model in the classroom that can be used to explain many changes undergone by matter, the students did not have a clear idea of how the particle model could be applied in all situations. From the analysis reported above, student conceptualization of what was happening at the particle level was largely constrained by what they could “see” at the macroscopic level. And the students tended to use the macroscopic properties to explain the microscopic ones, rather than the opposite. This is consistent with findings reported in the literature (see also Pozo & Crespo, 2005). Such a tendency, as can be argued, was due to the lack of clarity about the relationship between the microscopic model and the macroscopic phenomena. We propose that substance could be the key to unlock the macroscopic-microscopic relationship, and an explicit introduction to the idea of substance in particulate terms could have provided the students with a mechanism to generate the connection between the macroscopic phenomenon and the microscopic model, and could have helped the students to see how the particle model could be applied in a variety of situations.

Understanding the conceptual and representational demands of learning the language of school science

Lay-Hoon Seah, University of Gothenburg, Sweden; Christina Hart, University of Melbourne, Australia; David Clarke, University of Melbourne, Australia

The appropriation of the language of school science is a widely acknowledged goal of science education. By focusing on the role of language as both cognitive and semiotic tools, this study sought to understand the conceptual and representational demands on students when they employ the language of school science in response to written tasks. Grade 7 students' written assignments related to expansion were examined in terms of their content and their use of linguistic or lexicogrammatical (LG) resources. Similarities and differences in the use of LG resources among the students' writings were identified from which we derived patterns of language use that appeared to be significant for realising scientific meanings. To illuminate the challenges that students encountered when representing scientific meanings related to expansion, we examined these patterns of language use through the lens of an integrated framework of socio-constructivist and socio-semiotic perspectives. The findings of this study point to the productivity of examining the students' language at a lexicogrammatical level as well as some pedagogical strategies that can be adopted to facilitate the appropriation and employment of the language of school science.

Numerous studies have been conducted on the conceptual demands involved in the learning of particular science topics. By contrast, there are few studies that focus on the linguistic demands that students face when representing scientific meanings of specific topics. Research on the features of the language of school science generally focused on language used in science in general rather than that encountered in specific topic domains. With the data available, this study sought to address this gap in the research by surfacing both the conceptual and representation demands when students attempted to represent scientific meanings specific to the topic of thermal expansion. The classroom data source for this study was generated by a larger project entitled 'Causal Connections in Science Classrooms' (CCSC project), which employed a variety of data-generation techniques. Among them were: video-recordings of the lessons using four video-cameras (focusing on the teacher, the whole class, and two groups of focus students), video-stimulated teacher and student interviews after each lesson, and collection of classroom artefacts (including teaching materials and the students' written work).

This study adopted an interpretive approach to qualitative data analysis. In order to gain an in-depth understanding of the process of appropriation and employment of the language of school science, a single case study approach was adopted. A case study approach was particularly suitable for this study as it provided a bounded system that facilitated the study of language-in-use within, and as a consequence of, the social context. In this study, the case was the use of language in a sequence of lessons on the topic “States of Matter” conducted in a Grade 7 suburban Melbourne classroom. Within this case were instances in which the language used concerned a variety of distinct sub-

topics. Specifically, for the purpose of this study, the data presented were confined to the language related to expansion.

The data consisted mainly of the students' written responses to two tasks related to expansion. We subjected the students' writings to two phases of analysis:

Phase 1 - Content analysis: This phase involved classifying the students' writings according to their content, using coding categories (referred to as "explanatory foci") that were inductively derived through the method of constant comparison (Glaser & Strauss, 1967).

Phase 2 - Lexicogrammatical analysis: This phase involved identifying the lexicogrammatical (LG) resources (that is, vocabulary and grammatical resources such as pronouns and conjunctions) found within each explanatory focus and classifying these into linguistic classes taken from the ergative model of the Systemic Functional Linguistics framework (Halliday, 1994).

Both phases of analysis revealed similarities and differences in the use of LG resources among the students' writings, from which we identified several patterns of language use that appeared to be significant for realising scientific meanings. Some of these patterns of language use were: the association of the different explanatory foci with distinctive sets of LG resources; the use of the same LG resources across different explanatory foci; different expressions of heat-related cause of expansion; and the indiscriminate use of pronouns. We then examined these patterns of language use through the lens of the socio-constructivist (emphasizing the use of language as cultural and cognitive tools) and the socio-semiotic (emphasizing the use of language as semiotic tools) perspectives to understand the conceptual and representational demands that students face when representing scientific meanings related to expansion. The conceptual demands relate to the need to differentiate phenomena at the macro- and submicro-levels of representations, while the representation demands relate to the need to learn about the conventional and functional use of different types of LG resources so as to represent one's intended meaning accurately and precisely. This study further supports the assumption that underlines both the socio-constructivist and socio-semiotic perspectives of learning - that learning the language of school science is constitutive of learning science. Our findings point to the productivity of adopting an analytical frame that targeted students' written language at a lexicogrammatical level as well as pedagogical interventions that facilitate the learning of the language of school science specifically related to expansion.

"I need to think of a prediction" – An Analysis of Students' Meaning Making in Science Using Discurs

Jennifer Arnold, The University of Melbourne, Australia

This paper reports findings from a study concerned with students' meaning making in a middle school science classroom. Student discourse that was recorded in a sequence of classroom videotapes and post-lesson, video-stimulated interviews was analysed using discursive psychology and, in particular, positioning theory. Conversational episodes related to practical work on the expansion of solids, liquids and gases structured as P.O.E (Predict. Observe. Explain) activities have been selected as representative of the findings of the study. It was found that the students took the practice of writing practical reports as a personal responsibility. In taking personal responsibility, discussion and argumentation of their predictions and explanations related to the expansion activities using scientific concepts was limited. The practice of observing during practical activities was found to be taken by the students as a shared endeavour. In taking shared responsibility, their observations cannot be understood in terms of individual perception of an ontologically given reality such as the expansion of the liquid when it was heated, calling pedagogical initiatives grounded in cognitive psychology and perceptualism into question. The findings highlight the complex social process of meaning making in science classrooms and the need to attend to local moral orders of rights and duties in research on student language use and learning in science.

Researchers in science education have been concerned with understanding the science student (Goodrum and Rennie 2007). The need for such research is grounded in contemporary issues such as providing opportunities for all students to develop scientific literacy (Osborne 2003) and the failure of school science to connect with student's lives, interests and their sense of personal identity (Brickhouse 2001; Lemke 2001; Kozoll and Osborne 2004). The purpose of this research was to contribute to an understanding of the way students make meaning in secondary school science.

The focus on meaning rather than student attitudes (Costa 1995; Brown 2004), knowledge (Talanquer 2009), cultural affiliations (Costa 1995; Aikenhead 2001; Brown 2004) or identity (Brickhouse and Potter 2001) reflects the growing body of theoretical and empirically grounded insights in the social sciences that language use is a social act (Harre 1992b). This insight, often referred to as the discursive turn (Kroger and Wood 1998) or the second cognitive revolution (Harre 1992b) shifts the focus of research from hidden mechanisms behind discursive practices, such as cognitive or social structures to discourse as social practice (Potter and Wetherell 1987; Davies and Harre 1990; Edwards and Potter 1992).

From the discursive psychological perspective, science classroom practices are maintained or transformed relationally through interaction (Linehan and McCarthy 2000; Wood and Kroger 2000; O'Connor 2001; Harvey 2002). The focus from the discursive perspective shifts from the role of students as passive receivers of curriculum imperatives and pedagogical moves to the discursive practices of students as they make meaning in context, including the way they position themselves and are positioned by others (Davies and Harre 1999). The focus of this paper is meaning making by students in conversational episodes related to practical work on the expansion of solids, liquids and gases structured as P.O.E (Predict. Observe. Explain). The questions addressed are: How can the discursive practices of the students be described? How are students positioned, and how do they position themselves within science classroom discourses?

The discourse analytic perspective emphasizes the need to work with recordings and records (not reports) of verbal and nonverbal aspects of discourse (Wood and Kroger 2000). A year-seven class taught by an experienced middle school science teacher who had been recommended by his peers as a highly competent teacher of science and who agreed to participate was chosen for the study. Videotaped student discourse in and about their science classroom was the main data source used in the study. The generation of suitable data was achieved with support from the International Centre for Classroom Research at the University of Melbourne.

The results of the study have been presented as the discursive *umwelten* of three focus students (Tasha, Angie and Kesar), consisting of the representation and analysis of conversational episodes that were chosen as representative of the breadth of the students' science classroom discursive practices. Conversational episodes related to practical work on the expansion of solids, liquids and gases structured as P.O.E (Predict. Observe. Explain) activities have been selected as representative of the findings of the study. The focus students' practices have been described in terms of the degree of personal responsibility the students took with respect to the task at hand, specifically writing down predictions, making observations of the expansion of a liquid and explaining observed phenomena related to expansion of solids, liquids and gases. The consequences of these practices, evident in the analysis, have been discussed in relation to the students' learning and participation in science.

It was found that the students took the practice of writing practical reports as a personal responsibility. In taking personal responsibility, discussion and argumentation of their predictions and explanations related to the expansion activities using scientific concepts was limited. For example, Kesar drew upon a logic of pedagogical practice in writing her predictions rather than the scientific theories provided in instruction. The practice of observing during practical activities was found to be taken by the students as a shared endeavour. In taking shared responsibility, their observations cannot be understood in terms of individual perception of an ontologically given reality such as the expansion of the liquid when it was heated, calling pedagogical initiatives grounded in cognitive psychology and perceptualism into question. The findings highlight the complex social process of meaning making in science classrooms and the need to attend to local moral orders of rights and duties in research on student language use and learning in science. More attention needs to be directed to the consequences of our theories of learning and pedagogical initiatives for the public, collective practices promoted in science classrooms including the meanings made of these by our students.

SYMPOSIUM

Reflection

Researching reflection: Capturing the different ways reflection is being approached in teaching

Chairperson: Fritz C. Staub, University of Fribourg, Switzerland

Organiser: Juan Jose Mena Marcos, University of Salamanca, Spain

Discussant: Harm Tillema, Universiteit Leiden, Netherlands

This symposium explores research approaches to the domain of reflection in the fields of teaching and arts. Much of the available work (syntactic approach) focuses on trying out reflection model(s) and components (i.e. action-research steps) or classifying reflection into different levels (i.e. critical reasoning or pedagogical argumentation). Other studies content analyze practitioners' discourses and infer the conceptual categories (i.e. rules or artifacts) that were displayed for problem solving in practical settings (semantics approach). The main interest of this symposium is not only differentiating the way both approaches measure reflection but essentially to examine what knowledge for the profession they are giving rise to. These are the outcomes for practice (productions): i.e., the results from research that practitioners could use for their work. The symposium will aim at establishing new research criteria for addressing this issue in studies on reflection and will draw implications for practice.

Educational relevance

Reflection has been positioned as the central strategy for grounded practices since it helps to construct new situational understandings for the profession. In this symposium we regard gathering research productions as essential to construct an epistemology of practice. Three evaluative criteria may be followed: (a) validity of outcomes for practice (not only for research); (b) transference to other work-situations and (c) degree of impact on the profession (not only for academia).

Based on these criteria we invited three contributors to explicate their approach and means by which they study reflection. We intend to gain insights about solutions to extract outcomes for practices; not to offer strict guidelines for conducting research.

Quantitative Content Analysis of students' reflection: what are they writing about?

Eric Poldner, INHOLLAND university, Netherlands; P. Robert-Jan Simons, Utrecht University, Netherlands; Guus Wijngaards, Hogeschool INHOLLAND, Netherlands

This paper presents results of a quantitative content analysis (QCA) procedure for analyzing the reflective writing by students in the first year of a teacher education programme. We developed the QCA procedure as a part of an integrated model for analysing the concept of reflection in a curriculum. Different concepts of reflection and the implications for purpose, focus and process of reflection in the curriculum were introduced. It is widely held that teacher education should aspire to engender high-level critical reflection leading to professional growth. A coding schema was developed for analyzing students' reflective writings within a small sample of high and low reflective ranked students within teacher education. The implications of these findings are addressed.

Introduction

In higher education the main educational goal is to develop reflective practitioners (Dochy, 2001). The students should be prepared to function in the rapidly changing world of professional practice. In an education programme the development of students to become a reflective practitioner is based on a view or concept of reflection. In teacher education it is common to refer to the reflection concepts descriptive technical, deliberative, and social critical (Procee, 2006; Serafini, 2000; Valli, 1997; Van Manen, 1977). For example, Lee (2005) concluded that many researchers used the same reflection concepts for describing levels of reflective thinking. These reflection concepts can be described in dimensions purpose, focus and process according to Serafini (2000). The purpose of reflection is related to the view of what constitutes good teaching (Mansvelder-Longayroux, Beijaard, & Verloop, 2007). The focus is related to the object of reflection: thoughts, experiences, or feelings. The process of reflection is related to the context of the reflection (individual, individual in context, critical social in context) and could be seen as a cyclic process of learning, researching (see for example Harinck, 2007; Kolb, 1984; Korthagen & Vasalos, 2005). The stages of this cyclic process are mostly described in terms of noticing, analyzing, evaluating, developing alternatives, experimenting and acting, and again noticing. Mezirow (1998) described critical reflection of assumptions (CRA) and critical self reflection of assumptions (CRSA) as the crucial aspects in this reflection process for transformation or reflection development. CRA refers to objective reframing and CRSA to subjective reframing. Objective reframing means "critically examining the validity of concepts, beliefs or actions being communicated to you" (p. 192) and subjective reframing refers to be critical on "one's own assumptions" (p. 192). Both aspects are needed in our view for transformative learning.

Research on students' reflection development is concentrated on measuring the construct of reflection by analyzing reflective writings, students' reflective essays (Broekman & Scott, 1999; Hoover, 1994; Thorpe, 2004). The product of the reflective writing offers different opportunities for learning by writing, reading, discussion, feedback and re-writing activities (Vanhulle, 2005). Reflective writing is accepted as a tool for learning to stimulate reflective thinking (Broekman & Scott, 1999) and as a tool for assessment of reflective competence in productive tasks like portfolio's

(Borko, Michalec, Timmons, & Siddle, 1997; Orland-Barak, 2005; Van der Schaaf & Stokking, 2008). As a part of a curriculum evaluation study, 26 reflective essays were analyzed with QCA. The research questions of the study were the following: What are students in the first year of teacher education writing about in the reflective essays? Which aspects revealed the QCA of the reflective essays related to process, focus and purpose? Are highly reflective ranked students writing about different aspects in their essays than low reflective ranked students?

Methods

Participants and data collection In the School of Education of the Inholland University students in the first year have to write a reflective essay about the experiences in workplace after a period of ten weeks. First, we collected from 69 students several reflective essays. Second, we selected reflective essays of 26 students from four different groups by reputational case-selection (Miles & Huberman, 1994). Each teacher of a group had to rank the students in their group based on reading and assessing the reflective essays after 20 weeks and after 40 weeks. We used this reputational case selection for collecting essays from 13 high reflective ranked students and from 13 low reflective ranked students. We can characterize this research as a syntactic approach. We are interested if the content of the reflective essays mirror the aspects of (critical) reflection as formulated in the curriculum.

Data analysis

First, qualitative analysis or open coding (Boeije, 2005; Wester & Peters, 2004) was used for analyzing all collected reflective essays. Second, based on the results of the open coding process we developed a coding schema with categories and subcategories. A coding protocol was developed (procedures for analyzing units and a coding scheme with examples) and tested on reliability of coding for two coders on a sample of ten percent of the total coding units of 26 selected reflective writings. The categories were compared with aspects of the three reflection concepts. After coding these reflective writings descriptive statistics were calculated to find out if there were significant differences in coded categories in the reflective essays of high reflective ranked students and low reflective students.

Results and discussion

After the open coding process we established that there were three thematic codes related to student-mentor, student-pupil/group, and student learning process. Each thematic code had several sub codes. For example, the sub-categories of the third thematic code (student learning process) category were teaching activities, analysis of learning goals/situations, justification, learning goals, approach to learning goals/situations, lesson preparation plans, evaluation of learning goals/situations, learning benefits, and own feelings and own opinion. All coded fragments of reflective essays of high reflective ranked students and low reflective ranked student were related to the descriptive technical reflection concept. Students wrote a substantive part of the reflection report about the performance situation in relation to the context (group, mentor, pupils). This can be seen as noticing, the start of reflection. All the text fragments coded as "Evaluation" and "Analysis" were restricted to instructional and organizational activities, actions executed by the students. The combination of "Evaluation" and "Analysis" in the reflection papers is a possible indication of diagnosis (see Mansvelder-Longayroux, et al., 2007) the next step to reflection. Although students ranked as low-reflective and high-reflective devoted a substantial part of their reflection papers to "Evaluation" and "Analysis", we were unable to identify text fragments which point to critical processing, weighing up alternatives, an intending to experiment. We can conclude that QCA as a syntactic approach can reveal in a systematic way what the students are writing about in their reflective essays. Students, teachers and mentors can use this approach for better understanding of and reflection on students' reflective writing related to the practice.

An alternative approach to determine the quality of students' reflection

Ali Leijen, Tartu University, Estonia; Djuddah A J Leijen, University of Tartu, Estonia; Margus Pedaste, University of Tartu, Estonia

This paper discusses some of the ambiguities related to the concept of reflection in education and presents an alternative approach for determining the focus and quality of students' reflection. Accordingly, the focus of reflection can vary from a concrete technical aspect of an experience to the broader societal context of that experience, and the quality of reflection can be described through successive stages of argumentation: describing, justifying, evaluating, and discussion. The developed coding schema for determining the focus of reflection and the level of argumentation in reflection was pilot tested on reflection fragments written by a small sample of tertiary dance students. The findings, regarding dance students reflection and their implications for practice, are presented and discussed.

Introduction

Developing students' reflection on their learning and behaviour is currently one of the major learning goals in higher education. Reflection can generally be defined as a cognitive process carried out in order to learn from experiences

(Moon, 2004) through individual inquiry and collaboration with others (Dewey, 1933). It is known that reflection leads to deeper learning (Moon, 2004), to achievement of more complex and integrated knowledge structures, and to more accessible and usable knowledge (Billing, 2007). The high relevance and inclusion of reflection in several pedagogical practices of higher education would suggest that the term reflection is well defined in literature. However, several authors (e.g. Griffiths, 2000; Gur-Ze'ev, Masschelein, and Blake, 2001; Hatton & Smith, 1995; Van Manen, 1995) point out that the concept of reflection in literature is intangible and ambiguous regarding how to determine, facilitate, and assess reflection in practice. It seems that the term reflection contains a wide range of different or even conflicting concepts and strategies which are derived from different notions and schools of thought. Two most commonly known notions of reflection in education are the pragmatists' (e.g. Dewey, 1933; Korthagen, 1985) and social critical theory (e.g. Mezirow, 1991) approaches. The followers of these interpret reflection differently. However, in several writings, ideas of different or even contradicting traditions are used in a closely intertwined manner. This article aims to unfold some of the ambiguities related to the term and present an alternative view on determining the quality of reflection.

Unlike the dominating approach to determining the quality of reflection in education (Van Manen, 1977) where the focus of reflection (technical, practical, and critical reflection) has been used to determine the value of reflection, we propose an approach that looks at two components of reflection: the focus of reflection and the level of argumentation in reflection (syntactic approach, see summary of the symposium). The focus of reflection as a term is useful as it illuminates the scope of reflection and is sufficiently neutral to allow considering pragmatists' and critical social theory perspective to reflection on equal grounds. The most commonly used division is technical, practical, and critical reflection. Owing that critical reflection is mostly associated with the social critical perspective, we chose the term sensitizing instead, as suggested by Tsangaridou and O'Sullivan (1994), for our categorization. Regarding the level of argumentation in reflection, we adopted the categorization of Tsangaridou and O'Sullivan (1994), and McCollum (1997): a description (descriptive information), justification (logic or rationale), and critique (explanation and evaluation) of an aspect related to practice. Inspired by Moon (2004), a fourth level was added to this categorization. At this level of argumentation, one moves beyond self evaluation and discusses alternative solutions for changing one's practice. A pilot study among a small group of dance students was carried out to collect illustrative data about the focus and the level of argumentation in reflection. The research question of the study was: What is the focus and level of dance students' reflections in a ballet class and in a choreography class?

Methods

Participants and data collection

We analysed self reflections and peer feedback accounts collected in the context of a previous study (Leijen, Lam, Wildschut, Simons, and Admiraal, 2009) where dance students carried out reflection assignments in a ballet and a choreography course. Data was collected from 16 students (3 male, 13 female) who study in a dancer / choreographer bachelor's programme at a dance academy in the Netherlands.

Data analysis

The focus and level of reflection in the self evaluations and peer feedback accounts (180 fragments in total) were analysed by three researchers (investigator triangulation suggested by Denzin, 1970) using a developed coding scheme. Descriptive statistics related to the focus and quality of students' reflections were calculated. Chi square tests were used to find out whether there were differences regarding the division of reflection fragments on particular levels and foci in different phases (self evaluation phase, feedback phase) of the reflection assignment.

Results and discussion

Ballet students' reflections focused mainly on technical aspects of the ballet technique execution. The developed coding scheme allowed investigating the depth and the line of reasoning in reflections rather than considering the writings as low level, merely because of their technical focus. The translation of choreographic intentions into physical movements was the most important question for choreography students. They also reflected on the composition details presenting a more technical focus and on the frames of references in arts and in wider contexts displaying sensitizing reflection. This shows that, as also Hatton and Smith (1995) pointed out, different contexts may lend themselves more towards a certain focus of reflection, and it is the purpose of teachers and the instruction of reflection to guide students into the relevant foci. While considering the focus and quality of reflection among different stages of the assignment, it was noted that the focus of reflection did not differ across different stages of the assignment (self evaluation and feedback) in both courses. However, we found that the level of argumentation was higher in feedback than in self evaluations (more evidently in ballet class). The results showed that students had the ability to present higher order reasoning in their writing; however, it seemed to be more difficult for them to deepen the reasoning in reflection concerning own actions as opposed to looking at others. This finding suggests that peer feedback could raise the overall quality of students' reflection and presents for teachers an instructional principle how to improve the quality of students' reflection. A completely different topic of discussion is whether the highest level of

argumentation is always desired. We believe that similarly to the focus of reflection, it is the task of teachers and the instruction of reflection to guide students towards the necessary quality standards of reflection. Some topics might need mere descriptions or justifications; however, each discipline also has its core concepts and principles which need to be dealt with on the highest level of reflection.

Action-oriented knowledge: How teachers get professional expertise from reflection.

Juan Jose Mena Marcos, University of Salamanca, Spain; Maria-Luisa Garcia Rodriguez, University of Salamanca, Spain

Action Oriented Knowledge (AOK) is conceptualized as all profession-related insights that are relevant to the teacher's activities (Verloop, van Driel&Meijer, 2001) and can be formulated into concepts, pedagogic rules or strategies. Verbalizing and codifying this knowledge in practice could be as relevant for training processes in teacher education programs as placing teachers' reflections into predefined theoretical levels.

This study aims at extracting propositional knowledge from teachers' accounts. We try to (1) describe what AOK arises when student teachers reflect on practice (after the action is done) and in practice (during performance) (Schßn, 1983), and (2) value which knowledge is more precise to understand practice. One hundred and seventeen preservice teachers, who worked in 86 different schools, participated in the study. They wrote a report about their teaching (4-5 pages) and planned and taught a lesson as part of their practicum. Thirteen of them were also interviewed. Reports and interview transcriptions were content-analyzed following propositional analysis. Inter-rater reliability coefficients ranged from $\kappa = .78$ to .91. Three main sorts of AOK were found: appraisals (both positive and negative), rules (methodological strategies) and artefacts (instruments for practice). Results indicate that rules and artefacts may better help to understand teaching performance than appraisals, since they can be generalized and further applied to other situations. This primarily occurs when teachers reflect in practice rather than on practice. In addition there were statistically significant differences between the generation of some types of knowledge (i.e. artefacts) and more precise evaluation of teachers' performance.

Introduction.

One of the most significant trends in education in past decades is the notion of reflective practice (Schßn, 1983, 1987). Reflection makes teachers aware of their experiences through self examination and critical inquiry. Consequently it is a crucial process in sustaining teachers' professional competence (Loughran, 2002) since it enables us to genuinely understand the way they conduct their work. All of this has lead to the recognition of reflection as a central tenet of many teacher education programs all over the world (Valli, 1993; Brookfield, 2005). However what makes reflection substantial is the fact that calls attention to the type of action-oriented knowledge (AOK) that practitioners generate in problem-solving and decision-making situations (Urzúa and Vásquez, 2008). AOK could be defined as the representation and formulation of practice into concepts, pedagogical techniques and strategies. It refers to "...all profession-related insights that are potentially relevant to the teacher's activities" (Verloop, van Driel, and Meijer, 2001: 443). This in-practice knowledge needs to be researched in order to construct a knowledge for-practice (Cochran-Smith and Lytle, 1999) more useful for teacher training in education programs. In this study the objective is twofold: On one hand (1) examining what AOK is produced (semantic approach of reflection: please see the symposium abstract) when teachers reflect both on practice -after the action is completed- and in practice -while the action is performed-; and, on the other hand, (2) valuing the quality of AOK by analyzing the number of statements that have informative weight (e.g. precision) to reframe teachers' conceptions of their own practice.

Methods.

Participants and data collection

One hundred and sixty four students enrolled in the third year of teacher training at the University of Salamanca participated in a two year long study in which they learned about the basic concepts and strategies on problem-solving in the classroom. They all did their practicum in 86 Early Childhood Education Centres and Elementary schools. As part of their work, they did a planned lesson, video-recorded one session and wrote a field-learner report about their teaching experience under the supervision of their cooperating teachers. Out of 164, 104 preservice teachers submitted their planed lessons and action research reports. Additionally, 13 were interviewed watching their own performance following Stimulated Recall interviews techniques.

Data analysis

Reports and transcribed interviews were content-analyzed following propositional analysis (Bovair and Kieras, 1985; Kintsch and Van-Dijk, 1978). The content (propositions) was analyzed in three steps: (a) Selection of propositions ($k_1=0.82$); (b) Grouping propositions into themes ($k_2=0.88$); (c) Theme hierarchisation (categories) following the Grounded Theory Analysis (Corbin and Strauss, 1990), ($k_3=0.79$). Each proposition was also coded under

0=imprecise (vague information: i.e. the activity satisfied the children) or 1= precise (informative weight; i.e. the student can now properly read closed syllables), in order to measure the quality of the student teachers' knowledge production. Finally chi square tests were used to find out whether there were differences between the kind of knowledge generated and its precision.

Results and discussion.

Teacher productions.

Overall, 1750 propositions were identified in the reports and transcriptions which referred to self-learning statements on the lessons they taught. 1520 were finally coded into an inductive category. The acquired practical understandings revolved around three dimensions: pupils' learning (53.4%), teaching strategies (34.7%) and students' family support (21.9%). Much knowledge focused on realizing how pupils' attitudes such as coexistence, interactions or respect for norms and authority were difficult to manage (23.1%). Personal insights about how pupils become skilled at basic competences (i.e. reading fluently) allowed them to understand different learning paces (10.3%). Choosing motivational teaching methods seemed crucial for their lessons as well as collaboration with colleagues. Fewer insights were posted about family cooperation and home discipline, and most exclusively when teachers reflected on action. Effective use of school spaces and teaching materials were hardly ever addressed. These contents were further classified under three major types of AOK: (1) Appraisals: Teachers' self judgements about the consequences of their actions and decisions in the classroom. They may be either positive (i.e. Pupils paid attention the whole hour to the explanation) or negative (i.e. Andrew never finishes his class work). (2) Rules or practical principles: Methodological maxims that these student teachers extracted from their experiences (i.e. we teachers should control pupils' classroom behaviour according to previously agreed norms). (3) Artefacts: instruments or physical supports teachers envisage from what they have experienced. (i.e. I would hang a poster on the classroom board with the five agreed-upon behavioural rules to keep in mind). Reflection on action produced 61.1% appraisals, 12.3% rules and 1.6% artefacts. On the other hand reflection in action framed student teachers' knowledge mainly into rules (57.5%) and artefacts (13.2%). Fewer propositions were found as evaluative knowledge (i.e. positive appraisals: 12.1%).

Knowledge precision.

50.2% of the evaluations were precise and the other 49.8% imprecise. Precise positive appraisals accounted for 38.6%, whereas precise negative appraisals totalled 73.6%. 44.6% of the rules and 87.5% of the artefacts were concrete. It seems that evaluating teaching practice from negative appraisals and elaborating artefacts is regarded to be more informative ($\chi^2 = 93.31$; p

Theoretical significance

Characterizing the ways in which teachers conceptualize their practice (i.e. teachers' productions) is complex inquiry. It can be argued that much of the action-oriented knowledge resides outside of verbalized constructs. Professional performance is situationally and socially embedded (Eraut, 2004) and therefore "... we can know more than we can tell " (Polanyi, 1967, 4). However, this study shows how part of this knowledge can be stated through language operations that establish the correspondence between actions and concepts. In other words, teachers' productions may be sorted into propositional knowledge which, in the end, helps teachers to learn from their experiences. Main findings indicate that teachers' reflections on action essentially focus on recalling and valuing events (more episode-oriented: gathering experience). Reflection in action better allows for codifying experiences into practical principles (more skill-oriented: acquiring expertise). Finally, envisaging artefacts and appraising practice from its negative consequences permits the construction of more precise understandings of practice.

SYMPOSIUM

Reading

Sociocultural and linguistic determinants of reading in first- and second-language learners

Chairperson: Petra Stanat, Humboldt Universitaet Berlin, Germany

Organiser: Petra Stanat, Humboldt Universitaet Berlin, Germany

Discussant: Christina van Kraayenoord, The University of Queensland, Australia

Current theories of reading acquisition assume that reading comprehension is an active process which is influenced by a variety of factors on the individual as well as on the sociocultural level. However, only few studies on determinants of reading comprehension explicitly consider students' language background. As a result, it is largely unclear whether the models identified in these analyses are equally valid for reading comprehension in a first language (L1) and in a second language (L2) (cf., August & Shanahan, 2006). The presentations in the symposium focus on differential

relationships between sociocultural and linguistic predictors of reading skills and reading motivation in first- and second-language students. Based on theoretical models of reading comprehension and second-language acquisition, assumptions about the development of reading determinants and their influence on L2 reading skills are analyzed. The determinants considered include school factors, characteristics of student background, as well as linguistic skills that have been shown to be relevant for reading comprehension.

August, D., & Shanahan, T. (2006). *Developing literacy in second-language learners: Report of the national literacy panel on language-minority children and youth*. Mahwah, NJ: Lawrence Erlbaum.

The Development of Reading Skills and Reading Motivation in Students with Immigrant Backgrounds

Rebecca Miriam Hartmann, Technical University of Dortmund, Germany; Nele McElvany, Max Planck Institute for Human Development, Germany; Michael Becker, Max Planck Institute for Human Development, Germany

Text comprehension, vocabulary and reading motivation have been identified as important and mutually linked aspects of reading acquisition (Bialystok, 2002; Möller & Schiefele, 2004). International studies show significant differences in reading skills and motivational variables between students with and without immigrant backgrounds (Stanat & Christensen, 2006). The degree to which these are caused by group differences in socioeconomic status and cultural capital is disputed. Moreover, group-specific predictive power of socioeconomic status and cultural capital for reading achievement is discussed. The analyses are based on data of the Berlin Longitudinal Reading Study. Approximately 700 students were tested in grades 3, 4 and 6. Cross-lagged panel models show that the incongruity between home and school language has negative effects on text comprehension and vocabulary in grade 3 and on vocabulary development from grades 3 to 6 as well as positive effects on the development of reading motivation from grades 3 to 6. The successive introduction of socioeconomic status and cultural capital into the model leaves language incongruity a significant predictor. Multiple group analyses show reduced predictive power of socioeconomic status and cultural capital for text comprehension in the group of children with immigrant backgrounds. Confirming the crucial role of home language for reading acquisition, the findings indicate a need for intensified high-quality reading training for L2-learners to promote their reading development and, moreover, to identify potential starting points for interventions.

Goals

Children with immigrant backgrounds in the educational systems of many countries are considerably less successful than their peers from native families. This presents a major challenge to the educational policy, administrations and practitioners. The problematic situation was revealed by, for example, the results of the large international student assessment surveys PIRLS and PISA, which showed significantly lower competence levels for children with immigrant backgrounds compared to their native peers (Mullis, Martin & Gonzales, 2004; OECD, 2001). This is not only an issue for the individual students and their families, but also for society and the economy of the respective countries. In Germany, the differences are especially problematic because of the high selectivity of the school system. Achievement scores in the early grades are highly relevant for the transition to more advanced secondary school types and, as a result, for vocational training or tertiary education opportunities. It is assumed that reading literacy plays an important role in explaining group differences between students with and without immigrant backgrounds with regard to participation in the educational system, with the incongruity between school and family language being of major importance in this context. In order to identify starting points for the effective reduction of differences in educational success, it is crucial to identify and explain similarities and differences in the reading acquisition process of multilingual and monolingual children. Text comprehension, vocabulary and reading motivation have been identified as important and mutually related aspects of reading acquisition (Bialystok, 2002; Möller & Schiefele, 2004). International studies do not only reveal significant differences in reading skills between students with and without immigrant backgrounds but also heightened motivation in students with immigrant backgrounds (Stanat & Christensen, 2006).

The degree to which the reported gaps in achievement and motivation are caused not only by the incongruity between school and family language but also by differences in socioeconomic status and cultural capital is disputed. Many of the studies that are available use only one point of measurement and hence do not allow for the investigation of developments. Moreover, group-specific predictive power of socioeconomic status and cultural capital for reading acquisition may occur. The following research questions were addressed based on longitudinal data and will provide new insights into the long-term development of reading skills and reading motivation in students with immigrant backgrounds at the EARLI 2011-meeting: 1. Is the incongruity between school and family language a significant predictor of the level of text comprehension, vocabulary and reading motivation in grade 3 and of the development of text comprehension, vocabulary and reading motivation from grades 3 to 6? 2. Does the incongruity

between school and family language stay a significant predictor of text comprehension, vocabulary and motivation when socioeconomic status and/or cultural capital are taken into account?3. Are there group-specific differences in the predictive power of socioeconomic status and/or cultural capital for reading acquisition?

Methodology

The analyses were conducted with data from the Berlin Longitudinal Reading Study (READING 3-6), which was carried out by the Max Planck Institute for Human Development in Berlin, Germany. Approximately 700 students were tested in grades 3 (2003), 4 (2004) and 6 (2006). The points of measurement were chosen because students are expected to have completed the acquisition of basic reading skills in grade 3 and classroom instruction focuses increasingly on text comprehension in the following grades. Also, reading skills in grade 6 are highly important for the successful transition to high school, which takes place in Berlin, Germany, after grade 6. 32.4% of the students and parents in the sample indicated that they speak German and another language or exclusively another language at home.

Findings

Cross-lagged panel models show that the incongruity between school and family language has negative effects on text comprehension and vocabulary in grade 3 and on vocabulary acquisition from grades 3 to 6 and positive effects on the development of reading motivation from grades 3 to 6. The successive introduction of socioeconomic status and cultural capital into the model leaves incongruity between school and family language a significant predictor. Multiple group analyses show substantially reduced predictive power of socioeconomic status and cultural capital for text comprehension in the group of children whose family language differs from the school language.

Theoretical and Educational Significance of the Research

The panel design of the study allowed for the analysis of the relationship between reading acquisition and the incongruity between school and family language over the course of three school years. Thus, the study complements the numerous cross-sectional studies in educational research. Effects of the incongruity between school and family language on the level and on the development of text comprehension, vocabulary and reading motivation were analyzed and confirmed. The results demonstrate the crucial role of home language for reading acquisition, controlling for socioeconomic status and cultural capital. The findings of the analyses clearly indicate that there is a need for intensified high-quality reading training for L2-learners focusing on both text comprehension and vocabulary to promote their reading development and, moreover, to identify potential starting points for interventions.

First- and second-language reading: Differential patterns in the prediction of reading comprehension

Alexandra Marx, Humboldt University Berlin, Germany; Petra Stanat, Humboldt Universität Berlin, Germany; Thorsten Roick, Freie Universität Berlin, Germany; Robin Segerer, University of Würzburg, Germany; Wolfgang Schneider, University of Würzburg, Germany; Peter Marx, University of Würzburg, Germany

The present study explores the effects of linguistic determinants on reading comprehension in students speaking German as a first (L1) or as a second language (L2). Based on the simple view of reading model of reading comprehension, it was hypothesized that the link between listening comprehension skills and reading achievement is especially pronounced in L2 students and largely explains their weaker reading outcomes. In the context of the study, 473 9th-grade students completed the reading test administered in the 2009 cycle of the Programme for International Student Assessment (PISA) as well as measures of working memory, decoding skills, vocabulary, morpho-syntactic skills, phonological awareness, and listening comprehension. Results indicated that L2 students lagged behind L1 students on most linguistic measures. For L1 students as well as for L2 students, listening comprehension skills were strongly related to reading achievement. Multigroup structural equation modeling provided evidence that this

relationship is stronger for L2 students than for their monolingual peers. The results are discussed against the background of current models of reading comprehension in a first and in a second language.

Introduction

Findings from international studies, such as the Programme for International Student Assessment (PISA), suggest that immigrant students are highly overrepresented in the group of weak readers (Stanat & Christensen, 2006). In Germany, the achievement gap between students speaking the test language at home (L1) and students using another language at home (L2) is especially pronounced and continues to be substantial even after parents' socio-economic status and educational level are controlled for. The distinctive effect of the language use at home indicates that immigrant students may lack the opportunity to develop their oral L2 skills which, in turn, influences their L2 reading comprehension. This assumption is in line with the simple view of reading model of reading acquisition (Hoover & Gough, 1990). According to this model, reading comprehension is influenced by two major determinants, namely decoding skills and listening comprehension. While phonological skills are necessary to develop adequate word recognition skills, listening comprehension is more strongly related to vocabulary and morpho-syntactic knowledge (c.f. Lundberg, 2002). As data from various studies indicate, L2 students' oral proficiency skills tend to lag behind those of L1 students. Children learning to read in a second language often exhibit a smaller vocabulary size and less developed listening skills than their monolingual peers (c.f. Geva, 2006; Droop & Verhoeven, 2003; Proctor, Carlo, August & Snow, 2005). On the other hand, L2 students seem not to experience specific problems associated with decoding skills or their phonological awareness (Koda, 1998). Given that L2 students perform at lower levels of reading comprehension than L1 students, but rarely have problems mastering decoding, it can be assumed that their weaker listening skills strongly determine these students' reading outcomes. In the present study, determinants of reading skills and their impact on reading comprehension are analyzed in L1 and L2 students. We tested the assumption that German L2 students' reading achievement is more strongly influenced by their listening comprehension scores than are L1 students' reading skills. No differences are expected with regard to the influence of decoding and phonological skills on reading outcomes.

Method

Data from N = 473 9th-grade students attending the lower and comprehensive tracks of the German school system were analyzed. Of these, N = 294 learned German as a second language (L2). Reading comprehension was measured with the reading test administered in the 2009 cycle of the Programme for International Student Assessment (PISA). On a second test day, students completed computer-administered measures of phonological awareness, working memory, listening comprehension, and morpho-syntactic skills. In addition, paper-and-pencil measures of general cognitive abilities, vocabulary, and decoding skills were administered. Multivariate analyses of variance (MANOVA) were carried out to test differences between L1 and L2 students' achievement on all measures. Structural relationships between reading achievement and its determinants were investigated using multigroup structural equation modeling, with cognitive skills and socio-economic status serving as control variables. In a first step, the model was tested for measurement invariance across the groups. Subsequently, differences in the structural relationships between L1 and L2 students reading models were identified using Wald Chi-square tests.

Results

Preliminary results indicate that students with German as L2 reach significantly lower levels of vocabulary, morpho-syntactic knowledge, decoding skills, listening comprehension, and reading comprehension than their L1 peers. No group differences were observed for phonological skills or working memory. The structural equation model used to explain reading skills fitted the data well (Chi-square(201)=267,885; $p=.00$; CFI=.97; RMSEA=.04). For both groups, listening comprehension was shown to have a stronger impact on reading outcomes than decoding skills. However, the association between listening comprehension and reading comprehension was significantly stronger for L2 students. In contrast, no differential influence of vocabulary and morpho-syntactic skills on listening comprehension could be stated. In the symposium, we will present findings on differences in linguistic determinants of L1 and L2 student' reading skills as well as the results of the multigroup structural equation model of reading comprehension. The results will be discussed against the background of current models of L1 and L2 reading comprehension and implications for promoting L2 students' reading achievement will be drawn.

Linguistic and Socio-cultural Diversity in Reading Literacy Achievement: A Multilevel Approach

Andrea Netten, National Center for Language Education, Netherlands; Ludo Verhoeven, Radboud University Nijmegen, Netherlands

The purpose of the present study was to identify factors that explain the variation in reading literacy achievement among fourth grade children in the Netherlands, with a focus on the differences between first and second language students. Measures at the level of the students, his or her parents, and the student's school were used to predict reading literacy. The data of 3549 first language learners and 208 Turkish and Moroccan second language learners who participated in the IEA Progress in International Reading Literacy Study 2006 were analyzed. Multilevel analyses were conducted and showed the level of the student to account for most of the explained variance. The results of multilevel modelling showed 34, 7% of the total variance in reading literacy to be explained by the entered variables. Furthermore the results indicate that there are strong links between the entered endogenous and exogenous socio-cultural factors and reading literacy achievement.

Introduction

Previous studies have shown that first language students still outperform second language students in regard to their reading literacy skills in the Netherlands (Verhoeven, 2000; Droop & Verhoeven, 2003). Minority students make up about 15% of the school population in primary education in the Netherlands, students with a Turkish and Moroccan ethnic background form the largest group. Apart from linguistic diversity, several socio-cultural factors are associated with differences in reading literacy among both L1 and L2 learners. Factors on the part of the child, such as reading motivation, and self-confidence (Guthrie & Wigfield, 2000), as well as home factors, are related to the quantity and quality of parental input (De Jong & Leseman, 2001; Tabors & Snow, 2001) and school related factors (Rauh et al., 2003). The influence that these background factors have on a student's reading ability may differ between the subgroups of first and second language students (Van Elsäcker, 2002). However, so far a multilevel approach regarding differences in reading literacy for L1 versus L2 learners was generally lacking. The data in the research design have a hierarchical structure, students are nested in classes, which are nested within schools. For this reason a multilevel design, who takes into account the correlation and data dependence, seems a valid approach.

In the present study the relationship between various home, school, and student background characteristics, to the students' reading literacy achievement will be examined using a representative sample of first and second language learners living in the Netherlands, by means of a multilevel design. The following research questions will be addressed:

1. What are the differences between L1 and L2 learners in reading literacy achievement and various endogenous and exogenous socio-cultural factors?
2. To what extent are the endogenous and exogenous socio-cultural factors at the level of the student, family and school related to the students' reading literacy achievement at grade 4 in the Netherlands?
3. Are the endogenous and exogenous socio-cultural factors to the same extent related to the reading literacy achievement of L1 and L2 learners?

Method

A representative sample of 3757 children from 207 classes in 139 schools in the Netherlands who participated in the IEA Progress in International Reading Literacy Study 2006 were analyzed in the present study. To identify the groups of first and second language learners the question "Which language did you speak before you started school" from the student questionnaire (IEA, 2006) was used. The students who answered "yes" for either Turkish or Moroccan were selected for the second language group which consisted of 208 students. The students answering "yes" to another language than Dutch were deleted, leaving only those students in the first language group who indicated that they spoke Dutch before they started school (N=3549). Descriptive statistics, followed by Analysis of Variances (ANOVA) were carried out to investigate significant differences between the means of the L1 and L2 students on the predictor measures. To find an answer to the second research question, a series of multilevel analyses were conducted to explore the relations between the student's reading literacy and its predictors. The multilevel analyses were

conducted with MLWin software using sampling weights and plausible values (repeated analyses). Finally to answer research question three and to determine whether the strengths of the relationships between the entered variables are similar for the two subgroups of L1 and L2 learners the interaction effects for the variable Linguistic diversity, which entails the L1 and L2 students, were examined.

Results

First preliminary results confirm the results found in previous research and shows that Turkish and Moroccan fourth grade students lag behind their monolingual Dutch peers in their reading literacy abilities. Furthermore the results show that there are strong links between the entered endogenous and exogenous socio-cultural factors and the reading literacy results; the full model explained 34, 7% of the variance in reading literacy. The analyses that were conducted to examine the differences between first and second language students showed linguistic diversity to explain 5.34 % of the variance in reading literacy. Next the interaction effects were analysed. Although the effect sizes for some of the predictors were large, there were no significant interaction effects found. At the Earli, the results of the multilevel analyses and the differences between the two subgroups of first and second language students will be presented and the results will be discussed in terms of the theoretical starting points.

SYMPOSIUM

Cognitive Development

Working memory and metacognition - early development and relevance for reading and math

Chairperson: Claudia Maehler, Institute of Psychology, Germany

Organiser: Claudia Maehler, Institute of Psychology, Germany

Discussant: Lucy Henry, London South Bank University, United Kingdom

The current discussion of precursors for school achievement is taking domain-general as well as domain-specific competencies into account. In this symposium we will focus on domain-general competencies, especially executive functions, working memory and metacognition. Three contributions will answer typical questions within the developmental perspectives on preschool age: How can the development be described? What relationships and mutual influences can be detected? And how can development be enhanced?

The first talk by Piekny et al. will focus on metacognition and theory of mind and will analyze correlations between these concepts as well as common precursors. Results reveal a close relationship but not a complete redundancy between the two concepts. In the second talk by Rößthlisberger et al. not only the developmental progression within the preschool years is described in a longitudinal design, but also the relevance of executive functions for higher vs. lower achievement in maths and reading. Data clearly support the impact of executive functions on maths and reading, showing substantial differences between children with higher vs. lower skills. The last presentation by Kroesbergen et al. finally explored the possibility to improve children's working memory abilities with a domain-

general and a domain-specific training. Results reveal positive effects of both interventions not only on the working memory performance but also on early math skills.

In sum, the symposium may stimulate the discussion about the relevance of executive and metamemory functions as precursors of school achievement and especially about the need for early intervention.

Precursors of theory of mind and metacognition

Jeanette Piekny, University of Hildesheim, Germany; Kirsten Schuchardt, University of Hildesheim, Germany; Ariane von Goldammer, University of Hildesheim, Germany; Dietmar Grube, University of Oldenburg, Germany; Claudia Maehler, Institute of Psychology, Germany

Theory of mind (ToM) and metacognition research share the same object: They investigate cognitions about cognition. However, ToM and metacognition research have been predominantly unrelated so far (Flavell, 2000). The aim of this study was to analyze the relation between ToM and metacognition by investigating if ToM and metacognition performance can be predicted by the same or different domain-general cognitive precursors.

We included measures of language (expressive vocabulary, morphological rules), executive functioning (dimensional change card sort), working memory (word span, nonword repetition, corsi block, matrix span) and intelligence (verbal, nonverbal) as precursor key candidates and a ToM scale (Hofer & Aschersleben, 2007) and a declarative metamemory interview (Lockl & Schneider, 2007) into a larger longitudinal study (Grube & Mähler, 2008). 170 Children at the age of four were tested twice. At the first time of data collection, we administered the potential precursor measures. At the second time of data collection about half a year later, we assessed children's ToM and metamemory.

We found a moderate, but significant correlation between ToM and metacognition. Hierarchical regression analyses showed that expressive vocabulary and word span predict ToM performance, while metamemory performance was predicted by expressive vocabulary as well, but also by nonverbal intelligence and word span in the reverse direction. These results show a close relation but not a complete redundancy between two previously unconnected concepts in research on cognitive development.

Theory of mind refers to the ability to attribute mental states to oneself and to other people (Premack & Woodruff, 1978). One aspect that has recently been discussed in theory of mind research is the relation between theory of mind and metacognition. Metacognition has been defined as any knowledge or cognitive ability that takes as its cognitive object any aspect of any cognitive activity (Flavell, 1993). Following this definition, theory of mind research should be closely related to metacognition research because both research traditions share the same object, which is cognitions about cognition. In order to theoretically elaborate on the relation between these concepts, Kuhn (2000) suggested a conceptual framework, using the term "metaknowing" as an umbrella term. She distinguished two components of metaknowing: a declarative, "metacognitive knowing" component and a procedural, "metastrategic knowing" component. The metacognitive knowing component refers to young children's developing knowledge of mental states as a product, usually assessed using theory of mind paradigms, while the metastrategic component refers to what children know about their cognitive processes and how they affect performance, typically addressed by metacognition research. Though theory of mind and metacognition clearly seem to be theoretically connected, empirical research on young children's theory of mind and metacognition abilities and their relation to each other has been rare (Flavell, 2000).

Another recently discussed aspect in theory of mind research is the changed focus on theory of mind development. Instead of focusing on typical age-related changes, several performance-based approaches now concentrate on interindividual differences in theory of mind performance (Jenkins & Astington, 1996). It was argued that variance in theory of mind performance can at least partly be explained by domain-general cognitive skills (Jenkins & Astington, 1996). The domain-general cognitive skills that have been identified as key candidates in predicting theory of mind performance are linguistic skills (e.g. Astington & Jenkins, 1999), executive functioning (e.g. Carlson, Mandell & Williams, 2004), working memory (e.g. Hasselhorn, Mähler & Grube, 2005), and intelligence (e.g. Schneider et al. 1999).

The study reported here combines both of these new aspects in theory of mind and metacognition research. The first aim of this study was to investigate the relation between theory of mind and metacognition abilities in young children in order to find out if theory of mind and metacognition are not only theoretically but also empirically connected.

Our second aim was to apply the focus of the performance-based approaches on explaining interindividual differences to both theory of mind and metacognition task performance, in order to investigate if there are differences and similarities concerning domain-general cognitive precursors. Differences and similarities between predictors of theory of mind and metacognition task performance might help to elaborate on the conceptual differences and similarities between these two constructs.

One of the shortcomings of previous studies was that most studies only included one or two cognitive abilities as key candidate precursor measures. Accordingly, the third aim of this study was to include a wide range of cognitive abilities, in order to investigate how much variance these measures explain in theory of mind and metacognition performance when they are all included concurrently.

In order to achieve these aims, we included measures on theory of mind, metacognition and potential precursors into a longitudinal study that explores differential trajectories of cognitive development in preschool children (Grube & Mähler, 2008). 170 Children (93 boys, 77 girls) were tested twice, separated by intervals of half a year. At the first time of data collection when the children were approximately 4;0 years old, we used measures on language (expressive vocabulary, morphological rules), executive functioning (dimensional change card sort), working memory (word span, nonword repetition, corsi block and matrix span), and intelligence (verbal and nonverbal) as potential precursors. At the second time of data collection when the children were about 4;6, we assessed children's theory of mind using a theory of mind scale (Hofer & Aschersleben, 2007) and metacognitive abilities using a declarative metamemory interview (Lockl & Schneider, 2007).

In the first step of our analyses, we correlated the composite score of the theory of mind scale with the composite score of the metamemory interview and found a moderate, but significant correlation between these measures ($r = .30$, p

In order to find out if variance in theory-of-mind and metamemory performance can be predicted by the same or different precursors, we conducted two hierarchical regression analyses with the theory of mind composite score as the criterion in the first, and the metamemory composite score as the criterion in the second analyses. We decided to enter the potential precursors according to the relative empirical support we found for them in the literature. Our results show that expressive vocabulary and word span are significant predictors of the theory of mind composite score. The composite score of the metamemory interview was significantly predicted by expressive vocabulary as well, but also by nonverbal intelligence and word span in the reverse direction. These results are interpreted against the background of the relay race model on theory of mind development (Hasselhorn, Mähler, & Grube, 2005) and show a close relation but not a complete redundancy between two previously unconnected concepts in research on cognitive development.

Executive Functions from ages 5 to 8 in children with high and low math or reading skills

Regula Neuenschwander, University of Bern, Switzerland; Patrizia Cimeli, University of Bern, Switzerland; Claudia Roebbers, University of Bern, Switzerland; Marianne Rethlisberger, psychology, Switzerland

The present longitudinal study addresses developmental changes in different aspects of executive functions (EF) - working memory, inhibitory control and cognitive flexibility - in a sample of first/second graders (age in months : $M = 92.3$; $SD = 4.3$ / $M = 102.4$; $SD = 3.9$) showing different mathematical and reading abilities. Of special interest were issues of developmental progression and the predictive power of EF for a correct assignment to an either low or high achieving group. It was expected that children with different levels of math/reading skills at the end of the first or second class would show different performance in tasks measuring EF, and that specific aspects of EF, measured in the previous years, would correctly classify the low and high achieving school children. EF were assessed annually during three consecutive years; math and reading skills were measured only at the last measurement point. From a total of 353 children, subsamples of 80 (for math), 105 (for reading) children with either low or high skills were selected. The findings revealed that children with low vs. high academic skills differed substantially in all EF tasks over time, with consistently poorer performance in the low compared to the high achieving group. Concerning the predictive value of EF, cognitive flexibility together with inhibitory control allowed the optimal classification of children into the low and high achieving groups in math. For reading skills, inhibitory control best classified children into the low and high achieving groups two years later.

Aims:

It has consistently been shown that executive functions (EF) undergo substantial improvements in childhood with rapid changes typically being observed between the age of 4 and 8 (Carlson, 2005; Davidson, Amso, Anderson, &

Diamond, 2006; Cragg & Nation, 2008, 2009). Moreover, EF have proven to be predictive for both school readiness and later school achievement (Blair & Razza, 2007). However, educational research has rarely examined the association between EF and academic skills in the context of longitudinal studies or during early childhood, a phase of rapid growth. Although prior cross-sectional studies report a direct association between EF and children's mathematical skills in school age children, the specific functional relations between different aspects of EF and math achievement is less clear (Bull & Scerif, 2001; St Clair-Thompson, & Gathercole, 2006). Some researchers argue that working memory plays an important role in acquiring math skills (Bull, Espy, & Wiebe, 2008; Meyer, Salimpoor; Wu, Geary, & Menin, 2010), whereas others propose that inhibitory control accounts for unique variance in mathematical achievement (Espy, McDiarmid, Cwik, Stalets, Hamby, & Senn, 2004). With respect to reading skills, even less is known about the relationship or predictive power of specific aspects of EF (Alloway, & Alloway, 2010; Bull et al., 2008). Therefore, the aim of this study was to extend the existing research in terms of determining the specificity of the relationship between different aspects of EF and academic skills (in this case reading and mathematics) within a longitudinal framework. In order to present a detailed picture, two different approaches of analyses were chosen: First, we set the focus on the developmental progression of different aspects EF in low and high achieving children in math/reading skills over the course of three years. Second, we conducted a discriminant function analysis to evaluate the extent to which performance on different aspects of EF accurately predicted children's later classification into the low or high achieving group in math/reading skills. It was hypothesized that low achieving first and second graders would show significant lower EF performance compared to the high achieving group earlier in their development and that depending on the outcome, different aspects of EF would optimally classify the high and low achieving children in mathematics or reading skills.

Methodology:

N= 353 children from two age cohorts (5-yr-olds: N =182, 85 girls; 6-yr-olds: N = 171, 88 girls at the beginning of the study) were involved. To form the low and high achieving groups, first/second graders with a performance in math or reading skills 1 SD below, respectively 1 SD above the mean - based on the third measurement point within the corresponding age cohort - were selected. For the first graders, 47 children (low achiever: N =23; high achiever: N = 24) in mathematical skills and 49 children (low achiever: N =21; high achiever: N = 28) in readings skills were selected. For the second graders, 33 children (low achiever: N =15; high achiever: N = 18) in mathematical skills and 56 children (low achiever: N =25; high achiever: N = 31) in readings skills were selected. All children were tested at three measurement points with an interval of exactly one year. EF were assessed at all measurement points: For working memory, the Backward Color Recall Task, for inhibitory control, the Fruit-Stroop Task and for cognitive flexibility, an adapted Shifting Task from a standardized test battery were included. Reading and mathematical skills were assessed at the third measurement point: For mathematical skills, a composite score of three tests (addition & subtraction, equations, and sequences of numbers) and for reading skills, a composite score of two reading task were calculated. The data were analyzed with a mixed ANOVA with time (three measurement points) as within-subject factor, age cohort and achieving group as between-subject factors, and as well with a mixed ANCOVA with IQ, SES, and age as covariate. Furthermore, a discriminant function analysis was conducted with EF measures entered stepwise.

Findings:

First, it was expected that low achieving children in math/reading skills would show significant lower performance in EF compared to high achieving children. The analyses confirmed this hypothesis: The high achieving groups in math/reading skills performed consistently better than the low achieving groups in both age cohorts over time. Moreover, the high and the low achieving children showed mainly parallel developmental progression over the course of the study with one exception: The low achieving group increased performance in the inhibitory control significantly more pronounced than the high achieving groups. Even when IQ, SES, and age were statistically accounted for, performance on all EF measures was still significant different between the high and low achieving groups in math/reading skills. Finally, the discriminant function analyses revealed that the cognitive flexibility and inhibitory control measures were identified as reliable in classifying the low and high achieving children in math two years later (group membership was classified correctly for 82% of the children). For reading, the optimal classification of children was achieved with the inhibitory control measure (group membership was classified correctly for 72% of the children). Theoretical and educational significance: The results support the hypothesis that EF contribute to the acquisition of domain-specific skills (i.e. reading and math skills). Our findings extend previous cross-sectional research documenting a predictive relation between EF and later mathematical competencies (Espy et al., 2004; Meyer et al., 2010). Importantly, these findings suggest that early development of EF provides an important foundation not only for mathematical but also for reading achievement. Therefore, efforts to enrich pre-academic curricula should more strongly recognize the significance of EF and design programs for promoting EF already in preschool years. In addition, the findings show that children with low academic skills have early and persistent EF deficits. Specifically, inhibitory control was the best predictor that reliably classified first and second graders with low reading skills and for math skills both cognitive flexibility and inhibitory control were the most powerful predictors.

Training working memory in kindergarten children: Effects on working memory and early math

Evelyn Kroesbergen, University of Utrecht, Netherlands; Meijke Kolkman, Utrecht University, Netherlands; Jaccoline van't Noordende, University of Utrecht, Netherlands

This study explored the possibility to improve children's working memory abilities with a domain-general and a domain-specific training. The domain of the latter was early mathematical skills. Working memory and early math measures were administered to children in kindergarten who performed below the 50th percentile on a criterion-based mathematics test. A total of 51 second-year kindergarten children (mean age = 5.83 years, SD = 0.32) received a domain-general working memory training, a domain-specific working memory training or no training. After a pretest, four weeks of intervention took place, followed by a posttest. Children in both the domain-general working memory intervention and the domain-specific working memory intervention showed improvement on working memory tasks. Also both the domain-specific working memory intervention and the domain-general working memory intervention had a significant positive effect on children's early math skills. The domain-specific training had the highest effect on children's counting and number comparison skills.

Aims & background

Early mathematical tasks rely on a constant process of perceiving, coding, interpreting, comparing and retrieving information. In a numerical comparison task, for example, information about the numerical quantity of the presented numbers is retrieved from long term memory after which this information is integrated with the incoming information. The role of working memory in this is that the central executive helps to coordinate the processing of numerical information in order to perform the task. So it seems theoretically reasonable that performance on mathematical tasks is facilitated by working memory.

A large body of research (e.g. Geary, 2010, Passolunghi et al., 2008) has demonstrated correlations between working memory and (early) math. However, to test a possible causal relation, it would be better to investigate these relations with an experimental design. The main goal of this study was to test the hypothesis that improvement of working memory skills benefits early math learning. It should be noted that we do not pretend to offer an alternative for math interventions, because when the goal is to improve math, it would be better to use interventions focused on math itself. Two hypotheses were tested: (a) working memory can be trained in 5-year old children, (b) improved working memory leads to better early math performance. Working memory is always used within a domain-specific content. It appears that skills in a specific domain are related to working memory capacity in that domain (cf. Ericsson & Kintsch, 1995). Therefore, a distinction was made between domain-general working memory training, and a domain-specific training, focused on working memory within the numerical domain.

Methodology

A total of 51 second-year kindergarten children who scored in the lowest 50% on two standard national criterion-based math tests were selected to participate (mean age = 5.83 years, SD = 0.32) and randomly divided in three groups: (1) domain-general working memory training, (2) domain-specific working memory training, (3) no-intervention control group. The three groups did not differ in age, $F(2, 48) = 1.40$, $p = .26$, or sex, $\chi^2(2) = 2.56$, $p = .29$. Pre- and posttests were conducted to measure working memory and early math skills. The children were trained twice a week for about 30 minutes in groups of five children. The training lasted four weeks.

Working memory was measured with two subtests of the AWMA (Alloway, 2007), both a verbal and a visuospatial working memory task: word recall backwards and Odd one out. Early math was measured with a dot comparison task (cf. Gebuis, Kadosh & de Haan, 2008) and the Utrecht Early Numeracy Test-revised (Van Luit & Van de Rijt, 2009).

The domain-general training was aimed at improving the verbal and visuospatial working memory skills of the children. All the activities concentrated on working memory, in that they required the children to memorize, process and activate information simultaneously, which is in line with the definition of working memory as given by various researchers (e.g., Passolunghi & Pazzaglia, 2004, 2005). It was assumed that playing games that concentrate on working memory, is useful in enhancing working memory skills, as it has been shown that using (computerized) activities related to the processing and memorization of information are effective in improving working memory skills (Klingberg et al., 2005; Thorell et al., 2009).

The aim of the domain-specific working memory training was to improve the working memory skills in the domain of mathematics. It was tried to find similar activities as in the domain-general working memory training, but all with a

numerical content. The training thus included memorizing, processing and activating numerical and counting information simultaneously.

Findings

A repeated measures MANOVA showed significant differences for both training conditions (domain-general: $F(4, 11) = 10.91$, $p^3 = .80$; domain-specific: $F(4, 11) = 6.99$, $p^3 = .72$), but not for the control condition, $F(4, 17) = 1.61$, $p = .22$. Univariate within-subjects analyses showed large effects on working memory for both training groups (p

Between-group comparisons revealed a multivariate effect of condition on the posttest scores, $F(8, 82) = 2.79$, $p^3 = .14$. The univariate tests showed that both training conditions performed higher on Odd One Out than the control group (p). Furthermore, the domain-specific training group showed higher scores on the Early math tasks than the control group (p

Finally, it was investigated if improvement in working memory leads to improvement in early mathematics. Children who showed more improvement on the Odd One Out task, improved more on the Early Numeracy Test-Revised than children with less improvement on the working memory task ($r = .49$).

Theoretical and educational significance

This study shows large effects after a relatively short intervention. No significant differences were found between the domain-general and the domain-specific training group. It thus can be concluded that working memory skills can be enhanced by training at kindergarten age, and that the content of the trained working memory tasks is of minor importance. Furthermore, this study is the first that found generalization effects of working memory training on early math in young children. These results provide evidence for the causal relation between working memory and mathematics. Furthermore, it is promising that training working memory is effective, even in young children. These results could be helpful in interventions for children with either working memory deficits or mathematical deficits, although the largest effects may be found with children experiencing difficulties in both working memory and (early) mathematics.

SYMPOSIUM

Teaching and Instructional Design

Cognitive Load Theory revisited and revised

Chairperson: Joerg Zumbach, University of Salzburg, Austria

Organiser: Joerg Zumbach, University of Salzburg, Austria

Neil Schwartz, California State University, United States

Discussant: Tamara Van Gog, Erasmus University Rotterdam, Netherlands

One of the most successful theories for the design of instructional media during the past years is Cognitive Load Theory (CLT). CLT has spawned a large set of empirical. In fact, since its debut in 1988, hundreds of articles have investigated elements of instructional design through the lense of CLT. However recently, CLT has been criticized on a number of fronts. For example, intrinsic cognitive load has been considered by the designers of CLT as fixed and therefore immutable to instructional adjustments. Nevertheless, there is evidence that element interactivity is relative to a learner's prior knowledge of the material and the ontological characteristics of certain concepts. It also seems that extraneous cognitive load is not always deleterious to learning. Finally, germane cognitive load might not always be beneficial to learning, especially when, e.g., inadequate problem solving schemata are applied. Within this symposium, three different papers aim to clarify conceptual problems of CLT. Ayres suggests here to consider germane and extraneous cognitive load exclusively in terms of element interactivity. Thus, germane cognitive load is regarded here not as a separate source of working memory load. The contribution made by Schnotz introduces a motivational perspective of CLT. He argues that the cognitive load concept addresses rather heterogeneous aspects than a mere cognitive level. Finally, in the contribution by Zumbach and Schwartz, the role of germane cognitive load is re-conceptualized. In their empirical contribution they suggest a revised model of CLT where germane load is treated separately from both other kinds of CL.

Rethinking Germane Cognitive Load

Paul Ayres, University of New South Wales, Australia

Like any theory, cognitive load theory has had its fair share of doubters and critics. Unlike earlier times, when many criticisms were based on ideological grounds, commentators have recently adopted a more analytical and scientific based approach to identify some key conceptual issues that suggest potential weaknesses and inconsistencies in the theory. One major source of conceptual disagreement often reported focuses on considerations of the three different types of cognitive load (intrinsic, extraneous and germane), and in particular germane cognitive load. The main aim of this paper is two-fold. Firstly it documents some of the main problematical issues associated with germane cognitive load. Secondly it presents an argument that seeks to clarify some of these theoretical difficulties by reporting on a new conceptual framework that links germane cognitive directly to element interactivity and intrinsic cognitive load. It concludes by discussing the implications for the theory and educational outcomes.

Aims.

This paper has two main aims. Firstly it aims to document some of the problematical issues associated with germane cognitive load. Secondly it presents an argument that seeks to clarify some of these theoretical difficulties by reporting on a new conceptual framework that links germane cognitive directly to element interactivity and intrinsic cognitive load.

Methodology.

This theoretical paper brings together some of the key findings from three major sources (Beckmann, 2010; de Jong, 2010; Schnotz & Kyršchner, 2007) that have reported conceptual issues associated with cognitive load theory, and germane cognitive load in particular. It reports on a re-conceptualisation of germane load, that links it directly to element interactivity and intrinsic cognitive load (synthesised from Sweller, 2010; Sweller, Ayres & Kalyuga, 2010), thus providing a more robust framework.

Findings.

One major source of conceptual disagreement with CLT has been the various mechanisms associated with the three different types of cognitive load (intrinsic, extraneous and germane). In the early development of CLT, cognitive load was considered a single construct- the total working memory load invested in the learning episode. However, Sweller, van Merriënboer and Paas (1998) later identified three types of cognitive load- intrinsic, extraneous and germane. Intrinsic cognitive load was defined as the load caused by the materials to be learned; extraneous load by the load associated with dealing with the instructional materials; and germane load, the load directly invested in schema formation. A key aspect in this theoretical development was element interactivity that generates intrinsic cognitive load. Element interactivity is the number of elements that must be processed simultaneously. When the task to be learned is high in element interactivity, so is intrinsic cognitive load, and vice versa for low element interactivity (Sweller & Chandler, 1994). Sweller et al. (1996) considered each load as mutually exclusive and total cognitive load was calculated by adding the three loads together. The initial consideration of the three loads as independent has recently come under considerable scrutiny and has ultimately led to the changes outlined in this paper. A reconsideration of germane cognitive load by Schnotz and Kyršchner (2007) linked germane load to intrinsic by arguing that germane load is constrained by intrinsic load. In other words, germane cognitive load cannot exceed intrinsic load.

Whereas it is possible to have high intrinsic load and low germane load (little reflection on a difficult task) but not vice versa (much reflection on a simple task). Schnotz and Kyršchner concluded that it is the combination of germane load and intrinsic load rather than just germane load that leads to optimal learning, because little can be learned from easy tasks (low intrinsic load). Beckmann (2010) also theorised a closer relationship between intrinsic and germane load, arguing that germane load results from the cognitive behaviours that process element interactivity. Consequently, germane load is dependent upon intrinsic load. Beckmann also argues that element interactivity not only generates intrinsic cognitive load, but also extraneous cognitive load. Instructional materials contain a number of elements that need to be processed in working memory, in much the same way as the information to be learned. Sweller (2010), Sweller, Ayres and Kalyuga (2010) in their re-conceptualisation also argue that both intrinsic and extraneous load is generated by element interactivity. Furthermore, germane cognitive load can be considered exclusively in terms of element interactivity. It is defined in terms of working memory resources that are devoted to dealing with intrinsic cognitive load generated by the information to be learned. This consideration is in line with Schnotz and Kyršchner's argument that intrinsic load constrains germane load. However, germane load is not considered to be a separate source of working memory load, but purely a function of the number of interacting elements that generate intrinsic cognitive load. If intrinsic load is high (dependent upon the learner's prior knowledge) then a high amount of germane cognitive load is required to learn the materials. The reverse situation is true for materials low in element interactivity. The central role played by extraneous cognitive load in cognitive load theory remains the same, if extraneous cognitive load is high fewer working memory resources are available the less resources are available for dealing with intrinsic cognitive load. Hence fewer resources are available for germane cognitive load.

De Jong (2010) makes the point that cognitive load is often poorly defined in terms of mental load and mental effort, by frequently not making a clear distinction between a learner's efforts and the load imposed by the task. Sweller et al. (2010) make a much clearer distinction between the two by considering required cognitive load and invested cognitive load. The required intrinsic cognitive load is the load generated by the materials to be learned dependent upon the learner's prior knowledge. However, the learner still has to invest that level of cognitive load for learning to be optimised. If the intrinsic load demands are too high (exceeding WM capacity) or the learner does not invest enough due to motivational reasons (Beckman, 2010; Schnotz & Kýrschner, 2007; Sweller, 2010) learning is reduced. Measurement of cognitive load, and in particular the individual loads has been identified as another problematical area of cognitive load (Beckmann, 2010; de Jong, 2010; Schnotz & Kýrschner, 2007). Critics argue that learners are unable to differentiate between the three loads; not only through their own introspection but also because of the difficulty in defining them from a conceptual point of view. To-date attempts to measure the three loads separately have not been convincing (Sweller et al., 2010). The proposed reconsideration of cognitive load has direct consequences for measuring both individual and total cognitive load.

Theoretical and educational significance of the research.

This re-consideration of germane load has theoretical significance because it potentially improves the theory and reduces a number of conceptual issues. CLT has identified a number of effects that have facilitated learning and led to improved instructional designs. Any refinement of the theory has the potential to generate further effects and lead to further improvements in educational outcomes.

Working Memory and Learning: What Kind of Load Do We Talk about?

Wolfgang Schnotz, University of Landau, Germany

Cognitive load theory aims at integrating knowledge about the structure and functioning of the human cognitive system with principles of instructional design. Cognitive load theory makes a distinction between different kinds of cognitive load. Nevertheless, the general load concept is considered as something unitary, because the different kinds of cognitive load are assumed to draw on the limited capacity of working memory in an additive way. A closer look reveals, however, that the cognitive load concept addresses rather heterogeneous aspects. The paper will analyze some conceptual shifts that have been made in cognitive load theory. The concept of cognitive load in the original version of the theory was derived from the number of cognitive elements that have to be held simultaneously in working memory, which was called 'element interactivity'. When recent versions of the theory try to explain split-attention effects, however, they refer to maintenance processing rather than to element interactivity. When they describe waste of time and effort as cognitive load on the working memory of advanced learners, they refer to the amount of cognitive operations and to motivational resource rather than cognitive ones. The theoretical and practical implications of these conceptual shifts will be pointed out.

Cognitive load theory tries to integrate knowledge about the structure and functioning of the human cognitive system with principles of instructional design. The theory argues that many traditional instructional techniques do not adequately take the limitations of the human cognitive architecture into account as they unnecessarily overload the learner's working memory, the central "bottleneck" of his/her cognitive system (Paas, Renkl, & Sweller, 2004; Sweller, 2005). Intrinsic load is the unavoidable load caused by the task-intrinsic aspects of learning. Extraneous load is unnecessary load caused by inappropriate design and organization of the learning material. Germane load is caused by effortful learning and corresponds to the working memory capacity required for schema abstraction and automation (Sweller, van Merriënboer & Paas, 1998). Because the different kinds of load are assumed to draw on working memory capacity, the concept of cognitive load is generally considered as something unitary. A closer look reveals, however, that the concept addresses rather heterogeneous aspects. Whereas the concept of cognitive load of the original theory was derived from the number of cognitive elements that have to be held simultaneously in working memory (the so-called element interactivity), it includes nowadays also facets such as maintenance processing, amount of cognitive operations, and use of motivational resources.

Maintenance Processing

Working memory is limited not only in terms of capacity, but also in terms of duration. If instruction unnecessarily requires extra effort to compensate for the limited temporal duration of information in working memory, this is considered as an extraneous load. For example, if an instruction requires split of attention between text and pictures and if the two kinds of sources are presented in a segregated rather than in integrated format, the learner has to invest additional effort to keep information in working memory while his/her attention is shifting from one source to another source of information. Note, however, that there is no change in element-interactivity, because the number of cognitive elements to be held simultaneously in working memory is exactly the same. What makes learning more difficult when text and pictures are presented in a segregated format is the need of maintaining cognitive elements in working memory rather than an increase in element-interactivity. Amount of cognitive operations An instructional format that is beneficial for novices can lose its advantage with increasing expertise of the learners and finally become disadvantageous for individuals with higher expertise (Kalyuga, Ayres, Chandler, & Sweller, 2003). In order to explain this so-called expertise reversal effect, cognitive load theory assumes that information which is necessary for novices may become redundant for more advanced learners. Redundant information is assumed to impose an unnecessarily high cognitive load on working memory of advanced learners. It is obvious that this view is for the following reasons not consistent with the original concept of cognitive load as the amount of element interactivity (i.e. the number of cognitive elements that have to be held simultaneously in working memory). If an instructional format is beneficial for novices, it does obviously not overload their working memory. When novices increase their expertise through learning by construction of new schemata and automation, this results in lower (rather than higher) cognitive load for the same tasks. In other words, an information format that does not overload the working memory capacity of novices will not be able to overload the capacity of experts. It follows that cognitive load due to the processing of redundant information must be explained in a different way.

When cognitive processing of irrelevant information is considered as extraneous load, this load is simply a waste of time and effort on the side of the learner (Kalyuga, Chandler & Sweller, 1998). If, for example, an advanced learner studies a diagram that is perfectly intelligible for him/her without further explanation and if afterwards he/she reads an accompanying text that explains the diagram for novice learners, reading this text by an advanced learner means processing unnecessary information with no added value for learning. Note, however, that the text does not overload the working memory of the advanced learner, simply because it does not overload novice learners. Cognitive load due to waste of time and effort means that learners perform cognitive processes that do not result in additional learning. It is the amount of cognitive processing that seems to be critical here, which is very different from the original concept of cognitive load. Remember that the load concept was derived from the number of cognitive elements that have to be held simultaneously in working memory. Cognitive activities such as vocabulary learning (although time consuming and exhausting) were assumed to have a low cognitive load, because only a few elements have to be held simultaneously in working memory at any time (Sweller, van Merriënboer and Paas, 1998). However, cognitive load due to waste of time and effort is a load caused not by cognitive elements held in working memory, but by the amount of cognitive processes. Motivational Resources Learning is a process, which requires time and can be more or less exhausting. The effort invested by an individual can be considered as a kind of 'mental energy'. An individual's reservoir of energy can be exhausted by the process of learning and then needs to be recharged in order to continue learning. His/her willingness to invest energy into learning leads to the field of motivation. The close relation between cognitive load and motivation remains usually hidden, but becomes obvious when one considers the measurement procedures (Schnotz, Fries & Horz, 2010). Cognitive load is usually measured by self-judgements of the effort invested into learning or solving a task (Paas, van Merriënboer & Adam, 1994). However, the same measurement is also used in questionnaires for the learner's present motivation (QAM; Rheinberg, Vollmeyer & Burns, 2001). Highly motivated learners show higher persistence, invest more time and energy into the process of learning, which finally results in better learning results. In other words, cognitive load due to a waste of time and effort is essentially a load on a motivational resource rather than a cognitive one.

Cognitive Load Theory Re-Examined: A Dynamic Model of Cognitive Load

Joerg Zumbach, University of Salzburg, Austria; Neil Schwartz, California State University, United States

In two experiments, a revised model of Cognitive Load Theory has been examined. Within this model, we suggest that the assumption of additivity of all three types of cognitive load cannot be kept. We rather assume that intrinsic and extraneous cognitive load have to be treated separately when examining problem-solving. In addition, it is postulated here that germane cognitive load does have an active impact on how information occupying intrinsic and extraneous load resources are processed without being subject to cognitive overload itself. Using the Tower-of-Hanoi-task we could show that a series of highly difficult problem-solving tasks contributes to develop effective problem-solving

schemata better than a task with increasing difficulty. These differences finally vanish when the adequate problem-solving schema is trained in advance. Based on these findings we suggest a revised model of cognitive load mapped on working memory architecture.

Aims.

Learning performance is enhanced when instruction is properly designed; instructional design is best when it is guided by theory. One of the most successful theories for the design of instructional media is the theory of Cognitive Load (CLT). However, recently, CLT has been criticized on a number of fronts (de Jong, 2010)—among them, the nature of the specific types of cognitive load and the degree to which they are clearly distinguishable. Extraneous load reduction may undercut the potential for germane processing—processing that is good for learning; instructional material appearing to cause extraneous load is often circumvented by learners' prior knowledge; thus, some material incurring extraneous load does not necessarily compromise learning (cf. Mayer & Johnson, 2008). Higher cognitive load leading to better schema construction (and hence, better learning) is not always of the type that is germane to the task. Thus, the construct of CL, with its differentiation between the three types and the theorem of additivity, does not appear to accurately represent the nature of human information processing. It seems unlikely that ICL, ECL and GCL are well differentiated with each load type having a distinctive function during learning. Sources of CL are sometimes assumed to be "overload" when they are not, and the origin of their influence is not always clear. We contend that ICL and ECL are influenced by information from the outside, and GCL is influenced by information represented inside memory. If true, it is likely that GCL has a reserved storage space in working memory that maintains active information processing in severe conditions where ICL and ECL are high. We assume that under such circumstances, higher load (especially ICL) might even increase effort to process current information and foster schema construction better by using GCL more efficiently.

Methodology.

Here, we examined cognitive load using a task commonly employed to test the activation of executive function—the Tower of Hanoi. The Tower-of-Hanoi task is fixed in the ICL it incurs because its element interactivity is fixed, unless the number of disks, and thus the number of steps necessary to solve the task, is increased. GCL, alternatively, is a load type incurred by the deployment of cognitive operations associated with executive regulation. We manipulated the learning conditions of the Tower-of-Hanoi task in two experiments to examine schema construction and schema automation to determine: a) in which components of the working memory system the construction and automation is likely to occur, and b) which types of cognitive load are likely incurred during the construction and automation processes. We varied the number of disks required to solve the task and the training learners' received in the most efficient strategy for solution; we measured the time and number of moves to solve the task, as well as learners' perceptions of CL. In experiment one, participants had to solve the Tower-of-Hanoi problem over three consecutive trials. Half the learners were given six disks on each trial to construct the schema of the task. The other half were given four, five, and six disks on trial one, two, and three, respectively. If CLT is correct, the number of errors (of moves) as a percentage of the optimal number of moves should decrease over trials while the number of disks is increased. The increasing difficulty should contribute to develop a problem-solving schema that will, starting with subtask two, be able to reduce CL by means of chunking. There should also be no difference in the percentages when the number of elements begins high and remains high over trials since the intrinsic cognitive load remains consistently high. We argue that the need of active information processing in the condition with high difficulty contributes to the development of a problem-solving schema rather than the increasing difficulty condition. We assume that ICL and ECL must be treated separately from GCL. Here GCL might influence how information processing is handled depending on task difficulty and available resources. Consequently, a continuous series of high complex tasks might be better for developing adequate problem-solving schemata than increasing difficulty due to an increased need of information processing. This requires the assumption that GCL does not have an additive relation with ICL and ECL yielding an overall sum of CL. In experiment two, we replicated and extended experiment one by training two additional groups in the algorithm of the Tower-of-Hanoi-task. We expected the same pattern for the untrained groups as in experiment 1. For the trained groups, we did not expect to find differences between both conditions related to the number of discs because problem-related GCL should reduce ICL significantly.

Findings.

Results of experiment one (n=60) yielded significant effects for all three subtasks (pIn experiment two (n=120) the same findings were replicated (pSignificance of the research. Results of both experiments suggest that CLT is not able to explain the findings, and that the addition theorem of CL is not valid. Instead, it appears that ICL and ECL operate in a separate subsystem of working memory than GCL, though, both subsystems interact together. Furthermore, it seems likely that GCL occupies a reserved space in working memory—a space reserved for active information processing germane to a task. If the reserved space hypothesis is true, then learners have a reservation of resources that allows them to process information even under the worst conditions and might even foster and support problem-

solving processes better than CLT-adequate instruction. Based on these findings, we suggest a revised model of CLT that directly maps cognitive load to established working memory models.

SYMPOSIUM

Meta-cognition

Self-Regulated Study and its Cues: The Road to Hell Is Paved with Good Intentions

Chairperson: Nathalie Huet, University of Toulouse, France

Organiser: Ladislav Motak, The French National Institute for Transport and Safety Research (INRETS), France

Discussant: Rainer Bromme, Universität Muenster, Germany

Despite the undeniable progress of networking and globalism, current educational curricula may be successful only insofar as the target population is able to consequently self-regulate its activities in a well adapted and efficient manner. Indeed, it has been recently shown that people rely on metacognitive processes to regulate their behaviour: Those processes not only reflect--more or less correctly--one's cognitive states, but also allow for regulating one's cognitive activity strategically towards the predetermined goals. In this respect, the three presented papers are concerned with metacognitive cues and heuristics that may guide people's self-regulation in such tasks as learning (Undorf & Cýpper), understanding (Ackerman & Leiser), and even driving (Motak et al.). However, while it appears that human metacognition as a complex system is able to take into account a wide range of diverse metacognitive cues, the three presented papers not only approach the theme of self-regulation in thus far sometimes scarcely related contexts, but also point out metacognitive cues that may prove detrimental to one's efficient self-regulation: Implicit memory processes (Undorf & Cýpper), an inflated sense of understanding (Ackerman & Leiser), and a stereotype threat effect (Motak et al.). From an educational point of view, this summary of research on metacognitive regulation of study effort identifies cues and heuristics worthy to be aware of when conceiving educational curricula aimed at self-consciousness and self-regulation enhancement.

Implicit and Explicit Memory Processes Affect Self-Regulated Learning

Monika Undorf, Chair of Psychology III, Germany; Lutz Cüpper, University of Mannheim, Germany

Metacognitive processes are known to be important for successful self-regulated learning. This can, for example, be seen from the fact that people use judgments of learning (JOLs) to regulate their learning behavior. We present a series of three experiments that investigated whether JOLs rely selectively on either implicit memory processes or explicit memory processes or on both processes. In order to assess implicit and explicit memory processes, the process-dissociation procedure was used in combination with a word stem completion task. We found that explicit memory processes are more accurately reflected in JOLs than implicit memory processes are. Nevertheless, our results showed that JOLs are based on both implicit and explicit memory processes. The conducted experiments thus revealed that metacognitive monitoring is not confined to explicit memory processes. From a theoretical point of view, this finding emphasizes the considerable capability of the metacognitive system. In educational settings in which test performance is mainly governed by explicit memory processes, however, the influence of implicit memory processes on JOLs might be detrimental.

Metacognitive processes are known to be important for successful self-regulated learning. This can, for example, be seen from the fact that people use judgments of learning (JOLs) to regulate their learning behavior. JOLs are predictions of the likelihood with which recently studied information will be retrieved in future. Both people's choices concerning the relearning of to-be-studied information and people's allocation of study time to different pieces of to-be-studied information are systematically related to JOLs (e.g., Metcalfe & Finn, 2008; Son & Metcalfe, 2000).

Metacognitive judgments, as for example JOLs, in turn are generally agreed to be inferences on the basis of a variety of cues and heuristics that convey information about cognitive processes. Their validity in predicting cognitive processes therefore is not guaranteed but is an empirical question. In this context, an important question relates JOLs

to the well established distinction of implicit and explicit memory processes (e.g., Graf & Schacter, 1985). According to Jacoby (1991), implicit memory processes are considered as automatic processes—i.e., as fast processes that do neither demand attention nor exhaust cognitive capacity—whereas explicit processes are regarded as controlled processes, i.e., as slower processes that demand attention and can be deployed flexibly to achieve one's aims.

The question whether JOLs rely selectively on either implicit or explicit processes or on both has been discussed frequently (e.g., Benjamin, 2005; Daniels, Toth, & Hertzog, 2009) but was seldom investigated. A study that is related to this question was conducted by Daniels et al. (2009) and investigated how the accuracy of JOLs changes with memory retrieval experiences. The authors employed an experimental procedure that closely resembled the remember-know task (cf. Tulving, 1985), in which metacognitive judgments concerning the experiences associated with memory retrieval are used for separating the contributions of recollection and familiarity to recognition memory. The results obtained by Daniels et al. are consistent with the idea that recollection is more important for JOLs than familiarity. The validity of this conclusion, however, is challenged by an ongoing debate concerning the suitability of the remember-know task to disentangle implicit and explicit processes. First, it is controversial whether remember and know judgments reflect different memory processes at all (e.g., Dunn, 2008). Second, both remember and know response rates are affected by response bias and thus cannot be interpreted as pure measures of implicit and explicit memory processes (e.g., Erdfelder, Cýpper, Auer, & Undorf, 2007). Third, soliciting for each item both a JOL and a judgment on memory retrieval experience might distort results.

A less controversial and therefore preferable empirical approach that allows investigating the influence of implicit and explicit memory processes on JOLs and self-regulated learning is the process-dissociation procedure introduced by Jacoby (1991). The process-dissociation procedure separates the contributions of implicit and explicit processes by means of combining a facilitation condition and an interference condition. In the facilitation condition, controlled processes and automatic processes act in concert towards correct responses. In contrast, only controlled processes promote correct responses in the interference condition, whereas automatic processes favor erroneous responses. In word stem completion experiments, participants are asked to complete presented stems to previously studied words in the facilitation condition, whereas they are required to complete word stems with any meaningful word except for learned ones in the interference condition. Combining these tasks permits to estimate the relative contributions of controlled and automatic processes by means of an appropriate measurement model as the extended measurement model (Buchner, Erdfelder, & Vaterrodt-Plýnnecke, 1995; Cýpper & Erdfelder, 2004).

We conducted a series of three experiments that separately investigated the contributions of implicit and explicit memory processes to JOLs in both experimenter-controlled and self-regulated learning conditions. In these experiments, we used the process-dissociation procedure in combination with a word stem completion task to assess implicit and explicit memory processes. Our results first showed that JOLs are based on both implicit and explicit memory processes: The probabilities of implicit and explicit memory processes increased with increasing JOLs. Second, we found that explicit memory processes are more accurately reflected in JOLs than implicit memory processes are: The probability of explicit memory processes increased with increasing JOLs more considerably than the probability of implicit memory processes did.

The conducted experiments thus revealed that although explicit memory processes are more closely related to JOLs than implicit memory processes are, metacognitive monitoring is not confined to explicit memory processes; rather, both types of memory processes were subject to metacognitive monitoring. From a theoretical point of view, this finding emphasizes the considerable capability of the metacognitive system. In educational settings in which test performance is mainly governed by explicit memory processes, however, the influence of implicit memory processes on JOLs might be detrimental.

The Effect of Concrete Illustrations on the Metacognitive Regulation of Study

Rakefet Ackerman, Technion--Israel Institute of Technology, Israel; David Leiser, Ben-Gurion University, Israel

Study materials often include illustrations for decoration and organization of text. Ackerman and Leiser found that increased concreteness enhanced through inclusion of illustrations increased the metacognitive Sense of Understanding (SOU) even when illustrations did not contribute to actual understanding of the topic. The present study examined practical implications of this finding. In three experiments, participants studied texts, in either a plain text version or accompanied by uninformative illustrations. In two of the experiments, participants studied expository texts. Immediately after studying each text, they rated their SOU and were tested for comprehension, either with open books (Experiment 1) or without (Experiment 2). In Experiment 3 the texts were explanations of solutions for difficult logic problems. Participants attempted to solve each problem on their own, read explanation of its solution and rated their SOU for that explanation. Understanding was evaluated by a transfer problem similar to the initial problem. Under all the conditions tested, study efficiency was lower for illustrated texts than for plain texts. When more time was invested in processing illustrated texts, either during study (with closed books) or during testing (with open books), participants succeeded in reaching comparable test scores for the two versions. When no compensatory time was invested, illustrated texts led to a reduction in performance and to a larger upward bias of the SOU. These findings suggest that, by enhancing the subjective concreteness of texts, illustrations may bias the SOU and reduce study efficiency.

According to the metacognitive approach, efficient study depends on the accuracy of the subjective assessment of knowledge level. Knowledge monitoring that results in a mistakenly high self-assessment is expected to lead learners to cease studying too soon and perform lower than expected (Winne, 2004). Ackerman and Leiser (2010) suggested that one heuristic cue that may bias the metacognitive monitoring of understanding is the feeling of concreteness generated by the text. A sense of concreteness refers to the ability to focus on the surface level rather than on the abstract structure of the subject matter (Smith, diSessa, & Roschelle, 1993) and was operationalized in several studies by the inclusion of illustrations in study materials (Carney & Levin, 2002; Chen & Daehler, 2000). Indeed, Ackerman and Leiser (2010) found that concreteness increased by topic-related but uninformative illustrations enhanced the Sense of Understanding (SOU) even when they did not contribute to the actual understanding.

The three reported experiments aimed to specify conditions under which illustrations bias the SOU and affect regulation of study efforts. In Experiment 1, undergraduate students (N=44) studied printed explanatory texts (300-600 words). The illustrated versions included verbal examples and pictorial illustrations pointedly designed not to contribute to understanding and were compared to plain versions. Each participant studied one illustrated text and one plain text under self-paced study instructions. Time was documented at each step. Immediately after studying, the participants rated their SOU on a 0-100% scale and got tested by 5-7 inference questions. Importantly, the participants were allowed to look back at the text whilst taking the test (open-books condition).

The findings support the hypotheses (see Table 1). SOU was higher for the illustrated than for the plain versions of the texts, while the actual test scores did not differ significantly. At first sight, it seems that concreteness manipulation did not affect the study process. However, an examination of the time invested for achieving this similar performance revealed that although the study time was similar for the two versions of text, the test-taking time was longer for the illustrated than for the plain versions. This result suggests that during test taking the participants realized that their study of the illustrated versions had not been thorough enough, and took successful compensatory action by taking advantage of the open-books conditions.

Continuing this line of analysis, Experiment 2 examined the effect of more detailed text processing on SOU. Experiment 2 replicated the procedure of Experiment 1 but with closed books, now requiring participants to memorize in addition to high-order understanding. This procedure was expected to lead to one out of the following two outcomes: (a) If the study process is similar to that involved in Experiment 1, we would expect to find weaker performance, shorter study times, and a larger SOU bias for the illustrated versions, as participants were expected to regulate their study in accordance with an inflated SOU. (b) The requirement for memorizing may generate a qualitatively different study process, focusing participants' attention on the processing of details rather than on their overall feeling of understanding. Consequently, the need to integrate the illustrations with the text should increase cognitive load (Chandler & Sweller, 1991) and result in longer time investment and a sense of difficulty that in turn is expected to reduce the SOU (Rawson & Dunlosky, 2002). The results support the second outcome (see Table 1). SOU was now lower for the illustrated than for the plain versions and it took participants longer to achieve a similar level of performance. Thus, once again, study efficiency was lower for the illustrated versions.

In Experiment 3, we attempted to focus the participants' attention on an even higher order processing than that required in Experiment 1. We challenged the participants with four difficult logic problems. After trying to solve each, the participants read the solutions (70–150 words). The solutions appeared either with or without uninformative illustrations manipulated within participants. Participants rated their SOU regarding each solution and then faced a closely related transfer problem. The findings (see Table 1) support our hypothesis regarding the generalized effect of illustrations on the SOU when high-order inferences are required: SOU was higher for the illustrated than for the plain solutions and performance was (marginally significant) lower. Thus, in this case, the concreteness manipulation increased the SOU bias, the discrepancy between SOU and test score (overconfidence), with no evidence of any compensation attempt during study or test time. This increased bias is expected to misguide future regulatory decisions.

To summarize, across the three experiments study efficiency was lower for the illustrated versions than for the plain versions of the texts. Our findings strongly suggest that the effects of illustrations are not limited to being either helpful or neutral: illustrations can also harm the study regulation process, by biasing the SOU and reducing study efficiency. Calling attention to risks in inclusion of redundant illustrations may guide study-material designers and contribute to the development of metacognitive-instruction programs for students.

Keeping aware of being an older driver? Stereotype threat as a cue in older adults' self-regulation

Ladislav Motak, The French National Institute for Transport and Safety Research (INRETS), France; Nathalie Huet, University of Toulouse, France; Catherine Gabaude, The French National Institute for Transport and Safety Research, France; Jean-Claude Bougeant, University of Lyon 2, France

Research has previously demonstrated older adults succeed to self-regulate their activity respectfully of their available cognitive resources. Yet question remains, which metacognitive cues may allow--or hinder--older adults to self-regulate in an adaptive way. While stereotypes represent basically an extrinsic, theory-based cue, a stereotype threat effect--i.e. lower performance when facing a stereotype--occurs through depleting working memory resources, and as such represents an internal, experience-based cue. To which of these cues would then the older adults' self-regulation be more sensitive? Twenty drivers under stereotype threat of an "older driver" and twenty controls (mean age 70

years) drove on simulator through four differently difficult circuits, and had then only restricted time to train themselves before a fictitious test. If the older adults' self-regulation was based on internal cues, inducing a stereotype threat--i.e. an extra working memory charge--would result in a self-paced training focused on easier items. If their self-regulation was based on extrinsic cues, focus should shift towards harder items, as subjects might try to disconfirm the stereotype at hand. Control group drivers self-regulated in an adapted manner, focusing their training mostly on circuits of medium difficulty. However, inducing stereotype threat in experimental group resulted in absence of any metacognitively guided self-regulation, as drivers of this group allocated time almost equally to all four circuits, regardless of their difficulty. Results are discussed in terms of older adults' self-regulation cues, but also regarding possible contributions of metacognitive models to development of elderly drivers' preventive and educational programs.

The Region of Proximal Learning framework of self-regulated learning (RPL; Metcalfe, 2002) predicts that people should adjust their learning as a function of their available cognitive resources, and namely when given only a limited amount of time to enhance their performance. That is exactly what has been found recently in older adults (Motak, Huet, Gabaude, & Bougeant, 2010), thus challenging the longstanding view that despite their rather intact monitoring skills, older adults would not spontaneously draw on to accurately self-regulate their learning (see Hines, Touron, & Hertzog, 2009, for review).

However, it is not clear which metacognitive cues (Koriat, 1997) may allow--or hinder--older adults to self regulate in an adaptive way. Stereotypes represent basically an extrinsic, theory-based cue regarding one's cognitive characteristics. However, a stereotype threat effect--i.e. lower performance when facing a self-relevant stereotype--occurs through depleting working memory resources as one presumably tries hard to disconfirm the stereotype (Schmader, Johns, & Forbes, 2008). As such, stereotype threat may represent an internal, experience-based cue, turning the task at hand to a seemingly harder one. To which cue would then the older adults' self-regulation be more sensitive?

In accordance with the RPL experimental paradigm, twenty drivers under stereotype threat of an "older driver" (i.e. to whom the study has been portrayed as investigating why older drivers are more at risk) and twenty controls (to whom the study has been described as a study of driving simulator characteristics; mean age 70 years for both groups) drove on driving simulator through four differently difficult circuits, and had then only restricted time to train themselves before a fictitious test. If the older adults' self-regulation was based on internal cues, inducing a stereotype threat--i.e. an extra working memory charge--should result in a self-paced training focused on easier circuits. If their self-regulation was based on stereotype as an extrinsic cue, however, focus should shift towards harder items regardless of experienced difficulties, as subjects might try to disconfirm the stereotype at hand.

Metcalfe in her RPL framework advocates (Metcalfe, 2002; but see also Kornell & Metcalfe, 2006) that for a self-regulation to be adapted, it must be centred on items of medium difficulty, as spending more time in the easiest items would yield no further benefit and engaging in the hardest items would necessitate more time than allowed. Based on this assumption, our preliminary results suggest that control group drivers self-regulated in an adapted manner, focusing their training mostly on circuits of medium difficulty, i.e. presumably within their reach as predicted by the RPL framework. However, inducing the stereotype threat did not lead to a shift nor towards easier, neither towards harder items, and resulted simply in absence of any metacognitively guided self-regulation, as drivers of the experimental group allocated their time almost equally to all four circuits.

In respect to older adults' self-regulation, it can then be concluded that these are actually able to allocate their self-paced training time in a RPL-consistent, adapted way, but only thus far as their working memory resources are not overloaded. Our results further support findings reported by Inzlicht, McKay, and Aronson (2006), suggesting that stereotype threat affects not only one's performance, but also impedes one's capacity to self-regulate in an efficient manner--in other words, weakens one's self-control capabilities. It is argued that older adults' self-regulation is based namely--although presumably not solely--on internal cues, but that these can be easily shadowed by a stereotype threat.

Finally, results are discussed not only in terms of cues older adults use to self-regulate their activity, but also regarding the possible contribution of metacognitive models to the development of elderly drivers' preventive and educational programs.

SYMPOSIUM

Professional Development

Understanding and improving the quality of feedback processes

Chairperson: Regina Mulder, Universitaet Regensburg, Germany

Organiser: Regina Mulder, Universitaet Regensburg, Germany

Discussant: Thomas Garavan, Kemmy Business School, Ireland

Feedback can cause cognitive conflicts that can lead to reflection: feedback has the potential to improve learning. Research on feedback in education shows for instance it has to be given directly after an incident occurs to be most effective, and that it is a complex process. In this symposium, by discussing a selection of relevant aspects, insight will be gained in this process and opportunities are identified to improve the effects of feedback. In the concept of feedback culture (Kahmann & Mulder, 2007) one of the important aspects is the process of feedback: leading from seeking feedback (symposium-contribution C3), over giving feedback (C1), to receiving feedback (C2). To increase our understanding of the feedback process, C2 and C3 focus on understanding the processes, C1 intervenes to optimize feedback. A second aspect concerns the quality of feedback. In C1 it is tried to optimize the quality by discussing it, in C2 the quality is assessed by finding out what the relation between characteristics of feedback with learning activities is, and C3 focuses on the quality of feedback sought in the social network. All three contributions question how 'peer feedback', either with students or colleagues at work, can reach its potential.

Peer feedback in primary school: The effects of knowledge on feedback style

Frans Prins, Dept of Pedagogical and Educational Sciences, Utrecht University, Netherlands

This experimental study aims at examining the effect of a specific intervention – providing students in primary education with information about criteria and standards – on peer feedback style. Knowledge about criteria and standards could lead to terms such as 'right' or 'good', so called 'final vocabulary', and it is expected that our intervention will lead to final vocabulary, which in turn will lead to a more authoritative style. In total, 95 sixth grade students were randomly assigned to one of two conditions. In the experimental condition, the students first discussed the criteria and standards that a good brochure should meet. In the control condition, the students provided peer feedback without a group discussion of the criteria and standards. To determine the feedback style, the written feedback was analysed to identify different kinds of verifications and elaborations. A K-Means cluster analysis showed that students in the experimental group had a chance on having an authoritative style that was approximately three times bigger than in the control group. Theoretical and practical implications of the study are discussed. For instance, it is recommended that, besides providing students with information about criteria and standards, students in primary education should be prompted to substantiate their feedback comments and to provide suggestions and reflective questions for improvement. Furthermore, it is argued that the processes described in this study and the provided recommendations are also relevant for secondary and higher education and workplace settings.

(Quasi-)experimental studies and descriptions of specific peer assessment mechanisms are needed to unravel effects of peer feedback and peer assessment (Strijbos & Sluismans, 2010). Furthermore, there is very little research concerning peer assessment in primary school (Topping, 2010). This experimental study is aimed at revealing a peer

assessment mechanism in primary education, that is, the effect of a peer assessment intervention on peer feedback style was examined.

An often heard complaint about peer assessment is that the quality of peer feedback is low (e.g., Prins et al., 2006). This threat is probably more severe in primary education compared to higher education. Thus, when a teacher wants to use peer assessment in primary education, specific intervention concerning peer assessment is needed in order to reach a sufficient quality level of peer feedback. The examined intervention in this study is the provision of information about criteria and standards that a specific student product has to meet. When a feedback provider receives knowledge about criteria and standards, peer feedback quality is assumed to increase. However, information about criteria and standards could also affect the feedback style of the students in primary education. Knowledge about criteria and standards could lead to terms such as 'right' or 'good'. According to Boud (1995), great care has to be taken in using this so called 'final vocabulary' (Rorty, 1989), which included terms as 'right' or 'good'. Final vocabulary is positive, but it has a final say and it leaves no space for manoeuvre. Thus, it has no place in any discourse about learning. A judgment does not encourage the student to undertake further action (Boud, 1995, p. 45).

Thus, it is expected that our intervention will lead to final vocabulary, which in turn will lead to changes in feedback style. Van den Berg (2003), following Lockhart and Ng (1995), distinguished four types of feedback style: authoritative, where the provider gives feedback without explanations or suggestions for revision; interpretive, where the provider sticks to her/his own experience and ideas when giving suggestions for improvement; probing, where the provider takes the perspective of the receiver and explains her/his remarks, structures feedback according to the performance and provides suggestions for performance improvement; and collaborative, which resembles probing, but where the provider and receiver create a collaborative product. The first two styles can be linked to the controlling and directive way, the last two styles can be linked to the facilitative way of commenting (Straub, 1996). When in the feedback the judgement is emphasized, and less explanation is given, the style is authoritative. By the interpretative as well as the probing style explanations and suggestions for revising the performance are provided, but someone with an interpretive style sticks to his own experiences and ideas. Someone with a probing style takes the perspective of the student and gives explanations and suggestions that correspond with the intention of the student. With a collaborative style, the provider and the student deliberate about the performance, and create a collaborative product (Van den Berg, 2003).

In total, 95 students (58 boys, 37 girls) in sixth grade (age between 10 and 12 years) participated in this study. Students were randomly assigned to one of two conditions. In the experimental condition, the students first discussed the criteria and standards that a good brochure should meet. In the control condition, the students provided peer feedback without such a group discussion. To determine the style of the provided feedback, the written feedback was analysed to identify different kinds of verifications and elaborations. To establish the style of the peer feedback, the scores on these kinds of comments were clustered, using K-Means clustering.

Results showed that three clusters could be identified. Cluster one includes 27 students, who used a lot of prescriptions. These students provided feedback with a predominantly interpretative style. The 29 students in cluster two used a lot of positive judgments (i.e., final vocabulary), and thus provided feedback with an authoritative style. The third cluster included 39 students who used a lot of neutral statements. The students in this cluster predominantly used a probing style. The feedback style of the students depended on the condition they were in. The chance on having an interpretative style was about two times bigger for the students in the control group compared to students in the experimental group. The chance on having an explorative style is about twice as big for the experimental group. In contrast, students in the experimental group had a chance on having an authoritative style that is about three times bigger than this chance in the control group.

Theoretical and practical implications of the study are discussed. For instance, it is recommended that students in primary education should be prompted to substantiate their feedback comments and to provide suggestions and reflective questions. Furthermore, it is argued that the processes described in this study as well as the provided recommendations are also relevant for secondary and higher education and workplace settings.

The relation between feedback processes and informal learning activities at the workplace

Regina Mulder, Universitaet Regensburg, Germany

In this contribution we focus on the relation between the characteristics of feedback with informal learning activities that are caused by that. Based on a literature review on feedback a model of feedback culture is developed. Important aspects concern the quality of feedback (such as the content of feedback) and the importance of feedback. On all aspects of this model data is collected among 31 employees. They filled out a learning log. That consisted of standardized items on informal learning activities, such as asking colleagues for advice, reflecting on the incident, reading a journal, finding information on the internet. In total 367 feedback incidents caused 913 informal learning activities. The relation between the incidents and the learning activities correlation analyses are carried out. One example of a relation that was found is that if the feedback giver is in a bad mood, the receiver does not take feedback seriously, and it will therefore not lead to informal learning activities. In this contribution all relations will be presented and the results of the additional qualitative analyses.

Ongoing demographic and technological developments lead to increasing complexity in work settings. Therefore, there is a need for further development of employees. Many employees learn in formal training. Because of discrepancies between the content of the courses and the specific demands of the workplace, these trainings are not always perfectly fitting. Interesting is that although this seems an imperfect situation, employees can also learn from informal learning activities during work. These activities can result in profit for companies (e.g. Fuller et al. 2003). More understanding is needed on how companies can improve informal learning activities of their employees. In this research we focused on the role that feedback can play in this respect. The central question is: 'What is the relation between the feedback that employees get at the workplace with their informal learning activities?'

With feedback we mean: '... a subset of information available to individuals in their work environment. Feedback is that information that denotes how well individuals are meeting various goals. In the interpersonal realm, feedback involves information about how their behaviors are perceived and evaluated by relevant others' (p.372, Ashford and Cummings, 1983). We distinguish different components of feedback processes, such as the feedback source, the perceived quality of feedback, and the acceptance of feedback (e.g. Ilgen et al, 1979). Our assumption is that when researching feedback in relation to informal learning activities, the perceived feedback culture has to be taken into account. Therefore a model of feedback culture was conducted. With researching feedback culture companies are able to find out what the actual feedback culture is, and are able to optimize it. Feedback culture consists of the quality of feedback (e.g. the content of feedback and the support for using the feedback) and the importance of feedback (Kahmann & Mulder, 2007 /submitted).

Formal and informal learning has to be distinguished. Mostly with formal learning organized learning in a setting specifically focused on learning is meant, such as a training. These processes mostly lead to a certificate of diploma. With informal learning we focus on all kinds of learning that are not organized, and that happen during work performance. Eraut (2000) distinguishes deliberate learning, reactive learning and implicit learning. Examples of informal learning activities are (e.g. Kwakman, 2003) reading professional journals, exchanging knowledge with colleagues, reflecting on own behavior. The second dimension for learning activities we work with deals with how people learn, individually or in social exchange. This is a common distinction for learning activities in research literature (e.g. Anderson, Greeno, Reder & Simon, 2000).

For answering the research question data were collected amongst 31 employees. They filled out learning logs during 5 work days. They work in a private enterprise (n1=11), in the public sector (school; n2=13) or in the health sector (n3=7). These learning logs consisted of standardized items on informal learning processes. All components of the feedback culture are assessed. In the learning logs the participants wrote down what kind of feedback incident occurred, and if that resulted in a certain kind of informal learning activity. For instance reading professional

textbooks, trying out new strategies at work and reflecting on own work behavior. In addition, background variables were measured, such as age, sex, work experience.

With quantitative data analyses (factor analyses, reliability test, and correlations analyses) we found reliable scales of learning activities (deliberate, reactive, individual and social). We did not find all expected correlations between components of feedback and feedback culture with the informal learning activities (Mandl, 2007). Nevertheless, there are significant relations found, for instance between the items 'I ask my supervisor for advice', or 'I ask my colleagues for advice' with 'support for improvement at the workplace'. In total 367 feedback incidents were reported. They caused in total 913 informal learning activities. Only 45 feedback incidents did not lead to informal learning activities. So, there is a relation between the feedback processes and informal learning activities, but it is not a linear relation and there might be additional factors that are of importance. Because of the outcomes we analyzed our data more in depth with qualitative data analyses, to get more understanding of the relation between feedback processes, feedback culture and informal learning activities.

In this presentation we will elaborate on the theoretical framework, the quantitative and qualitative analyses that we carried out, and on the outcomes. For instance if feedback is given by someone with a bad mood (a characteristic of a feedback giver), feedback is not taken seriously by the receiver. The interpretation of the results will be presented. We gained better understanding of the relations between the perceived feedback culture, the received feedback and the informal learning activities.

Understanding Self-Motivated Feedback Exchanges: A social network perspective

Janine van der Rijt, Universiteit Maastricht, Netherlands; Piet Van den Bossche, University of Antwerp, Belgium; Margje W.J. van de Wiel, Faculty of Psychology and Neuroscience, Maastricht University, Belgium; Mien Segers, Universiteit Maastricht, Netherlands; Wim Gijselaers, Universiteit Maastricht, Netherlands

This study aims to get a more comprehensive understanding of the underlying dynamics of feedback processes during day-to-day interactions in the workplace, by viewing the informal feedback processes from a social network perspective. Furthermore, this study examines whether self-motivated feedback exchanges within the work-related social network lead to increased perceived career development and performance. This study was conducted in the expert field of Finance and Control. The main findings indicate that the quality of the relationships within the work-related social network is an important factor in feedback exchanges. Furthermore, the perceived quality of the feedback influenced performance positively. This underlines the suggested importance of the quality of the generated feedback for performance. There were no relations found between the feedback exchanges and career development. Additionally, the size of the work-related network was not related to performance, but did relate positively to perceived career development. Overall, the study highlights the importance of feedback exchanges in the workplace and put forward implications for practice.

Today's knowledge-intensive society, with its current uncertain economy, requires organizations to innovate and learn continuously. Therefore, many organizations invest in formalized training programs and coaching. However, a majority

of what people learn is tacit and is learned informally on-the-job from the people with whom they work (Tannenbaum, Beard, McNall, & Salas, 2010). In this respect, it is shown that one of the key components of informal learning processes in the workplace is feedback (Tannenbaum et al., 2010). Traditionally, feedback theories considered feedback as an organizational resource. More recently, research has moved from this traditional focus on feedback as a resource that is formally given and passively received to a more dynamic view of actively seeking feedback in everyday work lives (Ashford, Blatt, & VandeWalle, 2003). Feedback seeking behavior can be described as an active process by which professionals initiate a feedback exchange themselves. In spite of a growing body of research on feedback-seeking behavior, less attention is given to situational conditions that induce feedback seeking behavior in the workplace (Steelman, Levy, & Snell, 2004). Salas and Rosen (2010) recently called for a more comprehensive understanding of what drives feedback-seeking behavior and how to develop it in organizations. In response to this call, the current study makes a first step to address this limitation.

The prime purpose we are concerned with in this study is twofold. First, we aim to better understand the broader context that generates self-motivated feedback processing, by viewing the informal feedback processes from a social network perspective. Second, we examine whether self-motivated feedback exchanges lead to increased perceived career development and performance.

This study takes a social network perspective (Borgatti & Cross, 2003), instead of conventionally used measures in the feedback literature (e.g., Steelman et al., 2004). To our knowledge, the feedback literature has not addressed the implications of social network structures for feedback exchanges in organizations. Yet, social network research suggests that network relationships may be very important for learning (Borgatti & Cross, 2003), and outcomes in terms of career development and performance.

This study was conducted in the field of Finance and Control. Participants were 72 financial controllers from various multinational corporations (79.2 % men, ages ranged from 24 to 50 years with a mean age of 30.4 years).

Based on Borgatti and Cross (2003), we developed an egocentric network questionnaire in which respondents rated several network questions for all persons in their personal work-related social network. Further, job performance was measured by the respondents themselves using the 6-item performance scale developed by Becker, Billings, Eveleth and Gilbert (1996). Career development was measured using a 3-item instrument of intrinsic career development of Van der Sluis and Poell (2003).

Our findings concerning the relational characteristics of the work-related social network indicate that quality of the relationships within the work-related social network is an important factor in feedback exchanges. More specifically, the results indicate that the awareness of the knowledge and skills of persons in the network (awareness) and whether these relationships are characterized as safe (safety) are both positively related to feedback seeking behavior. Furthermore, we found a positive relation between feedback seeking behavior and performance. The average frequency with which the respondents turned to their contacts for feedback was not related to performance. Furthermore, the perceived usefulness of the feedback influenced performance positively. This underlines the suggested importance of the quality of the generated feedback for performance. Additionally, we found that the size of the work-related network was not related to performance, but did relate positively to career development. This means that a larger network is good for a person's career, but does not influence performance. A larger network related negatively to feedback seeking behavior, the frequency of feedback seeking, and the perceived usefulness of feedback. The awareness and the safety of the relationships are negatively related to a larger network as well. This could imply that persons with a smaller network seem to have a clearer picture of their contacts' expertise and that their relationships are characterized by a higher degree of safety. These findings also suggest that a smaller network is more beneficial for obtaining feedback. These outcomes relate to the findings of Cross and Thomas (2008). They found that high performers invest in the strength of relationships and do not necessarily have big networks.

Overall, this study underpins the importance of feedback exchanges in the workplace and puts forward implications for practice. Organizations should encourage employees to seek feedback and should recognize the value of feedback to support performance and professional development. Moreover, investing in the strength of relationships in the workplace seems worthwhile.

SYMPOSIUM

Motivational, Social and Affective Processes

An In-depth Understanding of the Dynamics and Practicalities of Teacher Autonomy-Support

Chairperson: Johnmarshall Reeve, Korea University, Korea, Republic of

maarten vansteenkiste, Gent University, Belgium

Organiser: Hyungshim Jang, Inha University, Korea, Republic of

Discussant: Avi Assor, Ben Gurion University, Israel

As a broad-band theory of motivation and personality development, Self-Determination Theory (Ryan & Deci, 2000) has attracted an increasing interest among educational scholars over the past 15 years (see Reeve, 2009 for an overview in the educational domain). Several studies have demonstrated the manifold advantages of autonomy-supportive, relative to controlling, teaching including deep level processing, higher engagement, more persistence, and better grades, presumably because autonomy-supportive teaching allows for greater satisfaction of the basic psychological needs for autonomy, competence, and relatedness. Yet, numerous questions remain unanswered to date. This symposium aims to gain a more in-depth understanding of the dynamics and practicalities of autonomy-supportive teaching. First, Hyungshim Jang (first contribution) presents classroom-based research on the longitudinal relations between perceived teacher autonomy-support and student outcomes, an understudied issue within SDT given the majority of available cross-sectional research. Second, Johnmarshall Reeve (second contribution) presents experimental research in which the effects of novel autonomy-supportive practices were tested against a standard or typical teaching approach. Those studies indicate that implementing an autonomy-supportive teaching approach is practically doable and beneficial. Given the benefits associated with teacher autonomy-support, the question is raised as to which factors lead teachers to adopt such a style. Guy Roth (third contribution) addresses this issue by examining which teacher characteristics are associated with an autonomy-supportive teaching style. Collectively, the current studies make use of variety of designs (correlational, experimental) and analytic techniques (SEM, multilevel modeling), and draw upon samples from diverse nationalities (Korea, US, Israel). As a whole, they provide deeper insight in the dynamics associated with autonomy-supportive teaching.

Longitudinal Test of Self-Determination Theory in a School Context

Hyungshim Jang, Inha University, Korea, Republic of

Empirical tests of self-determination theory's motivation mediation model (autonomy support → psychological need satisfaction → student outcomes) have consistently found support for the model. Without exception, however, all these empirical tests have used either a cross-sectional research design or only a prospective multi-wave design (Black & Deci, 2000; Jang, Reeve, Ryan, & Kim 2009). It is crucial to note, however, that cross-sectional research designs fail to address the issue of (temporal) causality. To test temporal causality among these variables requires the employment of a multi-wave longitudinal, classroom-based research design (Cole & Maxwell, 2003). The purpose of the present study was to test the temporal causative relations among perceived autonomy support, need satisfaction, engagement, and achievement via a three-wave longitudinal classroom design.

In the hypothesized model, students' perceptions of teacher-provided autonomy-support were predicted to explain changes in students' mid-semester psychological need satisfaction (controlling for early-semester psychological need satisfaction). Changes in students' need-satisfaction were then predicted to explain changes in the quality of students'

classroom engagement (controlling for early and mid-semester levels of quality of engagement). Finally, changes in the quality of students' engagement (rather than either perceived autonomy support or psychological need satisfaction) was predicted to explain students' achievement gains (or losses) during the semester (controlling for early-semester anticipated level of achievement). Participants were 500 students (257 females, 243 males) from 14 classes situated in a large, urban middle school in Seoul, Korea. Participants completed the same two-page questionnaire three times during the semester—three weeks into the semester (time 1), two weeks after the mid-term exam (time 2), and two weeks prior to the end of the semester (time 3). To test the motivation mediation model, structural equation modeling (LISREL 8.51; Joreskog & Sorbom, 1993) was used. To assess students' perceptions of teacher-provided autonomy support, participants completed the 6-item short version of the Learning Climate Questionnaire (LCQ; Williams & Deci, 1996; alphas of .89, .93, and .92). To assess psychological need satisfaction, participants completed the 10-item Activity-Feelings States scale (AFS; Reeve & Sickenius, 1994) that assessed perceived autonomy (alphas of .71, .73, and .73 across the three assessments), perceived competence (alphas of .76, .82, and .81), and perceived relatedness (alphas of .77, .83, and .80). To assess engagement, participants completed a 12-item engagement scale that assessed behavioral, emotional, cognitive, and agentic aspects of engagement (Skinner et al., 2009, alphas of .83, .86, and .84).

The hypothesized motivation mediation model (i.e., the structural model) was that perceived autonomy support (time 1) would predict changes in psychological need satisfaction (time 2) which would predict changes in the quality of engagement (time 3) which, in turn, would predict end-of-course achievement. Anticipated (time 1) achievement was added as a covariate so that our outcome measure was achievement gains rather than achievement per se. This model fit the data fairly well, $\chi^2(711) = 1,758.65$, SRMR = .062, RMSEA = .052, CFI = 0.94. Importantly, perceived autonomy-support at the beginning of the semester explained mid-semester changes in students' psychological need satisfaction (beta = .10, p beta = .16, p beta = .21, p R^2 = .45 for need satisfaction at time 2; R^2 = .53 for need satisfaction at time 3; R^2 = .52 for quality of engagement at time 3; and R^2 = .48 for end-of-course achievement). The findings provide rather strong support for SDT's the motivation mediation model. Relatively high temporal stability in students' self-reports of perceived autonomy support, need satisfaction, and engagement were observed (the betas from each latent variable from time 1 to time 2, from time 2 to time 3, and even from time 1 to time 3 were high). Still, perceived autonomy support early in the semester did contribute to increases in mid-semester need satisfaction, and mid-semester changes in student motivation predicted end-of-semester changes in student outcomes. In presenting this empirical support, this study is the first to show the hypothesized temporal causative relations among the variables within the SDT framework in the naturally-occurring setting of the classroom.

Effective but Impractical: Overcoming Instructional Roadblocks to Teacher-Provided Autonomy Support

Johnmarshall Reeve, Korea University, Korea, Republic of

Two empirical findings formed the foundation of the present research. First, students benefit when teachers support their autonomy; second, teachers do not commonly support students' autonomy during instruction (Reeve, 2009). Many reasons explain why teachers are not autonomy supportive, but a key reason is that supporting autonomy is hard, time consuming, and impractical (compared to standard practice). That is, in many teachers' minds, autonomy support is effective but impractical.

Autonomy support is what teachers say and do during instruction to promote students' perceived autonomy and psychological need satisfaction. In practice, it centers on the following five categories of instructional behavior: nurture inner motivational resources; provide explanatory rationales; rely on informational language; display patience to allow time for self-paced learning; and acknowledge and accept expressions of negative affect (Reeve, 2009). A meta-analysis of training programs to help teachers learn how to support students' autonomy showed that teachers can learn to become more autonomy-supportive (Su & Reeve, in press), with one exception—namely, teachers find it difficult to learn how to nurture students' inner motivational resources. Hence, a key part of what makes teacher-provided autonomy support hard (or harder than standard practice) is answering the question, "How do I nurture students' inner motivational resources?"

The goal of the present investigation was to test the validity of two instructional strategies that could serve as valid exemplars. Specifically, Study 1 was designed to nurture students' preferences and psychological need satisfaction, while Study 2 was designed to nurture students' perception of optimal challenge. In both studies, the methodology started with the same lesson and presented it to students in two different ways—one that was autonomy supportive and another that represented standard practice (the same lesson delivered in a neutral way) with the two lessons matched on teacher (a hired professional who was blind to the purposes of the study), content (subject matter), and duration (in minutes). The hypothesis was that when the lesson was designed to nurture (vs. neglect) inner motivational resources, students would perceive their teachers as more autonomy supportive and would experience enhanced motivation (i.e., psychological need satisfaction in Study 1, sense of optimal challenge in Study 2), engagement, and perceived learning.

In Study 1, a pilot test first determined students' preferred ways of learning a lesson. Students were shown a list of 10 ways to learn any lesson, rank ordered them, and two preferred ways were "view videotape" and "whole-class discussion" while two non-preferred ways were "independent work" and "drill-and-practice." In Study 1, all participants (51 students at a university in the Midwest) first received the same 12-minute PowerPoint presentation on attachment theory. Participants in the experimental group then viewed a 4-minute videotaped lesson and engaged in a 10-minute group discussion, using a prepared set of questions. Participants in the control group read the videotape's transcript for 4 minutes (independent work) and worked on the same set of prepared questions for 10 minutes (drill-and-practice). Hence, students in the experimental condition received instruction in their preferred (i.e., need satisfying) way, while students in the control group received instruction in their non-preferred (i.e., need neutral) way. After the lesson, participants completed a post-experimental questionnaire assessing perceived teacher autonomy support (6 items, $\alpha = .92$), psychological need satisfaction (10 items, $\alpha = .90$), engagement (4 items, $\alpha = .86$), and self-reported learning (3 items, $\alpha = .74$). Participants in the experimental group perceived the teacher to be more autonomy supportive (M_s , 6.04 vs. 4.61, $t(51) = 5.11$, $p < .001$, $d = 1.42$) and self-reported significantly greater need satisfaction (M_s , 5.74 vs. 5.11, $t(51) = 2.42$, $p < .05$, $d = .68$), engagement (M_s , 6.29 vs. 5.52, $t(51) = 3.01$, $p < .01$, $d = .85$), and learning (M_s , 6.24 vs. 5.71, $t(51) = 3.05$, $p < .01$, $d = .88$).

In Study 2, all participants (64 students at a university in the Midwest) received the same 12-minute PowerPoint presentation on the human brain (its anatomy and function). Following the lesson, all participants engaged in a 20-minute review session that featured 25 lesson-related questions. For participants in the experimental group, the review session involved a "Jeopardy" game in which the questions were arranged into 5 topics (e.g., Neurons) with 5 levels of difficulty. Participants were in small groups, and the teacher asked the questions and kept score of team points on the chalkboard. For participants in the control group, the review session involved independent seatwork in which they answered the same questions arranged in a prepared booklet (with attractive photographs). After the review session, participants completed a post-experimental questionnaire assessing perceived teacher autonomy support (6 items, $\alpha = .94$), perceived challenge (1-item), engagement (4 items, $\alpha = .84$), and learning (3 items, $\alpha = .70$). Participants in the experimental group perceived the teacher to be more autonomy supportive (M_s , 4.13 vs. 2.65, $t(62) = 3.79$, $p < .001$, $d = .95$) and reported experiencing significantly greater optimal challenge (M_s , 0.45 vs. 0.77, $t(62) = 2.01$, $p < .05$, $d = .50$), engagement (M_s , 5.34 vs. 3.69, $t(62) = 3.10$, $p < .01$, $d = .79$), and learning (M_s , 5.67 vs. 5.10, $t(62) = 1.98$, $p = .05$, $d = .52$). These studies affirm that standard lessons can be presented in an autonomy-supportive way and that, in doing so, can facilitate students' motivation, engagement, and learning, even while not requiring additional instruction time. Other researchers have shown that explanatory rationales (Jang, 2008) and brief videotestimonials (of how important the subject matter is, Husman et al., 2010) can be inserted into the flow of otherwise uninteresting lessons to nurture students' inner motivational resources ("perceived value" in these two examples). The long-term goal of this program of research is to create options and exemplars that teachers can use to nurture students' inner motivational resources (e.g., preferences, sense of optimal challenge) in an easy, practical way.

Personal Characteristics of Teachers and Schools' Principals as Predictors of their Autonomy-Support

Guy Roth, Ben-Gurion University of the Negev, Israel

Considerable research has indicated that autonomy supportive socializing context is associated with desirable outcomes for children and students (Deci & Ryan, 2008); however, research exploring antecedents of autonomy support is quite scarce. bridge this gap the current research project investigated the relations between teachers' and school principals' personal characteristics as predictors of their autonomy supportive behaviors.

Autonomy support is defined socializing agents act in ways that encourage choice and self-initiation, take the other's perspective, provide meaningful rationales and relevance and refrain from using language or other behaviors that are likely to be experienced as pressure toward particular conducts (Grolnick, Deci, & Ryan, 1997). Supporting autonomy in these ways has been found to result in autonomous regulation, effective performance, and psychological well-being (Deci & Ryan, 2008). Given the important role of autonomy supportive behaviors for adaptive socialization, the limited research on its antecedents is quite surprising. Grolnick (2003) explored contextual pressures that may predict parents' autonomy supportive behavior, whereas Pelletier, Seguin-Levesque and Legault (2002) explored the effect of contextual pressures on autonomy supportive teaching. Nevertheless, Landry et al. (2008) is the only study that directly explored a social agents' characteristic (namely, parental trust in organismic development) that may predict autonomy supportive behaviors.

The present research consists of three studies. Two studies focus on teachers' personal characteristics as predictors of students' perceptions of teachers' autonomy supportive teaching, and one study focuses on school principals' personal characteristics and their relations to teachers' perceptions of the principal's autonomy supportive behavior toward them. Specifically, the research explores four personal characteristics of teachers and principals that may predict autonomy support: (1) Teacher's/principal's belief that intrinsic motivation is essential for life-satisfaction and well-being, which stands in contrast to materialistic views in which life satisfaction is based mainly on one's possessions, status and fame (Kasser & Ryan, 1996). (2) Teachers'/principals' trust in organismic development (OD), which following Landry et al. (2008) and Deci & Ryan (2008), was defined as the belief that humans are active, growth-oriented organisms inclined to engage in interesting activities, to exercise capacities, and to pursue connectedness in social groups. More specifically, in terms of teacher-student relations, trust in OD would involve trust in the child's tendency to learn and to be considerate toward others. (3) Teachers' belief that organismic development is vulnerable and can be easily frustrated by the environment. (4) Teachers'/principals' authenticity (Kernis & Goldman, 2006). Data were collected from multiple reporters: principals, teachers and children.

The first study focuses on the relations between teachers' beliefs and students' perceptions of teachers' autonomy support. Thus, it was hypothesized that the teachers' three beliefs (that intrinsic motivation is essential for life satisfaction, the teachers belief in OD, and the belief that OD is vulnerable) will predict students' perceptions of autonomy supportive teaching. The research was based on 27 teachers and their 815 students in the 7th and 8th grades. The data was subjected to hierarchical linear modeling (HLM; Raudenbush & Bryk, 2002) analysis while following Krull and MacKinnon's (2001) approach for mediation testing. The results confirmed the hypothesis. The second study was based on 32 teachers and their 896 students and tested the hypothesis that teachers' authenticity would be related to students' perceptions of autonomy supportive teaching by predicting the teachers' three beliefs. A HLM analysis confirms the hypothesis. The third study extended the previous two by exploring the relations between principals' beliefs (the belief that intrinsic motivation is essential for life satisfaction and trust in OD) and teachers' perceptions of the principals' autonomy supportive behaviors. The sample consisted of 20 school principals and 220 teachers. A HLM analysis confirms the hypothesis. Theoretical and practical Implications of the findings will be discussed.

SYMPOSIUM

In-service Teacher Training

Research-based teacher education

Chairperson: Jan Vermunt, Utrecht University, Netherlands

Organiser: Jan Vermunt, Utrecht University, Netherlands

Discussant: Sanna Jarvela, University of Oulu, Finland

Evidence-based, research-informed, culture of evidence, inquiry-oriented: the increasing use of these terms signals a shared plea to employ research in the design and evaluation of teacher education. In an effort towards conceptual and empirical clarification, the authors in this symposium present work using different perspectives on research-based teacher education. They discuss a research-based design, research-informed content and a rigorous evaluation of teacher education programs in three different countries. In doing so, they draw attention to its promises, but also to its challenges. For one, how do we adequately measure the effects of purposeful interventions, as there is great diversity in the structure and content of the programs. The studies in this symposium try to achieve this by using mixed-methods and longitudinal designs. Next to this issue of methodological rigor in real-life contexts, the outcomes question (Cochran-Smith, 2001) is also addressed, as the different papers in this symposium use diverse outcome measures, all potentially valuable in research-based teacher education.

Building a culture of evidence: A longitudinal study on student teacher learning

Larika Bronkhorst, Utrecht University, Netherlands; Maaïke Endedijk, University of Twente, Netherlands; Bob Koster, Utrecht University, Netherlands; Paulien Meijer, Utrecht University, Netherlands; Jan Vermunt, Utrecht University, Netherlands

This study describes a two year longitudinal study into teacher learning and development in a one-year post-graduate teacher education program in the Netherlands. Using three different types of instruments, the authors documented the nature of student teachers' learning in the first year. Based on the alarming results, which were contrary to what could be expected based on theory, a small-scale intervention was conducted during the second year. The use of identical instruments, afforded the incorporation of two control groups, adding to the robustness of the analyses. Our analyses show that the nature of student teachers' learning is robust to change, as is their regulation of learning. Yet differences were found across both control groups in the perception of the learning environment: student teachers perceive the refined teacher education program to be more challenging, integrating theory and practice. This results illustrate the challenges involved in establishing and building on a culture of evidence in teacher education.

Building a culture of evidence

In the past years an increasing amount of research on teacher education, student and beginning teacher learning and development, and professional learning has been generated. Based on recent studies, we advocate that effective

(student) teacher learning constitutes meaning oriented learning (Oosterheert and Vermunt, 2001) and effective regulation of learning can be achieved with deliberate practice (Dunn & Shriner, 1999). Using the knowledge generated by these studies affords research-based teacher education: teacher education programs based on research – albeit not always evidence (Vermunt, 2006), including active incorporation of research in their programs' evaluation (Ludlow et al., 2008). This study describes a two year longitudinal study into teacher learning and development in a one-year post-graduate teacher education program in the Netherlands. The original aim was to document the development student teachers' learning orientations and regulation of learning using three different types of instruments, thus building a culture of evidence. As the results of the first year were rather alarming and contrary to what could be expected based on existing theory, the authors also conducted a small scale intervention during the second year to stimulate the desired nature of learning and regulation. This intervention was based on a synthesis of recent research into student teachers learning (summarized in Bronkhorst, Meijer, Koster, Vemunt, 2010). Our main research question is: what is the effect of this intervention on the development of student teachers' learning orientation and quality of regulation?.

Methodology

Context.

This study was conducted in a one-year postgraduate teacher education program, leading to the highest level of teacher certification in the Netherlands. Before enrolment, students first obtain their master's degree in a specific subject area. The program consists of weekly classes at the university, and teaching practice at schools – either as an intern or as a paid job.

Participants.

All student teachers of the teacher education program were invited to participate. In the first year 78 out of 90 student teachers participated; in the second year 71 out of 82 student teachers participated. The experimental group consisted of 17 of these 71 students. Two control groups are singled out: control group 1 is the matched group of students of the first cohort and control group 2 is the group of students of the second cohort that was not subjected to the intervention.

Intervention.

The 12 design principles obtained in prior work (Bronkhorst et al., 2010) formed the starting point to refine the teacher education program. These design principles are generic, in the sense they can be applied across different classes of the teacher education program. The principles specify the approach to instruction expected to lead to the desired student teacher learning and regulation of learning (being meaning oriented learning and deliberate practice). Recognizing that curriculum design principles can be worked out in many ways (Collins et al., 2004), the design principles were translated and adapted to the local context in close collaboration with all teacher educators involved in the experimental groups' classes.

Instruments.

All participants were asked to fill out 3 electronic questionnaires on two occasions: at the end of the first semester and at the end of the program. To measure student teachers' nature of learning the Inventory Learning to Teach Process (ILTP) was used (Oosterheert, Vermunt, & Denessen, 2002). Based on this questionnaire different learning orientations can be distinguished, namely survival-oriented, reproduction-oriented, dependent meaning-oriented or independent meaning-oriented learning to teach. The perception of the learning environment instrument that was developed for this study, measured three elements of the learning environment: Constructive Communicative press (.83), Integrating Theory and Practice (.84) and Support for Regulation of Learning (.84). These scales were developed based on the perception of the learning environment scales of Oosterheert, Vermunt, and Veenstra (2002). The regulation of learning was assessed with a structured digital log in which the student teachers had to describe six self-chosen learning experiences and corresponding regulation activities with help of multiple choice questions (Endedijk, 2010). For the current study the only some questions of these logs are used.

Analyses.

With the help of z-scores of the ten scales of the ILTP, student teachers' learning orientations were established. Comparisons between the experimental and control groups were done with Chi-square tests. The same tests were used to describe differences in spreading of the learning experiences over the different regulation activities. T-tests were used to compare differences in means between experimental and control groups on the different perception of learning environment scales.

Findings

Based on our analyses, it appears that the learning orientation of student teachers is robust to change, as the experimental condition does not significantly differ from the control conditions. The same applies to the regulation of that learning: small differences were found, which were not consisted across the two control conditions. Only in terms of perception of the learning environment a consistent pattern seems to emerge: student teachers perceive the refined teacher education program to be more challenging, integrating theory and practice. Moreover, they also experience more support for their regulation. Hence, our preliminary results indicate that altering the nature of student teacher learning, based on a culture of evidence, is a challenging task.

This implies that teacher education programs, even though aiming to support the desired teacher learning, might not work out as intended. And even with a purposeful, research-based intervention it appears to be challenging to alter student teacher learning during a one-year program. As meaning-oriented learning and deliberate practice are essential during teachers' professional careers, we should explore alternative ways to stimulate this part of the student teachers' professional development in the teacher education curriculum.

Uncovering practice and the horizon of observation: The dynamics of observation in teacher education

Paul Conway, University College Cork, Ireland; Rosaleen Murphy, University College Cork, Ireland; Kathy Hall, University College Cork, Ireland; Fianchra Long, University College Cork, Ireland; Dan O'Sullivan, University College Cork, Ireland

In the context of moves toward promoting research-informed perspectives on teacher education, this paper examines the dynamics of observation while learning to teach during a year-long post-graduate programme in initial teacher education (ITE). Adopting a socio-cultural research-informed perspective on teacher education, we focus on assisted performance (Tharp & Gallimore, 1998; Mewborn & Stinson, 2007) view of learning to become a competent secondary teacher. The central socio-cultural concept we address in this study is 'horizon of observation' (Hutchins, 1993) as it offers a lens on the nature and dynamics of student teachers' access to accomplished teachers in teaching practice schools. Adopting a mixed-methods approach, the study involved semi-structured interviews with 17 student teachers and a survey (n=133, i.e. 60% of the student cohort). The findings were (i) that only a minority of student teachers had opportunities to observe other teachers teach, (ii) the limited observation opportunities on teaching practice schools led to a reliance on apprenticeship of observation-based role models, (iii) student teachers' limited horizon of observation while learning to teach made the apprenticeship of observation and the lesson observation-based feedback from university tutors especially salient. We discuss the implications of the limited horizon of observation in ITE in terms of what Lieberman et al (2009) term 'uncovering practice' in the service of deepening engagement with pedagogy. In doing so, we draw attention to 'uncovering practice' as a key principle of research-informed initial teacher education.

Aims

In the context of moves toward promoting research-informed perspectives on teacher education, this paper examines the dynamics of observation while learning to teach during a year-long post-graduate programme in initial teacher education. The idea of research-informed teacher education is not new given that it was a central tenet of Holmes Group initiative from the mid-1980s onwards in the USA (Holmes Group, 1986; 1990; 1995). However, the identification of research-informed principles for guiding initial teacher education has been a significant feature of research on teacher education over the last decade (e.g. Darling-Hammond & Bransford, 2005; Darling-Hammond, 2006; Korthagen et al, 2010)

Adopting a socio-cultural research-informed perspective on teacher education, the study adopts an assisted performance (Tharp & Gallimore, 1998; Mewborn & Stinson, 2007) view of learning to become a competent teacher. The present study sought to understand the dynamics of observation, as a central feature of ITE, on a post-graduate ITE programme within a context where there have been no formal structures in relation to school-university partnerships, and consequently no formal agreement between schools and university on the type of assistance and structured support (observation, co-planning, co-teaching) that should be made available to student teachers. As such, our assumption, based on research, was that observation (Grossman, 1991) is a fundamentally important aspect of initial teacher education. That is, to observe others, to be observed and get feedback and to reflect on the legacy of the observation-based apprenticeship is central to becoming a competent teacher.

Methodology

The study adopted a mixed-methods approach involving semi-structured interviews, analysis of documents and a survey questionnaire. Using a multiple-case study research design, seventeen student teachers were interviewed on three occasions over the course of an academic year. A survey focused on the prior experiences and beliefs about

learning to teach and opportunities to learn to teach in schools was administered in March 2009 (n=133, with a response rate of 60% from the 2008-09 cohort of student teachers). In analyzing the interviews data, we used a phenomenological (Huntly, 2008) approach to understand student teachers' experiences of learning to teach.

Findings

Findings of the study are discussed under four headings:

- (i) There were few opportunities to observe experienced teachers or be observed by these same teachers in teaching practice schools. As such, the opportunities for deep professional engagement about pedagogy were significantly constrained. This finding is consistent with the OECD TALIS cross-national study which highlighted the dominance of 'exchange and coordination'-oriented professional collaboration in schools (Gilleece et al, 2009).
- (ii) Negotiating images of curriculum and relationships presented by teacher role models past and present (i.e. observational learning) was a significant feature of the learning to teach experience and the development of competence, for student teachers (Sugrue, 2004).
- (iii) Feedback following lesson observations provided by tutors was vivid, memorable and consequential in terms of student teachers' understanding of professional standards and expectations. The variation in emphases on particular aspects of practice by different tutors was a significant feature of student teachers experience of learning to be a 'good teacher' in their subject areas
- (iv) Finally, student teachers' limited horizon of observation while learning to teach made the apprenticeship of observation and the lesson observation-based feedback from university tutors especially salient.

Theoretical and educational significance of the research

The present study sought to understand the dynamics of student teachers' opportunities to learn to teach within a context where there have been no formal structures in relation to school-university partnerships, and consequently no formal agreement between schools and university on the type of assistance and structured support (observation, co-planning, co-teaching) that should be made available to student teachers. The central socio-cultural concept we address in this study is 'horizon of observation' as it offered a lens on the nature and dynamics of student teachers access to accomplished teachers in teaching practice schools. The term 'horizon of observation', refers to: Lines of observation and limits on observation of the activities of others have consequences for the knowledge acquisition process... Let us refer to the outer boundary of the portion of the task that can be seen or heard by each team member is that person's horizon of observation. (Hutchins, 1996, p. 52)

A number of significant issues emerge from this study. First, the focus on observation and its different forms proved informative in terms of extending our understanding of learning to teach. In particular, Hutchins' concept of horizon of observation was especially germane to theorising the role and dynamics of observation and its impact on the knowledge acquisition process in ITE. Second, we argue that the 'horizon of observation' available to students in ITE is limited by current structural and cultural arrangements - notwithstanding the existing significant support available to ITE students in schools. Third, we address two dimensions of the learning to teach context in terms of how they impact the dynamics of observation in ITE: school university partnership models (Maandag et al, 2007) and a school's professional learning cultures (Moore-Johnson, 2004; Meirink et al, 2009). Finally, we discuss the implications of the limited horizon of observation in ITE in terms of what Lieberman et al (2009) term 'uncovering practice' in the service of deepening engagement with pedagogy. In doing so, we draw attention to 'uncovering practice' as a key principle of research-informed initial teacher education.

Finnish teacher students' approaches to learning, cognitive and attributional strategies

Kirsti Lonka, University of Helsinki, Finland; Annamari Heikkilä, University of Helsinki, Finland; Juha Nieminen, University of Helsinki, Finland; Markku Niemivirta, University of Helsinki, Finland

Aim.

Current theories of learning emphasize the role of motivational and affective aspects in university student learning. The aim of the present study was to examine the interrelations among approaches to learning, self-regulated learning, and cognitive strategies in the context of teacher education. Cognitive-motivational profiles were identified among novice teacher students. It was also looked at, whether well-being, epistemological beliefs, and study success in an activating lecture course were related to these profiles.

Method.

The participants were 213 first year teacher students, who participated in an activating lecture course at a major Finnish university. The students filled in a questionnaire including items based on the MED NORD instrument (Lonka et

al., 2008). The structural validity of the scales was tested by means of a series of factor analyses. Latent class clustering was used for clustering students into homogeneous groups. Finally, a series of ANOVAs was conducted to examine between-group differences across the criterion variables.

Results.

A three-group solution described the data best: (1) students with insufficient regulatory skills (50%), (2) self-directed students (28%), and (3) non-reflective students (22%). The students in Group (1) expressed the highest levels of stress, exhaustion, and lack of interest. Group (2) received the highest grades.

Conclusions.

The profiles were not only related to study success, but also to the general well-being of the students. It was concluded that motivational profiles may have not been optimal, even in this highly-selected population.

Theoretical background

Current theories of learning emphasize the role of motivational and affective aspects in university student learning. When examining studying in university, previous research has applied a number of frameworks, such as student approaches to learning (SAL, e.g. Marton & Säljö, 1976; Entwistle & McCune, 2004; Lonka, Olkinuora & Mäkinen, 2004), self-regulated learning (SRL, e.g. Vermunt, 1998; Pintrich, 2004), and cognitive strategies (e.g., Nurmi, Haavisto & Salmela-Aro, 1995; Nurmi et al., 2003). However, the interrelations among these aspects have seldom been systemically examined.

In the present study, a group of highly-selected university students were looked at: first year teacher students. We wanted to see what was the starting point of their journey of becoming teachers. Teachers working in future learning environments should be able to actively regulate their own learning. In order to become an expert teacher, self-regulatory skills are necessary (Kreber, Castlede, Erfani, & Wright, 2005). It is not enough that teachers regulate their own learning, they should also be able to help their students to become active and self-regulated learners.

Aims

The present study aimed to examine the following research questions: 1) How are approaches to learning correlated with cognitive and attributional strategies among first year teacher students? 2) What kinds of cognitive-motivational profiles can be identified among these novice teacher students? 3) Are there differences among students with varying cognitive-motivational profiles in terms of well-being, and epistemological beliefs? 4) Were the profiles related to study success in an activating lecture course?

Method

The participants were 213 first year elementary teacher and kindergarden teacher students, who participated in an activating introductory lecture course in educational psychology during either of two consecutive fall terms at the University of Helsinki, Finland. Both courses were interactive in nature, and the students gave positive evaluations afterwards.

At the end of the course, the students filled in a questionnaire including items from various scales that were shortened versions, based on the MED NORD instrument (Lonka et al., 2008):

- 1) Approaches to learning (based on Entwistle and Ramsden, 1983 and ILS, Vermunt, 1998; Lonka & Lindblom-Ylänne, 1996). Deep approach (divided into Deep understanding and Critical evaluation), Surface approach, and Lack of regulation.
- 2) Cognitive and attributional strategies (SAQ, Nurmi et al., 1995): Optimism and Task avoidance.
- 3) Epistemological beliefs (Certain knowledge, Practical value; Lonka et al., 2008) and
- 4) Well-being (Exhaustion, Stress and Lack of interest)(Elo et al., 2003; Maslach & Jackson, 1981; Mäkinen et al, 2004)).

The structural validity of the scales was tested by means of a series of factor analyses. Correlations were computed in order to study relations among the scales. Latent class clustering was used for clustering students into homogeneous groups. Finally, a series of ANOVAs was conducted to examine between-group differences across the criterion variables.

Results

Correlative results.

Deep Understanding correlated positively with Critical Evaluation and Optimism and negatively with Lack of Regulation. Critical Evaluation had a positive correlation with Optimism. Surface Approach correlated negatively with Optimism. Lack of Regulation correlated negatively with Optimism and positively with Task avoidance. There was a negative correlation between Task Avoidance and Optimism.

Cognitive-motivational profiles.

The results from a series of LCCAs using Latent Gold statistical software suggested that a three-group solution described the data: The first group (n = 106) had a maladaptive profile with high scores on Task Avoidance and Lack of Regulation, low score on Optimism and average scores on Deep Understanding, Critical Evaluation, and Surface Approach. The second group (n = 60) had a very adaptive profile altogether: students in this group scored high on Optimism, Deep Understanding, and Critical Evaluation and low on Task Avoidance, Surface Approach, and Lack of Regulation. The third group (n = 46) scored the lowest on Deep Understanding and Critical Evaluation, but interestingly, also on Task Avoidance. The three groups were labelled, according to the score mean profiles, as (1) students with insufficient regulatory skills (50%), (2) self-directed students (28%), and (3) non-reflective students (22%).

iesinents to withdraw. a symposium8Pairwise comparisons showed that the students with insufficient regulatory skills reported highest levels of stress, exhaustion, and lack of interest. Non-academic and self-directed students did not differ from each other in terms of stress and exhaustion. Non-reflective students scored lowest on lack of interest, but most often expressed appreciating certain knowledge. Self-directed students received the highest grades in the course examination.

Conclusions

The correlative results support our previous findings with students from other fields (Heikkilä & Lonka, 2006; Heikkilä et al, in press): Deep approach (Critical Evaluation and Deep Understanding) was positively related with optimism and negatively to problems in self-regulation. Lack of regulation had a strong positive correlation with avoiding difficult tasks.

Three groups were identified: students with insufficient regulatory skills, self-directed students, and non-reflective students. Our results showed that cognitive and motivational aspects were not only related to study success, but also connected with general well-being of the students. The three groups differed from each other in terms of well-being, epistemological beliefs, and study success. The students with insufficient regulatory skills expressed some symptoms of burnout. For teacher educators, this study has an important message: only one third of the students showed a truly favorable and adaptive cognitive-motivational profile. Even in a highly selected teacher student population, two thirds of the students express some kind of a maladaptive profile in relation to the goals of the course. Teacher students may be, more that we believe, dependent on external regulation. Their problems may encompass insufficient study skills, lack of appropriate goals, emotional exhaustion, and concerns with their own competence. Many of the teacher students were coming directly from high school, and problems in self-regulatory or reflective skills made it difficult for them to understand complex concepts of educational psychology that were central in the course in question. Even if the students expressed enjoying the course, their approaches to learning and their attributions may have not been optimal.

SYMPOSIUM

Instructional Strategies

How Instructional Explanations Can Work

Chairperson: Kirsten Berthold, University of Bielefeld, Germany

Organiser: Kirsten Berthold, University of Bielefeld, Germany

Discussant: Joerg Wittwer, University of Goettingen, Germany

Instructional explanations are used widely, however, empirical studies show that they often have no effect on learning outcomes. This ineffectiveness might be due to several main factors. First, learners might lack relevant prior knowledge to understand the explanations. Second, learners often have problems to match instructional explanations with other learning materials such as animations. Third, learners might not be aware of their misunderstandings and, consequently, they think they do not need the explanation. Against the background of these problems, the aim of the symposium is to explore how instructional explanations can work. All contributions address this aim in experimental

studies and test different instructional approaches of how to foster the effectiveness of explanations in computer-based learning environments. In Contribution 1, the learners were prepared to learn from instructional explanation by constructing relevant prior knowledge. In Contribution 2, the authors combined explanations with attention-directing cues while the learners watched an animation. In addition, they presented the instructional explanations after the learners had self-explained on the topic. In Contribution 3, learners received explanations in combination with indications that included devices pointing out typical misunderstandings. As main findings, the authors of all contributions found positive effects of instructional explanations or the specific approach to foster the effectiveness of instructional explanations on learning outcomes. These findings are of important scientific and educational relevance because they show that a) instructional explanations can be effective, and b) that instructional approaches that construct relevant prior knowledge or point out typical misunderstandings can even increase their effectiveness.

How to Prepare Learners to Learn from Instructional Explanations

Julian Roelle, University of Bielefeld, Germany; Kirsten Berthold, University of Bielefeld, Germany

Instructional explanations are commonly used, however, previous studies have often shown that their effects on learning outcomes are minimal. This failure of instructional explanations may partly be due to a lack of preparation for future learning from explanations on part of the learner. In other contexts, a promising means to prepare for future learning is working with contrasting cases. When working with such cases it is as yet unclear whether instructional guidance is beneficial or detrimental for subsequent learning. Against this background, we developed two types of preparation intervention to foster learning with explanations in the domain of management theory: (a) contrasting cases plus an inventing task including the request to explore and interpret the contrasts between the cases (b) contrasting cases plus worked-out solutions which included highlighting and interpreting the contrasts between the cases. We tested their effects in a one-factorial design comprised of three experimental conditions: (a) contrasting cases plus an inventing task, (b) contrasting cases plus worked-out solutions, and (c) no preparation (control group). Participants were 57 university students. As main findings, we found that working with contrasting cases can effectively and efficiently prepare learners for subsequent learning from instructional explanations. In addition, contrasting cases plus worked-out solutions were more efficient than preparation by inventing.

Instructional explanations are commonly used, however, empirical studies often show that their effects on learning outcomes are minimal (Wittwer & Renkl, 2008). This failure of instructional explanations might partly be due to a lack of preparation to learn from the explanations on part of the learner. To learn from instructional explanations, learners rely on their prior knowledge that serves as a cognitive anchor for future learning. A beneficial cognitive anchor for future learning helps learners to make sense of subsequent instructional explanations and thus cognitively prepares the learners to deeply understand concepts and principles included in the explanations. If a learner has low prior knowledge in a domain, however, they might lack such a beneficial cognitive anchor for learning. A viable approach to generating a cognitive anchor was proposed by Schwartz and Martin (2004). They found that analysing contrasting cases (i.e., cases that differ in important features in a domain) prepared learners for future learning. In the field of fostering learning from instructional explanations, the effects of contrasting cases have seldom been explored. In addition, there remains the open question as to whether instructional guidance should be given or withheld in the phase of preparation. Schwartz and Martin (2004) argued that to make contrasting cases effective, learners would need to explore and compare the cases on their own within an inventing task. However, research in this field mostly indicates that minimally guided instruction is both less effective and less efficient than direct instruction (Kirschner, Sweller, & Clark, 2006). Therefore, given that understanding the contrasts between the cases cognitively prepares learners for subsequent learning, direct instruction highlighting the contrasts should be even better preparation than a minimally guided inventing task. Against this background, we aimed to prepare learners, either with contrasting cases plus an inventing task (i.e., minimal guidance), or with contrasting cases plus worked-out solutions (i.e., direct instruction) to foster effective and efficient learning from subsequent instructional explanations on the domain of management theory. The following hypotheses were tested: 1. Working with contrasting cases fosters effective and efficient learning from subsequent instructional explanations. 2. Working with contrasting cases plus worked-out solutions is more effective and efficient than working with contrasting cases plus an inventing task.

Methodology

We tested these hypotheses in a one-factorial between-subjects design comprised of three experimental conditions: (a) contrasting cases plus an inventing task, (b) contrasting cases plus worked-out solutions, (c) no preparation intervention. Participants were 57 university students. In the conditions that received a preparation intervention, the learners were provided with a pair of contrasting cases. The cases briefly contrasted two companies that were either managed in accordance to scientific management or to the socio-technical systems approach. Learners in the condition that received contrasting cases plus an inventing task were required to explore and interpret the contrasts

between the cases on their own, whereas learners in the condition that received contrasting cases plus worked-out solutions received an expository text that highlighted and interpreted the contrasts between the cases. The time spent on the contrasting cases was held constant (15 min). Afterwards, all participants worked on instructional explanations on the domain of management theory (specific topics: scientific management and socio-technical systems approach) that were provided within a computer-based learning environment. Learning outcomes were assessed with a post-test on both conceptual knowledge and transfer. Learning efficiency was computed as the ratio of the total post-test performance score and the learning time.

Findings

To test our hypotheses we followed the recommendations of Rosenthal and Rosnow (1985), and calculated a priori contrasts comparing the conditions that worked with contrasting cases to the condition without contrasting cases (i.e., hypothesis 1), and comparing the condition with contrasting cases plus an inventing task to the condition with contrasting cases plus worked-out solutions (i.e., hypothesis 2). Working with contrasting cases significantly fostered conceptual knowledge, $F(1, 54) = 29.28$, $p = .35$, and transfer, $F(1, 54) = 26.85$, $p = .33$. Additionally, we found that learners who worked with contrasting cases showed a higher learning efficiency, $F(1, 54) = 5.79$, $p = .020$, $\eta^2 = .09$. With respect to hypothesis 2, we found that working with contrasting cases plus worked-out solutions was as effective as working with contrasting cases plus an inventing task regarding the acquisition of conceptual knowledge, $F(1, 54) = 1.25$, $p = .269$, and regarding transfer, $F(1, 54) = 4.53$, $p = .038$, $\eta^2 = .07$.

Theoretical and Educational Significance of the Research

We found that working on contrasting cases effectively prepared learning from subsequent instructional explanations. Working with contrasting cases was more effective and more efficient with respect to fostering conceptual knowledge and transfer when compared to working without contrasting cases. Additionally, it was more efficient to work with contrasting cases plus worked-out solutions than with contrasting cases plus an inventing task. These findings imply two conclusions regarding learning and instruction: 1. Evidently, working on contrasting cases can cognitively prepare learners to learn from subsequent instructional explanations and hence creates a time for learning from instructional explanations. 2. Contrasting cases plus worked-out solutions are a more efficient preparation for subsequent learning from instructional explanations compared to contrasting cases and a minimally guided inventing task.

Talk or Listen, or Both? Understanding a Dynamic System by Producing and/or Receiving Explanations

Huib Tabbers, Erasmus University Rotterdam, Netherlands; Bjorn de Koning, Erasmus University Rotterdam, Netherlands; Denise de Jel, Erasmus University Rotterdam, Netherlands

In this study participants watched an animation on the cardiovascular system. In order to improve understanding of the dynamics of the system, participants were required to either self-explain or to listen to an instructional explanation, or to do both, while they were watching the animation. Subsequently, participants were given retention, inference, and transfer tests. Results showed better inference and transfer performance with instructional explanations only. Thus instructional explanations can be effective in promoting understanding animations, and do not need to be combined with self-explanations.

Keywords: instructional animation; self-explaining, instructional explanation; cuing

Understanding an animation depicting a dynamic system implies that learners create some kind of 'runnable' mental model that can simulate the dynamics of the system (Schnotz & Low, 2008). This model should capture the structural and temporal aspects of the system that can be directly perceived in the animation. In order to be able to reason about the dynamic system however, the mental model should also contain functional relations that cannot be perceived directly but have to be inferred from the animation. Recently, De Koning, Tabbers, Rikers, and Paas (in

press) showed that prompting learners to self-explain while studying an animation results in more correct inferences of functional information and higher transfer performance than studying the animation without self-explanations. In a follow-up study however, De Koning et al. (2010) showed that accompanying the animation with a narration describing the correct functional information seemed to be at least as effective as self-explaining. According to Renkl (2002), with self-explanations not all functional relations will be extracted accurately, which may leave learners with incomplete or incorrect mental models. Instructional explanations on the other hand only contain correct information and thus aid in creating a correct and complete mental model. Nevertheless, with instructional explanations learners do not actively build on prior knowledge and information is processed more superficially (Wittwer & Renkl, 2008). Moreover, learners may have difficulties integrating the instructional explanation with the dynamics of the animation. Although this problem can partly be solved by adding visual cues in the animation (De Koning et al., 2010), the integration of explanation and animation is more adaptive with self-explanations. In this study, we investigated whether a combination of self-explanation and instructional explanation would be the optimal way to improve learning from a dynamic system. We set up an experiment in which participants studied an animation and manipulated whether they had produce self-explanations or not, and whether they received an instructional explanation or not. In the combined condition, participants had to self-explain first and then received the narrated explanation, to stimulate activation of prior knowledge and inference of functional relations from the animation rather than recalling this information from the narration.

Method

Ninety-two students participated for course credits (28 males; age: $M = 21.73$ years, $SD = 3.00$). They were randomly assigned to one of four conditions: no explanation, self-explanation, instructional explanation and self-explanation followed by instructional explanation. Participants were first checked on their familiarity with the cardiovascular system. This was followed by a short animation on plate tectonics, to familiarize participants with the upcoming learning task and (if applicable) with the self-explanation strategy. Subsequently, participants studied a labeled diagram to learn the names of the main structures of the cardiovascular system. They then studied a 5-minute animation of the cardiovascular system, with each of its five subsystems being highlighted consecutively by slightly darkening the other four subsystems. In the no-explanation condition, participants just watched the animation twice in silence; in the self-explanation condition participants were prompted to self-explain aloud while they viewed the animation; in the instructional-explanation condition participants watched the animation while listening to a narration; in the self-explanation-followed-by-instructional-explanation condition participants were prompted to self-explain during the first viewing of the animation and listened to the narration in the second viewing. In the narration mainly functional information was given that otherwise had to be inferred from the animation. Finally, participants answered 32 multiple choice retention items (structural and temporal aspects), 14 open-ended inference items (functional relations), and five open-ended transfer items (reasoning about the system). This test was repeated after one week.

Results

A MANOVA on retention, inference, and transfer scores with instructional explanation (yes-no) and self-explanation (yes-no) as between factors and time of test as within factor only showed a main effect of instructional explanation, Wilks' $\lambda = 0.68$, $F(3,86) = 13.21$, $p F(1,90) = 22.69$, $p F(1,90) = 8.16$, $p = .005$, partial $\eta^2 = .08$, but not on retention, $F(1,90) = 1.75$, $p = .19$, partial $\eta^2 = .02$. So participants receiving instructional explanations knew more correct functional relations (inference: $M = 15.63$, $SE = 0.54$) and knew better how to apply their knowledge (transfer: $M = 7.08$, $SE = 0.34$) than participants receiving no instructional explanations (inference: $M = 12.00$, and transfer: $M = 5.70$).

Discussion

In our study only instructional explanations are effective in improving learners' understanding of the dynamic systems. This is quite surprising as previous research showed that self-explanations do seem to improve learning from animations (e.g., De Koning et al., in press). Perhaps watching the animation a second time has led to more active construction of functional information in the condition without explanations. Also, hearing the instructional explanation a second time or after having self-explained may in both cases have led to better processing of this information. To conclude, this study suggests that understanding animations can best be promoted by instructional explanations combined with attention-directing cues.

Fostering Active Processing of Instructional Explanations

Hector Garcia Rodicio, University of Cantabria, Spain; Emilio Sanchez, University of Salamanca, Spain

Instructional explanations can address learners' problems of understanding and help in repairing them. However, they are ineffective more often than not. Our goal was to evaluate a strategy to make learners deeply process them, which consists of presenting indications of learners' misunderstandings before providing the explanations. In Experiment 1, 65 participants learned about plate tectonics from a multimedia presentation with animation and concurrent narration. In addition to the presentation, participants received instructional explanations in one of three forms: explanations with indications, explanations in isolation or no explanations. After the presentation, participants solved retention and transfer tests. Participants receiving explanations in isolation outperformed those in the condition with no explanations whereas participants receiving explanations with indications outperformed both. This means that indications enhanced explanations' effectiveness. In Experiment 2 we explored why the strategy worked effectively. Fifty-one participants learned from a multimedia presentation on plate tectonics while thinking-aloud. In addition to the presentation, half the participants received explanations combined with indications while the rest received the explanations in isolation. As revealed by thinking-aloud protocols, participants receiving explanations with indications were more able to detect and repair flaws in their ongoing understanding, with respect to participants in the explanation alone condition.

According to Wittwer and Renkl (2008) there are two kinds of instructional explanations. Some explanations introduce new concepts to learners. Other explanations are given when learners have gained some knowledge on a topic with the goal of revising possible misunderstandings. We are interested in the latter. It is important to make these explanations effective as they have the advantage of providing learners with complete and correct information when they have problems of understanding but cannot do anything to solve them. Despite this, instructional explanations are ineffective very often (Wittwer & Renkl, 2008).

The mental model repair view (Chi, 2000) suggests that, in order to learn deeply from expository prose, learners have to perform two processes: (a) monitoring their ongoing understanding to detect flaws and (b) generating explanations to repair these flaws. In the light of this view, one possible interpretation for instructional explanations' ineffectiveness is that learners cannot detect flaws in their understanding, which makes them perceive instructional explanations as ancillary (instead of repairing) information, thus ignoring them. Experiment 1 In order to test this interpretation we combined instructional explanations with indications pointing out the flaws in learners' ongoing understanding. We expected these indications to make learners aware of the limitations in their understanding. This, in turn, would make learners profit from instructional explanations by using them as a basis for repairing their flawed understanding.

Method

Sixty-five undergraduate students were assigned to one of three conditions: explanations with indications (EwithI), explanations (Enol) and no explanations (control). First, participants started viewing the multimedia presentation. It consisted of seven modules comprising animation with concurrent narration, which described events concerning plate tectonics. The presentation also included instructional explanations, which were interjected in between the modules. The explanations were designed to revise typical learners' misunderstandings that were identified in prior studies. Participants in the EwithI condition received these explanations in combination with indications, which were devices pointing out the misunderstandings (e.g., "What you probably see is that in both the Andes and the Himalaya two plates collide forming mountains. This is correct, however, it is not enough to completely understand how plate collisions work. What you probably did not realize is that collisions in the Andes and the Himalaya have big differences, critical to understand the modules."). Participants in the Enol condition received the explanations in isolation whereas participants in the control condition received no explanations but only the multimedia modules. After the presentation, participants solved a retention test consisting of eight open-ended questions (max. score = 24). Finally, participants solved a transfer test consisting of ten open-ended questions (max. score = 30).

Motivation

Interest, Learning, and Development: Insights from Qualitative Data

Organiser: Flavio Azevedo, University of Massachusetts, United States

Discussant: Paul W. Richardson, Monash University, Australia

current study and use it as the basis for addressing the following questions:

- How is interest conceptualized as developing over time? What is the relation between learning and [interest?] development?

Paul Richardson will serve as discussant. Richardson's own work bridges research and practice. It draws heavily on qualitative methods and is informed by self-determination theory, expectancy-value theory, and interest theory.

Using Cognitive Validation to Explore the Development of Interest in Adolescence

Anne Christiane Frenzel, Universitat Augsburg, Germany; Anna-Lena Dicke, University of Tübingen, Germany; Reinhard Pekrun, University of Munich, Germany

Our research explored the development of mathematics interest across adolescence. We interviewed $N=70$ adolescents (grades 5 and 9), using the methodology of cognitive validation to explore changes in the conceptualization of interest. Findings showed significant shifts in students' conceptualization of interest across time, with aspects of autonomic task choice and thirst for knowledge gaining weight, and positive experiences losing importance for the conceptualization of the construct of interest among 9th graders as compared to 5th graders. Consequently, qualitative changes should be attended to when exploring quantitative changes of psychological constructs over time, and interventions for interest should be tailored to specific age groups.

Aims and Theoretical Framework

Considerable research attention has been directed to the construct of mathematics interest, not only regarding its (positive) effects on learning and achievement, but also regarding its (negative) trajectories across primary and secondary school years (Eccles et al., 1983; Eccles, Adler, & Meece, 1984; Eccles et al., 1989; Fredricks & Eccles, 2002; Gottfried, Fleming, & Gottfried, 2001; Jacobs, Lanza, Osgood, Eccles, & Wigfield, 2002; Koeller, Baumert, & Schnabel, 2001; Spinath & Steinmayr, 2008; Watt, 2004). Longitudinally, mathematics interest is typically assessed with identical items across several school years. The development of mathematics interest is then typically measured based on absolute differences in responses on these self-report measuring instruments (e.g., a change from "strongly agree" to "agree"). This approach assumes that not only the understanding but also the relevance of the different items is the same for all respondents, independent of respondents' characteristics, such as age. Thus, measurement invariance of responses over time is implicitly assumed in longitudinal studies. However, if statements about quantitative changes are to be unambiguous, it is important that the elements of composite measurements be invariant over time over which change is said to occur (Horn, 1991).

A key suspicion guiding our research on interest development during adolescence was that such invariance of measurement is not given because students of different ages might conceptualize the construct of interest differently. That is, we suspected that a subjective reconceptualization of the construct of interest would occur during the adolescent years. To test this, we used the method of cognitive validation. This method is predominantly used to judge the cognitive validity of newly developed items (Bowen, Bowen, & Wolley, 2004), but it is applicable also to the question of qualitative changes in the item interpretation across different ages in the developmental continuum (Karabenick et al., 2007). So far, no such tests regarding the invariance of cognitive validity in the assessment of academic interests seem to have been undertaken.

Methodology

Participants of our study were $N = 70$ students from the highest ability track of the German state school system from grade 5 ($n = 21/14$ girls/boys, mean age 10.4 years, $SD = 0.60$ years) and grade 9 ($n = 17/18$ girls/boys, mean age = 14.7 years, $SD = 0.60$ years). Students were interviewed individually using the recommended guidelines for cognitive validation (Bowen et al., 2004; Karabenick et al., 2007) to explore students' cognitive conceptualization of the six items on mathematics interest (e.g., "I am interested in mathematics", "I often find the things we deal with in mathematics are really exciting").

Interviews were digitally recorded and subsequently transcribed verbatim. Transcripts were coded using the computer program MAXQDA (Kuckartz, 1995-2007). Drawing upon current conceptualizations of interest, student answers were categorized into the following components of the construct (typical statements in parentheses): affective experiences ("It is fun"), value of the respective domain ("I like it"), subjective competence in the respective domain ("I can do it"), thirst for knowledge ("I want to know more"), (repeated) behavioral engagement in the respective domain ("I spend time with it"), autonomic task choice in the respective domain ("I do it voluntarily"), and energization or motivation ("I really want to do it").

Interviews were rated by three independent raters. Inter-rater reliability was obtained by cross-coding 6 of the 70 interviews (Cohen's Kappa rater 1/2 = .92, rater 1/3 = .84, rater 2/3 = .85).

Findings

To investigate potential developmental changes concerning item interpretation, we ran a MANCOVA with the seven predefined categories as dependent variables and age group as independent variable and verbal fluency as a covariate. The overall multivariate test for the age comparison of the category frequencies was significant ($F = 3.64$; p

< .01). In separate comparisons, significant differences occurred for the categories of affective experiences (higher for 5th graders), autonomic task choice, thirst for knowledge and behavioral engagement (higher for 9th graders). Thus, there were significant qualitative changes in the conceptualization of the construct of interest between the two age groups, with younger students associating predominantly affective experiences with the construct of interest, and older students increasingly incorporating more cognitive aspects into their conceptualization of interest.

Significance

Our findings clearly indicated that one fundamental prerequisite of assessing quantitative change across time, namely measurement invariance, might not be given for the construct of academic interest if measured with typical self-report items such as those used in our study, because the construct undergoes qualitative changes in its conceptualization across adolescence. Therefore, a qualitative check of potential measurement variation seems imperative for any future study addressing such questions.

In terms of educational implications, intervention directed at the improvement of academic interests should be designed according to the interest conception of the specific age group. Given our observed conceptual shifts in the interest construct across adolescence, younger students should be provided with positive affective experiences, while one should appeal to autonomy to instill academic interest among older students. Positive affective experiences could for example be conveyed by offering real-life, exciting mathematics problems or by enthusing the students through one's own authentic display of enjoyment of practicing mathematics (see Frenzel et al., 2010). Autonomy could be achieved by providing choices or by emphasizing that several solutions to a math problem are possible.

The Development of Well-developed Interests: Theoretical and Pedagogical Implications

Flavio Azevedo, University of Massachusetts, United States

Based on a 3-year-long ethnography of the hobby of model rocketry, I investigate the development of well-developed (i.e., individual) interests. Hobbies are paradigmatic of elective, self-motivated, open-ended practices, and thus they offer an excellent window into interest-based forms of participation. Using a grounded theoretical approach, I iteratively compare and contrast rocketeers' practices, looking for patterns in their pursuits. I then attempt to explain where such patterns emerge from (i.e., their structure), as well as how they change and evolve in the long haul. Overall, I find that an individual interest develops simultaneously in multiple directions, each of which represents the multiple motives that a hobbyist develops in the practice, as well as interactions among such motives. For example, a rocketeer may at one time engage the practice for the sake of doing design and construction work, while at another time using the hobby as a way to socialize and strengthen friendships, as well as to advance an identity of competence. Of course, all such motives could be (and most often are) pursued at the same time, interacting in specific ways across contexts. This complex, multi-dimensional structure has several theoretical and pedagogical implications. Indeed, while hobbies and schools are radically different institutions, I will show that the theoretical developments I propose here can inform classroom practice at several levels.

Aims and Theoretical Framework

Designing instruction such that students' emergent disciplinary interests can be nurtured towards more stable, well-developed interests is often proposed as a major goal of modern instruction. To support this goal, researchers have studied how interests develop from moments of fleeting attention in a topic or activity (i.e., a situational interest; Schraw & Lehmann, 2001) to long-term, individual interests (Hidi & Renninger, 2006). Here I contribute to this research agenda by studying how individual (i.e., well-developed) interests themselves constantly change and evolve. The premise is that understanding development of any phase of an interest (Renninger, 2009) may inform our overall understanding of larger processes of interest development.

The focus of my investigation is the hobby of model rocketry. Hobbies are paradigmatic of elective, self-motivated, open-ended practices (Valsiner, 1992), and thus they offer an excellent window into interest-based forms of participation. While hobbies and schools are radically different institutions, I will show that the theoretical developments I propose here can inform classroom practice at several levels.

An interest appears first as a curiosity or attraction (Hidi & Renninger, 2006), and with time it evolves and becomes established as a fabric of activities (diSessa, 2000). Framed in this manner, several strands of social, cultural, and historical approaches to the study of social practices bear on my research. For example, as in Lave and Wenger's (1991) study of communities of practice, I consider that long-term practice engagement is partly a result of one's felt sense of future in the practice and the communities that enact them. Facilitating these developments, guided

participation (Rogoff, 1995) in hobbies is part and parcel of the process through which individuals come to develop interests in the practice. Within this context, I pay particular attention to individuals' access to resources in the community (e.g., material infrastructures, such as rockets and rocket parts/tools), which function at times to mediate people's long-term engagement (Engestrom & Middleton, 1996), and at times as goals in and of themselves (Krapp, 2003). The point of my analysis is to elucidate how these structures and processes interact to shape and sustain individuals' long-term pursuits.

Methodology

In ethnographic fashion, my role was that of a participant observer (Hammersley & Atkinson, 1995) in two model rocketry communities. Empirically and analytically, my strategy was to focus on a single case—that of 14-year-old David, who has been a rocketeer since he was six—and to compare and contrast it to the practices of other rocketeers. For all subjects, I documented their practice-linked activities and routines (e.g., flying rockets and chatting about model rocketry), as well as any “parallel” activities (e.g., socializing) that the practice of model rocketry might serve to mediate. The ethnographic period lasted three years, and resulted in about 20 hours of videotapes and several pages of field notes.

My analytical procedure was the grounded theoretical methodology (Corbin & Strauss, 1990), which outlines a method for collecting and analyzing data such that conceptual categories reflecting emergent analytical codes are iteratively refined in subsequent data collection and analysis. Following my research goals, coding of the data was specifically geared towards identifying patterns of practice participation over the very long term and to explain (a) how such patterns change over time and (b) where these patterns emerge from (i.e., what is their structure).

Findings

Briefly, my analysis reveals three central aspects about the nature and development of individual interests:

1. An individual interest develops simultaneously in multiple directions, each of which can be seen in clusters of inter-related activities. For example, David engages in designing and building a variety of low-powered rockets made from cheap, reusable materials (e.g., Paper Cups and Bottles), as well as building off-the-shelf, high-powered rockets, among others. Each of these simultaneous “lines of work” in his practice—call them “cheap and wacky rockets” and “high-powered rockets,” respectively—entails a distinct set of activities, which themselves represent the various motives that a person develops in the hobby.
2. Over the long haul, each “line of work” in a hobbyist's practice shifts its focus of action. For instance, at the beginning of the ethnographic period, David's “cheap and wacky rockets” focused on a variety of rocket forms (e.g., Paper Cup, Bottle, and Shuttlecocks). Towards the end of the study, however, that “line of work” had shifted to a single rocket form (i.e., Shuttlecocks), with variations within—e.g., single- and multi-stage versions of it.
3. Also across the long run, an individual enacts his/her interest in different ways. Thus, David at times spent more time with his “cheap and wacky rockets,” say, building and flying them more often than other rockets in his fleet. At a later point, however, he dedicated more time to other lines of his hobby.

Significance

These observations have a number of theoretical and pragmatic implications, including:

- i. Item 1 above suggests that interests have a complex motivational structure, regardless of their phase of development. At the earliest stages of interest development in the classroom, then, we expect to see the student engaging in a particular activity from various angles, each of which reflects his/her emerging motives to participate in the activity. If any form of well-developed disciplinary interest is to evolve, we must design opportunities for students to continuously experience these disciplines from a variety of personally relevant positions. In the presentation, I will consider how this finding might be antithetical to our current schooling practices.
- ii. Items 2 and 3 afford us a better interpretation of dynamic phenomena in interest-based practice participation. For example, in long-term inquiry-based science activities, students' interests are sometimes interpreted as flailing (e.g., Blumenfeld et al., 1991). From the perspective advanced here, however, “flailing interests” might simply be an artifact of how interests evolve and/or are differentially enacted across time. In the presentation, I will offer a number of such “small” classroom interpretation/implementation lessons.

Rich Descriptive Data and Its Implications for Understanding Interest Development: “L” and Science

K. Ann Renninger, Swarthmore College, United States; Kathryn R. Riley, Swarthmore College, United States

Symposium questions will be addressed using data from a multi-method study of the case of L—, an adolescent girl, who was one of a total of 8 (5 girls, 3 boys) inner-city participants in out-of-school science workshops over five years. Participant observation, yearly pre-post and follow-up interviews, assessments of science literacy, artifacts from workshop participation, and interviews with parents inform this study. Findings from this study suggest that in order to engage, a learner needs to perceive the features of particular content, such as science, as something to which to attend. It also suggests that interest influences the “what” of cognition: to what the learner attends and how he or she engages.

Aims and Theoretical Framework

Consistent with Hidi and Renninger’s (2006) Four-Phase Model of Interest Development, interest is conceptualized as both a psychological state and a predisposition to return to engagement with particular disciplinary content (e.g., science). Phases in the development of interest range from an initial triggered situational interest that may only last for a few moments, to a well-developed individual interest that is relatively long lasting. They also have been described as including the learner’s evolving knowledge about, valuing of, and feelings for particular content.

Differences exist in researchers’ understanding of the relative emphasis of knowledge, value, and affect in the development of interest, however. The work on attention and cognitive processing suggests that there is individual variation in the types of questions and/or topic interest of the learner (e.g., Renninger, 1990; Neitzel, et al., 2008). The work on the characteristics of the learning environment calls attention to the role of others and objects as supports for engagement and to likely differences in learners’ needs for support for development (e.g., Nolen, 2007; Palmer, 2009). The work on knowledge and value as components of interest underscores potential differences in the contributions of each to interest and also to their coordination as interest develops (e.g., Lawless & Kulikowich, 2006; Schiefele, 2009).

Not addressed in these discussions is what needs to be in place for the learner independently to begin asking curiosity questions, seeking resources, and making use of feedback. Learners like L—, who initially have little to no interest in learning content such as science, pose a challenge for educators as well as researchers.

Methodology

L— was selected for study from a cohort of 8 (5 g, 3 b) inner city youth on whom we also have data over the years of their participation in the science workshops. She is emblematic of the participants: inner-city youth who at the beginning of the study had an average age of 10 years. She had little initial interest in science, no formal experience with science (her school did not teach science), and was a participant in the workshop because she was a participant in a choral training program run concurrently with the science workshops.

Methods employed included participant observation, pre-post workshop interviews each year of the study including three assessments of science literacy, and five-week-post-workshop interviews that included parallel assessments of science literacy. Interviews with parents each summer and artifacts from workshop participation also inform this study.

Interest was assessed using methods adapted from Renninger and Wozniak’s (1985) ethnological methods, assessing voluntary reengagement, engagement overall, independent engagement and complexity of engagement.

Findings

Participant observation notes and interviews with L— indicated that initially she thought about science the way she would think about anything else; she was more philosophical than scientific. For example, her questions during the week she and her workshop group learned about worms included: “What do worms die from?” “What kind of culture do they have?”

Five years later, L— asked to be a teaching assistant in the Chemistry Workshop, a position that had not previously existed.

She was now aware that science was fun for her. After some deliberation, the workshop programming was adjusted to allow her to help out with the younger children as a peer tutor. She worked with the younger children alongside a college student. Even before the workshop addressed acid-base neutralization, and only two weeks into the workshop, she asked to take an experiment further by combining an acid and base and observing the resulting solution. The instructors suggested that she share this idea with the group of children to whom she was assigned. She

did, and engaged them all in thinking with her about each of the trials (and, as it turned out, all of the other children's groups decided to explore this issue as well). (Notes, June 2009)

L—'s thinking about science had changed. She had a broader perspective. She now focused on patterns in phenomena and how they together provided explanation. She was willing to think about content generally and to explore new materials.

L— shifts from being a person with little to no background knowledge to seriously wanting to engage and learn. Data from L—'s participation in the workshops are consistent with those of the other participants in her cohort, and allow consideration of the interplay between interest development and cognition.

For the first few summers she participated in the workshops, L— has a triggered situational interest in the scientific material. Her affect can be heightened; she clearly is attending and has some questions, but it is not until the fourth year that her phase of interest begins to shift to a maintained—and soon after to an emerging—individual interest, signaled by her independent efforts to understand.

Significance

Based on the data from L—'s case, it appears that shifts in the development of interest can be expected, but may not be immediately obvious to the observer. However, patterns such as the kinds of questions asked and the extent to which these questions map onto the questioning of the discipline can be tracked. They suggest that the initial process of triggering interest occurs over time. Furthermore, they suggest that as interest develops, attentional resources are freed up. In the first workshop, L—'s own questions appeared to take so much of her energy that she did not have the capacity to benefit from the group, even though it is in the group that she continues to grow. In an open-ended inquiry context, moreover, questions and engagements of L— and her group appear to be increasingly aligned with the disciplinary goals and skills of science. Such data have intriguing suggestions about the role of the learning environment as a support for both interest development and learning.

Discussant: Elsbeth Stern, ETH Zurich Institute for Behavioral Sciences, Switzerland

For more than a century, psychology has delivered various scientific insights into reasons for success and failure of academic learning. Nonetheless, there is still a wide gap between what psychology has ascertained about powerful learning environments, and how these findings do inform daily classroom practice. On the one hand, schools are still governed by traditions that are in conflict with well accepted principles of human learning and functioning. On the other hand, findings from research on learning and instruction hardly ever go along with clear practical implications, and therefore may be more confusing than helpful for teachers. In principle, psychologists have good opportunities to inform educational practice because educational psychology is a core subject in teacher education programs at most universities, and psychologists get many invitations to participate in professional development programs for in-service teachers. In this panel discussion we want to generate ideas on how to use these resources more efficiently in future. What insights and concepts from Psychology should leave their mark on teacher education and how should this work? Should concepts such as motivation, working memory functions, or problem solving be taught similar to the way they are taught in psychology courses, or do they have to be translated from the very beginning into a language of didactics and merged into Pedagogical Content Knowledge? Psychologists from Finland, Germany, Switzerland, and the US with major responsibilities in teacher education programs will present their current practice as well as their future goals, and afterward controversial questions will be discussed.

What has been the contribution of Psychology to school reforms in Finland?

Erno Lehtinen, University of Turku, Finland

For more than a century, psychology has delivered various scientific insights into reasons for success and failure of academic learning. Nonetheless, there is still a wide gap between what psychology has ascertained about powerful learning environments, and how these findings do inform daily classroom practice. On the one hand, schools are still

governed by traditions that are in conflict with well accepted principles of human learning and functioning. On the other hand, findings from research on learning and instruction hardly ever go along with clear practical implications, and therefore may be more confusing than helpful for teachers. In principle, psychologists have good opportunities to inform educational practice because educational psychology is a core subject in teacher education programs at most universities, and psychologists get many invitations to participate in professional development programs for in-service teachers. In this panel discussion we want to generate ideas on how to use these resources more efficiently in future. What insights and concepts from Psychology should leave their mark on teacher education and how should this work? Should concepts such as motivation, working memory functions, or problem solving be taught similar to the way they are taught in psychology courses, or do they have to be translated from the very beginning into a language of didactics and merged into Pedagogical Content Knowledge? Psychologists from Finland, Germany, Switzerland, and the US with major responsibilities in teacher education programs will present their current practice as well as their future goals, and afterward controversial questions will be discussed.

On the other hand, findings from research on learning and instruction hardly ever go along with clear practical implications, and therefore may be more confusing than helpful for teachers. In principle, psychologists have good opportunities to inform educational practice because educational psychology is a core subject in teacher education programs at most universities, and psychologists get many invitations to participate in professional development programs for in-service teachers. In this panel discussion we want to generate ideas on how to use these resources more efficiently in future. What insights and concepts from Psychology should leave their mark on teacher education and how should this work?

Psychology has further developed many concepts which are relevant for education. However, this may have increased the gap between scientific understanding of those concepts and the way they are used in everyday contexts. For example, this is the case for the concept of motivation. In its everyday use, motivation is understood more like a trait. In contrast, Educational Psychology has researched the circumstances under which motivation can be changed. As a consequence of this research, psychologists understand motivation more like a competence which can be acquired by learning, rather than as a trait. It is thoroughly important to convey these insights to teacher education programs, but how do we ensure that teachers really make use of it in their daily classroom practice? Birgit Spinath will present attempts which go in this direction.

It is, however, a general question whether concepts such as motivation, working memory functions, or problem solving should be taught similarly to the way they are taught in psychology courses. In Finland, which is the most successful country in term of education in the Western World, teacher education is strongly based on scientific psychology, as Erno Lehtinen will show. In contrast, Lauren Resnick argues that insights developed in psychological research should be translated from the very beginning into a language of didactics and merged into Pedagogical Content Knowledge.

Recently, more and more teacher educational programs at various places try a compromise between basic research and applicable skills. Henrik Saalbach will present an example from the ETH Zurich where a program has been designed on the basis of the so-called supply-and-utilization-model (Angebots-Nutzungs-Modell) which conceptualizes instructional quality as depending not only on instructional methods but also on factors of the learner, the teacher, and the school. The learner side includes various learning processes as well as stable and unstable preconditions (e.g., SES, IQ, attitudes). The teacher side contains professional competencies such as content knowledge, pedagogical content knowledge and beliefs, diagnostic competencies, as well as skills concerning coping with the psycho-social demands of teaching. The program is thus based on four columns: subject matter (e.g., mathematics, physics, chemistry), didactics, teaching practice, and educational psychology. The latter part contains issues such as cognitive foundation of learning, learning theories with a special emphasis on constructionist approaches, motivation, conceptual change, formative assessment, instructional design, coping with stress as well as communication and conflict resolution skills. All courses are designed in a way that student are encouraged and supported to link theories to their subject and to teaching practice in order to build up content-focused pedagogical knowledge.

The panelists who have long-standing major responsibilities in teacher education programs in their countries will discuss the different approaches on how psychology can contribute to teacher education and professional development. The aim of the discussion panel is thus to develop recommendations for designing teacher education programs which are research based and ensure transfer to daily classroom practice.

Psychology in nested Learning Systems

Lauren B. Resnick, University of Pittsburgh, United States

For more than a century, psychology has delivered various scientific insights into reasons for success and failure of academic learning. Nonetheless, there is still a wide gap between what psychology has ascertained about powerful learning environments, and how these findings do inform daily classroom practice. On the one hand, schools are still governed by traditions that are in conflict with well accepted principles of human learning and functioning. On the other hand, findings from research on learning and instruction hardly ever go along with clear practical implications, and therefore may be more confusing than helpful for teachers. In principle, psychologists have good opportunities to inform educational practice because educational psychology is a core subject in teacher education programs at most universities, and psychologists get many invitations to participate in professional development programs for in-service teachers. In this panel discussion we want to generate ideas on how to use these resources more efficiently in future. What insights and concepts from Psychology should leave their mark on teacher education and how should this work? Should concepts such as motivation, working memory functions, or problem solving be taught similar to the way they are taught in psychology courses, or do they have to be translated from the very beginning into a language of didactics and merged into Pedagogical Content Knowledge? Psychologists from Finland, Germany, Switzerland, and the US with major responsibilities in teacher education programs will present their current practice as well as their future goals, and afterward controversial questions will be discussed.

A major message from Psychology: Understanding motivation as a competence rather than as a trait

Birgit Spinath, Heidelberg University, Germany

For more than a century, psychology has delivered various scientific insights into reasons for success and failure of academic learning. Nonetheless, there is still a wide gap between what psychology has ascertained about powerful learning environments, and how these findings do inform daily classroom practice. On the one hand, schools are still governed by traditions that are in conflict with well accepted principles of human learning and functioning. On the other hand, findings from research on learning and instruction hardly ever go along with clear practical implications, and therefore may be more confusing than helpful for teachers. In principle, psychologists have good opportunities to inform educational practice because educational psychology is a core subject in teacher education programs at most universities, and psychologists get many invitations to participate in professional development programs for in-service teachers. ICT DEMONSTRATION

Using Personal Digital Assistants (PDAs) in intrapersonal educational research

Lars-Erik Malmberg, University of Oxford, United Kingdom

An intrapersonal (within-person) approach to educational research offers a unique window into learners' and teachers' beliefs, experiences and behaviours, which is different from that of an interpersonal (between-person) approach. Techniques geared toward investigating experiences as they unfold in the real-world in real-time are referred to as diary studies and experience sampling. Such studies are still quite rare in educational research, although the process nature of learning and teaching lend themselves well to such a methodology. Inspired by developmental research in other fields (e.g., emotion), available and user-friendly technology for data-collection, and recent advances in statistical modelling, the workshop on intrapersonal modelling covers the following topics.

- (1) A brief introduction to the intrapersonal research approach
- (2) Planning and starting up an intrapersonal study. When, in which situations, and how to administer questionnaires?
- (3) Programming a PDA questionnaire using commercial software
- (4) Data management
- (5) Participant recruitment, training and monitoring
- (6) A brief overview of statistical modelling of intensive longitudinal data

Examples will be drawn from the literature, software comparisons and experiences from two empirical studies: the Learning Every Lesson (LEL) study (5,000+ lessons of 320 primary school children; Malmberg & Halliburton), and the Teaching Every Lesson (TEL) study (1,000+ lessons of 43 teachers; Malmberg & Hagger). The workshop is open for all researchers who are interested in the investigation of intrapersonal educational phenomena. No prior knowledge is required. About 60 minutes of demonstration time is allocated, leaving ample time for discussion.

Two broad approaches to the investigation of humans belief systems exist: the interpersonal approach (between-person, variable-approach) and the intrapersonal approach (within-person, process oriented). Much educational research is cross-sectional or longer-term longitudinal. Data collected in such studies, either by questionnaire or interview is susceptible to memory biases. Techniques geared toward investigating experiences as they unfold in the real-world in real-time are referred to as diary studies, experience sampling, and ecological momentary assessment

(Hektner et al., 2007). As learning and teaching are viewed as processes unfolding over time, it appears that an intrapersonal process approach would be fruitful to advocate in educational research. To date only few studies have, to the best of our knowledge, been carried out. Schmitz and Skinner (1993) investigated more than 25 homework learning experiences among primary school students. Tsai et al (2008) studied secondary school students' science and maths interest and perceived autonomy support during three weeks. Schmitz and Weise (2006) report on a six week self-regulation intervention study among university students. Carson et al. (2010) report that only four intrapersonal studies of teachers have been carried out. The benefits of an intrapersonal (process) approach are that they can increase our knowledge about: (1) interpersonal differences in stability of intrapersonal processes, i.e., to what extent persons vary in their stability from one situation to the next (from time-point T-1 to time-point T); (2) whether one aspect of an intrapersonal process predicts the same or another aspect of the intrapersonal process over time; (3) intrapersonal variance, that is how much a person varies with regard to an intrapersonal aspect within a given time-interval; and (4) the extent to which intrapersonal processes are related to (inter)personal characteristics and contextual features, for example whether students' intrinsic motivation is predicted by communication with the teacher (e.g., Nesselroade, 2001). Taken together, Zimmerman (2008) refers to the study of intrapersonal beliefs as the next generation of research into self-regulatory processes. Modern technology has made life easier for researchers who wish to investigate how persons vary in their experiences and beliefs from one situation to the next. Personal Digital Assistants (PDAs) have become reasonably accessible (Le et al., 2006), prices from £50 upwards. While some commercial software are quite expensive but relatively easy to use, non-commercial software are freely available, but at times more complex to programme for the non-savvy researcher. Modern statistical software (e.g., MLWin, Mplus) allow researchers to specify models taking account of the complex nested structures within which the data were collected (e.g., time-points nested within days, nested within students, nested within classrooms). The proposed demonstration workshop is geared towards researchers who wish to get a first insight into the methodology. Presentation time is approximately 60 minutes allowing ample time for participants to ask advice, discuss any points raised, and follow up on details. Examples will be drawn from the literature, software comparisons and experiences of two empirical studies: the Learning Every Lesson (LEL) study (Malmberg and Halliburton, 2007-08; more than 5,000 responses of 320 primary school children), and the Teaching Every Lesson (TEL) study (Malmberg and Hagger, 2009; more than 1,000 responses of 43 teachers). The contents cover: (1) A brief introduction to the intrapersonal research perspective (as juxtaposed with an interpersonal perspective; 5 min). (2) Planning and starting up an intensive longitudinal study (10 min). (2b) Focus on time. Whether to probe experiences at fixed time-points (e.g., end of lesson, lunch break), when a certain event occurs, or randomly? (2a) Questionnaire and item construction. Focus on trade off between content coverage (how many constructs to include?), and numbers of items per construct (how many items to ask in total?). (3) Programming. Example of how to programme Hewlett-Packard iPAQ 2140 PDAs (Windows 5 operating system), using the DaneSoft Survey System: Setting up templates and how to manage files. Other systems will be referred to (10 min). (4) Data management. How to download data, store and error check data. Using participant log-on codes and time-stamped data. How to create person-period datafiles (10 min). (5) How to recruit participants (e.g., longer term commitment), train participants to use PDA (e.g., technical info, how to charge machines), and monitor participant compliance (e.g., courtesy calls or e-mails)(10 min). (6) A brief overview of statistical modelling of intensive longitudinal data (Walls, Jung, & Schwartz, 2006), including the following: (a) Multilevel Confirmatory Factor Analysis (MLCFA) allows the specification of factor structures at two levels (i.e., time-points nested within students). (b) Random Intercept and Random Slope models allows the investigation of relationships between intrapersonal constructs at both the situation and person levels. (c) The Dynamic Factor Analysis (DFA) allows the time-dimension (lagged relationships between time-points) of the data to be taken into account (15 min).

ICT DEMONSTRATION

Demonstration of the SimScientists Formative and Summative Simulation-Based Assessments

Edys Quellmalz, WestEd, United States; Michael Timms, WestEd, United States

The SimScientists research and development program at WestEd combines a model-based learning approach with evidence-centered design into a powerful framework for transforming science assessment. This session will demonstrate simulation-based assessments for two middle school science topics, ecosystems and force and motion. The assessments were field tested in three states with 55 teachers and 5500 students. Findings documented the feasibility, utility, and technical quality of science simulations for formative, curriculum-embedded assessment and summative, end-of-unit benchmark assessment. SimScientists projects contribute to the research base on the design and validation of the next generation of assessments and their articulation throughout an assessment system.

Aims.

This session will demonstrate simulation-based assessments funded by the U.S National Science Foundation and the U.S. Department of Education designed as formative, curriculum-embedded assessments and as summative, end-of-unit benchmark assessments. The formative assessments provide immediate feedback and customized coaching along with reports for students and teacher on progress on content and inquiry targets. The summative benchmark assessments generate reports of proficiency and report it for teaching and accountability purposes. The SimScientists program at WestEd seeks to provide evidence that simulation-based assessments can gather and document evidence of students' understanding of connected science knowledge and extended inquiry not often or well measured in the U.S. by conventional tests (See simscienists.org).

In addition, these assessments are envisioned as components of multilevel, balanced state science assessment systems. The assessments to be demonstrated test U.S. national science standards at the middle school level (grades 6-8).

Methods.

The SimScientists research and development program combines a model-based learning approach with evidence-centered design into a powerful framework for transforming science assessment and learning (Buckley, in preparation; Mislevy et al, 2003). The SimScientists projects proceed through phases of design, expert review, programming, small scale feasibility testing, and classroom testing. The design process involves analyses of learning research, national science standards, and curriculum materials to specify grade-appropriate system components, interactions, and emergent behavior. For example, ecosystem components consist of organisms in the roles of consumers, producers, and decomposers. Interactions involve transfer of energy and matter through the ecosystem, represented in food webs. Emergent system behaviors involve population levels of organisms and changes in them due to varying conditions. Inquiry practices, as specified in the 2009 NAEP Science Framework, include designing, conducting, interpreting, and evaluating. Simulation shells specify the representations of science phenomena to be modeled by the simulation environment. Model-based progressions proceed from observations of organisms, inferences of interactions, and predictions, observations, and explanations of varying population levels.

In 2010, the U.S. Department of Education funded a large-scale pilot of simulation-based assessments for two middle school topics to investigate the feasibility, utility, and technical quality of the simulation-based formative and summative assessments. Fifty-five teachers, 5,500 students, in 28 districts in three states participated. Data included expert reviews of the alignments of the assessments with national science standards, quality of the science, items, and tasks, cognitive labs in which students think aloud as they respond to the assessments, classroom observations, teacher surveys and interviews, and psychometric analyses. An external evaluation of the project was conducted by UCLA's Center for Research, Evaluation of Students and Standards (CRESST). A Design Panel of representatives of six state departments of education science assessment directors reviewed the pilot test findings and a policy brief summarizing the pilot test and offering alternative models for integrating science simulations into state science assessment systems.

Findings.

Feasibility and utility of the simulation-based assessments were indicated by evidence that the students were engaged in the simulation-based assessments and that the teachers found the reports of student progress useful for

understanding student learning and for adjusting instruction. Across the 28 school districts and 55 classrooms, teachers were able to implement the simulation-based assessments in computer labs. Psychometric analyses of the benchmark assessment data indicated that they were reliable and valid.

Theoretical and Educational Significance.

A growing body of research shows model-based reasoning to be a signature practice of the sciences, as scientists create insights and understandings of nature through conceptual, physical, and computational modeling. Further, cognitive research shows that learners who internalize schemas of complex system organization – structure, functions, and emergent behaviors – can transfer this heuristic understanding across systems. Simulations can represent dynamic science systems "in action", making visible the causal, temporal, and spatial phenomena that are invisible and making models available for extended, active investigations of authentic problems. A technical infrastructure that captures and analyzes students' actions and answers can yield cognitively rich evidence of learning in reports for teachers and school systems and can also provide feedback and customized, graduated coaching. The multiple physical and symbolic representations in simulations can also reduce language demands.

In large-scale assessments, the area of science is leading the way in exploring complex, multi-faceted problem types and assessment approaches. The 2006 Programme of International Student Assessment (PISA) pilot tested a Computer-based Assessment of Science specifically to test knowledge and inquiry processes not assessed in the paper-based test booklets. Topics included the functions of a nuclear reactor and genetic breeding of plants. The 2009 National Assessment Educational Progress (NAEP) for Science administered Interactive Computer Tasks (ICT) to test students' inquiry practices. The 2014 NAEP for Technology and Engineering Literacy will be entirely computer delivered and will administer interactive, scenario-based tasks (See www.naep-tech2014.org). States such as Minnesota have online science tests with simulated laboratory experiments or investigations of phenomena such as weather or the solar system. The SimScientists projects to be demonstrated contribute to the research base on the design, development, and validation of the next generation of innovative assessments and their articulation throughout the levels of an educational assessment system.

ICT DEMONSTRATION

A multi-modal, web-based inquiry learning environment on Genetically Modified Organisms

Christothea Herodotou, Cyprus University of Technology, Cyprus; Iolie Nicolaidou, Cyprus University of Technology, Cyprus; Eleni Kyza, Cyprus University of Technology, Cyprus; Andreas Hadjichambis, Cyprus Center for Environmental Research & Education, Cyprus; Frederiki Terzian, Ministry of Education and Culture, Cyprus; Dimitris Kafouris, University of Exeter, United Kingdom

A multi-modal, web-based inquiry learning environment (LE) on Biotechnology and Genetically Modified Organisms (GMOs) is the focus of this presentation. The LE has been developed for use in science education as a means to raise students' interest in socio-scientific problems and create a bond between the scientific enterprise and human life through the use of new information technologies. The LE was built around the idea of software-based scaffolding, the role of which is crucial for successful reflective inquiry and synchronous and asynchronous collaboration among students. A design-based approach was followed for the development of the LE; the LE was designed by a Local Working Group (LWG) in Cyprus, piloted, redesigned and re-enacted in a high school class. The analysis of pre and post tests administered to students during the LE's reenactment demonstrated the effectiveness of the intervention; students' conceptual understanding and credibility skills were significantly improved by the end of the enactment. Such approaches can become the catalyst for making science education more attractive and appealing to students' learning needs.

Extended summary

Aims

Students' interest in science education has declined considerably during the past decade. A very low number of students wishes to pursue a career in science (Sjöberg & Schreiner, 2006), an indication that the "swing from science" phenomenon (Ormerod & Duckworth, 1975) still endures. This disinterest is attributed to schools' failure to sustain students' motivation to learn about science and a lack of authentic science teaching and learning. The role of new technologies is critical in this respect; they can be the conjunction between the scientific enterprise and human life, making science more appealing to young people. Integrating new technologies in the process of learning science - not only learning about but also learning with technology would be highly beneficial. In this study, we present one such approach. A multi-modal, web-based inquiry learning environment (LE) about Biotechnology has been developed on the STOCHASMOS platform (Kyza & Konstantinou, 2007) allowing students to learn about a socio-scientific issue working on a project-based investigation which integrates reflection, collaboration and scaffolding. This work was implemented under the European project "Digital support for Inquiry, Collaboration, and Reflection on Socio-scientific Debates" (CoReflect), the aim of which is to develop and validate a multi-lingual library of web-based, multi-modal inquiry LEs for use in science education.

Theoretical framework

The idea of scaffolding underlies the development of the presented LE. In the study of socio-scientific problems, scaffolding is of core importance (Davis, 1998) since learning is often based on understanding complex data sets which without appropriate scaffolding can become major obstacles for students' understanding. A software-based scaffolding mechanism is embedded in the development of the LE assisting students' reflective inquiry. Reflection is perceived as an ongoing process of students' thinking about and with the data, practiced throughout the learning process. The LE we present provides supports for organizing, analyzing, synthesizing and communicating evidence-based explanations promoting reflective practices. Finally, the software-based scaffolding supports collaborative learning practices specifically synchronous and asynchronous communication among students and between students and teachers. Description of the web-based inquiry LE The web-based inquiry LE consists of two environments: an authoring environment, in which teachers can develop web-based environments for use in the classroom and the students' inquiry environment, in which students collect, explain and organize data communicating their understanding of the socio-scientific issue at hand. The latter is the focus of this presentation. The students' learning environment is composed of (a) the inquiry investigation area, and (b) the reflective WorkSpace area, where students access template pages, articulation and inquiry management tools that help them structure their work. The topic of the LE was Biotechnology and Genetically Modified Organisms (GMOs). It was chosen because it affords authentic inquiries of multi-modal, rich scientific data and problem-based learning. The question driving the design of the LE was whether students would allow the growing of genetically modified plants in their country. Diverse sources of data for and against GMOs were accessible through the LE. The aims of the LE were for students to: (a) understand basic concepts related to Biotechnology and GMOs, (b) evaluate the credibility of evidence by applying specific criteria, (c) provide an evidence-based answer as to whether they would allow the growing of GM plants in their country.

Methodology/Research design

The development of the web-based inquiry LE presented in this ICT demonstration is the result of the collective effort of a LWG in Cyprus consisting of university researchers, teachers, and scientists. Following a design-based approach the LE was first piloted in an 11th grade class ($n=12$) over eleven 90-minute lessons. The LE was then redesigned, refined and re-enacted with a different 11th grade class ($n=21$) over eight 90-minute lessons. Pre- and post-tests were administered in order to assess the effectiveness of the LE. In particular, test items assessed students' conceptual understanding and credibility assessment skills.

Findings

Data from pre- and post-tests were statistically analyzed to evaluate the effectiveness of the intervention. Statistically significant results for both conceptual understanding and credibility assessment skills demonstrated the usefulness of the LE for students' learning, using non-parametric statistics, due to the small number of participants. Of 18 students, 11 had higher scores in the posttest on conceptual understanding ($Mdn=7$) and only 3 had higher scores in the pretest ($Mdn=6$). There were 4 ties. This difference was significant, $Z=-2.24$, $p=.025$, $r=-.52$. Similarly, credibility assessment scores as measured by the open-ended questions for evaluating credibility were significantly higher in the posttest ($Mdn=6$) than the pretest ($Mdn=4$), $Z=-3.63$, $p=.001$, $r=-.85$. Significant differences were also found for credibility assessment skills as measured by the 22-item scale, with $Z=-3.41$, $p=.001$, $r=-.88$. Scores in post test ($Mdn=97.5$) were higher than scores in pretest ($Mdn=86.5$).

Theoretical/educational significance

Teaching science and simultaneously promoting students' interest in scientific issues is a challenge educational systems are currently facing. This work presents an innovative way of meeting this challenge through the use of a web-based, inquiry LE that promotes collaboration, reflection, and scaffolding. The presented LE was found to be beneficial raising students' conceptual understanding and learning skills. Youth attitudes on the importance of scientific and technological issues to society are positive (Sjöberg & Schreiner, 2006) pointing out that the potential for making science attractive and meaningful exists. The step forward, therefore, is for school to become the catalyst for capturing students' interests and addressing their learning needs.

ICT DEMONSTRATION

The Writing-Pal: An Intelligent Tutoring System to Provide Writing Strategy Training

Danielle McNamara, University of Memphis, United States; Rod Roscoe, University of Memphis, United States; G. Tanner Jackson, University of Memphis, United States; Jianmin Dai, University of Memphis, United States; Roxanne Raine, University of Memphis, United States; Russell Brandon, University of Memphis, United States; Jennifer Weston, University of Memphis, United States; Loel Kim, University of Memphis, United States; Arthur Graesser, University of Memphis, United States; Scott Crossley, Georgia State University, United States

The purpose of this ICT demonstration is to provide researchers and educators with information about the Writing-Pal (W-Pal), which is a newly developed intelligent tutoring system that provides writing strategy instruction to high school students and entering college students. This is a ground breaking intelligent tutoring system that will allow educators and researchers to explore the value of writing strategy training on the quality of essay writing. A teacher interface allows the teacher (or experimenter) to create classes, co-manage other classes, monitor students' performance, post bulletins, assign practice essays, create and assign new essays, and make comments on essays. The student interface comprises nine strategy lessons: Prologue, Freewriting, Planning, Introduction Building, Body Building, Conclusion Building, Paraphrasing, Cohesion Building, and Revising. Each lesson includes game based challenges to practice writing strategies. The student also has opportunities to write essays with automated feedback driven by natural language algorithms and instructs the students to focus on 'next steps' and strategies to improve the essay. W-Pal is intended to improve high school students' writing abilities and reduce demands on teachers. Our current work in classroom studies is focused on evaluating the usability, feasibility, and efficacy of W-Pal. We are modifying W-Pal based on feedback from the teachers and students and we are analyzing the efficacy of W-Pal in improving students' writing abilities. We look forward to sharing W-Pal with other researchers and educators and working towards the objective of better understanding how to help students improve their writing skills.

The purpose of this ICT demonstration is to provide researchers and educators with information about the Writing-Pal (W-Pal), which is a newly developed intelligent tutoring system (ITS) that provides writing strategy instruction to high school students and entering college students. W-Pal is easily accessible via the internet. Although W-Pal targets the needs of high school students, who are often required to write short prompt-based essays, the writing strategies that W-Pal teaches are sufficiently general to be applicable for a wide range of students. It is interactive, adaptive, engaging, provides game-based practice, and provides automated, directive feedback on practice essays.

W-Pal consists of both student and teacher interfaces. The teacher interface allows an instructor (or experimenter) to create classes, co-manage other classes, monitor students' performance, post bulletins, assign practice essays, create and assign new essays, and make comments on essays (Figure 1 in the Appendix). The teacher interface also allows the teacher to engage in all of the student activities. The student interface comprises three principle components: Strategy Lessons, Lesson Challenges, and Essay Writing (see Figure 2).

The Strategy Lesson component includes lessons corresponding to three phases of the writing process: Prewriting, Drafting, and Revising. Lesson content is based on English Composition curricula and is designed to provide strategies that will help students to compose a persuasive essay. Although there is an implicit, recommended sequence for these lessons, the students are not obligated to complete them in any particular order and teachers are free to develop their own lesson plans.

The lessons, averaging 20-30 minutes in length, provide strategies that facilitate each phase of writing. Prewriting lessons include (a) Freewriting, and (b) Planning. Drafting lessons include (a) Introduction Building (b) Body Building, and (c) Conclusion Building. Revising lessons include (a) Paraphrasing, (b) Cohesion Building, and (e) overall Revising. In addition, a Prologue module introduces the students to the program. W-Pal lessons are presented by three pedagogical agents, Dr. Julie, a teacher agent, and Sheila and Mike, two student agents. The student agents learn the strategies, engaging in discussions and asking questions about the strategies. Throughout the lessons, students practice the strategies by completing brief exercises (i.e., checkpoints). Checkpoints are brief probes, multiple choice questions, tasks, or mini-games inserted into the lessons that help to maintain student engagement and provide reinforcement of learning through multiple testing opportunities.

The second component is game-based Challenges, which are accessible after the corresponding lesson has been completed. To potentially enhance student engagement, all of the challenges are designed as games (McNamara, Jackson, & Graesser, 2010; references can be found and downloaded at csep.psy.memphis.edu/vita.htm). Many of the challenge practices parallel the structure of one or more of a lesson's corresponding checkpoints. For example, within the Freewriting lesson, students practice freewriting in the context of a game called Freewrite Feud. The goal of this game is to freewrite, generating as many keywords as possible that overlap with the game's nine keywords. Points are awarded for matching keywords and bonus points are awarded based on an algorithm that assesses the quality of the freewrite. There are currently 16 game-based challenges that help students practice the various writing strategies covered in W-Pal, and more are being developed.

The third component of W-Pal is the Essay Writing module, in which students write complete essays and are provided feedback and suggestions to use particular strategies to improve the essays. One unique quality of W-Pal is that it provides feedback to students' natural language input (McNamara, Raine et al., in press). Teachers may choose to assign practice essays for which the students will receive automated feedback, or the teacher may create a new essay assignment within the W-Pal system, which is evaluated by the teacher.

Our motivation to develop W-Pal rests on two underlying assumptions. First, we assume that writing well is important to success academically as well as professionally. Writing skills allow individuals to articulate ideas, argue opinions, and synthesize multiple perspectives. Effective writing is essential to communicating persuasively with others, including teachers, peers, colleagues, co-workers, and the community at large. Second, we assume that strategies facilitate performance on tasks, and that teaching students to use strategies can hasten the acquisition of skills (McNamara, 2009). Strategies have been found to facilitate and enhance performance on a variety of learning-related tasks, which leads to the expectation that the same might be found for writing.

W-Pal was also founded on the successful implementation of the ITS, iSTART, which was developed to teach reading strategies to high school students (McNamara, Levinstein, & Boonthum, 2004). W-Pal modules follow the three heuristics that are used in iSTART (McNamara, O'Reilly, Rowe, Boonthum, & Levinstein, 2007). The first is that to-be-learned information needs to be presented, modeled, and practiced following a faded scaffolding model. The second is that of vicarious learning, whereby the learning process is modeled by animated pedagogical agents. The third is that the modules are interactive, eliciting responses from and holding interactive dialogues with the student. As such, computational algorithms guide the interactions with the students and provide adaptive feedback. These heuristics help to ensure that the system induces self-reflective, generative, and metacognitive learning for students.

Our current work is focused on evaluating the usability, feasibility, and efficacy of W-Pal. We are currently conducting studies in which teachers are using W-Pal in classrooms. We plan to modify W-Pal based on feedback from the teachers and students, and we also anticipate analyzing the efficacy of W-Pal in improving students' writing abilities. Additionally, we look forward to sharing W-Pal with other researchers to further our understanding of writing and how to more effectively improve writing skills.

W-Pal is intended to improve high school students' writing abilities and reduce demands on teachers. This objective contributes to a foundation for a better-prepared youth, as more adept writers have increased aptitude in career and personal success. Also worth noting is that the development of W-Pal's components will certainly have secondary

benefits to a number of other professionals, including teachers, human-computer interaction researchers, gaming designers, education researchers, linguistics scientists, computer scientists, and interface designers.

ICT DEMONSTRATION

Using videos to teach parent-teacher communication skills: The ProfKom learning environment

Martin Gartmeier, Technische Universität München, Germany; Johannes Bauer, TU München, Germany; Manfred Prenzel, TUM School of Education, Germany; Michaela Zupanec, Universität Witten-Herdecke, Germany; Grit Möller, Friedrich-Karls-Universität Kiel, Germany

Despite the important role of parent-teacher communication in teachers' work, the acquisition of respective competencies is currently not part of German teacher education programs. The project ProfKom aims at advancing prospective teachers' communicative competence by means of a blended learning environment which combines e-learning with guided role-play. The e-learning environment adheres to didactical principles and current theories of learning and instruction: As communication is a very practical skill, model based learning is realized through the usage of authentic videos of parent-teacher interviews. Learners comparatively analyse video clips demonstrating professional and inadequate communicative behavior in order to instigate reflection upon mistakes in communication. This comparative approach is based on theories of discriminative learning and negative knowledge. In this ICT demonstration, we present the ProfKom e-learning environment with a special focus on the use of the videos and the described approach of communication training. Moreover, we seek to discuss our conception of communicative competence in parent-teacher communication with the participants.

Communicating effectively with parents is a frequent and important task for teachers. Many parent-teacher conversations may be unproblematic and harmonious. However, teachers also experience difficult situations in the communication with parents: Parents may complain about certain practices of the teacher, teachers may have to deliver bad news to parents or it may simply be difficult to come to a shared understanding of a student's problems at school. For handling such difficult situations professionally, teachers need to acquire communicative competencies (Graham & Clay, 2005). This notion is further underlined by the relationship between parents and teachers being an important part of the educational quality of schools. Communication is a crucial aspect of this relationship, regardless if taking place in parent-teacher conferences or in other situations. Despite their importance, these skills are rarely part of teacher education curricula – at least in German universities. In the proposed ICT-demonstration, we present the virtual learning environment ProfKom. Drawing upon input from the audience, the presenter will demonstrate an instructional sequence realized in ProfKom which consists of instructional videos and video-based reflection. Together with a brief introduction to the theoretical ideas behind our approach as well as the hypothesized model of communicative competence, our aim is to instigate discussion on these issues. The main aim of ProfKom is to advance teachers' skills to communicate with parents concerning three frequent types of communicative situations. These situations include, (a) preparing a joint decision together with parents, (b) delivering bad news about a student, and (c) handling parents' complaints. While the first part of the ProfKom-learning environment imparts knowledge about generic principles of communication, the further parts focus specifically on these situations. All parts of the learning environment aim at fostering competences that concern four key tasks in parent-teacher communication: (i) to take care of the context of the conversation (e.g., concerning spatial, informational and timely aspects); (ii) to appropriately structure different phases of the conversation (e.g. greeting the parents, identifying the parents' interest etc.); (iii) to establish and maintain a positive interpersonal relationship to the parents; (iv) to take care of the problem solving processes and the outcomes of the encounter. The situation-specific parts of the ProfKom learning environment focus upon training students in recognizing and evaluating the application of these competence aspects when watching video clips of communication between teachers and parents (see image). For this purpose, videos are used as an instructional medium in the following way: In a first instructional step, a short video shows a teacher talking to parents and making mistakes in communication. The students watch this video with the purpose of recognizing the mistakes made by the teacher. They are asked (i) to write down the time(s) (of the video) at which the teacher makes a mistake, (ii) to describe the nature of the mistake, (iii) to relate it to one of the four competence facets hypothesized and (iv) to describe the possible effect upon the conversational partner. After having reflected upon the video clip in the described way, the learners watch another video showing the same passage of the conversation, but with the teacher showing good communication. The theoretical rationale behind the described approach is to demonstrate how the hypothesized facets of communicative competence apply in communicative practice by contrastively showing good and bad practice related to the facets. This strategy of video-based instruction applied in ProfKom is based on current theories of learning: Firstly, the theory of negative knowledge (Gartmeier, Bauer, Gruber & Heid, 2008) argues that knowledge about what not to do in a certain situation is valuable for professional practice. This is because an actor being aware of what is wrong in a certain situation is able to recognize the leading signs of certain disadvantageous situations and to purposefully avoid actions which lead to these situations. Because the ProfKom

learning environment realistically shows suboptimal communicative behavior as well as its negative impact on the further course of interpersonal interaction, it fosters the development of practically relevant negative knowledge. Secondly, the basic idea of the concept of discriminative learning (Dodge, 1986) is to model desired behavior and to inhibit undesired behavior by simultaneously or successively presenting respective stimuli. This basic idea of successive discriminative learning is realized in ProfKom by illustrating appropriate communicative behavior after the learner has watched and reflected upon instances of utterly bad communicative behavior. After having passed through the described instructional sequence for several times, the learners watch a video of the full conversation (which was only shown in outtakes before). The teacher shows good communicational practices throughout the whole of this final video clip. In this way, we seek to make use of a further advantage of video based learning – e.g. to allow for realistically modeling complex behavior (Gagne et al., 2003).

ICT DEMONSTRATION

Raising awareness and improving task performance of e-moderators using visualization and machine-learning

Astrid Wichmann, rub, Germany; Bruce McLaren, Carnegie Mellon University, United States; Rupert Wegerif, University of Exeter, United Kingdom; Ulrich Hoppe, University Duisburg Essen, Germany

Moderating e-discussions is a demanding activity. A teacher needs to keep track of the argumentation process in different sessions to be able to provide just-in-time feedback and scaffolding questions. Two studies were conducted to investigate the added value of support features in an e-moderation system. The first study focused on awareness support, whereas the second study investigated the effect of an alerting mechanism to facilitate moderation. Results from both studies showed that teachers who were provided with awareness support and alert support, performed better on tasks as compared to moderating without those types of support. The findings suggest that in order to enable effective e-moderation of multiple parallel e-discussions, teachers need to be supported with respect to awareness and just-in-time information.

Introduction

Supporting the learner during e-discussions has been a major focus in education (cf., e.g., Andriessen, Baker, Suthers, 2003) yet investigating the role of the teacher in e-discussions has not been fully investigated. The role of the teacher in e-discussions is important: On the one hand, a moderator needs to give learners opportunities for self-directed and autonomous learning (e.g., Zimmerman, 2000). On the other hand, a moderator should keep learners on track by asking questions. Findings in the area of tutoring have shown that scaffolding questions are important to engage learners in active knowledge construction (Chi, et al, 2001). Even for a single discussion, e-moderation is a complex task. If teachers need to moderate several e-discussions simultaneously, they quickly lose track and are unable to provide just-in-time feedback because of lacking awareness (Dourish & Bellotti, 1992). For teachers to effectively intervene, additional support is required, in particular, providing content, process, and social behavior information. One research project in this direction is the ARGUNAUT Project which developed and researched a moderation component called the "Moderator's Interface". The Moderator's Interface combines a display of students' graphical arguments with SNA-visualization techniques, machine learning and just-in-time alerts to pre-select relevant information avoiding mental overload. The Moderator's Interface displays actual discussion graphs as they are generated over time by students collaborating in different sessions. In addition, awareness support, alerts and a tool for sending messages are offered. Awareness support displays characteristics of a discussion in terms of content, process, and social aspects. Goal of StudyThe study presented investigates the additional value of awareness support for teachers while moderating several e-discussions simultaneously. Specifically, we compare moderation with a view of the discussion graphs and awareness support (With-Awareness) with moderation using a view of the discussion graphs only (No-Awareness). Study Methodology In a counterbalanced lab study, two teachers were asked to moderate discussions carried out by their students. Each teacher moderated three synchronous e-discussion sessions simultaneously, with 4 students in each session. In the With-Awareness condition, the teacher moderated the discussions using the Moderator's Interface including the discussion graph and awareness support. In the No-

Awareness condition, the moderator could only view the discussion graph; no awareness support was available. Ten tasks were carried out by each teacher during and after moderation for all three sessions, in every condition, resulting in 60 tasks. Findings Study I Results showed that in the With-Awareness condition both teachers performed better on the given tasks (e.g., who is the strongest collaborator in the discussion?) than in the No-Awareness condition. Particularly tasks that cannot be answered through first glance at the Discussion Graph display have been conducted not at all or incorrectly if awareness support was not available. In the No-Awareness condition, several tasks were not conducted at all or incorrectly. For instance, in the With-Awareness condition, the teachers could easily determine strong collaborators, which they were not able to determine in the No-Awareness condition. In a second study, we concentrated on the additional value of machine-learned alerts that were learned from prior discussions and that provide local, just-in time information with respect to students reasoning behavior, for instance, whether the students are on topic and whether they have made reasoned claims. Findings Study II The same study design was deployed but this time with only a single pre-service teacher moderating a discussion with two sessions, each consisting of three students, and with machine-learned indicators also provided to the With-Alert condition (McLaren, Scheuer, & Miksatko, in press). While knowledge-gain and task-performance dependent measures did not vary across conditions, the teacher did spend less time accomplishing tasks in the With-Alert condition. This is important, since quick, real-time moderation is a fundamental goal of ARGUNAUT and just-in-time feedback is necessary to provide effective support for the learner. An additional illuminating observation was that in the With-Alert condition, the teacher initially insisted that students had not engaged in off-topic conversation, even though they had; it was not until the teacher saw the results of the Topic-Focus alert, one of the machine-learned awareness indicators, that he realized off-task conversation had, in fact, occurred. Theoretical and educational significance Taken together, findings suggest that in order to enable effective e-moderation of multiple parallel e-discussions, teachers need to be supported with respect to awareness and just-in-time information. Procedures The authors will present the project itself and the principles behind the ARGUNAUT system. Particularly the role of the teacher in e-discussions and approaches to e-moderation will be presented, with an emphasis on how awareness indicators can support teachers. Subsequently, participants will be invited to explore the ARGUNAUT system. Participants can either take the role of a learner or the role of the moderator using the Moderator's Interface. Finally the challenges of moderating e-discussions will be discussed. Specifically the challenges of moderating multiple discussions at the same time as well as e-moderation styles in general will be emphasized. Technical Aspects At least three computers (running java) and a router and connection to a network are necessary. In the worst case we could bring those with us.

ICT DEMONSTRATION

Study skills and plagiarism: developing on-line learning resources in a multicultural context

Tine Wirenfeldt Jensen, Aarhus University, Denmark; Gina Bay, Library of Social Sciences, Aarhus University, Denmark

In this demonstration we present and discuss two interrelated on-line learning resources aimed at supporting international students at Danish universities in building study skills (the Study Metro) and avoiding plagiarism (Stop plagiarism). We emphasize the necessity of designing online learning resources about these topics which take aesthetic aspects into account in order to create an engaging and supportive learning climate (Biggs, 2007) in which discourse and design strategies are employed to construct the student as "trustworthy" (MacGregor, 1960). Finally we point to the need for and challenges associated with making tacit knowledge about these topics explicit in a multicultural educational context, and we share our experiences with using cross-disciplinary/institutional collaboration as a method to overcome these challenges.

Stop plagiarism and the Study Metro

'Stop plagiarism' is a web tutorial about plagiarism and how to avoid it for international students in Denmark.

[Illustration: Stop plagiarism']

The tutorial consists of several components. The introduction provides a definition of plagiarism and examples of plagiarism. An explanation of why plagiarism is unacceptable is provided, along with information about the consequences students can expect if they do plagiarize. The second section presents the basic tools for ensuring academic integrity by introducing the basic concepts necessary to avoid plagiarism: quotations, in-text citations and summarizing. A quiz allows students to test their knowledge about plagiarism and gives them an idea of how and where they might improve. The tutorial also presents six videos in which experts discuss plagiarism from their particular viewpoints. Finally, the site offers students links to additional resources, and educators are offered suggestions on how to teach and talk about plagiarism.

'Stop plagiarism' is a collaboration between four Danish universities and the Danish Research Library Association's Forum for Library User Education, and the English version is funded by the Conference of Directors of Research Libraries.

The Study Metro is a digital learning resource designed to support international students in building the study skills necessary to succeed in a Danish educational context. The Study Metro is shaped like a subway map with four routes: Standards for Academic Papers, Writing an Academic Paper, Studying and Information Literacy. Each route has several stations with material in the form of texts (including advice, lists and guides), exercises, tasks, links to relevant external material and literature. The metaphor of the subway map provides students with a mind map of the key skills they need to build in order to be able to study at university level and to visualize the interconnectedness of these skills.

[Illustration: The Study Metro]

The Study Metro is designed and run by the Centre for Educational Development, Faculty of Arts, Aarhus University and the material on information literacy is based on the work of Søren Elle (Library for Language, Literature and Culture) and Jette Bohn (Library of Aesthetic Studies), Aarhus University.

The two learning resources described above are intertwined in several ways. The Study Metro situates the 'Stop plagiarism' material in a broader context, showing that the topic is an essential study skill and closely related to other skills such as writing, oral presentation etc., and the designer of the Study Metro shares an educational developer's perspective on the concept of plagiarism in a podcast in 'Stop Plagiarism'. Both learning resources reflect a holistic understanding of the academic learning process which views finding information, handling sources, choosing a topic, formulating a research problem as well as writing techniques as deeply integrated elements of the academic work process.

The importance of creating an engaging and supportive learning environment

When teaching subjects such as plagiarism and study skills, the student can easily be constructed as a cheater and a poor student by discourse that emphasizes rule-breaking or which highlights poor study skills rather than focusing on knowledge building. This view of the student as "untrustworthy" (McGregor, 1960) can be communicated not only through explicit discourse; it can be implicit in the design of learning materials (for example, a list of rules). A learning climate that does not construct the student as trustworthy will not inspire students to want to learn how to become

better students. Therefore both Stopplagiarism and the Study Metro are designed to create an engaging, inviting learning environment where the student is offered the role as a learner who can be trusted to make independent, constructive decisions about how to engage with the learning material.

The need for and challenges associated with teaching study skills and how to avoid plagiarism in a multicultural educational context.

Both learning resources were originally designed for Danish students, and Danish versions of both are available. Both resources received positive feedback, and both tools seemed to fill a gap in available materials. But 75 percent of the feedback was: 'Does this exist in English?' It became clear that there was a need to teach the concepts of study skills and plagiarism in a local academic culture to international students in Denmark. Recent years have seen an apparent increase in the incidence of plagiarism among international students in Denmark, which points to a need to make aspects of Danish academic culture, which is primarily monocultural, more accessible to students from diverse cultural backgrounds. It is a challenge for educators to make such culturally bound expectations and practices explicit, as they exist primarily as tacit knowledge. One means to reaching this goal is for educators from different fields and institutions to work together. Even when they come from the same cultural context, the situation requires them to make expectations, rules and desired behavior explicit for one another, a process which may act as a bridge to making such tacit knowledge explicit for students with a non-Danish cultural background. Part of both the Study Metro and Stop plagiarism were developed in interdisciplinary collaborations between university educators, librarians and others.

Demonstration format

As a part of this demonstration we will use student personas with specific needs connected to completing specific tasks. We also invite the participants to share their own experiences with related learning materials as well as their institution's approach to preventing plagiarism and building study skills in a multicultural educational context.

ICT DEMONSTRATION

Dialogue, Social Media and the New Education Practises

Harri Jurvela, University of Tampere, Finland; Teemu Mikkonen, University of Tampere, Finland; Mikko Vuorinen, University of Tampere, Finland

In the present paper we introduce the interactive conference assistant application which aim is to enrich the interaction and learning in the context of conference and lectures. We have developed a new interaction tool to improve the communication between speakers and audience. The application enables to send questions to the speaker and to make references via Twitter or via our specific web page. The idea is to add some useful properties (like question tags, video stream etc.) to make the social media tools more suitable and more useful to use in the conferences and lectures. We have also designed an ethnographic research setting to test how the chosen social media tools with our additions work in real-life. The research and application development is emphasizing the ideas of dialogue and learning. The dialogic approach in the conference presentations, lectures etc. expands the (possible) learning activity from the one-way communication to the multi-directional communication. This means that the learning situation becomes more active, more open and more respectful. Harri Jurvela harri.jurvela@uta.fi University of Tampere Teemu Mikkonen, teemu.mikkonen@uta.fi University of Tampere Mikko Vuorinen, mikko.vuorinen@uta.fi University of Tampere

Our ICT demonstration is based on the results of CoEx (Communal Activity Supporting Spaces in Sharing Experiences)-research project. The primary objectives in the CoEx -project are to diversify and deepen the conference experiences, increase the interactivity between the participants and the performers, bring the new networking opportunities to the conference participants and to observe the applicable educational potentials in general. In our research and application development we are emphasizing the ideas of dialogue and learning (see e.g. Burbules, 1993; Bakhtin, 1981; Enqvist & Aarnio, 2003). More specifically this means the dialogue and the learning affordances in the conference and lecture context. We think that the dialogic approach in the conference presentations, lectures etc. expands the (possible) learning activity from the one-way communication to the multi-directional communication. This means that the learning situation becomes more active, more open and more respectful. The practical solution that we are suggesting is based on one of the most popular social media tool, Twitter. The idea is to add some useful properties (like question tags, video stream etc.) to make it more suitable and more useful to use in conferences and lectures. We have designed an ethnographic research settings to test how the chosen social media tools with our additions works in real-life. The first experiment was implemented at ITK -conference in April 2010, another one was implemented at MindTrek -conference in October 2010 and the next experiment will be carried out again at ITK# -conference in April 2011. The Conference Assistant Application in MindTrek 2010 In autumn 2010 we've made a conference application to MindTrek 2010# -conference consisting of session based Twitter -hashtag channels, bambuser videostreaming and an application that aggregates and integrates tweets, videostreaming and parts of conversations together. The application can be found in the MindTrek website <http://www.mindtrek.org/2010/coex/>. The main purpose of this conference application was to support the virtual collaboration in the communal activity space (e.g. the physical conference). The main view of the application is illustrated in the following picture (Picture 1.).

Picture 1. MindTrek -conference assistant: the main view. First users see the main view where they can tweet using their Twitter account or using anonymous chatting space in the website (Picture 1 & 2). Users can follow Bambuser video streams from the presentation, panels and competitions and at the same time comment, make questions or give a short summaries about the presentations.

Picture 2. MindTrek Conference Assistant: Following view If a user wants to concentrate to only one presentation, she/he can choose the proper session which opens the session view. In the session view it is possible see more detailed information about the speaker and the present subject. It is also possible to see what questions people have left to the speaker by using proper tag (q:) and what speaker have answered. One extra function is an automatic reference monitor, which gathers the referred topics, comments etc. of the speakers. It helps people inside and outside the conference concentrate to the major issues. Roadmapping to the Conference and Lecture Assistant Application in ITK 2011

Our previous development has been mainly focused on the conference perspective. The next step is to bring in a new version of application, which supports more an everyday lecture use. At the end of the year 2010 and the beginning of the year 2011 we will be testing the settings for the lecture use to develop the user interface further. There has been some positive feedback for using Twitter in educational settings. For example Monica Ranklin has used Twitter to activate students in the class room discussions at the university of Dallas (Ranklin, 2009). By using the virtual communication space people who normally won't dare to ask or comment the presentation, may do it easier. Many educators would agree that large classes set in the auditorium-style classrooms limit teaching options just to lecture and that is not the most effective way to teach. Even so, lots of mass lectures are held, because of the financial matters or small group situations and more active learning methods are not possible to organize. In the proper learning context, it is possible to increase the interactivity of the speaker and audience. This will bring new pedagogical opportunities to achieve more active and open learning practises.

ICT DEMONSTRATION

EuroCAT, a Collaboration Awareness Tool aiming to enhance organisation in collaborative learning act

Margarida Romero, Esade, Spain; Cyril Todeschini, Ouak.net, France; Niki Lambropoulos, London South Bank University, United Kingdom

In long term Computer Supported Collaborative Learning (CSCL) tasks, the students' face organizational difficulties that could hinder the knowledge construction and convergence activity. The reduction of the Group Awareness (GA) cues in the Computer Learning Environments (CLE) is one of the factors that hinders the GA development and the subsequent difficulties to coordinate the group activity in the collective level. Considering these difficulties we analyzed the organisation and collaboration awareness challenges the students face in the context of CSCL and the GA cues that could be introduced in the CLE to foster the organization of the group. Once these concepts are described we introduce the way EuroCAT tool supports the GA in CSCL. We finalize discussing the EuroCAT tool impact in the students' organisational activity.

This ICT Demonstration introduces the Collaboration Awareness Tool EuroCAT developed under the FP7 Marie Curie project Euro-CAT-CSCL. For this objective, we start introducing the organisation and collaboration awareness challenges the students face in the context of CSCL. Then we introduce the concept of Group Awareness (GA) in the context of long term CSCL tasks and design a Collaboration Awareness Tool (EuroCAT) to support group awareness in CSCL. EuroCAT includes organizational awareness cues by displaying the progressions on the subtasks and the group responsibilities. It also supports implicit peer evaluation in a dynamic and constantly updated environment. The EuroCAT tool is discussed at the end considering its impact on the overall organizational activity.

1. Students' organisation in CSCL

When engaging in CSCL activities some negative results show low participation rates and performances and/or varying degrees of disappointing collaboration that can lead to social and learning difficulties (Lakkala et al., 2000; Kreijns et al., 2002; Kirschner, 2009). Examples of such difficulties are the different time zones of cooperation, collaboration awareness, interaction difficulties (Sproull & Kiesler, 1991), time tracking and coordination (Lakkala et al, 2000; Dillenbourg, 2002). Such difficulties have an effect on communication and interaction patterns (Liu & Tsai, 2008) as they create problems on sharing roles in tasks and tools (Bourguin & Derycke, 2000). We consider GA as a common factor in several organizational difficulties in distance CSCL situations.

2. Group Awareness in long term CSCL tasks

Awareness is the understanding of the activities of others, which provides a context for own activity (Dourish & Bly, 1992). GA is essential for collaboration as it allows peers to understand their team-mates' intention and so coordinate their own task coordination within the group activity (Kalika, Boukef & Isaac, 2007).

In CSCL, group awareness considers the intersubjective perception of the way students have to collaborate: task distribution, roles, turn taking rules, work phases, deliverables, etc. The aim is to coordinate the individuals' as well as the group's activities in order to achieve convergence (Lambropoulos, 2010). In distance CSCL situations, the students' organizational difficulties are augmented by the low level of group awareness cues reflected in the CLE. Trying to compensate the lack of group awareness cues, Buder and Bodemar (2008) considers augmenting collaboration GA by increasing the CLE reflective properties. Such GA Tools provide contextual cues in their construction of a situation (Bazerman et al. 2000), by informing learners with respect to what their group thinks. In this way collaboration awareness is increased and in turn, participation and group engagement. According to McCarthy and Garavan (2008), enhancing GA supports group coordination and facilitates learning activities regulation.

3. Impact of collaboration group awareness in learners' organisation

GA is enhanced by the CLE mirroring capabilities (Soller et al., 2005). The CLE awareness cues can facilitate collaboration even before collaboration starts. Structuring and mirroring can create favourable conditions for learning by designing. For example, structuring approaches aim to create favourable conditions for learning by designing or scripting the situation even before the interaction begins (Dillenbourg, 2002). Mirroring and structuring not only facilitate proactiveness in activities organisation but also support meta-activities organisation based on reflection and self- and group- regulation. System regulation functionalities support collaboration by taking actions and support a pattern of collective arrangement once the interaction has begun (Soller et al., 2005; Tchounikine, 2008). In this way group self organisation and organic guidance is enhanced.

4. EuroCAT, a Collaboration Awareness Tool

A few CSCL systems have been employed to support collaboration and GA. They mostly targeted on internal group feedback (Kimmerle & Cress, 2008); for example, Janssen et al. (2007) uses the augmented GA tool Shared Space for feeding back information about cognitive and social variables in a group. Buder and Bodemar, (2008) focus on conflicting information in a group based on explicit ratings from learners. Within the European context IntelLEO (Devedzic et al., 2010) is a tool to support collaboration GA; the pedagogical experts define activities and processes that take these factors into account and equally consider individual as well as the organisational needs.

Considering the learners' needs in CSCL long term task, the Collaboration Awareness Tool EuroCAT has been designed to enhance the development of the organization GA in order to facilitate the students' organization in the CSCL task. Integrating different information visualisation and communication tools, EuroCAT supports sharing the specific learning objectives and shared activities described by the tutors, their sequencing as well as role distribution, peer evaluation. EuroCAT supports the organisation of task- and sub-task related information by displaying the progressions on the subtasks and group responsibilities. It also supports the peer evaluation process in a dynamic and constantly updated environment. As for monitoring group progression and effectiveness, EuroCAT is anchored on peer's performance ratings on all three social, cognitive and team activities to support self- and group- regulation. The main EuroCAT screen allows all three types of activities to be coordinated with an automatic display of team-members' availabilities and synchronous time. The relational social interactions within the team by subjective ratings of team-members' tasks and team skills. Learning objectives displayed on EuroCAT provide an overview toward the 'correct' direction of the learning tasks and activities. The tool can increase the GA by supporting the group coordination via collaboration and organisational awareness. EuroCAT functionalities support the overall collaboration convergence in small group activities by offering a support for collective planning and time regulation, by displaying and monitoring group activities.

The impact of the Collaboration Awareness Tool EuroCAT tool is currently studied in the context of 5 European countries involving more than 1100 students in authentic collaborative learning tasks. The first results of the impact of the EuroCAT will be analyzed in the forthcoming months.

Authors note: We acknowledge financial support from the Marie Curie People IAPP program within the EC. FP7, under the Euro-CAT-CSCL project (contract 218306).

ICT DEMONSTRATION

How an eTeaching-Portfolio Supports Development as Teacher in Higher Education

Marianne Merkt, Centre for Higher and Further Education, Germany

The Centre for Higher Education at the University of Hamburg offers a two years study programme called "Master of Higher Education" to improve academic teaching quality. Since 2009 an eTeaching-Portfolio concept is implemented to enable participants to document their ongoing individual development as university teacher. The web-environment includes learning diaries structured as blogs, the drop-box - a folder for related documents - and textboxes. Programme participants are introduced to the eTeaching-Portfolio concept at the very beginning of the master-programme. The portfolio work is supported by peer groups, tutors and teacher feedback throughout the whole study programme and will lead to the master thesis.

A longitudinal research project accompanies eight participants of the Master of Higher Education over two years and explores their development as university teachers. Participants are interviewed, their teaching practice is observed and eTeaching-Portfolios are documented at different stages. Next to areas of development in teaching practice participants' beliefs about teaching and learning in higher education are under investigation. First outcomes indicate that teachers need to become aware of and altercate with different aspects regarding their teaching in order to develop. The eTeaching-Portfolio stimulates this growing awareness and reflection. Consequently we regard the eTeaching-Portfolio-concept a highly valuable method in fostering development in teaching individually, which leads to an improved teaching quality in higher education. Furthermore a fruitful transfer of the ePortfolio concept into other disciplinary fields is expected.

We would like to present an eTeaching-Portfolio concept supporting growth as university teacher individually. It is imbedded into the curriculum of a Masters programme for academic teaching development offered by the Centre for Higher Education at the University of Hamburg. The syllabus consists of four modules: planning teaching and learning processes, leading and managing communication and group processes, methods of teaching and learning and handling e-learning and digital media. Interdisciplinary exchange, a hands-on practical course and practical peer-reviews are important features of the master-programme.

Since 2009 a teaching portfolio concept supported by an electronic portfolio environment (Jafari & Kaufman, 2006) is implemented. The platform gives the possibility to create a variation of layouts by integrating different multimedia and internet formats like audio files, pictures, films or blog postings. It supports the exchange and feedback processes on individual chosen parts of an individual e-portfolio by "view" features. It enables peer group work by an integrated group and message system (Merkt, 2009).

Starting their study programme with a kick-off workshop the participants are introduced to the e-teaching portfolio work. Based on theoretical and practical input on e-teaching portfolio work they work out their own criteria of portfolio work as guidelines for their further studies. They get a guided instruction to different structures within the portfolio environment. The first element are learning diaries structured as blogs. Participants are recommended to blog about theories and literature they read as well as their teaching and its development. The second element called "drop box" is a folder to collect relevant documents, such as innovative didactical concepts, evaluation questionnaires and results, observation reports, theoretical elaborations on teaching and learning or PodCasts of performed teaching. The third element are text boxes holding participants' biography and documents reflecting different aspects of being an academic teacher, such as personal educational philosophy and concept of science, concept of students' learning processes, ones image of man (=learners), description of ones teaching and managing personality, a repertoire of adequate teaching and learning methods, didactical concepts, documented teaching practice and aims of further development, description of an individual quality concept and considerations of the university as teaching context. As master thesis participants submit an individual teaching portfolio with scientific background (Merkt, 2009).

The eTeaching-Portfolios is embedded into the hands on practical course, which runs alongside the whole study programme. The course offers time slots for writing on the portfolio and for receiving advice and feedback from peers and teachers. During the kick-off workshop also peer groups are build. These groups aim at supporting participants in their portfolio work through feedback, exchange of ideas and social support. In the long run they also aim at creating communities of teaching in which participants get to know significant others who support their development in teaching after completing the programme (Boud & Middleton, 2003; Roxå & Mårtensson, 2009; Warhurst, 2006). Furthermore tutors are available to give advice and technical support.

A longitudinal research project accompanies eight participants of the Master of Higher Education over two years and explores how they develop as university teachers during the programme. Participants are interviewed, their teaching practice is observed and their eTeaching-Portfolios are documented at different stages.

Next to areas of development in teaching practice participants' beliefs about academic teaching and learning are under investigation. First outcomes indicate that teachers need to become aware of and altercate with different aspects of their teaching in order to develop. The eTeaching-Portfolio stimulates this growing awareness and reflection. First outcomes indicate that teachers need to become aware of different aspects regarding their teaching in order to develop. They need to become aware and reflect on their beliefs concerning these areas in order to professionalize as teachers in higher education. The eTeaching-Portfolio stimulates this growing awareness and reflection. Establishing a habit of reflection is also seen as necessary condition for lifelong improvement of professional practice (Schßn, 1983).

Additionally we believe that development as academic teacher is a highly individualized process depending on the personality of the teacher, the subject, the discipline and its scientific culture, context conditions of teaching, the target group of learners and others. Therefore it can only be fostered and later assessed in a highly individualized manner. The eTeaching-Portfolio-concept can manage both, which makes it a highly valuable method contributing to the improvement of teaching quality in higher education. Apart from that we assume portfolios a helpful tool to stimulate professionalization processes in more than the teaching profession. And we consider the e-environment with its web 2.0 characteristics attractive for the current generation of students.

In our ICT demonstration we would like to share our experience with:

- the integration of the eTeaching-Portfolio into an existing curriculum,
- designing assignments which support participants in developing their own structure rather than passively using an existing one which may lead to defensive reflection,
- developing a support-structure of teachers, tutors and peer students and
- different e-environments.

Also we want to discuss with participants changes and pitfalls of our concept and possible transfer into other disciplinary fields.

WORKSHOP

Didactic Sequences (DS): a socioconstructivist model for literature education at secondary school

Xavier Fontich, UAB - Universitat Autònoma de Barcelona, Spain

In this work we present three experiences of literature education carried out in secondary school classrooms (15-16 years old) in Barcelona. The experiences focus on the compulsory novels and poems of the curriculum and search to broaden students' interpretative repertoire. The model adopted is that of Didactic Sequence (DS). It helps the teacher to create a dynamic, collaborative and rich context and to define explicitly the objectives, the content and how to solve the tasks. It overcomes a purely transmissive vision of literature education and promotes an active and constructive role of the students, which are meant to write, to talk, to interact, to explain the project, to observe models, etc. in order to assimilate the key elements of the literature interpretation. The model of DS organizes activities in three phases. Phase 1 is focused on reading the text collaboratively while establishing a frame of joint interpretation; in this phase the teacher proposes the goals of the DS and the written task. In Phase 2 the task is solved through the joint action and the teacher scaffolds the writing process. Phase 3 promotes a metacognitive activity, with a written final report and a formal oral exposition about the experience carried out. All along the experience the students describe the activities and give their opinion on the whole project both in their learning log and in a blog. The results show that such a way of working increases not only students' interpretative repertoire but also their motivation to study literature.

In this work we present three experiences of literature education carried out in secondary school classrooms (15-16 years old) in Barcelona in 2009 and 2010. The experiences focus on the compulsory texts of the curricula and search to broaden students' interpretative repertoire. A teacher attempts to create a rich context through collaborative settings in which students talk, read and write to assimilate the key elements of the literature interpretation (Mercer, 2008; Chambers, 2003; Colomer, 2005). He integrates in this process the use of ICT (PC projector, blog and video) as instruments of metacognitive reflection. However research explores the important potential of ICT to modify educational practices some studies highlight the fact that ICT do not guarantee by themselves a significant learning (Mercer & Littleton, 2007). According to Coll (2008), a basic condition should be the teacher's action, guided by socioconstructivist models. The model adopted in the experiences that we will describe here is that of Didactic Sequence (DS) (Camps, 2003; Bordons & Ferrer, 2009). This model overcomes a purely transmissive vision of literature education and promotes an active and constructive role of the students. It is inspired in the project work tradition and is influenced by different disciplines and theories such as sociocultural psychology, theory of the activity-CHAT, cognitive psychology, action-research perspectives and research on literature didactics. The model of DS organizes activities in three phases. Phase 1 is focused on reading the text (partially in the classroom and at home) and discussing and sharing opinions on difficult issues, in which the students are guided and in which a frame of joint interpretation is progressively established. In this phase the teacher proposes the goals of the DS and the task; it is an initial and dynamic phase, with preponderance of oral interaction. In Phase 2 the task is solved through the joint action, it is a synoptic phase with preponderance of written activity. The teacher models the writing process with a PC projector and a "thinking aloud" protocol. Phase 3 promotes a metacognitive activity, with a written final report that will be published in a blog, a formal oral exposition and the elaboration of a video about the experience carried out. All along the experience the students describe the activities and give their opinion on the whole project both in their learning log and in the blog.

Next, we describe three examples of DS.

Didactic Sequence 1. In Phase 1 the students and the teacher altogether read Fred Uhlman's *Reunion*. They work the literature topic of the war, exploring fiction and non-fiction texts of different length, difficulty and genre (novel, study, report, biography and comic). Each one takes one of these perspectives on the topic: the concentration camps, the roots of the conflict and the survivors. In Phase 2 the students have to solve a specific task: an interview to a character. Different aspects of the interview are worked and the teacher writes his own interview "live" through a "thinking aloud protocol" and the use of a PC projector. In Phase 3 the texts are published in a blog: <http://demicaenmicasomplelapica.blogspot.com/>.

Didactic Sequence 2. In Phase 1 students read the novel *Cold skin* by A. S. Pióol and see a movie based on D. Trumbo's novel *Johnny got his gun*. In Phase 2 they work on symbolic and narrative aspects of both the novel and the movie. In Phase 3 the results of the work are published in a blog (www.quart20092010.blogspot.com). Students also go to the Universitat Autònoma de Barcelona to present the work carried out to students of the Faculty of Education, who are

currently studying Literature Education. Finally the students take part in a 20 minutes video report in which they explain the experience: http://mickey2.uab.es/CR-APED/Produccions_SAE/temporals/versio-anglesa.wmv.

Didactic Sequence 3. In Phase 1 a romantic poem is read, *La pàtria* (The homeland) (1833) by B. C. Aribau, and the students have to work on the references to the History of the Catalan Literature since the Middle Ages. In Phase 2 the teacher proposes a task: the information gathered has to be adapted for 5th graders (9-10 years old). This makes students transform the knowledge in accordance with the addressee and it leads them to higher understanding of some of the notions of the History of Literature studied. This also makes them aware of the complexity of written composition. In Phase 3 an oral exposition for the 5th graders is made and the students explain the experience in a 7 minutes video:

http://mickey2.uab.es/CR-APED/Produccions_SAE/temporals/historia-anglesa.wmv.

In these three experiences we can observe a new way of getting the students involved while studying literature, beyond a transmissive setting. Students are meant to write, to talk, to interact, to explain the project, to observe models, etc. The model of DS has helped the teacher to create this dynamic context and to define explicitly the objectives, the content and how to solve the tasks. Regarding the use of ICT, we think that it has helped to create these significant contexts of learning and it has promoted the metacognitive reflection of the students. Several authors defend such a role for the ICT (Zayas, 2008; Hernández Ramos, 2005; Ferreiro, 2007). The PC projector has been useful to observe the process of modeling by an expert writer (the teacher) and to contrast it with their own practices. The blog has been useful to publish the texts elaborated by the students and to write their learning log, as well as to communicate with the University students. Finally, the video has promoted a global metacognitive reflection on the sequence carried out: the students work in groups and describe the experience, and it also helps to share it with other students (of the same school and of the University). The experiences we have described integrate oral interaction, writing, reading and use of ICT for the literature education as well as increases students' motivation (Bergen, 1999).

THEMATIC POSTER

New Modes of Assessment

Competence Assessment programme as an instrument for self-evaluation

Asha Dijkstra, Avans University of applied science, Netherlands; Han Blankert, Avans Unveristy of Applied Science, Netherlands; Liesbeth Baartman, Eindhoven University of Technology, Netherlands

Self-evaluation has become a topic of debate in the Netherlands since vocational institutions have to demonstrate the quality of their assessments to an external quality board in order to retain their accreditation. In 2011, a new accreditation system for Bachelor and Master education will implemented in the Netherlands and Belgium. In this new system, assessment is no longer a subcategory but become one of the main subjects besides program and goals. Institutions for higher education have to thoroughly prepare themselves for this accreditation and collect evidence to demonstrate assessment quality. In this poster, we discuss if self-evaluation is a way to do this. However, the trustworthiness of self-evaluations is highly debated, for example showing differences between the outcomes of self-evaluations and external evaluations. Therefore, an online self-evaluation method for assessment quality was developed, to prepare institutions for their external accreditation. This study compares the self-evaluations of five faculties of a University of Applied Sciences to the outcomes of their external accreditation. Research questions are: (1) in what way can self-evaluation prepare institutions for the external evaluation of assessment quality, (2) are there any differences between the outcomes of the self-evaluation and the external evaluation?

Self-evaluations will be carried out in Spring 2011. Participants are 7 teachers, 5 students and 2 coordinators per faculty. Evaluation is based on 12 quality criteria and quantitative ratings and qualitative examples are collected. Better self-evaluations – in terms of collected evidence - are expected to better prepare for external evaluation.

Theory and aims

Higher vocational education is undergoing fundamental changes in many European countries. In the Netherlands, new qualification structures for vocational education have been developed which are based on competences and work-related experiences. The rationale behind this innovations is to better link educational programs to job requirements (Tillema, Kessels, & Meijers, 2000).

Also, the role of assessment is becoming more and more important since vocational institutions have to demonstrate the quality of their assessments to an external quality board in order to retain their accreditation. In the new accreditation system (2011) for Bachelor and Master education in the Netherlands and Belgium, assessment is no longer a subcategory but one of the main criteria besides program and goals. Institutions have to thoroughly prepare for this accreditation by collecting evidence to demonstrate assessment quality. One way to do this is self-evaluation. Thus, self-evaluation is used as a preparation for external evaluation (McNamara & O'Hara, 2005).

However, the trustworthiness of self-evaluations is highly debated. It is questionable whether self-evaluation can be used for internal improvement and external accountability at the same time (Vanhoof & Petegem, 2007). Also, self-report studies have been criticised for showing only reported behaviour, instead of actual behaviour (Falchikov & Boud, 1989). Therefore, this study focuses on the merits of self-evaluation as a preparation for external evaluation and accreditation. Research questions are: (1) in what way can self-evaluation prepare institutions for the external evaluation of assessment quality, (2) are there any differences between the outcomes of the self-evaluation and the external evaluation?

A self-evaluation method was developed, based on earlier work (Baartman et al., 2007), which helps institutions to evaluate online the quality of their Competence Assessment Programme (CAP). The focus is on CAPs – combinations of both traditional and new assessment methods – because single assessment are seldom used and not fit to assess competence (Baartman et al., 2007).

Data and methods

Participants

This study will be carried out at a large University of Professional Education in the Netherlands, a type of higher vocational education. In Spring, when the new accreditation system has been implemented, five faculties will carry out a self-evaluation of the quality of their CAP: In each faculty, the evaluators are 7 teachers, 5 students and 2 coordinators. They are selected on their familiarity with the CAP and provide input from different perspectives.

Self-Evaluation Method

The self-evaluation uses 12 quality criteria including ideas of validity and reliability, complemented by criteria deemed important in competence-based education specifically, for example authenticity, meaningfulness and self-regulated learning. A self-evaluation method was chosen it is assumed to stimulate reflection and internal school improvement (McNamara & O'Hara, 2005). The self-evaluation consisted of three phases. First, the evaluators receive a short training on the 12 quality criteria and the CAP to be evaluated was defined. Second, all evaluators rate their CAP on a numerical scale. For each criterion, they are asked to provide evidence of the quality of their CAP. This evidence is considered important for the external evaluation, as it can be used to demonstrate assessment quality. Third, all individual evaluations are collected and summarised by the researchers in a short powerpoint-presentation, to be discussed in a two-hour group interview. The goal of the group interview is twofold: formulate concrete points for improvement (school improvement) and review the available evidence for external evaluation (accreditation).

Questionnaire

All evaluators are asked to fill out a questionnaire on the usefulness of the self-evaluation for external accreditation. This will be done twice: immediately after the self-evaluation, and after the external accreditation has been carried out.

Data analyses

To answer the first research question, group interviews will be recorded. The evidence collected in the self-evaluation will be summarised in a data display, and compared across cases (Miles & Huberman, 2003). Analyses of the quality of the evidence will be based on previous research (Baartman et al., 2007). For the second research question, we will compare all self-evaluation reports with the external accreditation reports

Anticipated results

We expect the self-evaluation to better prepare the faculties for external evaluation, as suggested by the literature (Nevo, 2001; McNamara & O'Hara, 2005). The more and better evidence is collected during the self-evaluation, the better we expect the faculties to be able to demonstrate assessment quality during the accreditation. With regard to the differences between the self-evaluations and the external evaluations, we expect small differences, as the faculties know the self-evaluation is meant to prepare for the accreditation, so a realistic picture of assessment quality is most valuable.

A method to assess the modifications of mathematics pre-service teachers in their learning portfolio

Jose Chamoso, Facultad de Educacion, Spain; Maria Jose Caceres, Universidad de Salamanca, Spain; Pilar Azcarate, Universidad de Cadiz, Spain

During the last few years, many changes have taken place not only regarding learning but also teaching. To foster this change, the training of mathematics teachers should involve pre-service teachers in a variety of interesting activities. Reflection about how to solve situations and problems linked to their future educational practice is what allows ideas and forms of understanding Mathematics Education to be put into practice. This means that assessment needs to involve using a selection of instruments that provide evidence about learning. Portfolio can include several of these aspects. In this study we focus on the use of the learning portfolio. There has been little systematic attention given to the ways in which the learning portfolio it is being used in teacher-training classrooms. Our work has focused

specifically on how pre-service teachers reconstruct the initial ideas they set out in a project that was included in their learning portfolio at the beginning of their teacher-education program and based on the instruction received during this program. This system was used in the studies within a university teacher-education program. The project consisted of designing a lesson plan for teaching mathematical knowledge taking into account Content, Activities, Methodology and Reflection. The outcomes showed significant differences in the revisions carried out in all categories except Activities. The training received during the teacher-education program had limited influence on these four categories.

Theoretical framework

Reflection on teaching practice is one of the main objectives of teachers' professional work. Much has been written about the importance of reflective practice, scarce attention has been given to the reflective process which future teachers have to experience in making a learning portfolio (Tillema, 1998). However, there are hardly any empirical studies about the use of reflective thinking when pre-service teachers try to improve their own work as a result of the training developed in the teacher-education program.

In the last few years, the use of portfolios has become commonplace internationally in teacher education for different purposes (e.g. Farr Darling, 2001). Although great expectations have been placed on the use of the portfolio, research studies on the efficiency of the instrument have been few and far between (Imhof & Picard, 2009). We need to learn more about the nature and quality of reflection that emerges under different conditions of portfolio use (Zeichner & Wray, 2001). Empirical research is still needed to determine what effect portfolios have made on pre-service teachers' individual thinking (Wade & Yarbrough, 1996). Concretely, Xu (2003) recommended extending the use of portfolios during the pre-service years to promote teachers' future professional development.

This study was set within the context of a proposal for innovation that linked a teaching-learning process with an assessment process that included the construction of a learning portfolio. In this context, the main specific research question was: What kind of changes did pre-service teachers of primary mathematics make in one of the projects included in their learning portfolios after receiving instruction in the university teacher-education program?

Method

30 pre-service teachers, at one Faculty of Education of Spain, took part in the experiment. The instruments used for the collection of the data were the papers referred to the following project that the pre-service teachers included in their learning portfolio. At the beginning of the course the contents of the syllabus were distributed among the pre-service teachers and they were given a week to design individually how to teach them at the primary level (IP), taking into account: (a) Content, (b) Activities, (c) Methodology, and (d) Reflection. At the end of the module each pre-service teacher revised his/her own work based on the training received during the module (FP). To evaluate the process, we considered the following:

1. The differences in the assessment of each pre-service teacher's IP and FP overall and in each of the categories Content, Activities, Methodology and Reflection.
2. The modifications made in the FP with respect to the IP of each pre-service teacher, analysing both the level of depth and the aspects to which they refer in their work.

To evaluate the work carried out, we established three general levels for classifying each pre-service teacher's degree of learning: participation in the process as a spectator, active participation in the process, and, involvement in the process by taking his/her own decisions. These general criteria were adapted to evaluate each of the elements identified in the project in question in the four categories above mentioned. An assessment template was drawn up for each of them.

The first step in analysing the work of each pre-service teacher was to identify complete units of information. Next, the corresponding assessment was applied to the work of each pre-service teacher. The results for each aspect were collected in tables in which each section 1, 2 or 3 reflected the amount of complete information units of each pre-service teacher. The sum of the outcomes of each pre-service teacher multiplied, respectively, by the factor of the corresponding category and, the final outcome, divided by the sum of all the complete information units, was considered the score in each of the aspects considered.

Secondly, to study the depth of the modifications made in the FP, we established the following 5 levels according to the reflection process each pre-service teacher made in each case in order to improve their IP: The IP was completely revised, the IP was completely reorganized and perhaps some things were added, only some parts of the IP were reorganized or modified, new knowledge was added without modifying or reorganizing the IP, the IP was not modified.

For the analysis of the quantitative data, related samples t-test and Pearson's chi-square test were used.

4. Results

In the first place, a related samples t-test showed that the overall assessment of each pre-service teacher considering the 4 categories increased significantly in the FP after revision of the IP as a result of the reflection carried out owing to the training received [$t(29)=5.820$, $p<.001$]. Content, Activities, Methodology and Reflection, related samples t-test showed significant differences between the scores obtained by the pre-service teachers in the IP and FP in all the categories except Activities.

Secondly, the number of pre-service teachers who made a completely new FP in all the categories was greater than the number who made another type of modification except in the case of Activities. Most of the pre-service teachers improved their score in the FP with respect to the IP in all the categories except Content and Activities, where 4 (13% of the total) and 6 (20% of the total) pre-service teachers obtained a lower score in the FP, 3 of whom coincided in both cases. Then, based on the analysis of the pre-service teachers' work, we compared the aspects of the knowledge to which they referred both in the IP and the FP.

Conclusions

This study allows us to conclude on the effect that continuous revisions of their work can have on future teachers' ideas and on personal reflections development on the decisions taken. On the other hand, this study provides a method to assess the work of pre-service teachers and the modifications they make in their written reports that could be used in future research. This method can also be helpful to teacher educators working both in the context of teacher training and in lifelong professional education.

Gender Analysis of Czech General Reasoning Tests

Jiri Dvorak, SCIO, Czech Republic; Denisa Denglerova, SCIO, Czech Republic; Petr Gilar, SCIO, Czech Republic

This article is focused on the gender analysis of Czech General Reasoning (CGR) tests. Tests similar to the other reasoning tests like tests of GRE, SAT, Cambridge Assessment and other. Using such tests suggests a question whether there are any measureable differences between reasoning of males and females. And more specifically, whether the tests themselves respect such differences and in this sense of meaning provides a fair measurement. We have analyzed more than 3400 items and every item was answered by a few hundred to a few thousand highly motivated persons. The analysis shows interesting differences between responses of males and females. And moreover offers a good base to other research and future test makers.

This article is focused on the gender analysis of Czech General Reasoning (CGR) tests. In the Czech republic there is a system of so-called Comparative Exams organized every school year. A main part of these exams are General Reasoning tests similar to the other reasoning tests like tests of GRE, SAT, Cambridge Assessment and other. Using such tests suggests a question whether there are any measureable differences between reasoning of males and females. And more specifically, whether the tests themselves respect such differences and in this sense of meaning provides a fair measurement. Thank to the number of persons performing CGR test each year and the number of test items used we have a good base to answer these questions. An essential precondition of this kind of research is an appropriate data base. We have analyzed more than 3400 items (two tests every testing day, 17 testing days in three years). Every item was answered by a few hundred to a few thousand persons. Persons were highly motivated because results of CGR test are recognized as the entrance exams by many Czech universities. Because of the number of various Czech universities recognizing CGR tests and the number of persons performing the tests we assume that the sets of males and females answering items of the test is a random sample. Therefore we could make general conclusions required by the research questions we have asked. Similarly we are assuming that the large set of various items is also random enough to avoid the influence of items answered better by either males or females because of reasons other than a reasoning of a person (for example because of a vocabulary used in an item). The method of analysis had to follow some particular characteristics of CGR tests. Items in the CGR tests are multiple-choice items organized into nine groups of similar items. Therefore we have decided to make an analysis for each group of items separately. A three types of answer are recognized: correct answer, incorrect answer and no answer. Incorrect answers are evaluated as a worse results than no answers, so people are motivated to rather not answer at all if they are unsure about the correctness of their answer. To respect this characteristics of CGR we are computing four variables for each item (separately for males and females): the rate of correct responses to the total number of possible responses (V1), the rate of incorrect responses to the total number of possible responses (V2), the rate of no responses to the total number of possible responses (V3) and finally the rate of correct responses to the number of responses (ie total number of possible responses minus number of no responses) (V4). After that the average rates are computed within various groups of items: groups of similar items (as mentioned before) within each test, groups of

similar items within each test day, groups of similar items within each year and finally groups of similar items overall. Performed analysis brings a couple of interesting results. We have discovered significant differences between responses of males and females to the particular groups of items. Moreover we have discovered that the difference between reasoning of males and females is more clearly seen on the variables V3 and V4 than on the other two rates. For example in some item groups items are left unanswered by males significantly less than by females, but in some groups items are answered by females as much as by males. There is also one group answered by females more than males, but the difference is quite small. An analysis of the variable V4 says that there is no significant difference in reasoning between males and females. Once a person decided to answer an item the probability of correct response is almost the same regardless of gender. Results of the analysis brings on a couple of important conclusions. At first the main difference between males and females in reasoning tests is made by the unanswered items not by the items answered correctly or incorrectly. The second conclusion is very important for the test makers: there are big differences in responses to items even if the items are very similar. In particular: inappropriate setting of an item could dramatically influence the rate of not answering by either males or females and therefore influence the success of either group. This result of the analysis makes a good basement for making a fair tests which will avoid unintentional influence of external factors (ie factors we do not want to measure).The presented also analysis opens some interesting new directions of future research. Especially we should identify and describe items which make inappropriate difference between males and females. Also the analysis itself could be improved by checking up claimed assumptions, especially the assumption of random samples.

A cross-national comparative study on reading achievements:data from PIRLS2006

Jen Jang Sheu, Center of Teacher Education, Taiwan, Province of China

The aim of this study is to progress a cross-national comparative study on the relations among reading abilities, reading attitudes, and reading achievement, based on the published results from Progress in International Reading Literacy Study (PIRLS 2006) by the Association for the Evaluation of Educational Achievement (IEA). Subjects selected in this study are Russia, Hong Kong, Canada (Alberta), Singapore, the top four countries of the reading achievement in PIRL 2006, and Taiwan, which ranked 22nd. Hierarchical Linear Modelling will be applied to the modelling building process with level-1 being students' attributions (including reading abilities, reading attitudes, and students' gender) and level-2 being ways of teaching strategies adopted in the top four countries and Taiwan to examine the different efficacy in reading instruction. Research findings in this study can be offered to the domestic educational authorities, schools and practicing teachers in each countries in reading instruction as reference resources to improve and adjust their teaching strategies to help lifting students' reading literacy, then consequentially national competitiveness can be enhanced.

The aim of this study is to progress a cross-national comparative study on the relations among reading abilities, reading attitudes, and reading achievement, based on the published results from Progress in International Reading Literacy Study (PIRLS 2006) by the Association for the Evaluation of Educational Achievement (IEA). There were 45 countries and area as benchmark participated in the study of PIRLS 2006, Subjects selected in this study are Russia(students' average score 565), Hong Kong(students' average score 564), Canada (Alberta) (students' average score 560), Singapore(students' average score 558), the top four countries of the reading achievement in PIRL 2006, and Taiwan(students' average score 535), first time to join in PIRLS study, which ranked 22nd. Hierarchical Linear Modeling, the second generation statistical tool, with high efficiency for the contextual data, will be applied to the modeling building process. There level-1 in the research framework being students' attributions (including reading abilities, reading attitudes), students' reading achievements as the outcome variable, reading abilities and reading attitudes as predictors, students' gender as the moderator. Level-2 being ways of teaching strategies as predictors adopted in the top four countries and Taiwan to examine the different efficacy in reading instruction(including direct understand process and explanatory process in students' reading comprehension). Another important reason to use Hierarchical Linear Modelling method in this study is because when PIRLS reported each country's students' reading achievements, there included five plausible values which were gained by an imputation procedure, and Hierarchical Linear Modelling can get standardized estimated error form these five plausible value directly.

The research framework was defined as follows (Insert fig 1 here)Two research questions will be explored:

1. How do students' reading ability, reading attitude and teachers' teaching strategy affect the reading achievements on fourth graders in each country? Do they have between-school differences?
2. What are the differences among these countries on the above issues.

According to the research questions, we will use HLM 6.08 software to analysis the data given, and starting with the null model whether there is cross schools difference in each country, then exploring the effect when add students' reading abilities and reading attitudes as predictors (including fixed effect and random effect), after that teachers'

teaching strategies will be added as predictor to see what kind of effects will appear. Reside, the gender variable as moderator and there interaction will be discussed too. When make the cross-national comparison steps, the adjusted class mean should be considered, there will be four models to be processed step by step:

Model 1: one-way ANOVA with random effects The aim of model 1 is to test if there are between-group and within-group variation in students' reading achievements, because in doing multilevel analysis we need to divide students' reading achievements into two parts, between-group and within-group variation, and according to the rule the between-group variation can't be zero in significant level.

Model 2: random coefficients regression model The aim of model 2 is to test if students' reading abilities and reading attitudes can predict or explain students' reading achievement.

Model 3: intercept -as-outcomes model The aim of model 3 is to test if students' reading abilities and reading attitudes can predict students' reading achievement.

Model 4: slopes-as-outcomes model The aim of model 4 is to test if teachers' teaching strategies as moderators on students' reading abilities, reading attitudes and students' reading achievement. Research findings in this cross-national comparative study can be offered to the domestic educational authorities, schools and practicing teachers for each country in reading instruction as reference resources to improve and adjust their teaching strategies to help lifting students' reading literacy, then consequentially national competitiveness can be enhanced.

Online Curriculum-Based Measurement for First-Graders in Mathematics

Martin Salaschek, University of Muenster, Germany; Natalie Foerster, University of Muenster, Germany; Elmar Souvignier, University of Muenster, Germany

Developing basic numeracy skills for all children is one of the main goals in elementary school. Curriculum-Based Measurement (CBM) offers ways to continually monitor students' improvement and identify children that do not benefit from regular classroom work. The aim of this study was to analyse the adequacy and statistical quality of a newly developed, internet-based CBM concept for first-graders in mathematics.

Nine first-grade classrooms with 205 students participated in the study. After a standardized maths test for first-graders (DEMAT 1+) was conducted, classes worked on three parallel versions of the CBM test in 3-weeks-intervals. Additionally, teachers completed a questionnaire concerning the usability of the program, the usefulness of the diagnostic information, and the usage of the data for classroom work.

The test results show that students were able to improve significantly from test to test. The results underline that online CBM tasks in maths can be conducted as early as in first grade, and that the results are useful for forming classroom work. Further studies will show whether this positively affects learning outcomes of classes that use CBM tasks.

Theoretical background

One of the main goals of education in elementary school is to develop numeracy: Establishing a sound understanding of the numeric system and basic mathematical operations. However, there are precursors which have high predictive value of mathematical achievements at the end of fourth grade. These precursors - such as early quantity-number competencies - already start to develop before school enrolment (Krajewski & Schneider, 2009). One method of monitoring students' competency progress that has received much recognition particularly in special education is Curriculum-Based Measurement (CBM) which monitors student progress over time with periodic measurements of contents from the curriculum (Deno, 2003; Foegen, Jiban, & Deno, 2007; Stecker, L. Fuchs, & D. Fuchs, 2005). The CBM concept seems particularly suitable for mathematics, since curricular goals are well-defined.

Aims

The main aim of the study was to analyse the adequacy of the newly developed internet-based CBM test concept for first-grade maths students. More specifically, it was examined (a) if the developed CBM tasks showed satisfactory sensitivity, reliability, and construct validity; and (b) if the children were able to use the internet-based testing software with a computer at this young age.

Moreover, since CBM is a young research field in Germany - especially in regular education settings -, teachers' general acceptance and usage of the results was under review.

Methodology

The CBM test was constructed of tasks from the curriculum sampling as well as from the robust indicators approach. It consisted of 52 items in 11 different tasks, measuring four basic competencies: (a) calculation skills, (b) understanding of quantities, (c) digit knowledge, and (d) working memory skills. The first competency sampled the curriculum with exercises such as addition and subtraction tasks in the range of 1-20. The second and third competencies served as specific robust indicators for basic mathematical understanding, based on the triple code model (Dehaene & Cohen, 1995) and Krajewski and Schneider's model of early mathematical development (Krajewski & Schneider, 2009). The assessment of the children's working memory skills served as a general risk indicator for overall school performance.

Nine first-grade classrooms with 205 students participated in the study. Three parallel versions of the test were conducted from May to July 2010 in intervals of approximately 3 weeks. Testing order of the three tests was randomized for each participating class. The children worked on the tests autonomously; instructions for the tasks were given via headphones. The results of the CBM tests for all four competencies could be separately reviewed by the teachers online directly after the test on student- and class-level; comparative data from all participating classes were given. The CBM tests were preceded by a standardized paper pencil test for first-graders (DEMAT 1+). After the last CBM test, teachers were asked to complete a short questionnaire concerning the usability and adequacy of the test, the acceptance of the program, and the usage of the results for teaching and individual fostering.

Findings

Firstly, measures for sensitivity, reliability and validity of the CBM test were evaluated. The test showed adequate difficulty levels with mean overall scores ranging from 73% in the first test to 79% in the last test. The test was sensitive to students' learning outcomes, resulting in increased performance from test to test ($p < .05$). The test appeared to be significant ($p < .05$) as a measure of parallel forms reliability ranged from $r = .53^{**}$ to $r = .55^{**}$. Overall correlation of the three tests with DEMAT 1+ scores ranged from $r = .36^{**}$ to $r = .48^{**}$. However, due to randomization effects, not all tests were conducted by the same amount of students at the same testing time. The results should therefore be interpreted with caution.

Secondly, usability and usefulness were assessed. The majority of the teachers stated that they used the CBM test results for adjusting their teaching (87% agreement) as well as that the children were able to conduct the tests independently and had fun doing so throughout all tests (100%, 83% agreement, respectively).

Theoretical and educational significance of the research

The statistical findings suggest that the newly developed CBM test is sensitive to changes in students' skills. Reliability and validity measures are not fully satisfying; indications for task modifications were obtained, and a revised test is being conducted in the school year 2010/2011 with additional parallel tests as well as with more participating classrooms.

Furthermore, teachers' ratings for the adequacy and usability as well as for the usefulness for general classroom work and individual fostering were remarkably high. Against the background of the successful implementation of CBM tasks with older students in special education settings, the newly developed internet-based concept proved the CBM concept to be valuable in regular education settings as early as in first grade.

Effects of reading progress assessment in regular education

Natalie Foerster, University of Muenster, Germany; Elmar Souvignier, University of Muenster, Germany

Providing teachers with diagnostic information on the reading progress of each student should lead to better individual support and higher learning gains. The method of curriculum-based measurement (CBM) was designed to

describe the progress in learning. This concept stands in clear contrast to standardized tests and traditional measures of achievement in the classroom which do not focus on the documentation of change. CBM has proven to be eligible to document and improve reading progress, especially for students with special educational needs. Hence, the aim of our study was to investigate the efficacy of reading progress assessment compared to providing teachers with diagnostic (state) information from a standardized test in regular education. Using a pre- and post-test design, learning gains were assessed with two standardized reading tests (ELFE; SLS) at the beginning and the end of the school year. A total of 1491 third- and fourth-graders (996 CBM vs. 495 control) participated in the study. CBM-students completed eight parallel forms of a 10-minute reading test in intervals of two weeks. While all teachers obtained information about reading achievement at the beginning of the school-year, teachers of the CBM-students additionally obtained information about the reading progress of each student. Overall, students of the CBM-group showed higher improvement in reading achievement than control students ($d = .26$ (ELFE) and $d = .20$ (SLS) for third-graders, and $d = .68$ (ELFE) and $d = .22$ (SLS) for fourth-graders. Thus, information on learning progress seems to be helpful for teachers to foster reading achievement.

Aims

The aim of our study was to investigate the efficacy of reading progress assessment compared to providing teachers with diagnostic (state) information from a standardized test in regular education. Diagnostic information is needed to adapt instructions to children's individual needs. The more often teachers have information about achievement and progress of their students, the better they can select individual aid. Thus, providing teachers with diagnostic information on the reading progress of each student beyond state information about reading achievement should lead to better individual support and higher learning gains of the students.

The method of curriculum-based measurement (CBM) was designed to describe the progress in learning in contrast to standardized tests and traditional measures of achievement in the classroom which do not focus on the documentation of change. CBM has proven to be eligible to document and improve reading progress, especially for students with special educational needs (Deno, 1985; Fuchs & Fuchs, 1998). We developed an internet-based measurement tool with an automated routine for data analysis to apply the assessment of reading progress in regular education classrooms.

Methodology

A total of 68 third- and fourth-grade-classes (1491 students) participated in the study. Classes were assigned to either a CBM-group (46 classes with 996 students) or a control group (22 classes with 495 students). All students completed two standardized reading tests (ELFE and SLS) at the beginning (pretest) and at the end of the school year (posttest). In addition, CBM-students completed eight parallel forms of a 10-minute internet-based reading test in intervals of two weeks during the school year. While in CBM reading competence is usually assessed by tasks such as one-minute oral reading or a maze task, we developed short internet-based reading tests consisting of a maze task and comprehensive questions. While all teachers obtained information about reading achievement at the beginning of the school-year, teachers of the CBM-students additionally obtained information about the reading progress of each student. Feedback of the pretest results of two standardized reading tests (ELFE 1-6 and SLS) was provided not later than six weeks after testing and at least 16 weeks before the posttest.

Findings

Overall, students of the CBM-group showed higher improvement of reading achievement than students of the control group indicating that teachers really made use of the diagnostic information for instructional decisions. For third-graders effect sizes are $d = .26$ (ELFE) and $d = .20$ (SLS). Effect sizes for fourth-graders appeared to be slightly higher ($d = .68$ (ELFE) and $d = .22$ (SLS)). All differences proved to be statistically significant.

Theoretical and educational significance of the research

Assessment of individual difficulties and individual progress provides the basis for adapting instructions to individual needs. The computer-based CBM method facilitates the collection of progress data for each student in regular educational settings. Moreover, teachers have proven to be successful in using the information for planning adaptive teaching, which led to higher achievement gains for their students. Hence, our findings are in line with research in special educational contexts.

The results of this study underline that providing teachers with diagnostic information on the learning progress of their students is – as a first step – sufficient to bring about higher learning gains (Stecker, Fuchs & Fuchs, 2005).

THEMATIC POSTER

Cognitive Development

Number sense in kindergarten children and its relationship with calculation fluency in later grades

Manuel Aguilar-Villagran, University of Cadiz, Spain

In this poster an early math longitudinal study of a group of children from kindergarten to the third year of Primary is presented. All children were assessed with the Early Numeracy Test (Van Luit et al., 1994) at 5 years old. The different ENT components were used to predict fluency in basic math operations at the end of the first, second and third grades of Primary Education. We also used a longitudinal study to identify the differences between initial high and low ENT achievers. The participants were a group of 87 children (49 boys and 38 girls) aged between 60 and 70 months old (mean 66 months). They were evaluated when they were in the third year of kindergarten (Fall 2006) with UENT (Van Luit, Van de Rijt, & Pennings, 1994). We calculated the correlation between UENT and the different measurements of math fluency in the first three grades of Primary education. A statistically significant correlation was found between counting sub-tests (verbal counting, resultative counting, structural counting and general number knowledge) and addition, subtraction, multiplication and division fluency measures (range .36 - .62). No statistically significant correlations were found between the relation sub-tests and fluency measurements. A hierarchical regression calculation showed that verbal counting and resulting counting explained the maximum variance in basic math operations.

Students start school with differing levels of number sense development. Low early number sense development may be one of the variables explaining math learning disabilities in older children (Gersten et al., 2005; Mazzocco & Thompson, 2005). For example, Aunio et al., (2005), Kavkler, et al., (2003) consider that between 5 and 10 % of children have severe counting skill difficulties. This skill could be an important precursor for later math abilities (Aunola et al., 2004; Aunio & Niemivirta, 2010). Fluency refers to the ease and precision with which an activity is performed. Calculation fluency is a tool for solving the majority of math problems. For example, solving multi-digit calculations depends on knowledge of basic combinations, number facts, and recovery fluency. Poor number fact skills reduce the necessary attentional resources (i.e. attention, working memory) for decoding and solving more complex tasks. (Dehaene, 1997). Some research has shown that low calculation fluency characterises students with math learning difficulties. (Hanich, et al., 2003; Barnes et al., 2006). The main aims of the study were, on the one hand, to identify the importance of number sense development, evaluated in kindergarten, on calculation fluency in the first three years of Primary education. In addition, we aimed to assess and analyse fluency differences between high and low early math performers. The participants were a group of 87 children (49 boys and 38 girls) aged between 60 and 70 months old (mean 66 months). They were evaluated when they were in the third year of kindergarten (Fall 2006) with UENT (Van Luit, Van de Rijt, & Pennings, 1994). We assessed their early math competence with 8 ENT sub-tests: (a) relational or Piagetian concepts: comparison, classification, 1:1 correspondence and seriation (b) numerical concepts: verbal counting, resultative counting, structural counting and general number knowledge. All children were assessed on calculation fluency (addition [$8 + 9 = ?$], and subtraction, $8 - 3 = ?$) at the end of the first grade of Primary education (June 2008). Then they were evaluated at the end of the second grade of Primary education on addition, subtraction and multiplication fluency ($7 \times 5 = ?$) (June 2009) and finally at the end of the third grade they were assessed on addition, subtraction, multiplication and division fluency ($24 : 8 = ?$) (June 2010). We calculated the correlation between UENT and the different measurements of math fluency in the first three grades of Primary education. A statistically significant correlation was found between counting sub-tests (verbal counting, resultative counting, structural counting and general number knowledge) and addition, subtraction, multiplication and division fluency measures (range .36 - .62). No statistically significant correlations were found between the relational sub-tests and fluency measurements. A hierarchical regression calculation for each measurement year showed that verbal counting, structured counting and resulting counting explained the maximum variance in basic math operations (table 1). Table 1. Hierarchical regression calculation for additions, subtractions, multiplications and divisions assessed in 2008, 2009 and 2010

Models

In addition, we compared the low and high ENT achievers. We selected children with a standard deviation below ($N = 10$) and above ($N = 14$) the total ENT average (21.76). Significant differences were found for high ENT achievers

The fact that these differences were maintained for three years suggests the importance of early instructional programs for counting in order to reduce the gap between low and high early math achievers. This study also has some implications for educational practice. It should be understood that counting fluency is an important early math skill which may require specific support in order to provide a firmer basis for future learning of math in primary school. This is particularly relevant for early childhood education, and it may be critical in preventing future learning difficulties or lower early math performance. Our results call for all children to be provided with possibilities for training their potential math skills in early childhood education.

Personal Epistemology, Critical Thinking, and Moral Reasoning: Keys to Active Citizenship

Lisa D. Bendixen, University of Nevada, Las Vegas, United States; Lori Olafson, University of Nevada Las Vegas, United States; Raelynn Frazier Lee, UNLV, United States; Cristina Salinas, University of Nevada, Las Vegas, United States

With citizenship as its context, the current study examines the relationships among what we think are key components of effective ill-defined problem solving: epistemic beliefs, critical thinking, and moral reasoning. Participants included 149 (107 females, 42 males) undergraduate ($n = 103$) and graduate ($n = 46$) education students. We hypothesized that views of citizenship would be significantly related to our main variables (i.e., epistemic beliefs, critical thinking, and moral reasoning). Findings indicated that graduate-level education students had more advanced moral reasoning and viewed themselves as more capable in citizenship skills. In addition, critical thinking and epistemological beliefs significantly predicted principled moral reasoning. Implications such as providing more opportunities for students to actively engage in citizenship problem solving are discussed.

Aims

Informed and active participation of citizens is a hallmark of democratic societies. Education's role in training its citizens is also a key aspect of most Western cultures. Currently, there is debate regarding whether or not the educational system in the U.S. is doing an adequate job of preparing its future citizens for some of the complex tasks required of them (Torney-Purta, Hahn, & Amadeo, 2001). Some of the problems required of citizens to solve would be considered ill-defined problems (i.e., problems with no single correct answer or way to achieve the answer). For example, active and effective participation in political campaigns and juror decision-making require critical thinking skills, sound moral reasoning, and epistemic competence. The goal of the current study is to examine the relationships among moral reasoning, epistemic beliefs/competence, and critical thinking in undergraduate and graduate students. The more we can understand key components of the problem solving required of future citizens the more we can address their educational needs.

Epistemic Beliefs

The study of epistemic beliefs (i.e., about knowledge and knowing) has been a focal point of educational research over the last forty years (Hofer & Pintrich, 1997). Viewing personal epistemology as a set of beliefs originated with the work of Schommer-Aikins. Schommer (1990) proposed that there are five dimensions of epistemological beliefs and these epistemological dimensions have also been shown to develop and advance over time as age and education levels increase (Schommer, 1993).

Moral Reasoning

The moral reasoning of adults has also been a major focus in developmental and educational psychology for a number of years. Based on the moral development theory of Kohlberg (1981) research using The Defining Issues Test (DIT) (Rest, 1987) has been widely used and has yielded consistent and useful results in terms of how individuals reason about open-ended moral situations typically found in society.

Critical Thinking

Encouraging critical thinking in students has been a main focus in terms of learning and instruction (Ennis, 2003). Critical thinking and its importance in more everyday situations has also been pursued (Halpern, 2006).

Methodology

Participants

There were 149 (107 females, 42 males) undergraduate ($n = 103$) and graduate students ($n = 46$) who completed the study as part of their educational psychology course requirement. The mean age was 24.57.

Materials

All participants completed 5 surveys and one essay online. Three dimensions of the 28-item Epistemic Belief Inventory (Schraw, Bendixen, & Dunkle, 2002) were used. The naïve end of the dimensions include: 1) simple

knowledge (i.e., knowledge consists of discrete facts), 2) certain knowledge (i.e., absolute knowledge exists), and 3) omniscient authority (i.e., all authorities have access to otherwise inaccessible knowledge).

The Halpern Critical Thinking Assessment Using Everyday Situations was also given (Halpern, 2006). This measure includes 25 everyday situations with open-ended and Likert scale items designed to assess participants critical thinking.

The short-form of the Defining Issues Test (Rest, 1987) was also administered in this study. The short form includes 3 moral dilemmas that participants were asked to rate in terms of their judgments about the dilemmas in order to give an indication of their level of moral reasoning.

Two surveys about citizenship were also administered: 1) The Citizenship Questionnaire (10 items, 4-point Likert scale) is designed to measure individuals' view of community involvement and other aspects of participatory citizenship (Westheimer & Kahne, 2004). 2) The Project Citizen Survey (10 items, 4-point Likert scale) adapted from Root & Northup (2007) was also used and asks participants to rate how good they are at various activities related to citizenship.

An open-ended essay question about citizenship was also given and is currently being analyzed using the Westheimer & Kahne (2004) framework.

Findings

Independent - Samples t Tests

When comparing means for the undergraduate and graduate students, the P Score (Undergrad Mean = 29.06, SD = 16.27, Graduate Mean = 33.33) and ProjectCitizen (Undergrad Mean = 24.86, SD = 3.86, Graduate Mean = 26.89, SD = 4.20) variables were significantly different

Gender was also significant on the CitizenshipQuest

Multiple Regression

To examine the relationship between Moral Reasoning (DV) and our other variables (predictors), multiple regression was performed. Results indicate that critical thinking (Beta = .24) and epistemological beliefs (Beta = .31) significantly predicted principled moral reasoning. The model accounted for 21% of the variance ($R = .46$, $R^2 = .21$).

THEORETICAL/EDUCATIONAL SIGNIFICANCE

Critical Thinking and Citizenship

Consistent with the results of the current study, links have been established between moral reasoning and epistemological beliefs (e.g., Bendixen, Schraw, & Dunkle, 1998, Olafson, 2003). We think that an important addition to this association is critical thinking as our findings indicate that this type of reasoning also plays a role in moral decision making.

This study illuminates the possibility of addressing both the epistemological beliefs (Bendixen & Feucht, 2010) and critical thinking (Kuhn, 2005) of students in the classroom to aid in moral reasoning within the context of participatory citizenship. For example, more critical thinking activities in the arena of citizenship could have many short- and long-term benefits for students in and out of the classroom (Torney-Purta et al., 2001).

Level of Education and Citizenship Graduate-level education students in the current study had more advanced moral reasoning and viewed themselves as more capable in citizenship skills. Although a solid educational trend in moral reasoning is apparent in the literature (e.g., Thoma & Davison, 1983), views of citizenship becoming more advanced with education is a relatively new finding. One reason for this could be that graduate students have had more time and experience being a citizen and thus gain more self-efficacy in this arena than their undergraduate counterparts. More opportunities for reasoning in citizenship situations may better prepare high school and undergraduate students for what's to come in terms of their responsibilities as citizens.

The Epistemology of Counseling: Inroads to More Effective Counselor Education

Lisa D. Bendixen, University of Nevada, Las Vegas, United States; Wendy Hoskins, University of Nevada, Las Vegas, United States; Randall Astramovich, University of Nevada, Las Vegas, United States

Graduate level counselor education involves a variety of learning experiences and instructional methods designed to help new counselors integrate theory and practice. In particular, understanding the beliefs that counselors-in-training hold in regard to counseling theory, skills, and knowledge (i.e., counseling epistemology) helps to better prepare them for working effectively with students/clients. The aim of the current study is to explore the development of beliefs about counseling epistemology among beginning master's students enrolled in a theory-based Counselor Education course. Forty-seven students participated (Females = 37, Males = 10, Mean Age = 28.65) in the study during their first semester of entering a Master's level Counselor Education Program in the U.S. Paired-samples t tests results indicate that students' at the end of the entry-level course viewed counseling knowledge as more complex and integrated (rather than made up of simple, unrelated facts). This may be due, in part, to being exposed to the course content that includes a number of theories and skills associated with counseling. Additional implications for learning and instruction are also discussed.

Aims

Graduate level counselor education involves a variety of learning experiences and instructional methods designed to help new counselors integrate theory and practice. In particular, understanding the beliefs that counselors-in-training hold in regard to counseling theory, skills, and knowledge (i.e., counseling epistemology) helps to better prepare them for working effectively with students/clients. The aim of the current study is to explore the development of beliefs about counseling epistemology among beginning master's students enrolled in a theory-based Counselor Education course.

Framework

A growing body of research literature supports that counseling students' general beliefs about knowledge and knowing can change over the course of their training (e.g., Fong, Borders, Ethington, & Pitts, 1998). One framework used to consider this growth is based on the work of Perry's (1970) theory of general epistemological development that includes three broad levels: 1) Dualist (i.e., knowledge is seen as right/wrong), 2) Multiplist (i.e., knowledge is considered completely relative and based on personal views), and 3) Evaluativist (i.e., knowledge is viewed as relative but certain within contexts based on evidence) (see also Kuhn & Weinstock, 2002).

Using Perry's scheme, Granello (2002) found longitudinal evidence to support this developmental view over the course of counseling students' training and that shifts in beliefs were most associated with interaction with clients later in their educational experience (e.g., counseling students close to completing their programs had more advanced or evaluativist views).

Epistemological development can also be examined in terms of specific and interrelated dimensions of epistemological beliefs (Schommer, 2004) and research supports that these beliefs can be domain-specific (Muis, Bendixen, & Harle, 2006) and/or topic-specific (Braten & Stromso, 2005). To gain a more nuanced view of student counselors' epistemic beliefs we adapted and used a measure developed by Braten and colleagues (Braten, 2006) that assesses four dimensions of counseling knowledge and knowing. Each dimension is based on a continuum of beliefs ranging from more naïve views to more advanced beliefs and includes: 1) Certainty of knowledge about counseling (i.e., absolute truth exists – knowledge is tentative and evolving), 2) Simplicity of knowledge about counseling (i.e., knowledge is based on simple, discrete facts – knowledge is complex and highly integrated), 3) Source of knowledge about counseling (i.e., knowledge resides outside the self – knowledge is constructed), and 4) Justification of knowing about counseling (i.e., knowledge can be justified by what feels right or from authority – knowledge is based on critical thinking and evaluation).

Methodology

Participants. Forty-seven students participated (Females = 37, Males = 10, Mean Age = 28.65) in the study during their first semester of entering a Master's level Counselor Education Program in the U.S. Theory-Based Practice for use in the counseling setting is a fundamental entry course in a Counselor Education Program. The curriculum and instructional methods are developed to incorporate knowledge components including: an understanding of basic theories of counseling, a better understanding of the student's own views of counseling, and to understand the process of building collaborative relationships within the counseling experience. In addition to knowledge, there is a skills-based curriculum that focuses on student's ability to: incorporate methods of theory-based interventions in the counseling setting, to incorporate the core skills of attending and responding in the counseling experience, and to better understand their own personal philosophy of counseling.

Measures. As was described previously, we adapted and used a version of a topic-specific measure of epistemological beliefs developed by Braten (2006). This measure contains 49 items based on a 10-point Likert scale and includes four

dimensions of epistemological beliefs related to counseling: 1) Certainty of counseling knowledge, 2) Simplicity of counseling knowledge, 3) Source of counseling knowledge, and 4) Justification for knowing about counseling.

In addition, students were asked to identify one of three theoretical umbrellas (pre and post) that seemed to fit their personhood best. The three theoretical umbrellas include: 1) Psychoanalytic/Psychodynamic, 2) Behavioral/Cognitive Behavioral, and 3) Humanistic/Transpersonal (Nye, 1992). We were interested in student selection as an indicator of personal and professional growth, insight to self, and level of personal autonomy as indicated by the Spectrum Model of Counseling Theories (Astramovich, 2002).

Procedure.

The two questionnaires, along with a demographic sheet, were administered at the beginning and the end of the course.

Findings

To investigate if there were shifts in students beliefs about counseling over the course of the semester, means on each of the four dimensions of epistemological beliefs were compared (pre and post) using paired-samples t tests.

The Simple Knowledge dimension showed a significant increase in mean from pre ($M = 78.11$) and post ($M = 83.14$) at the Interestingly, the Justification of Knowledge dimension slightly decreased for the pre ($M = 87.15$) and post ($M = 86.58$). In addition, preliminary analyses indicate that 30% of the counseling students changed their theoretical umbrella at the end of the course.

Theoretical/Educational Significance

The findings of the current study offer a number of important implications for counselor education. To begin with, we see the more topic-specific view of counseling epistemology (Braten, 2006) explored in this study to be an important addition to the more general view of how counseling students view may change over the course of their training (Granello, 2002). Obtaining information on students' beliefs along the lines of the four epistemic dimensions may offer counselor educators a better chance to more effectively reach their students. For example, students' at the end of the entry-level course viewed counseling knowledge as more complex and integrated (rather than made up of simple, unrelated facts). This may be due, in part, to being exposed to the course content that includes a number of theories and skills associated with counseling. Also encouraging is the fact that other shifts to a more sophisticated view of counseling knowledge were apparent at the end of the course.

Critical analys of models of adult cognitive development and implications for higher education

Eeva Kallio, University of Jyväskylä, Finland

Post-formal relativistic-dialectical thinking has been widely claimed to be a new developmental stage of intellectual development in adulthood. Some other theoretical models come very close to post-formal thinking with overlapping features, such as the study of wisdom and epistemic understanding, as well as models of expertise and critical thinking. No coherent theory exists in fields of post-formal and relativistic-dialectical thinking or in the other fields mentioned, though scholars have claimed that there is some similarity between the models. While some empirical evidence of interconnectedness between them exists, a major difficulty lies in the theoretical definition of concepts. Concept of integrative thinking is suggested to be used as substitute for mentioned terms. Implications for teaching integrative thinking will be discussed especially in the field of higher education.

Relativistic-dialectical postformal thinking in adulthood Research on adult thinking has aroused keen interest in the topic in different fields of research during the last few decades. Indeed, scholars from separate traditions of thought have introduced different conceptualizations. There seems to be at least some consensus as to the basic characteristics as shown in meta-theoretical analyses (Gurba, 2005; Hoare 2006; Kramer, 1983; Marchand, 2001). These numerous adult thinking models have been defined as focus to relativistic-dialectical thinking (Kramer, *ibid.*). Three features are thus included: the realization of the relativistic nature of knowledge, an acceptance of contradiction, and integration of contradiction into whole. Adult cognitive development is thus described with the concept of post-formal thinking (Bassett, 2006). Wisdom, epistemic understanding and expertise knowledge. The word wisdom has many meanings: it is a complex phenomenon and several different conceptualizations have been made (Bassett, *ibid.*). According to Baltes and Staudinger (2000) concept of relativistic-dialectical post-formal thinking is a cognitive sub-component of wisdom, indicating that the relationship between these constructs is supposed to be close. Wise action is defined to include integration of will, emotion and thinking. Research on epistemic understanding is understood as the study of assumptions about the certainty of knowledge claims, argumentation, and the limits of knowledge (Kitchener, King & DeLuca, 2006; Baxter-Magolda, 2004). The traditions in the study of critical thinking

(Phillips & Bond, 2004) is also related variations on the theme. Also, the study of expertise in adulthood is an established branch of research (Merriam & Clark, 2006). According to a brief definition of expertise, one is able to make judgements with practical experience in complex situations based on tacit knowledge (Bereiter & Scardamalia, 1993). Preliminary empirical research on the interconnectedness between the mentioned models (post-formal relativistic-dialectical thinking, wisdom, and epistemic understanding) suggests that they indeed share common features and, thus, gives us reason to assume that they deal, at least partially, with the same phenomenon (e.g. Baltes & Staudinger, 2000; Kitchener, King, DeLuca 2006). As an example, scholars have identified a connection between wisdom and relativistic-dialectical beliefs (Lyster, 1996; Kramer, 2003). Theoretical analysis also indicate common features between models (Kallio, in press). Integrative thinking as alternative term and its' pedagogical implications However, clarification the nomenclature of mentioned models shows that there are major problems in using philosophical terminology in psychological theorization (Kallio, *ibid.*). Also, overlapping features of mentioned models should be taken seriously, as assumption of epistemic relativism and synthetizing knowledge. It is suggested that the most apt candidate as a common core of models would be the term 'integrative thinking' (*ibid.*). The integration of mental actions seem to be the 'hard core' in different models. For example, in the field of the development of epistemic understanding, it refers to coordination of the different sources of knowledge, as expert knowledge and one's subjective experiences (Limon, 2006), and in another case, several subcomponents of the psyche are integrated (e.g. emotion, thinking, and conation) in wise action (Yang, 2008). Implications for training of integrative thinking in higher education are of importance as it is question of adult cognitive development. Model of integrative pedagogy (Tynjälä & Kallio, 2010) will be thus discussed, especially in connection to university pedagogy and training of scientific thinking.

Mental Representations of the Magnitude of Fractions

Florence Gabriel, University of Cambridge, United Kingdom; Denes Szucs, University of Cambridge, United Kingdom; Alain Content, Universite Libre de Bruxelles, Belgium

This research investigated the mental representations of the magnitude of fractions and their development. There is an on-going debate in the literature about the nature of fractions processing in adults. Some authors argue that fractions processing is componential, that is, based on the magnitude of numerators and denominators. Others argue that fractions processing is hybrid that is, based on the magnitude of components and the global magnitude of fractions. Experiment 1 examined the mental representations of the magnitude of fractions in adults. Participants carried out two experiments: a Same/Different task and a Numerical Comparison task. In the Same/Different task, participants were asked to answer same when a pair of fractions shared the same global magnitude and different when global magnitudes were different. In the Numerical Comparison task, participants had to determine which one of two fractions was larger. Results showed different strategies in both tasks. In the Same/Different task, participants based their judgments on the magnitude of components only. In the Numerical Comparison task, they used hybrid strategies. Experiment 2 explored the development of those mental representations. 5th-, 6th- and 7th-graders were tested with the same paradigms as in Experiment 1. Results showed that from 6th-grade, children develop the same strategies as the ones used by adults. This finding could have implications for teaching fractions.

Introduction

Although fractions have interested psychologists for a long time, little is known about their processing and representations. The aim of this research was to determine how fractions are processed and represented in numerate adults (Experiment 1) and how they develop with education (Experiment 2). Previous studies in adults showed that fractions processing can be whether based on the magnitude of the numerators and denominators (componential) [1,2] or based on the global magnitude of fractions and the magnitude of their components (hybrid) [3,4].

Experiment 1

Experiment 1 contrasted the evaluation of fractions in a semantic Same/Different task (participants decided whether two fractions were numerically equivalent) and in a Numerical Comparison task (participants decided which of two fractions was larger). We hypothesized that the magnitude of the components would always be activated, but the global magnitude of fraction would be optional. The objective of Experiment 1 was to examine participants' magnitude decision strategies in two different experimental contexts, both requiring making judgments on the magnitude of fractions.

Method

Participants were 15 graduate students.

Fractions with denominators up to 9 were used. The magnitude of fractions was always less than 1. In the Same/Different task, there were three conditions: Identical (e.g. $1/2_1/2$), Equivalent (e.g. $1/2_2/4$) and Different (e.g. $1/2_2/3$). In the Numerical Comparison task, we used the same fractions as in the Different condition of the Same/Different task.

Results

Task \times Global Distance repeated measures ANOVA was run on response times. There was a significant task \times global distance interaction: $F(2,28) = 15.974$, $p = 0.000$. Tukey post hoc tests showed a global distance effect in the Numerical Comparison task, but not in the Same/Different task.

In the Numerical Comparison task, a linear regression analysis was run showing a global distance effect ($R^2 = 0.404$, $b = -0.635$, $F(1,89) = 60.236$, $p = 0.000$).

In the Same/Different task, regression analysis showed no global distance effect ($R^2 = 0.036$, $b = -0.190$, $F(1,89) = 3.335$, $p = 0.071$) for different pairs of fractions, but a significant distance effect between denominators was observed ($R^2 = 0.069$, $b = 0.263$, $F(1,89) = 6.636$, $p = 0.012$).

Discussion

Our results showed that different strategies were used in both tasks. There were only distance effects between components in the Same/Different task. In contrast, in the numerical comparison task, there was a global distance effect determined by global fraction magnitudes and componential distance effects. Subjects used hybrid processing strategies. Thus, even when the same stimuli were used in both tasks, and even when both tasks required accessing the magnitude of the fractions, participants applied different heuristics to perform both experiments.

Experiment 2

We also investigated the development of fractions processing in children. 5th-, 6th- and 7th-graders were tested with the same tasks as in Experiment 1, a Same/Different task and a Numerical Comparison task. Our main research

question was to determine if younger children who are still learning fractions use the same kind of strategies as adults and if so, at what point in the learning process those different strategies appear.

Method

Forty 5th-, 6th- and 7th-graders were tested. The procedure and stimuli were the same as in Experiment 1. Results A repeated measures ANOVA was run on response times with tasks and distance as within-subjects factors, and grade as between-subjects factors, revealing a significant interaction between task and distance, $F(2, 64) = 7.95$, $\eta^2_p = 0.181$, $p = 0.001$. Tukey post hoc tests showed a global distance effect in the Numerical Comparison task and not in the Same/Different task.

Regression analyses were run in the Numerical Comparison task, revealing no global distance effect in 5th-grade, but a global distance effect and a distance effect between denominators in 6th-grade ($R^2 = 0.05$, $b = 0.223$, $p = 0.035$) and 7th-grade ($R^2 = 0.052$, $b = 0.228$, $p = 0.030$). They also showed a significant distance effect between denominators in 6th-grade ($R^2 = 0.112$, $b = -0.334$, $p = 0.001$) and 7th-grade ($R^2 = 0.156$, $b = -0.395$,

Regression analyses showed no global distance effect in the Same/Different task, but a distance effect between denominators in 6th-grade ($R^2 = 0.047$, $b = 0.216$, $p = 0.040$) and 7th-grade ($R^2 = 0.035$, $b = 0.188$, $p = 0.05$). Discussion Results showed that pupils used different strategies in both tasks. In the Same/Different tasks, they used componential strategies. In the Numerical Comparison task 6th- and 7th-graders used hybrid strategies, suggesting that pupils start developing mental representations of the magnitude of fractions from 6th-grade. In 5th-grade, correct responses rates were low and results showed no evidence of holistic representations of the magnitude of fractions.

Conclusion

This research investigated how the magnitudes of fractions are mentally represented and how they develop. Experiment 1 examined the representations of the magnitudes of fractions in adults, and Experiment 2 the representations in children. Two paradigms were used: a Same/Different task and a Numerical Comparison task. Adults used different strategies in both tasks. Componential strategies were used in the Same/Different task, and hybrid strategies were used in the Numerical Comparison task. As it has been shown with adults, children are able to flexibly use different strategies to process the magnitude of fractions from 6th-grade. Further research should investigate how the global magnitude of fraction can be accessed. A better understanding of the nature of the mental representations of fractions could lead to the development of more adequate teaching methods.

Early quantity-number- competencies in three year old children

Christina Balke, University of Hildesheim, Germany; Kirsten Schuchardt, Institute for Psychology, Germany; Claudia Maehler, Institute of Psychology, Germany; Dietmar Grube, University of Oldenburg, Germany

In the present work, we investigated the psychometric assessability and factorial structure of basic numerical competences in children at the age of 3;6 years. For this purpose, we created eight numerical tasks, while for each task we referred to one of the four categories of basic numerical competences as distinguished by Krajewski (2003). Krajewski worked out a dimensional structure of numerical basis competencies in preschool children one year before their school enrolment. This structure comprised of two basic dimensions, (pre-) knowledge of quantities and of Arabic numbers, while the latter is further subdivided into Arabic number knowledge, counting ability and arithmetic competencies.

Using AMOS, we conducted a Confirmatory Factor Analysis (CFA) based on the maximum likelihood estimation principle in order to test the factorial validity of the Krajewski model in the investigated age group. Basically, the CFA revealed a good model fit with coefficients that all met the standard criterion. Thereby, sub-tasks (i.e. the associated

latent variables) related to number knowledge yielded an especially good representation while corresponding factor loadings were slightly reduced for quantity knowledge, but still in a fully satisfactory range.

Our findings strongly suggest that children already at the age of 3;6 possess a differentiated set of numerical and quantity competencies which can be reliably measured. The structure of numerical competencies appeared to correspond to the one which has been repeatedly defined for later developmental stages.

Gathering knowledge about the development of basic (phonological and numerical) competencies at preschool age and creating psychometric instruments to quantify them provides the basis for the early detection of children at risk for later developmental disorders and the consequent initiation of adequate therapeutic-preventive interventions. This specifically concerns numerical competencies and it is, hence, a question of high importance and relevance from which age on such competencies can be found and reliably measured. A series of studies, which used habituation paradigms (e.g. Starkey & Cooper, 1980), strongly suggests the existence and measurability of basic numerical competencies already in infancy. Wynn (1992) even found evidence for a primitive concept of addition and subtraction already in 4-5 month old children. Most importantly, these early numerical or quantity competencies appear to have a relevant predictive value. For instance, in a four-year longitudinal study, Krajewski und Schneider (2006) could show that quantity and number competencies in preschool children can efficiently predict later school performance in mathematics.

In the present work, we investigated the psychometric assessability and factorial structure of basic numerical competences in children at the age of 3;6 years. For this purpose, we created eight numerical tasks, while for each task we referred to one of the four categories of basic numerical competences as distinguished by Krajewski (2003). More specifically, Krajewski worked out a dimensional structure of basic numerical competencies in preschool children one year before their school enrolment. This structure comprised of two basic dimensions, quantity (pre-) knowledge and (pre-) knowledge of Arabic numbers, while the latter is further subdivided into Arabic number knowledge, counting ability and arithmetic competencies. This leads us to a total of four relevant dimensions in the present work - one dimension representing quantity (pre-) knowledge and three dimensions representing pre-knowledge of Arabic numbers - for which we created tasks (see below).

Thereby, our basic aim was to confirm the factorial structure of numerical competence as postulated by Krajewski (2003) for our younger age group. For our purpose, we created three tasks to represent the category "Arabic number knowledge", wherein one task comprising 17 items involved number naming (German label: "Benennen arabischer Zahlen", abbreviated as BAZ) and a second task comprising 6 items required transcoding of verbal number information into a number symbol (by means of a choice selection) (German label: "Transkodieren", abbreviated as T). The third task of this category was called "knowledge of number in everyday life" (German label: "Zahlenwissen im Alltag", abbreviated as ZA) and comprised 10 items in form of questions like "how many fingers are on one hand" or "how many wheels has a car". The category "counting ability" was operationalized by two tasks, one task requiring children to verbalize (i.e. to follow up) the number sequence beginning from 1 going as far as they know (German label: "Aufsagen der Zahlenreihe", abbreviated as AZ) and a second task of 11 items requiring counting of visually presented objects (German label: "Abzählen von Objekten", abbreviated as AO). Krajewski's "computational abilities" were implemented in two further tasks. In one task comprising 7 items, children were to add two simultaneously presented amounts of geometric objects (i.e. cubes) (German label: "Addition zweier sichtbarer Mengen", abbreviated as AzsM) while in the second task 8 items required to add objects which were presented successively and that thus had to be mentally maintained (i.e. a varying number of cars that successively vanished in a garage) (German label: "mentales Operieren mit Objekten", abbreviated as MOO). The category "amount or number pre-knowledge" was assessed in one task referred to as "amount or number comparison" (German label: "Mengenvergleich", abbreviated as MV) including 24 items in which children had to make a "more or less" decision with regard to two simultaneously presented amounts of objects (e.g. balls).

The tasks were administered during the morning hours to a total of 170 children (93 boys /77 girls) in 15 different kindergardens of the city of Hildesheim. The mean age of the investigated children was 3;6. We expected to confirm the basic factorial structure of numerical competence as postulated by Krajewski (2003), which so far has only been demonstrated for later developmental stages.

Using AMOS (Analysis of Moment Structures), we conducted a Confirmatory Factor Analysis (CFA) based on the maximum likelihood estimation principle in order to test the factorial validity of the Krajewski model in the investigated age group. Basically, the CFA revealed a good model fit with coefficients that all met the standard criterion (e.g. CFI>.95; Hu & Bentler, 1999). Thereby, sub-tasks (i.e. the associated latent variables) related to number

knowledge yielded an especially good representation while corresponding factor loadings were slightly reduced for quantity knowledge, but still in a fully satisfactory range.

Our findings have a significant practical relevance. They strongly suggest that children already at the age of 3;6 possess a differentiated set of numerical and quantity competencies which can be reliably measured. The structure of numerical competencies appeared to correspond to the one which has been repeatedly defined for later developmental stages (cf. Krajewski, 2003).

THEMATIC POSTER

Beliefs

Reformed Mindset and Knowledge: An Analysis of Teachers Beliefs and Knowledge

Margareta Pop, NC State University, United States; John Nietfeld, NC State University, United States

The purpose of this study was to investigate Elementary Education (ELM) and Mathematics, Science and Technology Education (MSTE) preservice teachers' beliefs about reformed science teaching and learning as related to self-efficacy, monitoring accuracy and content knowledge. ELM students reported a higher level of reformed thinking and were less apt to support a realist framework for science teaching than their MSTE peers. However, MSTE students exhibited higher levels of content knowledge, more confidence and more accurate monitoring of that knowledge, and higher levels of self-efficacy for teaching science than ELM students. These discrepancies in preservice teacher knowledge and beliefs have important implications for preservice teacher education and classroom learning.

Purpose

The purpose of this study was to investigate Elementary Education (ELM) and Mathematics, Science and Technology Education (MSTE) preservice teachers' (PT) beliefs about reformed science teaching and learning. Learner characteristics such as content knowledge and self-efficacy were explored in relation to science reformed beliefs and beliefs about learning in general.

Theoretical Framework

The National Research Council (NRC, 1996) claims that "to teach science as portrayed by the Standards, teachers must have theoretical and practical knowledge and abilities about science." However, elementary teachers' difficulties in presenting science content are well documented, and many studies have found that elementary teachers do not have basic mathematics and science content knowledge and often hold negative attitudes toward science (Huinker & Madison, 1997; Hill, Rowan, & Ball, 2005). Studies demonstrate a direct relationship between beliefs and innovative instructional practices (Lee, Hart, Cueves, & Enders, 2004; Richardson & Liang, 2008).

In science education it is not uncommon for pre-service teachers to come to their teacher preparation programs with traditional beliefs about these subjects: a belief that science is a fixed body of knowledge to be delivered to students usually through lectures. Thus, the need to examine the complex relationship between teacher preparation programs, preservice teacher knowledge, and professional practice (Cochran-Smith & Zeichner, 2005) continues to be great and researchers are calling for enlisting the support of multiple disciplines and methods (Borko, & Whitcomb, 2008; Wilson, Floden, & Ferrini-Mundy, 2002) to evaluate teacher education in order to deliver better instruction. In light of this need to examine the nature of knowledge and beliefs more fully across program areas we addressed the following research questions in this study:

1. How do ELM preservice teachers differ from MSTE teachers with respect to their beliefs about reformed science, teaching science as inquiry, self-efficacy and science content knowledge?

2. What are the relationships in general, between preservice teachers' beliefs about reformed science, teaching science as inquiry self-efficacy and science content knowledge? Methodology

Participants included 202 PTs. Of these 103 were ELM students, 18 were MSTE Science Education students, and 81 were MSTE Math & Science Education students (dual specialization). Most students were juniors ($N = 85$) and seniors ($N = 71$); also four freshmen, 29 sophomores, and 13 other.

Participants completed a 20 min survey in one session, measuring: Beliefs About Reformed Science Teaching and Learning Questionnaire (BARSTL, Sampson & Benton, 2006), Science Teaching Efficacy Beliefs (STEBI, Enochs & Riggs, 1990), Epistemic Beliefs Inventory (EBI, Schraw, Bendixen, & Dunkle, 2002), Epistemological World View scale (Schraw & Olafson, 2002), Science Knowledge Test (Praxis II), Monitoring Accuracy (Schiffman, Reynolds, & Young, 1981; Schraw & Roedel, 1994).

Results

A number of significant differences emerged between groups on the science content and beliefs inventories using ANOVA procedures. With regard to science knowledge ELM students ($M = 11.45$, $SD = 2.55$) scored significantly lower, $F(2, 191) = 5.46$, $p = .005$, than the MSTE Math& Science ($M = 12.51$, $SD = 2.76$) and the MSTE Science students ($M = 13.17$, $SD = 2.26$). MSTE Science students ($M = 67.49$, $SD = 14.84$) were more confident, $F(2, 190) = 5.00$, $p = .008$, in their answers than either the ELM ($M = 54.50$, $SD = 15.30$) or MSTE Math&Science students ($M = 55.13$, $SD = 17.72$), were more accurate ($M = .31$, $SD = .09$) in their judgments, $F(2, 188) = 4.47$, $p = .013$, than the MSTE Math& Science students ($M = .37$, $SD = .08$), and were nearly perfect in their overall bias ($M = .02$, $SD = .13$, where .00 is complete lack of bias) for over or underconfidence.

With regard to beliefs about teaching and learning, ELM students ($M = 2.75$, $SD = 1.08$) were significantly less apt to subscribe to the realist teaching model, $F(2, 199) = 6.90$, $p = .001$, in comparison to the MSTE Math & Science students ($M = 3.30$, $SD = 1.03$) with borderline significant differences ($p = .056$) with MSTE Science students ($M = 3.39$, $SD = 1.33$). Scores on the EBI revealed only one significant difference between groups, on omniscient authority $F(2, 198) = 3.39$, $p = .036$, where ELM students ($M = 17.23$, $SD = 2.90$) subscribed more highly than MSTE Math & Science students ($M = 16.09$, $SD = 3.07$). MSTE Science students ($M = 53.72$, $SD = 5.72$) reported significantly higher levels of perceived self-efficacy for teaching science, $F(2, 197) = 33.30$, $p = .000$, $M = 41.96$, $SD = 8.33$ and with borderline ($p = .06$) higher levels than the ELM students ($M = 49.50$, $SD = 6.48$). On the BARSTL, $F(2, 197) = 33.73$, $p = .000$, $M = 85.29$, $SD = 7.19$ students scored significantly higher than their MSTE Science ($M = 76.83$, $SD = 6.59$) and MSTE Math& Science ($M = 78.22$, $SD = 4.99$) peers indicated stronger beliefs aligned with current reform movement in science education.

Results from the bivariate correlations of the major study variables reveal that higher scores on the BARSTL relate significantly to more complex views of knowledge (negative correlations with simplex knowledge, complex knowledge, quick learning, and fixed ability). BARSTL scores also show positive correlations with science teaching efficacy however no relationship with science knowledge. In addition, BARSTL scores correlate negatively with the realist stance and positive with the contextualist and relativist stance.

Findings and Theoretical Implications

In sum, MSTE Science Education students exhibited higher levels of content knowledge, more confidence and more accurate monitoring of that knowledge, and higher levels of self-efficacy for teaching science than ELM students. However, ELM students reported a higher level of science reform and were less apt to support a realist framework for science teaching than their MSTE peers. Interestingly, there was no correlation between science knowledge and scores on the BARSTL nor did the groups differ in their EBI scores. The discrepancy between the ELM and MSTE students in knowledge and beliefs is an important finding for PTs education. It is reasonable to assume that MSTE students would score higher in content knowledge but why would they not subscribe to reformed mindset as much as the ELM students? This is critical for teacher education programs because beliefs and knowledge should be aligned.

Math Exam-Related Anticipatory Joy and its Proximal and Distal Personal Antecedents

Iris Dinkelmann, Zurich University of Teacher Education (PHZH), Switzerland; Alex Buff, University of Teacher Education, Switzerland

Emotions are considered an integral component of practically all school-related activities of students, and it is assumed that they play a central role in learning processes, upon which they have a long-lasting influence (cf., for example, Linnenbrink, 2006; Pekrun & Schutz, 2007; Schutz, Hong, Cross, & Osbon, 2006). For several years, the focus of interest has not been solely on negative emotions, particularly test anxiety, but rather also on positive emotions such as joy (cf. for example Buff, Reusser, Rakoczy, & Pauli, in press; Goetz, Frenzel, Stoecker, & Hall, 2010). This forms the focus of the current contribution.

Against the background of the Control-Value Theory of Achievement Emotions (cf. Pekrun, 2006; Pekrun, Frenzel, Goetz, & Perry, 2007), the contribution examines the cause-and-effect relationships of subjective control and subjective value, as well as anticipatory joy, in terms of two real-life math exams, taking into account long-lasting mathematics-related beliefs and joy.

Data will be analysed of approximately 200 children, who are participating in the longitudinal study "TRANSITION: Parental support and motivational-affective development in the transition to lower secondary level" (Buff & Reusser, 2008). In line with theory, first path analyses regarding the two math exams show main effects of subjective control and subjective value on anticipatory joy, but no reciprocal effects of anticipatory joy on subjective control in the first exam and on value in the second exam.

Theoretical and educational significance

Emotions are considered an integral component of practically all school-related activities of students, and are assumed to play a central role in learning processes, upon which they have a long-lasting influence (Linnenbrink, 2006; Maehr, 2004; Meyer & Turner, 2002; Pekrun, 2000; Pekrun & Schutz, 2007; Schutz & DeCuir, 2002; Schutz, Hong, Cross, & Osbon, 2006; Schutz & Lanehart, 2002). Although it has been repeatedly mentioned that in terms of their emotional experience in learning and achievement situations, school and university students report positive emotions just as frequently as negative ones, little is known in particular about positive emotions (cf. Goetz, Frenzel, Hall, & Pekrun, 2008; Pekrun, 1992; Pekrun, Goetz, Titz & Perry, 2002a, b; Schutz & Pekrun, 2007). Accordingly, for several years, interest has increasingly turned to positive emotions such as joy (cf. Buff, Reusser, Rakoczy, & Pauli, in press; Goetz, Frenzel, Stoeger, & Hall, 2010; Pekrun et al., 2002b). This forms the focus of the current contribution. Central in this regard is the question of individual proximal and distal antecedents of the experience of anticipatory joy regarding two upcoming math exams.

The Control-Value Theory of Achievement Emotions (CVTAE) (cf. Pekrun, 2000; Pekrun, 2006; Pekrun, Frenzel, Goetz, & Perry, 2007) deems cognitive appraisals of control (subjective control) and value (subjective value) and their interaction, respectively, as central proximal antecedents of exam-related anticipatory joy, whereby "antecedents, emotions, and their effects are thought to be linked by reciprocal causation over time" (Pekrun et al., 2007, p. 16). Considered as central distal antecedents are, on the one hand, long-lasting, domain-specific control and value beliefs, which influence the situation-specific appraisals of control and value (Pekrun et al., 2007; cf. also Boekaerts, 2001; Op't Eynde & Turner, 2006; Schutz et al., 2006), and should thus indirectly unfold an effect regarding situation-specific, exam-related anticipatory joy. On the other hand, it can be assumed that the habitualised enjoyment of a subject exerts an influence on the math-exam-related anticipatory joy (cf. Pekrun et al., 2007).

The theoretically postulated main effects of control and value on joy have been confirmed in several studies (cf. Goetz et al., 2010; Goetz, Pekrun, Hall, & Haag, 2006; Jullien, 2006; Pekrun, 2000; Pekrun & Hofmann, 1999). Moreover, Barrera (2001, cited following Pekrun et al., 2002b, p. 166) and Goetz et al. (2010) were able to prove the theoretically postulated interaction effect of control and value on joy. Regarding the question of the importance of distal antecedents in terms of the interaction both of situation-specific appraisals and situation-specific emotional experience, Seegers and Boekaerts (1993) and Boekaerts (1999; cf. also Boekaerts, 2001) showed that control appraisals mediate the influence of constructs relating to control beliefs on emotional state.

Aims

Research gaps in educational psychology as a whole concern the consideration both of appraisals and emotions in real-life situations and of their distal personal antecedents (cf. Boekaerts, 2001). Specifically with regard to the CVTAE, it can be established that in addition to main effects, interaction effects of subjective control and value on emotions should also be tested, and reciprocal cause-and-effect relationships should be modelled (cf. Goetz et al., 2010; Pekrun, Goetz, Daniels, Stupnisky, & Perry, 2010).

Against the background of the theoretically postulated cause-and-effect relationships, the available empirical findings, and the research gaps outlined, the poster focuses on

1. examining (reciprocal) cause-and-effect relationships of subjective control, subjective value and anticipatory joy regarding two successive math exams (in a first step without, and in a second step with, consideration of potential interaction effects), and
2. examining the cause-and-effect relationships in these situations, taking into account mathematics-related control and value beliefs and mathematics-related joy measured at an earlier time point.

Methods

The analyses are based on information from approx. 200 12-year-old boys and girls who are participating in the study "TRANSITION: Parental support and motivational-affective development in the transition to lower secondary level" (Buff & Reusser, 2008). Questionnaires were completed on three separate occasions: first relating to mathematics generally (control beliefs, value beliefs, joy), and then following each of two math exams (subjective control 1st/2nd math exam, subjective value 1st/2nd math exam; anticipatory joy 1st/2nd math exam). The whole measurement period spanned from mid-November 2008 to mid-March 2009. The longitudinal design refers to the three measurement time points – within the individual measurement time points, the concern is effectively with cross-sectional data.

Due to the rather small sample size, data analyses are ensuing through path models with manifest variables using Mplus 5.2.

Preliminary Results

Analyses conducted so far are related to the (reciprocal) cause-and-effect relationships of the variables of interest in the two math exams. Examined in this respect were main effects of subjective control and value on anticipatory joy, and main effects of the constructs measured in the first math exam on their manifestations in the second math exam (in the case of anticipatory joy also the reciprocal effects on subjective control and value). As presented in figure 1, the main effects of subjective control and of value on anticipatory joy can be modelled in the postulated manner. A reciprocal effect of anticipatory joy (first math exam) on subjective control or subjective value (second math exam) is not shown by the current data. By contrast, students appear to evaluate the second exam against the background of the first (positive effects of subjective control and value appraisal first exam on the corresponding appraisals second exam), and also experience it against this background (positive effect of anticipatory joy first exam on anticipatory joy second exam).

Fig. 1 First results

In a next step, it is being analysed whether, in addition to main effect, also possible interaction effects of subjective control and value on anticipatory joy exist. Finally, a model will be tested which takes into account the cause-and-effect relationships of the situation-specific constructs when considering the mathematics-related beliefs and mathematics-related joy, as well as indirect effects on anticipatory joy.

Gender differences in the effects of mathematics anxiety on mathematics performance

Amy Devine, Centre for Neuroscience in Education, University of Cambridge, United Kingdom; Kayleigh Fawcett, University of Cambridge, United Kingdom; Denes Szucs, University of Cambridge, United Kingdom; Fruzsina Soltesz, University of Cambridge, United Kingdom

Mathematics anxiety (MA), a state of discomfort associated with performing mathematical tasks, is thought to affect a notable proportion of the school age population. Some research has indicated that MA negatively affects mathematics performance and that girls may report higher levels of MA than boys. The current study compared the MA, test anxiety (TA) and mathematics performance of 433 secondary school children. No gender differences emerged for mathematics performance but levels of MA and TA were higher for girls than for boys. Both genders showed a positive correlation between MA and TA and a negative correlation between MA and mathematics performance. TA was also negatively correlated with mathematics performance, but this relationship was stronger for girls than for boys. When controlling for TA, the negative correlation between MA and performance remained for girls only. Furthermore regression analyses revealed that MA was a significant predictor of performance for girls but not for boys. These results have clear implications for mathematics teaching practices; efforts should be made to reduce MA in the classroom, especially in girls, for which MA appears to have a significant detrimental effect on performance.

Mathematics anxiety (MA) is typically defined as a state of discomfort caused by performing mathematical tasks (Cemen, 1987, as cited in Ma & Xu, 2004). MA can be manifested as feelings of apprehension, dislike, tension, worry, frustration, and fear (Ashcraft & Ridley, 2007; Ma & Xu, 2004; Wigfield & Meece, 1988). MA is related to general anxiety associated with taking tests (test anxiety; TA) however it is regarded as a distinct construct (Ashcraft, Kirk & Hopko, 1998)

Importantly, MA has several negative effects on the learning of mathematics, for example, withdrawal from mathematics classes, avoidance of mathematics courses and careers, and the development of negative attitudes towards tasks involving mathematics (Ho et al., 2000; Ma & Xu, 2004). The relationship between MA and mathematics performance has been studied extensively. Past studies have shown small negative correlations between mathematics performance and MA (Hembree, 1990; Ma, 1999), indicating that those with high mathematics anxiety show poorer mathematics achievement.

Two of the most important, though still not adequately responded questions are whether a gender difference exists in MA and whether MA affects the mathematics performance of girls and boys differently. Hembree's 1990 meta-analysis revealed that females reported higher levels of mathematics anxiety than males (Hembree, 1990). More recent studies investigating MA in school children have not consistently shown gender differences, with some studies replicating Hembree's finding (e.g., Baya'a, 1990; Jain & Dowson, 2009; Ma & Cartwright, 2003; Ma & Xu, 2004; Yuksel-Sahin, 2008) whereas others have not found any difference in reported levels of MA with gender (e.g., Birgin et al.; Chinn, 2009; Gierl & Bisanz, 1995; Newstead, 1998).

Similarly, evidence for gender differences in the effects of MA on mathematics performance is inconclusive. Some studies have shown that MA affects males' and females' mathematics performance differently (e.g., Betz, 1978; Ma and Xu, 2004; Wahl, 1987) whereas other studies have failed to find gender differences in the relationship between MA and performance, (e.g., Ma, 1999; Meece, Wigfield and Eccles 1990; and Sepie and Keeling, 1978).

Given that the findings reported in the literature are contradictory, the current study sought to investigate whether gender differences occur in overall levels of MA and whether MA affects girls' and boys' mathematics performance differently. Furthermore, the current study controlled for the children's levels of TA.

Method

482 pupils in Year 7, 8 and 10 were studied in total. 49 pupils were excluded from the investigation because they did not give at least one correct response in the mathematics test. The remaining 433 children were included in the data analysis.

The Abbreviated Math Anxiety Scale (AMAS; Hopko et al, 2003) was used to measure levels of maths anxiety. This is the shortest valid maths anxiety scale; it contains only 9 items, uses a 5-point scale and has been shown to be just as effective as longer MA questionnaires (e.g., MARS, sMARS; Richardson & Suinn, 1972; Suinn & Winston, 2003). A modified version of Sarason's Test Anxiety Scale (Sarason, 1978) was used to measure general TA. This was a 36-item questionnaire, with 'True/False' response options.

Standardised mental mathematics tests were used in order to assess mathematical performance. Each year group was given a specific mathematics test suitable for their age range.

Results

- A MANOVA was run on MA, TA and performance scores with factors Gender and Year.
 - o The main effect of Gender was significant
 - o Year was marginally significant ($p=0.053$).
- Univariate ANOVAs were run on each dependent variable with factors and Gender and Year.
 - o MA was higher in girls than in boys
 - o TA was also higher in girls than in boys
 - o Maths performance did not differ by gender, but differed by Year ($p=0.039$). The performance difference was marginally significant between Years 7 and 8 (Tukey $p=0.052$).
- Pearson correlations were computed with age, Year, MA, TA and performance.
 - o Girls: MA positively correlated with TA ($r=.363$;
 - o Boys: MA was positively correlated with TA ($r=.457$;
- Partial correlations were used to control for the effect of TA.
 - o Girls: MA remained strongly negatively correlated with performance ($r=-.301$;
 - o Boys: the correlation of MA and performance was not significant ($r=-.104$;
- Stepwise multiple linear regression was used to assess the relationship of mathematics performance, MA and TA. MA and TA were used as predictors of mathematics performance.
 - o Girls: the regression model was highly significant ($p2$). MA was a significant predictor variable of performance (p
 - o Boys: the overall model reached significance

Conclusions

In line with past research, the results of the current study suggest that cognitive and affective variables impact the mathematics performance of secondary school children. Overall, girls showed higher levels of MA than boys, however this may be because females are more willing to report anxiety than males. Nonetheless, girls showed a strong negative relationship between MA and mathematics performance, which remained even when TA was controlled for. On the contrary, boys only experienced marginal effects of general TA on performance and when TA was controlled for, did not show a relationship between MA and performance. These results suggest that teaching practices need to

take into account anxiety associated with performing mathematics tasks and efforts should be made to address anxiety in the mathematics classroom. The results suggest attention should be directed towards reducing MA in girls, whose performance may be more susceptible to the negative effects of MA; however further research is needed to ascertain the direction of this relationship.

Patterns in the relationship between Conceptions of Learning and Epistemic Beliefs

Walter Terrazas, Universidad Catolica del Norte, Chile; Mariane Frenay, Universite catholique de Louvain (U.C.L.), Belgium

Traditionally research about examining Conceptions of learning and Epistemic beliefs suggests a consonance relationships between them. However, several methodological and theoretical issues must be considered to evaluate the scope of this claim. The main goal of this paper is to analyze the relationship between Conceptions of learning and Epistemic beliefs in the light of perceptions about learning demands. Based on comparative method (Rihoux & Grimm, 2006), a particular combination of elements from both representations was used to analyze each individual case. Participants were thirty eight undergraduate students from several programs from Universidad Católica del Norte at Antofagasta, Chile. Data were collected by individual interviews, using open questions about (1) conceptions of learning, and (2) perception about learning demands; also the dilemma about the construction of the Egyptian Pyramids was used to identify (3) epistemic beliefs. To analyze relationships among these 3 elements, individual profiles were used as a main methodological strategy.

Results indicate two types of relations between Conceptions of Learning and Epistemic Beliefs. A Consonance relationship, when those two elements go in the same direction. A Non-Consonance relationship when those elements go in a different direction. Additionally, both types of relationships seem to be associated with their particular level of correspondence with the perception about learning demands. The implications of the analysis of individual profiles as a methodological strategy to study this relationship are examined.

The manner on which students represent their academic work has an important effect on the approach and strategies used to learn, but also on their academic performance (Boulton-Lewis et al., 2003; Cano, 2005; Debacker et al., 2008; Trigwell & Ashwin, 2006). To examine these representations, two different theoretical frameworks have been developed. The first is called Conceptions of Learning and it refers to representations related to learning experiences. The second one, it is called Epistemic Beliefs and it refers to representations relate with the nature of knowledge and with act to know (Hofer & Pintrich, 1997; Marton et al., 1993). Even when both frameworks have been developed in an independent way, it is possible to observe some similarities between them in the following areas: the importance of knowledge in the process, the degree of complexity that can be captured by these representations, the role that individuals play in their learning process and in their knowledge generating, and also on the role played by educational experiences changing those representations. Based on these similarities, some studies have focused on identifying relations between both types of representations. These studies postulate that representations imply different degrees of complexity, and also that the variation on complexity explains the unequal distribution of resources used by students to face their academic challenges (Cano & Cardelle-Elawar, 2004; Lonka & Lindlom-Yläne, 1996). Although the results of these studies suggest a consonance relationship between conceptions of learning and epistemic beliefs, several conceptual and methodological issues must be taking into account to evaluate validity and scope of those previous claims. In that sense, Lonka and Lindlom-Yläne (1996) emphasizes the role that individuals profile could be played there. Similarly, Cano and Cardelle-Elawar (2004) suggest using a qualitative method and including controls by contextual variables. The main goal of this paper is to analyze the relationship between conceptions of learning and epistemic beliefs, including perceptions about demands of learning. To achieve that, some elements from the comparative method proposed by Rihoux and Grimm (2006) are used. A sample of students was selected, and a particular combination of elements from both representations was used to analyze each individual. The sample was composed by thirty eight undergraduate students from several programs (physics, engineering, psychology, and journalism) from Universidad Católica del Norte at Antofagasta, Chile. Data were collected by individual interviews, using open questions about conceptions of learning, and perception of demands of learning (Klatte et al., 2001; Marton et al., 1993; Tynjälä, 1997); also the dilemma about the construction of the Egyptian Pyramids was used to identify epistemic beliefs (Kitchener & King 1994). In methodological terms, the researcher establishes for each participant a profile of conceptions of learning, epistemic beliefs and perception of demands of learning, using a set of categories identified in previous studies (Terrazas & Frenay, 2008, 2009). Particularly, to determine conceptions of learning two categories were used: the Knowledge Restitution and the Knowledge Reorganization. The first one establishes that knowledge is acquired by simple assimilation and the second that, during the learning process, the knowledge is acquired by reorganizing and integrating new elements with previous knowledge. To operationalize epistemic beliefs, both empiricism and relativism categories were used. Empiricism supposes that knowledge is to discover a univocal reality; on the other hand, relativism implies that knowledge is an interpretation of reality, in the

last case many possible interpretations can co-exist about a particular phenomenon. To operationalize perception of demands of learning, a set of two categories were used: reproductive and elaborative demands. Reproductive demands include memorization and accurate reproduction of learning material on test. Elaborative demands include analysis and decision making process using different points of view. The results indicate two types of relations between conceptions of learning and epistemic beliefs. 1) A Consonance relationship, it is when those two elements go in the same direction; in other words it means that two cases are possible: a. Knowledge Restitution and Empiricism, or b. Knowledge Reorganization and Relativism. 2) A Non-Consonance relationship, it is when those two elements go in a different direction. For example: Knowledge Restitution and Relativism. Moreover, both consonance and non-consonance relationship between conceptions of learning and epistemic beliefs are related to a third element, it is the particular experience of learning that is represented by the specific perception of demands of learning. Usually, mismatch occurs between the epistemic beliefs and the perception of demands of learning. In conclusion, those results are partially supporting previous investigations, given that the relationship between epistemic beliefs and conceptions of learning is not always located in the consonance case. Results suggest reconsidering the issue concerning relationship between them focusing on the analysis of the coexistence of consonance/non-consonance cases. Furthermore, those results imply that the consonance scenario requires also the existence of a specific congruence with experience of learning that is taking place into each particular undergraduate program. On the other hand, the congruence between conceptions of learning and perception of demands of learning seems to be more important than the congruence between perception of demands of learning and epistemic beliefs. These results are in line with previous research emphasizing the contextual nature of conceptions of learning (Elen & Clarebout, 2001; Trigwell & Ashwin, 2006). Finally, the research about individual profiles and their configurations appears to be a next step to understand the co-existence of those cases of concordance / non-concordance. Future research should include larger samples and additional contextual controls, such as academic discipline, teaching practices and its link with the conceptions of learning and epistemic beliefs.

How teachers' daily attributions and perceptions predict children's success and performance?

Katja Natale Upadaya, University of Michigan, United States; Yi-Miau Tsai , University of Michigan, United States; Kaisa Aunola, University of Jyväskylä, Finland

Previous research has shown that among the most typical causes to which teachers attribute children's academic success are ability, effort, task difficulty and help from others. Previously it has been found that when children's performance at school is high teachers tend to attribute children's success to their abilities, whereas when children's performance is poor teachers tend to attribute their success to effort or others' help. However, less is known about how teachers' daily attributions and perceptions of success contribute to children's academic success and performance during the children's first year of primary school. Consequently, the present study aimed at investigating the associations between teachers' daily attributions, perceptions of success and children's performance in math during the children's 1st grade. In the present study, 160 children and their teachers were followed up for one school week once during the fall (Time1) and once during the spring (Time 2) of children's first year of primary school. Each day of the week teachers filled in a questionnaire concerning their daily interaction and causal attributions for children's daily success and failure. Children's performance in math was examined once during the fall (Time 1) and once during the spring (Time 2) of their 1st grade. The results were analyzed by using multiple regression. The results showed, first, that when teachers perceived children's success during the fall term of their 1st grade (Time 1) was due to their ability, the children is more likely to experience more success later on during the spring (Time 2). Similarly, when teachers attributed children's success to effort (Time 1), they also perceived children as being more successful later on (Time 2).

Previous research has shown that among the most typical causes to which teachers attribute children's academic success are ability, effort, task difficulty and help from others (Clark & Artiles, 1990; Georgiou, Christou, Stavrindes, Panaoura, 2002; Weiner, 1994). Teachers' causal attributions vary also by the internal-external dimension: ability and effort are typically considered as internal characteristics of a child, whereas task difficulty and teachers' help are external properties for a child (Weiner, 1985, 1986). Previously it has been found that when children's performance at school is high teachers tend to attribute children's success to their abilities, whereas when children's performance is poor teachers tend to attribute their success to effort or others' help (Holloway & Hess, 1985; Natale, Viljaranta, Lerkkanen, Poikkeus, & Nurmi, 2009). It has also been found that teachers' causal attributions contribute to children's performance: when teachers attribute children's success to internal causes, such as ability and effort, children's subsequent performance and motivation increases (Natale et al., 2009). Some studies have also found gender differences in teachers' causal attributions. Especially when explaining children's success in math, teachers may think that boys succeed because of their abilities, whereas girls succeed because of effort (Fennema, Peterson, Carpener, & Lubinski, 1990). However, less is known about how teachers' daily attributions and perceptions of success contribute to children's academic success and performance during the children's first year of primary school. Consequently, the

present study aimed at investigating the associations between teachers' daily attributions, perceptions of success and children's performance in math during the children's 1st grade. Moreover, the possible gender differences related to teachers and children were also controlled for in the analyses. The present study is a part of a larger Development of Motivation and Academic Skills in Family and School Environments study, in which 160 children and their teachers were followed up for one school week once during the fall (Time1) and once during the spring (Time 2) of children's first year of primary school. Each day of the week teachers filled in a questionnaire concerning their daily interaction, perceptions of children's success, and causal attributions (e.g. ability, effort, task difficulty and others' help) for children's daily achievement. Children's performance in math was examined once during the fall (Time 1) and once during the spring (Time 2) of their 1st grade. The results were analyzed by using multiple regressions by using the STATA program. To investigate the unique predictive effect of teacher' attribution, other variables of achievement and earlier school success were controlled. The results showed, first, that when teachers perceived children's success was due to their abilities during the fall term of their 1st grade (Time 1), they also perceived children as being more successful later on during the spring (Time 2). Similarly, when teachers attributed children's success to effort (Time 1), they also perceived children as being more successful later on (Time 2). The results showed further that teachers' daily causal attributions predicted rather the perception of children's success than children's actual performance at school. The results of the present study suggest that teachers' internal attributions (e.g. ability and effort) impact how successful teachers perceive children to be later on during the school year. No such predictions were found for teachers' external attributions. On the one hand, this may be due to the accuracy in teachers' causal attributions, and on the other hand may reflect bias between perceived success and teachers' internal attributions. Moreover, no gender differences related to teachers or children were found in the present study. This may be due to children's age, and cultural differences. These results also suggest that teachers perceive the success of first grade boys and girls in a similar way. However, more gender differences in teachers' perceptions may emerge when the children grow older.

The Relationship between Epistemic Beliefs and Goal Orientation: Changes across Adolescence

Amber Harris, Middlebury College, United States; Barbara Hofer, Middlebury College, United States

As part of a larger four year, cross-sectional and longitudinal examination of students' epistemological development, this study examines the relationship between adolescents' epistemic beliefs (beliefs about knowledge and knowing) and motivational goals. Students from New England rural public schools (6th- 12th grades) participated in a think-aloud online search task, a retrospective interview, an epistemic stance interview, and a follow-up survey at two time points, one year apart. Results suggest that students' epistemic beliefs, motivational goals, and academic achievement are part of an inter-related system, and that the relationships between these variables may change throughout the course of adolescence. Results of this research could allow teachers to more effectively design instruction to meet the needs of students at all developmental levels.

In recent years, psychologists have increasingly turned their attention to the field of personal epistemology (Hofer & Pintrich, 2002) or epistemic cognition (Greene et al, 2008), the system of beliefs that individuals hold about knowledge and knowing (Hofer & Pintrich, 1997). Researchers have also begun to explore the link between epistemic beliefs and motivation (Hofer, 1999; Paulsen & Feldman, 1999; Cano, 2005; Buehl & Alexander, 2005). Studies that provide support for the link between epistemic beliefs and motivation have not fully considered the potential influence of domain differences or developmental patterns of epistemology and motivation during adolescence. The current study was designed to address the following research questions:

Research Question 1: Do epistemic beliefs and motivational goals change during the course of adolescence?

RQ2: What is the relationship between epistemic beliefs and motivation?

RQ3: Does the relationship between epistemic beliefs and motivation change throughout adolescence?

RQ4: Will students' epistemic beliefs be related to academic achievement, as measured by students' grade point averages?

RQ5: In addition to these between subject questions, we were also interested in within-subject changes from the first to the second interview and survey administration. How do these relationships change within subjects?

Method

Participants

Initially, participants were 106 students in 6th (n=25) 8th, (n=31) 10th, (n=28) and 12th (n=22) grades; 56% were males. Participants were randomly selected from school rosters and compensated for time and transportation.

Procedure

Following a warm-up task, students were asked to think-aloud while completing an online search on a science topic. Students participated in a retrospective interview, as well an epistemic stance interview. Students later completed a

web-based survey that included epistemic beliefs measures (general and domain specific) and motivational measures, among other assessments. One year later, students returned to the lab to complete a similar set of tasks.

Results

RQ1: We first ran a one-way MANOVA to determine effect of year in school (6th, 8th, 12th) on the five dependent measures of motivation. Results of post hoc analyses revealed that scores on the performance approach subscale differed significantly between eighth ($M = .88$, $SD = 0.89$) and twelfth grade ($M = 2.74$, $SD = 0.89$), and between sixth ($M = 2.04$, $SD = 0.91$) and twelfth grade ($M = 2.74$, $SD = 0.89$). Additionally, scores on the interest subscale differed significantly between sixth ($M = 3.69$, $SD = 0.95$) and eighth grade ($M = 2.88$, $SD = 1.19$).

RQ2: We found a negative correlation between students' scores on the performance avoidance sub-scale of and both the general epistemic belief scale, $r(74) = -.295$, $p = .011$, and science epistemic belief scale, $r(74) = -.243$, $p = .037$. Conversely, a significant positive correlation was found between students' scores on the general epistemic belief scale and the mastery sub-scale, $r(74) = .308$, $p = .008$.

RQ3: Performance approach goals and epistemic beliefs. In sixth grade, a significant negative correlation was found between science epistemic beliefs and performance approach, $r(25) = -.455$, $p = .022$. However, by twelfth grade a significant positive correlation existed, $r(19) = .561$, $p = .013$.

Performance avoidance goals and epistemic beliefs. Within the sixth grade cohort, science epistemic beliefs were significantly negatively correlated with performance avoidance, $r(24) = -.573$, $p = .003$. Eighth graders' scores on the general epistemic belief scale and the performance avoidance sub-scale were also negatively correlated, $r(31) = -.395$, $p = .028$.

However, by twelfth grade, the opposite relationship can be seen. Although no significant relationship was found between these variables, the correlation between the science epistemic belief scale and the performance avoidance sub-scale has become positive, $r(19) = .192$, $p = .431$. Furthermore, this correlation differs significantly at the .05 level from the correlation between these variables in sixth grade.

Mastery goals and epistemic beliefs. At the sixth grade level, a significant positive correlation existed between history epistemic beliefs and mastery, $r(24) = .481$, $p = .017$. Although the correlation between eighth graders' scores on general epistemic beliefs and mastery was not significant, it did approach significance, $r(31) = .337$, $p = .064$. Similarly, the correlation between history epistemic beliefs and mastery also approached significance in twelfth grade, $r(18) = .459$, $p = .056$. Students with more sophisticated epistemic beliefs regarding the certainty of knowledge were more likely to adopt mastery goal orientations, regardless of year in school.

Research Question 4

General beliefs and academic achievement. Significant positive correlations were found between general epistemic beliefs and all three measures of academic achievement: overall grade point average, $r(70) = .430$, $p = .000$, grades in science, $r(68) = .343$, $p = .004$, and grades in history, $r(67) = .364$, $p = .002$. Thus, students with more sophisticated beliefs about knowledge were more likely to obtain higher grades in school, both overall and in science and history.

Domain specific beliefs and academic achievement. No significant correlation was found between science beliefs and grades in science, $r(68) = .224$, $p = .066$, but this correlation was approaching significance. Similarly, no significant correlation was found between history beliefs and grades in history, $r(65) = .223$, $p = .075$, but this correlation also approached significance. However, students' overall grade point averages were positively correlated with both the history epistemic belief scale, $r(68) = .286$, $p = .018$, and score on the science epistemic belief scale, $r(70) = .303$, $p = .011$. General epistemic beliefs seemed to be more strongly correlated with both overall grade point average and achievement in science and history.

Research Question 5

We have begun coding data from the second round of interviews and survey administration and will be examining the within-subject changes in the next few months.

Discussion

Results of our study provide support for a connection between epistemic beliefs and motivational goals during adolescence. Across all grades, students who had more sophisticated beliefs about the certainty of knowledge were more likely to hold adaptive motivational goals, such as mastery goals, interest, and utility. Additionally, students with less sophisticated beliefs were more likely to adopt less adaptive motivational goals in their learning, such as

performance goals. The current research also suggests that the relationship between these variables may change during adolescence. Consistent with previous research (Pintrich & Schunk, 2002), the results of our study indicate that students' rely more frequently on mastery goals earlier in their education, and then begin to adopt performance goals more frequently later in their education.

THEMATIC POSTER

Reading

The effects of familiarization with oral expository text on listening and reading comprehension level

Irene-Anna Diakidoy, University of Cyprus, Cyprus

This study explored the effects of text type (narrative vs. expository) and early familiarization with oral expository text structures on second graders' listening and reading comprehension levels. Early listening comprehension skill is hypothesized to facilitate and predict reading development after mastery of decoding skills (Hoover & Gough, 1990; Sticht & James, 1984; Vellutino et al., 2007), with important implications for early reading assessment and instruction. However, this hypothesis has found support only with narrative texts, as expository listening and reading comprehension levels have been found to be comparable even in the early elementary grades (Diakidoy et al., 2005). Therefore, this study examined the extent to which differential results can be attributed to lack of early familiarization to oral expository texts or to particular text characteristics. Two hundred second grade students read and listened to a set of narrative and expository texts, and their comprehension was assessed with a sentence verification task. Half of the students had participated in an intensive nine-week-long intervention designed to familiarize them with oral expository structures in the previous year while in Grade 1. Preliminary results indicated that expository listening and reading comprehension levels remained comparable in the intervention group, indicating that simple lack of early exposure is not a viable explanation for the results obtained with narrative and expository texts. These findings have implications for the generalizability of the main hypothesis advanced by contemporary reading models (Hoover & Gough, 1990; Vellutino et al., 2007) as well as conceptualizations of comprehension as a unitary process construct.

The purpose of the present study was to explore the effects of text type (narrative vs. expository) and early familiarization with oral expository text structures on second graders' listening and reading comprehension levels. According to a unitary process view, early listening comprehension skill facilitates reading acquisition and predicts the level of skill that is achieved in reading after decoding skills have been mastered (Sticht & James, 1984). This unitary process view has provided the main theoretical framework for contemporary models such as the Simple View of Reading (Hoover & Gough, 1990) and the Convergent Skills Model (Vellutino et al., 2007). In both models, the implicit assumption is that learning to read involves decoding plus language comprehension skill, with comprehension conceptualized as a unitary process applicable across stimuli and tasks. Therefore, listening comprehension is hypothesized to precede, relate to, and predict reading development. In addition, listening comprehension levels are hypothesized to be higher than reading comprehension levels in the early elementary grades when decoding skills have not been fully mastered. Although, the hypotheses originating from a unitary process view have found general support in research, there are indications that this may not be the case across language stimuli and tasks. Specifically, Diakidoy et al. (2005) found differences in favour of listening comprehension in the second grade, but only with narrative texts. In contrast, oral and written expository comprehension performance was comparable regardless of grade level. These diverging results may be attributable to either the particular characteristics of expository texts (unfamiliar and abstract content and variable structures) or to simple lack of early exposure to oral expository text. Therefore, this study sought to examine (a) the extent to which previous findings in relation to oral and written expository text comprehension can be replicated and (b) the extent to which differential results can be attributed to lack of early familiarization to oral expository texts or to particular text characteristics. The sample included 200 second-grade students representing a range of oral and written language comprehension ability as indicated by their teachers' ratings. All students read and listened to two narratives and two expository texts, and their comprehension was assessed with a sentence verification task. However, half of the students had participated in an intensive nine-week-long intervention designed to familiarize them with oral expository structures in the previous year, while still in Grade 1. The intervention involved teachers reading aloud a selection of age-appropriate expository texts and posing key questions designed to facilitate class discussion and text comprehension. Repeated measures analyses with Presentation Mode (oral vs. written text) and Text Type (narrative vs. expository) as the within-subject variables, Group (intervention vs. control) as the between-subject variable and General Language Comprehension ability as the covariate indicated significant main effects of the covariate and the Presentation Mode and a significant Mode X Group interaction (p < .05). These findings replicate previous results and further suggest that the differential pattern of results obtained with oral and written expository texts cannot be attributed to simple lack of early exposure and familiarity. These findings have both theoretical and practical implications. First, they indicate that the main hypotheses advanced by current reading models may not generalize across language stimuli, texts, and tasks.

Although narrative listening comprehension skill may precede and provide the basis for the development of reading comprehension skill, this is not the case with expository listening comprehension. These findings leave open the possibility that the demands posed by expository texts and other text types and stimuli may require the application of different comprehension mechanisms or strategies. Second, the present findings suggest that language comprehension as a construct is far too complex to be captured by a single score obtained in a single assessment context. Therefore, the assessment of listening comprehension skill is more properly thought of as an indicator of the ability to process a particular type of text when presented orally than as a predictor of overall reading potential. Finally, these findings also imply that early reading instruction needs to extend beyond decoding to familiarize students with the content and the structures of different text types and to provide a context for the development of more effective comprehension strategies.

Beliefs about Explanation Moderates the Effects of Explaining Expectancy on Text Comprehension

Tatsushi Fukaya, The University of Tokyo, Japan

Although previous research investigated whether explaining expectancy promotes text understanding, their results were inconsistent with some research reporting positive effects and others reporting no effects. The present study examined that beliefs about explanation (i.e. tutors' role perception) moderate the effects of explaining expectancy on text comprehension. An experiment was conducted with 51 8th grade students. Participants in the experimental condition were all given the explaining expectancy before studying the text. On the other hand, participants in the control condition were not. Results showed that the effects of explaining expectancy differed depending on their knowledge-transforming tendency. With explaining expectancy, knowledge-transforming tendency predicted the scores of text comprehension. But, without explaining expectancy, knowledge-transforming tendency did not. Results suggested that explaining expectancy exercise an influence only if the learners have the beliefs that they need to elaborate or organize the materials for explanation.

Introduction

In peer-tutorial programs, tutors could benefit from explaining learning materials even more than tutees (e.g., Cohen, Kulik, & Kulik, 1982). One of factors causing this learning is the explaining expectancy. Several studies compared an experimental group, in which subjects expected to explain the content of a text to another person, with a control group, in which subjects did not have such an expectation. Although some of them reported the positive effects (e.g., Bargh & Schul, 1980), some also reported there were no effects of the explaining expectancy (e.g., Renkl, 1995).

A major problem of the cited studies is that moderational impacts of the explaining expectancy were not investigated. That is, the explaining expectancy might promote effective ways of studying for some students, but might result in a superficial processing of learning for some. Roscoe & Chi (2007) argued there are two types of explanation, knowledge-telling and knowledge-transforming. If students perceive their role to paraphrase the materials with elaborations (knowledge-transforming tendency), explaining expectancy might promote the learning outcomes. On the other hand, if students perceive their role to just summarize the materials without any elaborations (knowledge-telling tendency), explaining expectancy might deteriorate the learning outcomes. So, this research investigated whether the beliefs about explanation moderates the impact of explaining expectancy on text comprehension.

Method

Participants

Participants were 51 Japanese 8th grade students (22 male, 29 female). They voluntarily participated the 5-days learning seminar held in the University of Tokyo. Participants were randomly assigned to one of the two conditions. Half of the participants were expected to explain the content after learning (n=25), and half were not (n=26).

Procedure

About 1 month before the learning seminar, a questionnaire about participants' achievements and beliefs about explanation was mailed out to them. Items of beliefs about explanation were created based on Roscoe & Chi (2007, 2008). The items consisted of the 3 items asking their knowledge-telling tendency (Cronbach's alphas = .77) (e.g., "An important thing in explanation is to recall exactly what the author said or wrote in the text.") and 4 items asking their knowledge-transforming tendency (Cronbach's alphas = .81) (e.g., "An important thing in explanation is to paraphrase difficult concept to be easily understood.") on their daily classroom lessons.

On the first day of the learning seminar, a booklet including the instructions, a question about motivation for learning the following text, the learning materials, and the post-tests were given to the participants. Instructions differed for the two groups. Subjects in the experimental condition were informed that after studying the material, they will write the expository text to explain the learned content to an imaginary 6th grade student. Subjects in the control condition

were not. Then, they studied a 1000-words article arguing "how art impresses human" or an 1100-words article arguing "technical development since Edo-era" for 20 minutes. Then, participants took the two-part post-tests for 25 minutes, which were designed to tap the memory, with the cued-recall task (8 items), and the comprehension, with the multiple-choice task requiring the elaborative inferences from texts (6 items). The overall sessions took about 50 minutes.

Results

A question of interest for this study is that explaining expectancy promote deep learning, not just rote learning, so the analysis focused on the scores of the multiple-choice questions which require inferences for understanding texts (i.e. text comprehension scores).

To check the manipulation, scores of a question about motivation for learning the following text were analyzed by ANCOVA with achievement scores as a covariate. The score in the experimental group was better than that in the control group ($F(1, 45) = 3.99, p = .052$), and was not moderated with the beliefs about explanation. Thus, the explaining expectancy was adequately manipulated.

Although comprehension scores were nearly equal in both groups (experimental group, mean = 2.60, SD = 1.19; control group, mean = 2.96, SD = 1.46), the focus of this study was to investigate whether beliefs about explanation moderate the effects of the explaining expectancy. According to Baron & Kenny (1986), moderational effects were analyzed by multiple regression analysis. The interaction term of explaining expectancy and knowledge-transforming tendency reached marginally significant ($t(45) = 1.92, p = .06$), and except this variable, all variables were not significant (Table 1). This interaction is illustrated in Figure 1, which shows that the simple slope of knowledge-transforming tendency is significantly different from zero when given the explaining expectancy ($t(23) = 3.23, p = .004$), whereas the slope is not significantly different when not given expectancy ($t(24) = -0.17, n.s.$).

Discussion

The primary goal of this study is to analyze the moderation by comparing the impacts of beliefs about explanation on text comprehension with or without explaining expectancy. The data supported the hypothesis. The results of this study suggested that inconsistent results of earlier research might be attributed from ignoring the different effects of explaining expectancy for different students.

But, how did explanation expectancy enhance the understanding with participants having knowledge-transforming tendency? Knowledge-transforming tendency reflects a learner's belief that they need to elaborate and organize the materials for the explanation so that they employ deep learning strategies. This tendency seems activate under the explaining expectancy, because scores of knowledge-transforming tendency did not predict the comprehension scores without the explaining expectancy.

Thus, for the tutorial-program to be effective, the administrators and classroom teachers need to focus on what kind of beliefs their students have. Their beliefs about explanation might not only lead to their bad explanation for the tutees, but hinder their own learning by explaining. Considering their important roles in the process of peer-tutoring, a line of research examining teaching methods to promote the learners' knowledge-transforming tendency would be promising for a future direction.

The depth of secondary school students' German (L2) word knowledge

Olga S. Hrebik, University of Szeged, Hungary

The depth of vocabulary is the qualitative characteristic of word knowledge referring to the internal structure of the sets of word meanings learnt and their different connections to other words (Meara and Wolter, 2004; Read 2000, 2007). This study investigated the depth of Hungarian secondary school students' German L2 word knowledge. The analysis focused on (1) the response patterns of a word association test, (2) the similarities and deviations between the response patterns of students at various German proficiency levels and (3) the correlations between the depth of lexical knowledge and reading comprehension, as well as between word knowledge and background factors (motivation and parental education). Three instruments were used: a German word association test, an adaptation of a Hungarian (L1) original, a German reading comprehension test (Cronbach's $\alpha=0.83$) developed by the author, and a questionnaire of language learning motivation (Cronbach's $\alpha=0.94$) and social background (Józsa, 2007). The sample comprised 205 students (grade 12, 18-year-olds) studying German (L2) and consisted of three sub-samples, based on the intensity of their language studies. The qualitative analysis of the response patterns of the word association test revealed that the structure of the bilingual students was more stable than that of the other two

groups, therefore difference in the intensity of language learning seems likely to result in different internal semantic structuring. The correlations between vocabulary depth, text comprehension and background factors were significant.

Theoretical background

Learning words is a traditionally privileged area in learning and teaching foreign languages. Experience has shown that the specific levels and qualities of vocabulary are important conditions for the development of language skills, reading comprehension among them (Qian, 1999; Zareva et al., 2005). Research has traditionally targeted two main dimensions of lexical knowledge: vocabulary width and depth. The width of vocabulary comprises all the words one knows, while the depth of vocabulary characterises the quality of the smaller or larger sets of words learnt, that is, their internal structure and semantic links to other lexical elements (Meara and Wolter, 2004; Read 2000, 2007). Word knowledge develops through a long learning process; it is enriched through learning experiences and is transformed by recurrent restructuring processes. In its complexity the acquisition of words resembles the development of skills and abilities (Vidákovich and Cs. Czachesz, 2006). For measuring vocabulary knowledge, various instruments are available (Read and Chapelle, 2001; Schoonen and Verhallen, 2008).

Aims

This study investigated the depth of secondary school students' German (L2) word knowledge. The analysis focused on (1) the response patterns of a word association test, (2) the similarities and deviations between the response patterns of students at various proficiency of learning German, and (3) the correlations between the depth of lexical knowledge and reading comprehension, as well as between the deep word knowledge and the background variables of motivation and parental education.

Methods

In 2009, a sample of 205 students studying German (L2) in grade 12 (18-year-olds) from ten secondary schools participated in the study. Based on the intensity of learning the language, the sample contained three sub-samples: group A studying German in the standard curriculum, (n=65, 3 or 4 hours/week); group B, taking a high number of German classes (n=71, >4 hours/week); and group C, studying German in a bilingual programme (n=69).

Three instruments were administered. The word association test was a German adapted version of Schoonen and Verhallen's Word Association Task (WAT). The test (14 tasks) examined the meaning subjects attributed to targeted words by asking them to select three of the six presented words in different semantic relationships (paradigmatic, partonomic, syntagmatic etc.) with the target word.

The students' L2 reading comprehension performance was assessed by a 40 item reading test, based on three newspaper articles and developed by the author (Cronbach's $\alpha=0.83$). Information on language learning motivation was collected with a separate questionnaire (Cronbach's $\alpha=0.94$) used in earlier research (Józsa, 2007).

Results and discussion

(1) The qualitative analysis of the data from the word association test revealed a high variety of response patterns in all three sub-samples. In order to analyse the internal structures of response patterns, the frequencies of individual response alternatives were identified in all three samples, and cluster analyses were performed for each task. It seems that, although the most frequent response patterns are mostly composed of the most frequent response alternatives, the students selected these three components with differing frequencies. The structures of response patterns are not stable and the choice of neither component determines the selection of the other two.

(2) In order to compare the samples and to describe the distances between the characteristic response patterns for each sample, a proximity index was created by calculating the differences between the shortest and the longest distances, the values of which show the degree of the proximities of the response patterns in the samples on a given task. In several cases, the differences are considerable, occurring more frequently between groups A and C, and less frequently between groups B and C.

Despite these differences, it is obvious that the students in the bilingual program (group C) had more stable structures to their word patterns, as their choices are less diverse than those of the other groups. Students in group A (standard curriculum) had the least stable response patterns, and of the whole sample, they are the most likely to have had the least experience in studying German. In general, it may be said that the decontextualised syntagmatic (definition-type) response patterns were more frequent in group C and the least frequent in group A. The different intensities of language learning thus seem likely to result in different internal semantic structuring. The variety within the sub-samples may be due to individual characteristics in word acquisition.

(3) As regards the results of the reading comprehension test, the performance of group A (55%) was significantly (p

The correlations between vocabulary depth and motivation (0.171,)

Methodological and educational significance

The adaptation and piloting of the word association test to German (L2) yielded important methodological experience. On the one hand, the study provided evidence that the instrument and the process are suitable for the identification of the similarities and deviations in the qualitative characteristics of students' vocabulary depth; on the other hand, it also provided information on, and confirmed the correlation between, vocabulary and reading comprehension.

The nature and composition of word knowledge and the role it has in foreign language acquisition and comprehension are areas barely studied in Hungary when learning foreign languages is concerned. The better understanding of the nature of word acquisition in a foreign language and its correlations with the different factors of language learning and language knowledge requires further investigations.

The Role of Interest and Concreteness on Reading Time and Recall of Expository Text

Gregory Schraw, University of Nevada, United States; Lori Olafson, University of Nevada Las Vegas, United States; Ivan Ivanov, University of Nevada, United States; Kendall Hartley, University of Nevada, United States

We investigated the effects of interest and concreteness on reading time and recall of sentences in an expository text. 66 participants read the text on a computer and recalled the text afterwards. High-interest sentences were read faster, while high-concreteness sentences were read slower. High-interest and high-concreteness sentences were remembered better. In addition, interest and concreteness produced an interaction on recall such that sentences high on both dimensions were recalled better than those high on only one. Results were discussed in terms of Dual Coding Theory, which postulates separate verbal and imaginal systems in memory that draw on different pools of cognitive resources and yield additive effects on recall, or the Integrative Model of Text and Picture Comprehension, which postulates separate verbal and imaginal systems in memory that draw on a single pool of resources and yield interactive effects on recall. Our findings were more consistent with the Integrative Model.

Purpose and Hypotheses

This study investigated the effects of interest and concreteness on reading time and recall of sentences in an expository text. Previous studies have investigated the effects of interest and concreteness separately on text processing; however, none of these studies examined their conjoint reading time and recall in expository text. We parsed a 50-sentence expository text into four categories based on whether sentences were above or below the mean on interest and concreteness. 66 participants read the text on a computer and recalled the text afterwards. We hypothesized significant main effects for interest and concreteness on both the reading time and recall outcome measures. In addition, we predicted a significant interaction between interest and concreteness variables such that the combined effects of high interest and concreteness would significantly improve reading and recall compared to high interest or high concreteness alone.

Theoretical Framework

Previous research shows that interest and concreteness increase memory for expository text (Ainley, Hidi, & Berndorff, 2006; Alexander & Jetton, 1996; Durik & Harackiewicz, 2007; Hidi & Renninger, 2006; Sadoski, 2001; Schraw & Lehman, 2001). The majority of studies investigated interest and concreteness separately. However, several studies examined the relationships between interest and concreteness when used simultaneously to predict learning (Sadoski, Goetz & Fritz, 1993; Sadoski, Goetz & Rodriguez, 2000; Sadoski, Goetz, Stricker, & Burdinski, 2003), reporting significant positive correlations between the two. In these studies, the effects of interest and concreteness have been explained using either Dual Coding Theory (Sadoski, 2001), which postulates separate verbal and imaginal systems in memory that draw on different pools of cognitive resources and yield additive effects on recall, or the Integrative Model of Text and Picture Comprehension (Schnitz, 2002), which postulates separate verbal and imaginal systems in memory that draw on a single pool of resources and yield interactive effects on recall. In terms of the current research, Dual Coding Theory predicts a significant main effect for interest and concreteness, but no interaction between them. It also predicts faster reading times for high-interest and high-concrete sentences. In contrast, the Integrative Model predicts a significant interaction effect for interest and concreteness due to interactive, conjoint processing. It also predicts faster reading times for segments that are high-interest and high-concreteness than segments that are high on only one dimension. Methods30 undergraduates read the text from a computer sentence by sentence without being timed and then rated the interestingness and concreteness of each of the 50 sentences in the text. The text was 1,200 words long and described the formation and potential dangers of lightning (Harp & Mayer, 1998). Ratings were made on a 4-point Likert scale. These ratings were used to partition the sentences into four categories: 14 high-interest, high-concreteness (HIHC), 4 high-interest, low-concreteness (HILC) sentences, 3 Low-interest, high-concreteness (LIHC) sentences, and 29 low-interest-low concreteness (LILC)

sentences). 66 different participants from the same pool then read the text sentence by sentence on the computer and were timed.

Results

Sentences were scored for total recall by two judges with 96% agreement. Reading times are reported in milliseconds per word to equate the four categories. The analysis consisted of a 2 X 2 repeated-measures ANOVA in which each variable was treated as a within-subjects variable. There were significant main effects for interest $F(1, 65) = 21.29, p < .001$. Recall scores were converted to proportions. The findings were significant main effects for interest $F(1, 65) = 19.67, p < .001$.

Discussion

Our results suggest several findings. One is that high-interest segments are read faster than low-interest sentences. High-interest sentences also were recalled better than low-interest sentences. These findings are consistent with a variety of previous studies and are consistent with both the Dual Coding Theory and Integrative Model frameworks, which predict that high interest facilitates engagement and enables readers to integrate this information into a mental representation of the text with greater ease. A second finding is that concreteness affects reading differently than interest. Although high-concrete sentences were recalled better than low-concrete sentences, they took significantly longer to read. This finding is inconsistent with Dual Coding Theory which predicts faster reading times for high-concreteness sentences because they facilitate processing in imaginal memory. In contrast, longer reading times are consistent with the Integrative Model which predicts that verbal and imaginal systems engage in conjoint processing to establish a more elaborate representation in memory. Processing in two systems simultaneously may increase the amount of time and effort needed to process these sentences. A third finding was that interest and concreteness interacted to yield significantly better recall than either interest or concreteness alone. This finding supported the Integrative Model, which predicts conjoint processing between verbal and imaginal memory systems in a manner that integrates multiple facets of meaning into a single representation in memory. In contrast, the Dual Coding Theory perspective predicts additive effects for interest and concreteness due to separate processing in verbal and imaginal memory, but not interactions due to conjoint processing.

Beyond vocabulary and memory: Inference skills contributes to the development of listening comprehension

Riikka Roman, University of Turku, Finland; Julie Lynch, Saginaw Valley State Univ., MI, U.S., United States; Janne Lepola, Univ. of Turku, Finland

The aims of the present study were to analyze the concurrent and longitudinal contributions of inference making, vocabulary, memory and phonological skills to narrative listening comprehension. One hundred thirty Finnish-speaking children participated in a longitudinal study. The participants' narrative listening comprehension, inference skills, memory of sentences, vocabulary and phonological awareness were assessed individually at time 1 (4-year-olds), time 2 (5-year-olds) and time 3 (6-year-olds). Narrative listening comprehension was assessed by free recall task and prompted literal comprehension questions. Inference making skills were evaluated by implicit comprehension questions (Paris & Paris, 2003) in the context of narrative picture-book reading. The results show that among younger children vocabulary and memory for sentences played a more fundamental role in concurrent listening comprehension. The results also show that inference making skills at the age of 4 and 5 years had a significant contribution to later listening comprehension over and above the effects of the autoregressor and language skills. The present study contributes to previous research on text comprehension by identifying both language-related and higher-order skills that underlie the development of listening comprehension among young children.

Summary

Aims

The aim of the present study was to analyze the concurrent contributions of inference making, vocabulary, memory and phonological skills to narrative listening comprehension. An additional interest was to examine the unique role of inference making skills in predicting the development of narrative listening comprehension from the age of 4 to 6 years.

Methodology

Despite the large body of research on early reading skills (see, e.g., Lyytinen et al., 2004), and the progress made in supporting children's reading difficulties (Vellutino & Scanlon, 2002), less attention has been paid to the development of comprehension skills (Paris & Paris, 2003) among nonreaders. As a consequence, there is a serious gap in our knowledge about the development of listening comprehension before children have become fluent readers.

To understand a narrative through listening, the child not only needs to segment the spoken message to word units and derive and integrate the meanings of individual words and sentences, but s/he also needs to make inferences in order to identify characters and their motives, the plot of the story, and to make links between the text elements (van den Broek et al., 2005).

A longitudinal study by Sénéchal, Oullette, & Rodney (2006) showed that when controlling for prior listening comprehension, literacy skills and SES, vocabulary at kindergarten made a unique contribution to grade 1 listening comprehension. What is more, only a few studies have examined the relationship between memory and listening comprehension among young children (Dufva, Niemi, & Voeten, 2001). A study by Florit et al. (2009) showed that both forward and backward word span tasks were unique predictors of listening comprehension over and above language skills among the 4- and 5-year-olds. In addition, the ability to make inferences is shown to be an important source of individual differences in text comprehension. A study by Cain, Oakhill and Bryant (2004) showed that inference making skill was a significant predictor of concurrent reading comprehension (children aged 8, 9 and 11 years) even after the contribution of working memory, vocabulary, and word reading skills were controlled for. Moreover, the study by Kendou et al. (2008) showed that inference making had a unique contribution to narrative comprehension over and above vocabulary and phonological skills both at the age of 4 and 6 years, and, the predictive power of inference making increased with age. The present study contributes to previous work by examining the role of inference making, vocabulary and memory skills in predicting the development of listening comprehension.

Method.

130 Finnish-speaking children participated in longitudinal study. The participants' narrative listening comprehension, inference skills, memory, vocabulary and phonological awareness were assessed individually at time 1 (4-year-olds), time 2 (5-year-olds) and time 3 (6-year-olds) by trained experimenters. Parallel narrative texts describing the behaviour of a cat in specific setting (91 words) were used in the assessment of listening comprehension. Listening comprehension was assessed by retelling task scored according to story grammar framework (Mandler & Johnson, 1977), and by four prompted comprehension questions. Inference making skills were evaluated by five implicit comprehension questions (e.g. feeling, causal relation, prediction) in the context of narrative picture book reading (Paris & Paris, 2003). The subtest of sentence repetition (Korkman et al., 1997) was used to assess children's memory of progressively longer sentences. The word definition task was used to assess children's skill in analyzing knowledge of word meanings (WISC—III; Wechsler, 1999). Phonological awareness was evaluated by 10 rhyme and 10 alliteration tasks (Silvén et al., 2002).

Results demonstrate that the scores were normally distributed in listening comprehension (LC), inference making and language-related variables. Floor effect was observed to some extent only in retelling task at time 1 and time 2. To determine whether inference making skills make a unique contribution to the prediction of concurrent and later LC over and above vocabulary, memory of sentence and phonological awareness, a series of fixed-order hierarchical regression analyses was performed. The findings are reported in tables 1 and 2. As shown in table 1, both vocabulary and memory of sentence were significant concurrent predictors of LC at time 1, and vocabulary predicted unique variance in LC at each time point. Inference making skills started to account, from time 2 onwards, for a significant amount of variance in LC over and above vocabulary and memory skills. Table 2 displays that inference making explained a unique variance in later listening comprehension after the effects of prior LC, vocabulary and memory were controlled for.

The present study extends our knowledge about the role of higher-order skills such as inference making in the acquisition of narrative listening comprehension skills, and that listening comprehension is based on the same skills that have been shown to underpin reading comprehension. Educational implications include the value of early instructional practices to enhance not only children's knowledge of word meaning but also inference making skills that are shown amenable to training as well (Paris & Paris, 2007).

Computer-supported Learning Environments

The Impact of Self-regulated Feedback on Learning Outcome in Computer-based Learning Environments

Antje Schatta, University of Erfurt, Germany; Helmut M. Niegemann, University of Erfurt, Germany

The requests of this study were to develop and evaluate self-regulated feedback for complex learning tasks. The principles for the design of self-regulated feedback are the attempt to find a simple technical solution for multimedia learning. The effects of these feedback forms on learning were examined in a computer-based learning environment. We suppose that feedback, including typical sources of error will be more useful than sample solutions.

Need for the Study

Why is it necessary to pay attention to self-regulated feedback? One problem is the high complexity of technical solutions for giving feedback for complex learning tasks in computer-based learning. We want to find out if the design of self-regulated feedback can be an adequate solution to substitute personal feedback for complex learning tasks in computer-based learning environments.

Theoretical background

Feedback is considered as an important framework in many theories of learning and instruction.

The cognitive view of feedback is important for this research project. From this point of view feedback is a source of information that is necessary to correct false responses of learners (Kulhavy & Stock, 1989).

Self-regulated feedback

Studies (e.g. Mory, 1992) turn the focus to feedback models that view feedback in the context of self-regulated learning (Butler & Winne, 1995). If we talk about self-regulated feedback we have to distinguish between internal and external feedback. For self-regulated learning the most important function of feedback is tutoring or guiding the learner to regulate their own learning process successfully. Elaborated feedback should support self-regulated feedback (e.g. sample solutions).

Research question and hypotheses

This paper deals with one of our research questions concerning the learning outcome: Are there differences in consideration of learning outcome between the treatments? We hypothesized that learners following the feedbacks, including typical errors conditions of this study will reach higher learning outcomes compared to those with only sample solutions. We also suppose students with feedback including typical errors will reach higher learning outcomes in the ten tasks including typical errors as distractors.

Method Participants and design

The participants were 307 college students (267 women, 40 men) majoring in education. They were randomly assigned to one of the five conditions: feedback as personalized sample solutions (Mayer, 2005) referring to typical sources of error (n=63), sample solutions referring to typical errors (n=64), feedback as guidelines referring to typical errors (n=51), feedback as personalized guidelines referring to typical errors (n=66) and a control group with sample solutions (n=63).

Procedure

The field experiment was carried out within the lecture "Learning and Instruction". The lecture was presented online at a computer-based learning environment (CBLE). According to the five conditions there were five learning rooms in which students worked with the materials and feedback. The same mini lectures, materials from the textbook, complex learning tasks were presented to the students in each of the rooms. The complex learning tasks requested students to name and explain certain processes in learning and instruction (e. g. "Explain 'schema', 'mental model', 'script' and find an example for each one."). Every week students were asked to listen to one or two mini lectures, read the relevant pages in the textbook and answer five or six learning tasks. At the end of every week students had to load the solutions of their complex learning tasks onto the learning platform. On Mondays, we loaded the different feedback forms onto the platform. Then students should compare their own solutions for the learning tasks with the feedback given. While working with the feedback, students were asked to compare the typical errors given with their own solutions of the complex learning tasks (e. g. "Attention: This is a typical source of error in this task: the mix-up of examples for mental model and script"). In the personalized forms of feedback, we showed students how to use the feedback ("Now you can compare your own solution with the sample solution. You can go back to the lesson if you found errors and repeat again") and motivated them ("If you have got the same solution, you are well prepared for the exam at the end of the term").

Learning outcome was measured at the end of the term by an exam consisting of 60 items. Students had to choose the correct answer out of four answers given. Ten items included typical errors as distractors.

Analyses and expected results

At the moment we test our hypothesis with MANOVAs.

We suppose that learners following the feedbacks including typical errors (experimental group) will reach higher learning outcomes compared to those with only sample solutions (control group). We also suppose the experimental group to gain better learning outcomes in the ten tasks including typical errors as distractors compared to the control

group. This is because comparing the feedback with typical errors with their own solutions should be able to relate to errors (learning from mistakes) and thus, lead to a higher learning outcome.

Scientific significance

If at least one of the formats of self-regulated feedback turns out to be effective, instructional designers will have a strong argument to use more complex learning tasks in multimedia learning environments.

The impact of competition in a game-based learning environment on motivation and language learning.

Sylke Vandercruysse, Katholieke Universiteit Leuven, Belgium; Mieke Vandewaetere, University of Leuven - Campus Kortrijk, Belgium; Geraldine Clarebout, Katholieke Universiteit Leuven, Belgium

Although games are recently quite popular in education, not much empirical studies have focused on the effectiveness of games in educational settings. Of the studies that examined this, many contain flaws resulting in unclear conclusions. As proposed by Aldrich (2005), focusing on gaming elements rather than on games as such may be a possible solution for these shortcomings. In the current effectiveness study, the competition element, more specifically the competition against others, will be investigated. The game based learning environments used in the experiments are developed according to the principles of the 4C/ID-model (van Merriënboer, Clark, & Croock, 2002). The presumed results are that the students confronted with the competition element will be less intrinsically motivated and they are expected to improve less on the posttests than the students playing in a non-competitive learning environment.

Introduction

Notwithstanding the large amount of recent research on (educational) games and the promising claims that are spread into the world about them (see for example Gee 2003; Prensky, 2001), there is only sparse empirical research available on the educational effectiveness of these games. Consequently, drawing general conclusions about the effectiveness of educational games is difficult, if not impossible. Therefore, it is more interesting to focus on gaming elements rather than on games as such to find the crucial elements for defining the successful implementation of a game in educational settings (Aldrich, 2005; Vandercruysse et al., 2010). Games consist of different gaming elements. Some gaming elements are inherently present in a game environment (e.g., story, goals and rules) others are not, depending on the definition the authors give to 'educational games', for example competition. This element has already been defined in different ways and can take several forms, e.g., competition between the user and the computer, against oneself, chance, time, etc. or a combination of these elements (Alessi & Trollip, 2001). According to Cheng, Wu, Liao, and Chan (2009) competition is a well-structured activity with a clearly defined goal for students which can be a motivator for excelling themselves. Competition may thus provide an additional challenge to the learner in educational settings, which may result in greater attention and excitement, which in turn indirectly influences students' performances. Next to this, competitive game design can encourage students' belief that investing effort will obtain the harvest and encourage them to work (Wu, Liao, Chen, & Chan, 2010). However, implementing competition also seems to have drawbacks (Cheng et al., 2009). When applying competitive elements in the game-environment, especially external rewards are given to the students which can lead to lower sense of control and subsequently to lower intrinsic motivation (Deci, Koestner, & Ryan, 1999). Also, confronted with competition, students are exposed to social comparison which can influence their self-concept or emotions. Especially students with low self-concept may suffer from this and undermine their performance (Bandura & Locke, 2003), feel more depressed, frustrated or inferior (Cheng et al., 2009). In sum, no univocal results on effectiveness of games for learning seem to occur. Some studies support the positive effects (e.g., the motivational aspect) of competition as a separate variable in a game on performance, others show no or negative effects (e.g., too much extrinsic motivation). Consequently, the following research questions are examined: (1) Is competition as gaming element more motivating

and engaging than a game-based environment without this gaming element? (2) Does competition affects students' performance in comparison with students playing in a non-competitive game-based learning environment?

Method

Learning environments

Two different game-based language learning environments have been developed. These environments were based on the four-component instructional design model (4C/ID). This is an instructional design model that supports and enables educational developers to construct learning materials for complex tasks (van Merriënboer, et al., 2002), here English language learning, more specific English conversation skills. The two environments differed only with respect to the inclusion of the competition element. Participants were randomly distributed over both learning environments/conditions.

Participants

Hundred first year-university students participated in this experiment. All students already received English courses in general secondary education. Nowadays they receive no English language courses, however some of their study content is presented in English.

Competition element

In the competitive game-base learning environment, different competitive elements are included. It should be noted that we exclude competition against oneself as a study object, since it can be argued that overcoming a problem or learning new things can also be called competition and hence this is present (or at least is expected to be) in all learning environments. Competition against others is included since the score of the player is compared with a mean score during the game. The students are told this is the mean score of the other players in the classroom, in fact this score is measured during a pilot-study. In this pilot study, students received the questions as a traditional paper-and-pencil test. The mean score on this test was calculated and afterwards implemented in the environment. This was done because of technical limitations: calculating the mean score during the game-play of the students was impossible. Next to this, after finishing a task (class) students see a high ranking list. In this list, students can find their position in comparison to the other players. Also in this case, the scores were measured before-hand and are equal for all players, only the position of the students differed, depending on their own individual score.

Procedure

The participants received a pretest to measure their prior English language knowledge related to the content that is taught in the game (i.e. the difference between formal and informal language). Based on this test, the prior knowledge level of the participants concerning English language could be determined. If differences occurred, correction for the prior knowledge was made during the analyses. Next to the pretest, participants also received a motivation questionnaire. After completing both, the students were introduced in the learning-environment and the goals were explained. During the gameplay the players practiced their English language knowledge, more specific the difference in language use in formal or informal contexts. After playing the game, students received a posttest and two questionnaires. The posttest measures again their performances. The first questionnaire measures motivation after game-playing. By means of this survey the hypotheses concerning motivation are investigated. Next to this, also their competition experience is questioned to be sure that the intended competition feeling is realized. Tracking and logging data were stored on an external SQL-server from which information was extracted such as the score during game-playing, their end-score, time-spent during learning phase, etc.

Results

Because this is a work in progress and the data-analysis is still ongoing, only the presumed results are mentioned. The hypotheses we pose, based on the literature, is that students learning in a competitive game-based learning environment will show a decrease in intrinsic motivation and lower improvement on the posttests than students playing in a non-competitive game-based learning environment. For a graphical representation of the hypothesized effects, see Figure 1.

Self-reported and observed attention behaviour

Mandy Hommel, University of Technology, Germany

Observing attention behaviour is impeded by feigning and covert aspects. The difficulty to conclude cognitive engagement via observing attention is obvious. In a research project (sample size N = 100) with the aim to compare the attention and learning performance in different kinds of teaching and learning situations, this problem was addressed. In line with the test of the validity of the developed observing instrument the self-reported attention

behaviour of five randomly selected students was compared with the coding of two independent observers. The results show possibilities and limits of observing attention behaviour of students in classroom situations.

Attention is the first cradle in the learning process. Processes of attention are mediators (HELMKE, 2009) between individual conditions and situation features. Thus, questions how to get and hold attention and how attention influences learning, are important for teachers as well as for students.

The aim of the research project is the comparison of attention behaviour and its courses in more traditional and more activity oriented lessons (business game and case study instruction). Starting with the assumption of a better level of attention in activity oriented lessons caused by real complex problems and orientation towards prior experiences of the students, the courses of attention behaviour within the lessons and influences on learning results will be investigated. In this context, critical phases of attention and the features of these situations will be identified.

Based on the well tested "Mýnchner Aufmerksamkeitsinventar" (Munich attention inventory, HELMKE & RENKL, 1992) an extended and modified observing instrument was developed. Attention was determined by observable behaviour relating to time the students spent on-task (SLAVIN, 2000; KARWEIT & SLAVIN, 1981). Each class was videotaped by four cameras. In a first step the observing instrument was tested in a business game lesson. The degree of observer agreement between three independent observers reached Spearman's $\rho = .847$. In a second step the agreement between self-reported attention behaviour of students and the coded categories of the observers was determined to proof the validity of the coding scheme. Therefore, five students were randomly selected from the whole sample. During a retrospective interview the students were asked to describe their attention behaviour and thoughts in the learning situation. Out of the videotaped lessons sequences of 10 minutes were randomly selected to be the basis for the stimulated recalls. With the help of 30 seconds time intervals the students reported and valued their own behaviour by coding it appropriate to the given coding categories. The retrospective interviews were videotaped as well. Afterwards, two independent observers coded the behaviour of these students in the same lesson sequence to enable the determination of the agreement. Additionally the interviews were transcribed and analyzed.

The percentage agreement between the two observers was 0,863, between the self-reported attention of all learners and the first observer 0,876, and the second observer 0,863. Counted with the more cautious measure Spearman's ρ ; the agreement between self-reported attention of all students and observed attention reached values between $\rho = .743$ (observer 1) and $\rho = .765$ (observer 2). The differences in the agreement rates showed the lowest value for student 11 ($\rho = .264$ observer 1, $\rho = -.081$ observer 2) and the highest for student 43 ($\rho = .944$ observer 1, $\rho = .948$ observer 2). To figure out the reasons for the low agreement the transcript of the retrospective interview with student 11 was analyzed. Surprisingly the student reported insightful about her strategies of feigning attention while preparing a presentation for another subject. The engagement in another topic was not observable for certain. The resultant uncertainty concerning the valuation of the behaviour is reflected in the low agreement rates. The content of the poster will especially report and highlight the detailed results of this part of the project.

The investigation and its results are a vividly example for possibilities and limits of observing attention behaviour in context of classrooms.

Interactive learning tasks – useful learning tools or senseless time wasting?

Felix Kapp, TU Dresden, Germany; Susanne Narciss, TU Dresden, Germany; Hermann Koerndle, TU Dresden, Germany; Antje Proske, TU Dresden, Germany

One possibility to support learners in computer-based learning situations is to provide them with interactive learning tasks. Working on learning tasks can facilitate the learner's retention and understanding of learning material, the learner's knowledge organization and application, as well as the learner's assessment of his progress of knowledge and skill acquisition (Proske, Kßrndle & Narciss 2004).

Learning tasks have been proved to be an effective support for learners (Hamaker, 1986). The present study reports findings on the use of interactive learning tasks in six different learning environments. The learning environments were based on the same content management system but deal with different domains.

The number of participants ranged between 23 and 26 students for the different web-based learning environments. Students were randomly assigned to the control-group (learning environment without interactive learning tasks) or experimental-group (learning environment with interactive learning tasks). A significant learning effect for the experimental group was found for two domains. Results are discussed regarding the different learning activities.

Introduction

One possibility to support learners in computer-based learning situations is to provide them with interactive learning tasks. Working on learning tasks can facilitate the learner's retention and understanding of learning material, the learner's knowledge organization and application, as well as the learner's assessment of his progress of knowledge and skill acquisition (Proske, Kördle & Narciss 2004). In contrast to test exercises, interactive learning tasks offer the possibility to solve tasks interactively by providing multiple-try strategies and informative tutoring feedback (Narciss, 2008). Interactive learning tasks have the explicit goal of promoting learning by stimulating and guiding desired learning activities (Proske, Koerndle & Narciss, 2010).

Based on a review Hamaker (1986) reported that learning tasks have an effect on learning achievement. This review excluded learning tasks with informative feedback and studies from the field of computer-based instruction. Yet, it is a widely acknowledged assumption in educational research that learning tasks are useful in CBLs as well. The purpose of the present study was to investigate learning outcome effects of interactive learning tasks in different domains, to identify relevant characteristics of interactive learning tasks and processes which are responsible for those effects.

Method

Material and Participants.

The six learning environments, the corresponding interactive learning tasks and the knowledge tests were constructed by six groups of students during a psychology class at the Dresden University of Technology, Germany. Each group of students (consisting of five to six students) designed one learning environment and then served as participants by working on the learning material of the other five groups. Participants ranged between 23 and 26 persons. Topics of the learning environment that were chosen by the students themselves were "surviving in the wild", "Psychodrama", "didgeridoo", "pygmies", "emission trading" and "chameleon". Material in the six learning environments contained between 1050 and 1651 words and 0 to 15 content related pictures. All learning environments were based on the same content management system. The experimental group received access to 12 interactive learning tasks with informative tutoring feedback (Narciss, 2008). Each interactive learning task was constructed based on the content of the particular environment. All 12 interactive learning tasks were multiple choice questions in a single-best choice format. The informative tutoring feedback consisted of knowledge of result, specific information about why it was correct or wrong and in case of a wrong answer additional information which supports the learner to find the correct solution on his/her own. After the second incorrect trial the learning environment presents the correct solution.

Design and Procedure.

An experimental-control group design with just one posttest was used. Each participant worked on the learning material either with interactive learning tasks (experimental-group) or without (control-group). Participants started with studying the learning material after login on the web-based learning environment. They were randomly assigned to the experimental conditions. After finishing the study period they were asked to answer a multiple choice knowledge test consisting of 15 test items. The learning environments were accessed via the internet. Participants were free to choose the time and place of studying during a period of one week as long as they worked on the material and the knowledge test without interruptions.

Achievement measures.

Learner's achievement in the post-test was assessed by a post-knowledge test consisting of 15 multiple choice items.

Learning activities.

To gain information about the learning process the logfiles were analysed with regard to the use of interactive learning tasks and study time. Time on tasks and the correct and incorrect attempts of answering the interactive learning tasks were also recorded in the data base.

Results and conclusion

Achievement and learning activities.

The results of the knowledge tests for each learning environment and the learning activities are presented in table 1. [table 1 - appendix]

Data analysis of the post-tests revealed a significant effect only for the learning environment "surviving in the wild" ($t(22) = 2.60$, $pd = .91$) and "pygmies" ($t(24) = 3.78$, $pd = 1.22$). In those two learning environments students using interactive learning tasks performed significantly better than the control-group without interactive learning tasks. It should be emphasized that in both learning environments experimental- and control-group do not differ in study time. Data of the other four learning environments show that interactive learning tasks were used and sometimes lead to more learning time compared to the control-group (e.g. learning environment "Emission trading") but had no effect on the learning achievement.

The conclusion of the present study is that interactive learning tasks can promote learning. They serve as a useful tool which can support learners in achieving better learning effects even without investing more study time. On the other hand results show that providing learning tasks to learners is not per se useful. They should be constructed based on psychological findings (e.g. Klauer, 1987). Further research should consider aspects like the cognitive operations, different formats, the domain and the dimension interactivity especially in computer-based learning environments. Due to the limitations of the study further research with an experimental paradigm in a controlled setting is necessary. A special focus should be on the variety of interactive learning tasks and the question of how the learning process is affected by different types of learning tasks.

Ways of Contributing to a Knowledge-Building Dialogue in Elementary Classrooms

Maria Chuy, OISE/University of Toronto, Canada; Monica Resendes, OISE/University of Toronto, Canada; Bodong Chen, OISE/University of Toronto, Canada; Christian Tarchi, University of Florence, Italy; Marlene Scardamalia, OISE/University of Toronto, Canada

This paper addresses new ways for education to strengthen society's capacity to produce new knowledge. Collaborative knowledge creation is a "self-organizing process" fostered by idea diversity and continual improvement of ideas. An important challenge is to understand how different contributing roles might increase levels of knowledge creation. The current research aims: (1) to develop an empirically grounded list of ways of contributing to knowledge building dialogue, (2) to examine the extent to which these are present and evolve during the first years of elementary school, (3) to explore how various contributions support each other in a dialogue, and finally, (4) to probe ways of contributing to conceptual breakthroughs. The participants were 61 students from grades 1-3 from a school, where "knowledge-building discourse" is integral to day-to-day work. The dataset analyzed in this research covers 4 months of online science discourse archived in Knowledge Forum (Author, 2004), an online environment designed to support knowledge-building dialogue. Early analyses of results have revealed that the majority of students' contributions focused on two ways of contributing—*theorizing* and *working with evidence*. This suggests a powerful influence of teacher and technology supports, enabling young students to propose and improve explanations to scientific phenomena. Correlations further suggest different contribution types operate in tandem, with advances in one type supporting advances of another type. Follow-up path analyses will focus on the course of contributions leading to conceptual breakthroughs, developmental changes in contributor roles, and discourse dynamics to engage processes of collaborative knowledge creation.

Introduction

Innovation is increasingly important in determining the health and wealth of societies, and from this perspective, a citizenry's capacity for knowledge creation represents an important challenge for education. Collaborative knowledge creation is a "self-organizing process" (Resnick, 1996) fostered by idea diversity and continual improvement of ideas. Different contributing, complementary roles are believed to foster knowledge creation, and collaborative knowledge

creation has been explored through assigned roles. For instance, Edward de Bono (1985) distinguishes 6 different thinking strategies (e.g., critical thinking, idea generation, providing information, etc.) Similarly, Hogan (1999), observing student interactions in science discourse, identified 8 naturally occurring roles: promoter of reflection, contributor of content, creative model builder, and mediator of group interactions and ideas. The current research fosters different types of contribution through engaging students in use of an online environment with supporting scaffolds. Pedagogical work and analyses focus on (1) developing an empirically grounded list of ways of contributing of finer grain than the above, (2) examining the extent to which these are present and evolve during the first years of elementary school, (3) exploring how various contributions support each other in a dialogue, and finally, (4) probing which ways of contributing lead to conceptual breakthroughs. Toward this end, we selected an elementary school site where "knowledge-building discourse" (Author et al., 2003) is integral to the day-to-day work of classes. Evolving practices at the Institute of Child Study, University of Toronto, are aimed at improving collective responsibility for knowledge advancement in students (Author et al., 2007). More precisely, students reference, evaluate, build on, and work to continually improve ideas—their own and those of community members. In addition to face-to-face discussions, students work in an online environment—Knowledge Forum (Author, 2004)—that provides a community space for collaborative work with ideas, with stored records providing data for this study. Teachers and students are experienced in Knowledge Building pedagogy and technology, so the situation represents what Fischer and Bidell (1997) call "optimal conditions" for identifying cognitive developmental goals.

Method

Participants and Dataset

The participants were 61 primary school students from the Institute of Child Study (notably, 10 girls and 10 boys from Grade 1; 9 girls and 11 boys from Grade 2; and 11 girls and 10 boys from Grade 3). Their teachers have been committed to Knowledge Building and have used Knowledge Forum for several years. The dataset analyzed in this research covers 4 months of online discourse on one study unit of each grade: water cycles (Grade 1), salmon (Grade 2) and fungus (Grade 3). Knowledge Forum scaffolds were available to support students' discussion around scientific objects. The total 679 notes that were posted in the Knowledge Forum space during this period constitute the dataset of this research.

List of Ways of Contributing

On the basis of informal observation as well as knowledge creation literature, a provisional list of contribution types was created. Then, using well-recognized iterative procedures of "Grounded Theory" (Glaser & Strauss, 1967), this list was revised and extended. Six major categories with 20 sub-categories have been identified: I—Formulating thought-provoking questions (i.e., explanatory, design and factual questions); II—Theorizing (i.e. proposing, supporting, improving explanations, or seeking an alternative explanation); III—Designing an experiment (i.e., proposing or describing an experiment; identifying a design problem; thinking of design improvements); IV—Working with evidence (i.e. asking or looking for evidence; providing evidence or reference to support or discard a particular idea; identifying new facts); V—Creating syntheses and analogies (i.e. summarizing previous ideas by integrating multiple notes into a rise-above note); VI—Supporting discussion (i.e. using diagrams to communicate or support ideas; giving an opinion; acting as a mediator). Four independent raters participated in the analysis. A quarter of the notes were scored by all four coders, and the remaining three-quarters were equally distributed among four raters for individual coding.

Preliminary Results

Results reveal that the majority of students' contributions were dedicated to theorizing and working with evidence. One of the possible interpretations is related to the use of scaffolds that are available within Knowledge Forum: most of these scaffolds intended to support young students with creating new explanations and justifying them with evidence (e.g., scaffolds such as "My theory," "A better theory," "This theory does not explain," "New information," etc.). These scaffolds, supported by teachers in classroom and online discussion, seem to have had a powerful influence on the discourse forms in evidence in each of the classes under investigation. Correlation analyses further suggest that different contribution types operate in tandem, with advances in one type supporting advances of another type. For instance, the interest in explanatory questions was closely related to the ability to propose explanations and synthesize ideas, and interest in factual questions led to the search in authoritative sources for new facts that could be used to support theories. Other analyses in progress focus on the developmental changes of contributor roles (i.e., do some contribution types appear earlier or later in the discourse, and to what extent is this influenced by use of scaffolds?) and conceptual breakthroughs (i.e., are particular types of contributions associated with conceptual breakthroughs or "aha!" expressions?). Follow-up research underway will allow us to determine the extent to which giving priority to different discourse forms, especially those most directly related to conceptual breakthroughs, will serve to better engage processes of collaborative knowledge creation.

Learning in blended environment - face-to-face with social media and Mahara

Terhi-Maija Itkonen-Isakov, Metropolia University of Applied Sciences, Finland

The aim of the study is to research the changes of learning strategies in a global, networked learning environment, including also online environments and social media. In particular, the changes of educational practices are regarding the changing roles of teachers, the students and the the learning environments, including technology use in learning and instruction. The instruction combined face-to-face with online offerings, blended learning, and the pedagogical approach was inquiry and collaborative learning. The pedagogical frameworks also included shared expertise with the interaction of higher education and working life. The research questions were:- How learners build a shared understanding in social media environment? - What exactly sharing means in social media environment?- What kind of learning strategies support learning in social media environment? The participants were students and teachers of Helsinki Metropolia University of Applied Sciences Faculty of Culture. The data was collected in autumn 2010. The procedure was made with the server tools an a questionnaire and the data was reduced with content analysis and compared with learning outcomes. There is a methodological challenge to explain precisely the role of social media on all phases of blended learning and to explore the distinctions between individually and socially shared learning. Although, there seems to be some strategies supporting learning in social media learning environment: - combination of individual and group perspectives- target-orientation- working both online and in real life and openness for new ideas. The findings indicate that blended social media learning environments support collaborative inquiry learning.

The aim of the study is to research the changes of learning strategies in a global, networked learning environment, including also online environments and social media. In particular, the changes of educational practices are regarding the changing roles of teachers, the changing role of students and the changing role of the learning environments, including technology use in learning and instruction. The study is part of piloting project of open e-portfolio system Mahara in Helsinki University of Applied Sciences. Mahara itself features a weblog, resume builder and social networking system, connecting users and creating online learner communities, groups, blogs and forums, but also other open internet based tools were used. Wiki was used as a co-operative online learning tool, Moodle was used as CMS and new continent to the personal Mahara pages was updated with RSS feeds from e.g. Twitter, Youtube, Facebook, Slideshare and LinkedIn. The instruction combined face-to-face with online offerings, and the pedagogical approach was inquiry and collaborative learning. Inquiry-based learning is a constructivist approach, in which students have ownership of their learning. It starts with exploration and questioning and leads to investigation into a worthy question, issue, problem or idea. Collaborative learning is based on the model that knowledge can be created within a population where members actively interact by sharing experiences and take on asymmetry roles. Collaborative learning is heavily rooted in Vygotsky's views that there exists an inherent social nature of learning which is shown through his theory of zone of proximal development. The pedagogical frameworks also included shared expertise with the interaction of higher education and working life (Eteläpelto & Tynjälä, 1999). Using local experts and expert organisations as sources of information and as learning partners, the learning networks will be created, and the members of the network share knowledge and expertise as a form of human capital. Combining face-to-face with online instruction is also called blended learning. The goal of blended learning should be to unite the best features of oncampus and workplace learning with the best features of online learning, to promote active, self-directed learning opportunities for students. Although, learning in community is not a new idea. John Dewey suggested in his book *Democracy in Education* (1916) that the development of community is essential to a successful educational experience and that community is created through meaningful association, which is based on common interest and endeavor. The research questions were:- How learners build a shared understanding in social media environment? - What exactly sharing means in social media environment?- What kind of learning strategies support learning in social media environment? The context of the study was Helsinki Metropolia University of Applied Sciences. The participants were students and teachers of the Faculty of Culture. There were 230 students enrolled in Mahara e-portfolio environment during the piloting project, and they were allowed to form their own groups and use the social media environments as they liked. Data was collected from general activity, from number of discussion and social activities, from connections

("friends"), from group memberships, from the number of shared updates and from the number of comments to others' updates. The data was collected in autumn period 2010, from the beginning of August until the end of December 2010. The procedure was made with the server tools, including also graphical pictures of the development, and a questionnaire. The server data was analysed by quantity, and the questionnaire was reduced and analysed qualitatively with content analysis method. Finally, the results will be compared together with learning outcomes during spring 2011.

There is a methodological challenge to explain precisely the role of social media on all phases of blended learning and to explore the distinctions between individually and socially shared learning. Although, there seems to be some strategies supporting learning in social media learning environment: - combination of individual and group perspectives- target-orientation- working both online and in real life and openness for new ideas

The findings indicate that blended social media learning environments support collaborative inquiry learning. Also wiki as a tool supports learners building online communities of learning (Wikipedia, Wikiversity, and other wikis and social media). The members of the communities share their learning, support and help each other to learn even without realizing it (see also Suoranta, 2011). This not surprising, but what will happen in learning, if the learning environments change more and more towards online or blended environments in social media, and the conservative or preventing features are not at all supported by this kind of new learning environment? Also there is a question, if there will appear any problems of transformation when transferring learning from social media environment into real life environment?

THEMATIC POSTER

Technology in Education and Training

Learning to organize digital information

Jaap Walhout, Open Universiteit, Netherlands; Saskia Brand-Gruwel, Open University, Netherlands; Rob Martens, Open University, Netherlands

The skill to search, find, evaluate, select, process, organize and present information in order to acquire new knowledge is defined as information-problem solving (IPS). For two reasons instruction in IPS is needed. First, the information environment changed considerably. With the emergence of the internet, people have nearly unlimited access to information. But this information is not filtered or organized and the question of reliability is of importance. Secondly, students often get assignments which require searching for information. However, research reveals that many students are not able to solve information-based problems successfully, and that they have especially problems with the ability to organize found information.

The skill to organize information during web searches is determined by several factors. Prior knowledge functions as an ontology in order to structure the newly found information. Also meta-textual knowledge is of importance. This refers to explicit knowledge of the role and function of organizers and also knowledge of the relevance of a document as a function of its source.

Instruction in organizing web-based information should foster the use of a non-hierarchical tagging approach, make use of ontological schemes, should be embedded in schools curricula, and should be adaptive. It is expected that instruction in organizing information with the tagging technique will improve students' organization of information, the ability to select relevant and reliable information and will have a positive result on overall task performance. Moreover, adaptive instruction concerning the used ontological schemes will lead to better results for especially intermediates and novices.

In our democratic information societies, learners conduct searches through a variety of sources when informing oneself about a specific topic of interest. Being able to search, find, evaluate, select, process, organize and present information in order to acquire new knowledge is an important skill. This skill is defined as information-problem solving (IPS) (Brand-Gruwel, Wopereis, & Walraven, 2008). The Internet is today's primary resource for information searchers, offering an unprecedented access to an enormous amounts of information. However, research reveals that many students are not able to solve information-based problems successfully (Walraven, Brand-Gruwel & Boshuizen, 2008), and that they have especially problems with the ability to organize found information (Stadtler and Bromme, 2008). In this paper we will analyze the skill of organizing information. The main question to be answered is; 'How can instruction improve students' ability of organizing information?'

Organizing information in a proper way is not easy. Before the internet, information was in books which were stored in libraries. A book cannot be on two shelves. The main subject of a book was therefore used to classify the book into a certain category. Adopting the library way of organizing information, web directories were created to bring order in the available content. Because people are used to such a hierarchical system, it seemed natural to categorize information in classes and subclasses (Shirky, 2005). But problems can raise when unusual or new pieces of information are difficult to classify because they do not fit properly to the classification rules. Another problem is encountered when an information object fits in more than one (sub)class. Which one to chose? The more information is created, the bigger this problem gets. Although hierarchical classification systems are a good way of bringing order in a collection of physical objects, with the use of virtual information objects it becomes possible to organize the information with labels or 'tags'. Consequently, information can be attributed to different classes. With the emergence of social bookmarking, which lets people define their own tags (folksonomy), users are given more control over organizing the contents of the web using own rules and categories. This means that information is not structured in advance but afterwards (Wichowski, 2009).

The skill to organize information during web searches is determined by several factors. The first important factor is students' prior knowledge. Ones' prior knowledge influences the search process (e.g. Fidel et al., 1999; Hirsch, 1999) and also seems to influence evaluation behavior. Studies by Britt and Aglinskias (2002), Nievelstein (2008), Rouet, Britt, Mason and Perfetti (1996) and Wineburg (1991) revealed that, compared to novices, experts used better strategies for evaluating and selecting information than novices. This indicates that people use prior knowledge as a sort of ontology in order to structure the newly found information.

Meta-textual knowledge is another important factor for the ability to locate and organize information. In order to determine whether a piece of information is useful, it is important to be able to quickly determine what the contents are. Text organizers as headings, introductions or tables of contents can be used for this purpose. As Rouet and Bigot (2007) discovered, using text organizers results in selecting more relevant information and a better understanding of the information. As a result it can be assumed that people with better meta-textual knowledge will also be better in organizing information.

The third important factor when organizing web-based information concerns feelings and motivation. According to Kuhlthau (2004) feelings play an important role in the IPS-process. The feelings of uncertainty, confusion and frustration are associated with vague, unclear thoughts about a certain topic (Kuhlthau, 2004). When people develop more clearer thoughts, they start to feel more certain and confident. When you find something interesting or fun, the possibility that you learn something is quite high. Ryan and Deci (2000) explained this with their self determination theory (SDT). They identified three basic psychological needs as the basis of self-motivation: the need for competence, the need for autonomy and the need for relatedness. When the feelings of competence autonomy and relatedness are well developed, it can be expected that people are more motivated and thus better able to organize their information. Instruction in IPS or more specific in organizing information can help students to feel more competent in solving information-based problems and can help students to regulate their emotions and become more motivated. That instruction in IPS is important and necessary is widely accepted (Brand-Gruwel & Gerjets, 2008).

Instruction in organizing web-based information should foster the use of a non-hierarchical tagging approach and make use of ontological schemes. Moreover this instruction should be embedded in the schools curricula and should be adaptive. For instance the amount of guidance in learning to organize will be adapted to the learners needs. Students with more prior knowledge should be able to use own categories and adapt the existing or given ontological schemes. It is expected that instruction in organizing information with the tagging technique will improve students' organization of information, the ability to select relevant and reliable information and will have a positive result on overall task performance. Moreover, adaptive instruction concerning the used ontological schemes will lead to better results for especially intermediates and novices and will have a positive effect on motivation.

This paper will present a theoretical framework to address the problems encountered when people organize web-based information and the mechanisms that should be taken into account when organizing web-based information. Furthermore, instructional solutions will be addressed, with a special attention of the design of adaptive embedded instruction.

Is Touching Better Than Watching? – The Effects of Modalities on Motivation and Performance

Tahmine Tozman, Goethe-Universität Frankfurt am Main, Germany; Mona Seikel, University of Frankfurt, Germany; Marc Grahmann, University of Frankfurt, Germany; Regina Vollmeyer, Goethe-Universität, Germany; Paul W. Dierkes, University of Frankfurt, Germany

Most theories in the field of multimedia learning suppose positive effect of including more modalities during learning. Mayer's cognitive theory of multimedia learning assumes that an active engagement with the learning media leads to a coherent mental representation of the existing knowledge. As media affects motivation, we include Vollmeyer and Rheinberg's cognitive-motivational process model that describes how initial motivation affects flow during learning which then influences performance. According to these theories, we assume that more modalities increase motivation and consequently performance. We examined six elementary school classes ($N = 161$; 78 male) at the age of 9 -11 years. In eight different learning-units students learned the mechanism of respiration. At the third unit we split up the classes into three groups (media). One group watched a film, one worked on a worksheet and the third group constructed a lung-balloon-model. Via questionnaires we tested the students' prior knowledge and their initial motivation. At the end of the unit, the students filled out a flow-scale and a knowledge posttest. We calculated a path analysis with the predictor variable media and considered their effects on flow as a mediator between media and performance. There is a significant effect from media to flow, $b = .18$, $p = .021$, but there is no significant effect from flow to performance, $b = 1.83$, $p = .69$. As expected, using more modalities increased motivation and flow, but did not increase performance. Our results could not support hypotheses from multimedia theories regarding performance.

Aim:

In our study we investigate the influence of different learning material (media) on the motivation and performance of students. According to multimedia theories, we assume that using more modalities increase motivation and in consequence performance.

Theory:

Most theories in the field of multimedia learning suppose positive effects of increasing the number of modalities during learning. Mayer's (1999) cognitive theory of multimedia learning (CTML) assumes a two channel system (visual and auditory) for information processing. Further, Mayer differentiates between a presenting modus of the learning media (spoken text or printed text) and a sensory modality – the perception of the presented media and their representation in the working memory. The aim of designing or using learning media is to activate both channels for the information processing. Mayer assumes that an active engagement with the learning material leads to a more coherent mental representation. Similar to CTML, the cognitive-affective theory of learning with media (CATLM) includes more sensory memories like tactile, olfactory and gustatory (Moreno, 2005). The authors also assume that motivational factors indirectly influence the learning process by increasing the students' cognitive engagement (see Pintrich, 2003). Focusing on motivational aspects of learning, the cognitive-motivational process model (Vollmeyer & Rheinberg, 1999) describes how initial motivation affects strategies and flow during learning which in turn influences performance. Vollmeyer and Rheinberg emphasize the importance of understanding the learning process as well as its outcome. Hypotheses: According to these theories we assume that including more modalities leads to an increased motivation and consequently to a better performance. Further we hypothesize that a more positive initial motivation facilitates flow (initial motivation includes: interest, challenge, probability of success and anxiety). In addition, motivation and flow-experiences can explain performance differences.

Methods:

In the context of a student-lab day at the department of biology didactics at the University of Frankfurt, we examined six elementary school classes (N = 161; 78 male) at the age of 9 -11 years (Mage = 10.31, SD = .50). They were presented with eight units about respiration. Each group got the same information about respiration, but presented with different media. We split up the classes into three groups and labeled this manipulation media. Each group consisted of two classes. All groups completed the same learning units with the exception of the third one. In the third unit each group worked with different learning media. That is our manipulation. One group watched a film about respiration. To understand the contents of the film the students needed to process visual and auditory information. The second group worked on a worksheet about the same topic. To understand the text and the pictures on the worksheet, visual information processing was needed. The third group constructed a lung-balloon-model. The students in this group had to listen to the instructions and information (auditory Information). At the same time they also had to look at their model (visual information) so that they could finally construct their own model (tactile information). We controlled prior knowledge with a pretest. Before starting with the third unit, the students were given an instruction about the upcoming learning unit and they were required to fill out the questionnaire on current motivation (FAM, Rheinberg, Vollmeyer & Burns, 2001). After finishing the unit (film, worksheet or lung-model) flow was measured with the flow-short scale (FKS, Rheinberg & Vollmeyer, 2001). After completing all eight units each student was asked to fill out a posttest. Results: First we tested whether the groups differ in motivation and flow. They differ on interest, $F(2, 158) = 6.46$, $p = .002$, probability of success, $F(2, 158) = 5.42$, $p = .05$, anxiety, $F(2, 158) = 3.43$, $p = .035$. There were no significant differences on challenge, $F(2, 158) = .19$, $p = .83$. We also found a significant difference between the groups on flow, $F(2, 158) = 5.53$, $p = .005$. There were no significant differences in knowledge between the groups on the pretest, $F(2, 158) = 1.76$, $p = .18$ and on the posttest, $F(2, 158) = 1.17$, $p = .31$. There were also no significant differences in knowledge between the groups when we consider the discrepancy between pre- and posttest, $F(2, 158) = .75$, $p = .48$.

Means are presented in Table 1. We calculated a path analysis with the predictor variable media and considered their effects on flow as a mediator between media and performance (dependent variable). There is a significant effect from media to flow, $b = .18$, $p = .021$, but there is no significant effect from flow to performance, $b = 1.8$, $p = .69$.

Discussion:

In our study we investigated that including more modalities leads to increased motivation and flow, but did not increase performance. Therefore, we could not support hypotheses from multimedia theories regarding performance. However, if students are not motivated to learn, it is helpful to increase their motivation through using media with more modalities. Then they might have more fun during learning. Although there is no immediate increase in performance, still their knowledge may grow on the long-term.

A meta-analysis on the influence of spatial ability on learning with visualizations

Tim Hoeffler, IPN - University of Kiel, Germany

This meta-analysis focuses on the role of spatial ability when learning with pictorial visualizations. Regarding 27 different experiments from 19 studies, several sub-factors of spatial ability are considered as well as dynamic and non-dynamic, interactive and non-interactive visualizations. An overall effect of $r = .34$ (95%-CI .28 to .39) demonstrating a medium advantage for high-spatial ability learners when working with visualizations is calculated. More importantly, two moderators could be identified: Learners with low spatial ability can be significantly supported by a dynamic instead of a non-dynamic visualization as well as by 3d- instead of 2d-illustrations. Results are discussed in consideration of contemporary theories of multimedia learning.

Introduction

In educational practice, non-dynamic and, increasingly, dynamic visualizations are a common tool to support the learning process. While the positive influence of visualizations in general seems undisputed and well-documented (cf. Mayer, 2005), there is more skepticism as to dynamic visualizations. What is more, the role of individual differences increasingly shifts in focus: Do all learners profit equally from visualizations? And if not, how can those learners be supported? In this sense, the role of spatial ability on learning with visualizations is still rather unclear. Though, at first glance, an obvious moderator variable, previous studies did not find consistent results as to its role. Hence, the present meta-analysis aims at revealing if and in which way spatial ability influences learning with visualizations. While the meta-analysis itself is quite narrowly focused, the overall goal to demonstrate the importance of considering individual differences in learning is not.

Theoretical Background

While it seems to be beyond dispute that spatial ability plays a crucial role in multimedia learning (e.g., Hays, 1996) there are, for example, disagreements as to possible aptitude-treatment interactions. Hegarty (2005) offers the

hypothesis that, in learning with dynamic visualizations (in contrast to non-dynamic visualizations), spatial ability might play the role of an enhancer (ability-as-enhancer hypothesis).

On the other hand, some authors (e.g., Hßffler & Leutner, 2010) point out the possibility of a compensating effect for low spatial ability in that animations might act as a "cognitive prosthetic" (Hegarty & Kriz, 2008) for learners with low spatial ability, because the visualization provides the learners with an external representation of a process or procedure that helps them to build an adequate mental model. It should be unequally more difficult to construct such a model by using static pictures.

Moreover, many questions concerning possible moderating effects of the role of spatial ability are still open: If learner's spatial ability is low, how should the format of instruction be designed to support the learning process? For example, Huk (2006) found the role of 3d- versus 2d-visualizations important as to this question. Garg, Norman, and Sperotable (2001) indicated a possible compensating effect of self-paced versus system-paced visualizations.

On the whole, the role of spatial ability on learning with visualizations is still rather unclear and superficially defined; therefore, the present, narrowly focused meta-analysis is warranted and aims at examining the relations between spatial ability and different characteristics of visualizations more closely.

Method

To identify relevant studies on the learning effects of spatial ability, the computerized databases SSCI (1993-2009) and ERIC (1966-2009) were searched. Apart from the articles found in databases, cross-references from identified articles helped to find some additional studies. However, for being able to include them in the meta-analysis, several criteria had to be fulfilled, for example the provision of the basic statistics needed for computing effect sizes. In the end, 19 articles (with 27 different experiments) remained.

Results

The overall effect of high-spatial ability learners versus low-spatial ability learners when using visualizations, disregarding all other variables, was calculated to be $r=.34$ (95%-confidence interval .28 to .39). This can be classified as a medium effect.

An overall homogeneity test indicated the overall effect size to be conditioned by one or more moderators: $Q_{total}=99.05$, $df=58$, p When comparing high-spatial ability subjects and low-spatial ability subjects, a significant difference could be found between dynamic ($r=.25$, $CI=.10$ to .39) and non-dynamic ($r=.41$, $CI=.28$ to .52) visualizations ($z_{contrast}=1.67$, p Another significant difference was found for the comparison of 2d- ($r=.35$, $CI=.27$ to .43) and 3d-visualizations ($r=.23$, $CI=.09$ to .36): $z_{contrast}=1.68$, p As to the level of realism of the visualization, no significant differences were found. Concerning the role of interactivity, the comparisons between system-paced, self-paced, and highly interactive visualizations were not statistically significant.

Discussion and Conclusions

To summarize the results of the meta-analysis in one sentence: Spatial ability plays an important role in learning from visualizations (mean effect size $r=.34$), but is moderated by – at least – two compensating factors; learners with low spatial ability can be significantly supported by a dynamic visualization as well as a 3d-visualization.

Thus, it has been confirmed that spatial ability is a factor which should be considered when designing visualization experiments. Learners with low spatial ability can be supported by some design modifications of visualizations. The suggestion of the usage of 3d-visualizations (which leads directly to the controversial question of an "appropriate" level of realism) stands in contrast to other results (cp. Huk, 2006) and certainly warrants further examination. Other established notions about multimedia design (e.g., the use of a secondary modality) could not be supported – which in no way contradicts those notions.

The suggestion to use dynamic visualizations for learners with low spatial ability, on the other hand, may sound controversial at first – but this finding could be one perfectly good reason for the many different findings concerning static pictures versus animations in the past (e.g., Hßffler & Leutner, 2007; Tversky, Morrison, & Béêtrancourt, 2002): Some learners (in this case, learners with high spatial ability) learn better when provided with non-transient static pictures which give them the opportunity to build their own mental model thanks to their highly developed spatial ability. And other learners (e.g., those with low spatial ability) seemingly learn better with animations; possibly because animations provide them with a ready-made dynamic mental model of the process shown.

Therefore, the present paper underlines the importance of the consideration of individual differences when learning with visualizations but also makes some contributions regarding design issues of learning environments.

Developments in interactive media practices of young people

Antoine van den Beemt, Fontys University of Applied Science, Netherlands

This paper presents a cross-sectional analysis of interactive media practices of young people, in perspective of consequences for education. Contemporary youth moves in a range of physical and virtual spaces, which together form their 'learning ecology'. In these learning ecologies, youths engage in activities that allow for the development of expertise, identity and interest. However, individual learning ecologies will develop over time. In order to understand this development, the following research question was formulated: How do patterns of interactive media participation develop among students?

The measurements were done, respectively, among 2138 youths, aged 9 to 23, in 2009, and among 350 first year students in higher education, aged 17 to 23, in 2010. The data analysis consisted of factor analysis and cluster analysis. The results of the first measurement showed a diversity in interactive media practices. The preliminary results of the second measurement showed a shift in both membership of usergroups as well as in specific activities. The results of this study indicate the importance for educators to acknowledge diversity in experiences and preferences among students. Considering consequences for education of this diversity, it is important to acknowledge the development in diversity and to address students' interactive media experiences and preferences with tailor made assignments, regardless of the application of interactive media.

Introduction

This paper presents the results of a cross-sectional analysis of interactive media practices of young people in perspective of consequences for education. It extends and builds on the results of a survey study analysing diversity in young people's use of interactive media, consisting of internet applications and games (Van den Beemt, Akkerman, & Simons, 2010a).

Aims

Contemporary youth moves in a range of physical and virtual spaces. These movements involve connections and actions in relation to others, which in turn bring forward opportunities to learn. Barron (2006) speaks in this respect of a 'learning ecology', which helps to conceptualise the development of expertise and experiences across the spaces of home, school, work, and community. In this learning ecology, young people engage in activities, such as playing games, maintaining a webpage or explaining the use of social software to peers. These activities allow for the development of expertise, while simultaneously supporting the development of identity and interest.

Barron (2006) argues that to understand the relation between technology use and learning, it is important to analyse pathways of participation, by looking at events, activities, and processes that spark interest in learning. Subsequently, the changes in a person's learning ecology should be charted for advancing theories of learning and assessing educational interventions.

An analysis of students' pathways of participation showed the importance of peers and informal networks of likeminded people in developing expertise in interactive media (Van den Beemt, et al., 2010b). More profound analysis of the interactive media practices of young people showed a diversity in both activities and related opinions and preferences (Van den Beemt, et al., 2010a). This diversity has been described in terms of patterns of participation.

The next step in understanding young people's learning ecology should be describing the development of patterns of participation over time. This leads to the following research question: how do patterns of interactive media participation develop among students? By answering this research question, this paper aims to reach a more profound understanding of the position of interactive media in young people's learning ecologies.

Methodology

The research question for this paper will be answered by means of a cross-sectional analysis. The first measurement was done among 2138 Dutch youths, aged 9 to 23, in 2009. Among this sample were 323 first-year students in higher education. The second measurement was done in 2010, among 350 Dutch first-year students in higher education, aged 17 to 23.

The survey was conducted online and consisted of 25 questions. The questions covered three main topics: media use, opinions about specific media and preferent media for specific activities.

The results of the first measurement were used as a jump-off for analysing data from the second measurement. The data analysis consisted of exploratory factor analysis and cluster analysis. Factor analysis allowed to describe differences between groups in terms of interactive media activities, while cluster analysis allowed to describe group membership.

Findings

The results of the first measurement showed a diversity in young people's interactive media use and in corresponding preferences and opinions. This diversity in experience, preferences and opinions gave rise to a description in patterns of participation. The results of the second measurement showed a shift in patterns over time.

In both measurements a categorisation of activities was found. Four categories were discerned, each representing a specific type of activity: interacting, performing, interchanging and authoring. The category interacting consists of traditional internet activities, focused on the consumption and exchange of information, such as e-mail, surfing the web, searching for information and MSN. The category 'performing', consists of gaming activities where users play a certain role on a virtual stage. The category 'interchanging' consists of all kinds of social networking activities. The last category, labelled 'authoring' consists of a larger number of activities, all of them comprising some form of interactive content production.

Furthermore a categorisation of users was found. There is a group of relatively low-end technology users, that mainly engage in the traditional Internet activities. This group was labelled Traditionalists. There is a small group of high-end technology users, which was labelled Producers. Furthermore, two groups of intermediate technology users are defined by mid-level technology use. One group, labelled Gamers, shows an emphasis on playing games, and the other, labelled Networkers, shows an emphasis on using all kinds of social software. The Networkers and Producers are relatively intensive users of the more traditional interactive media as well.

The preliminary results of the second measurement showed 1) a shift from Traditionalists towards the group of Networkers, and 2) as a shift in specific activities.

Relevance

Although learning is traditionally associated with schools and schooling it is increasingly recognised that children learn in everyday life by using interactive media. In terms of a learning ecology, it is important to avoid the binary opposition between in school and out of school, especially when the use of interactive media is concerned.

The results of this study indicate the importance for educators to acknowledge diversity in interactive media skills and preferences among students. However, the diversity itself should not be seen as a new truth, but rather as a developing process. In the consideration of consequences for education of this diversity, it is important to a) acknowledge the development in this diversity among students and b) address students' interactive media experiences and preferences with tailor made assignments, or broad learning contexts, regardless of the application of interaction media.

In this manner, this study aims at contributing to educational insights in how to organise learning so that it is in line with daily practice and interests of students.

Computer use in second language learning: A developmental model

Florian Feucht, The University of Toledo, United States; Nathan Ziegler, The University of Toledo, United States

With the growing demand for computer-based technology in the classroom, teachers are continually challenged with the task of integrating technology into their curricula in a manner that supports their theoretical and pedagogical orientation. The second language classroom is no different in this respect, and even though there is a plethora of technology that can be used in a second language classroom, teachers may find that some of the technology is not helpful for their students because of the language and cognitive development of the learners. Despite this demand,

the existing literature often does not bridge the fields of technology, second language learning and instruction, and cognitive development in childhood. Therefore, the goal of this paper is to establish a theoretical framework for technology in second language classrooms that stems from a critical literature review of conceptual and empirical works as they pertain to technology, second language learning and instruction, and cognitive development. Furthermore, this framework is used to describe conceptual issues and to identify educational implications for the use of technology in the second language classroom.

Introduction

In order for children to participate in an increasingly networked global ecology, it is imperative that children begin to study second languages at an early age. With the importance of second language learning and the prevalence of technology in the global landscape and in education, we have established a theoretical framework that looks at the relationship between cognitive development, second language teaching methods, and technology. More specifically, this framework aligns the different teaching methods and technology with Piaget's four levels of cognitive development. Thus, this conceptual framework is designed to assist second language teachers in designing developmentally appropriate lesson plans with technology.

Assumptions of language

Traditional theories of language assume that language is a real-world construct that people use to communicate. In this view, language consists of grammar (i.e., nouns, verbs) and words. Yngve (1996) shows that language and grammar are abstractions that are not scientifically observable, but rather logical constructs that lie in the minds of the people communicating. Therefore, it is important to look at the real-world properties of the communicative event when studying human communication. In Yngve's (1996) scientific framework for studying human communication in the real world, he defined the communicative event as a linkage that consists of participants (i.e., the people), props (i.e., the objects used in communication and that are referred to), settings (i.e., the places where the communication is occurring), and channels of communication (i.e., the energy flows—sounds, light waves, text). In this framework, sounds and texts are correlated with participants' behaviors, the props, the setting, and the outcome of the communicative event. Because Yngve's framework shows that language and grammar are abstractions, it has become the foundation for our integrated framework of second language teaching methods, technology, and cognitive development. Cognitive Development and Language LearningIt is important to consider the cognitive development of learners to ensure the success of the teaching method and to select the appropriate technology for each method. Some methods require more abstract thought and some technology requires more complex skills than children at certain stages of their cognitive development are able to understand and/or carry out. Piaget described four stages of thought that are qualitatively different from each other: Sensorimotor, preoperational, concrete operational and formal operational stages (Piaget, 1952; Sigelman & Rider, 2008). Children progress through these four stages in the same order but may differ in the timely occurrence of the stages. Towards the end of the sensorimotor stage (i.e., birth to 2 years), children develop the ability to develop mental representations or symbols of people, objects, and events in their immediate and concrete environment. They can communicate with and about them by pointing, gesturing, and using words or forming very basic sentences. During the preoperational level (i.e., 2 to 7 years), children learn language about people and objects that are not present and past or future events of their life. They can verbalize and solve simple, concrete problems that do not require any form of logical thought. During the concrete operational stage (i.e., 7 to 11 years), children master the ability to effectively think and talk about concrete objects and events. At the formal operational stage (i.e., 11 years and older), older children learn to think and talk at a more abstract level of thought, and are able to solve hypothetical problems with an increasing number of components and solutions to them.

Second Language Teaching Methods and Technology

In this section, second language teaching methods and computer-based technology used in a language classroom will be aligned with Piaget's stages of cognitive development based on the theoretical framework of Yngve (see Table 1). First, we will provide a brief overview of a selection of second language teaching methods such as the Grammar-Translation method, the Audio-Lingual method, the Audio-Visual-Lingual method, the Content-Based Instruction method, the Communicative Language Teaching method, and the Hard Science Linguistic method. An overview of each method will justify our juxtaposition with Piaget's cognitive development model and Yngve framework for studying communication. For example, because the Grammar-Translation method focuses on translating words from one language to another (Brown, 2007) and students learn and apply grammatical rules of the target language (Oller, 1979; Purpura, 2004), learners must be able to perform at an advanced level of cognitive development (i.e., formal operations) to be able to think about abstract constructs such as grammar and translating words.

Second, computer-based technology will be looked at from a cognitive development perspective to enhance the instructional practices of teachers of a second language and the learning for the second language learners. Therefore,

technological tools such as digital video recording, simulated learning environments, internet based chat programs (both written and verbal), email, and computer-based concept mapping are placed in juxtaposition to the different developmental stages of cognitive development and will be addressed from the different methodological perspectives. For example, we suggest that email is most suitable for learners at the concrete and formal operation levels because they are increasingly able to communicate in writing about events in their immediate life (i.e., concrete operations) and more abstract concepts (i.e., formal operations). Further, Table 1 shows how it would correspond with the different teaching methods.

Conclusion

Due to the changing landscape of this technologically interconnected global society, it is crucial that we begin to teach second languages to children as they start early-childhood education. However, it is important that we consider the cognitive level of the language learners when choosing teaching methods and technology to assist in instruction. Second language learners at the sensorimotor, preoperational, and concrete level of cognitive development should be taught with teaching methods and technology that present communication in a second language in real-world contexts. As second language learners develop, they are able to understand more abstract aspects of communication and can use technology that facilitates their second language abilities at the formal operations and meta-cognitive level.

Ethics, social media and teacher education

Brita Bjorkelo, University of Bergen, Norway; Aslaug Almas, Stord/Haugesund University College, Norway

Research has shown that the role of the teacher is one of the most vital contributors to student academic outcomes (see e.g. Hattie, 2009). The Norwegian school system places great emphasis on the use of information and communication technologies (ICT) (Almås & Krumsvik, 2008) and digital competence is an essential part of teacher education (Krumsvik, 2008, 2009a). Teachers may also act as role models in their use of social media, and it is important that they conduct themselves in an ethical manner. Preliminary findings are presented from a Norwegian study from a larger, international project. The aim of the study is to understand the role of ethics in the decision to participate in social media as a teacher education student. The context of teacher education in Norway will be outlined and media cases related to teachers and their use of social media will be presented. Data from a survey of Norwegian pre-service secondary teachers will also be outlined. The survey investigated professional interactions and behaviours (PIBS; Morris, Richardson & Watt, 2010) and their relation to the amount of ethical training received to date. Demographic comparisons (e.g., age, gender) are discussed.

Research Context

The project has its background in the role of digital competence as one of the five basic competencies in the "Knowledge Promotion" (Kunnskapsløftet) (see e.g., Krumsvik, 2009b). The Knowledge Promotion is the ongoing reform within the Norwegian 10-year compulsory school and upper secondary education and training. The reform introduces changes in how digital competencies should be a part of the substance, structure and organization of teaching from the first grade of 10-year compulsory schooling to the last grade of upper secondary education and training. Research has shown that the role of the teacher is one of the most vital parts of student academic outcomes (see e.g. Hattie, 2009). Simultaneously, the Norwegian school system prioritises information and communication technologies (ICT) (Almås & Krumsvik, 2008). Digital competence is therefore an essential element of teacher education, as illustrated in the Digital literacy model (Krumsvik, 2008, 2009a). Teachers are role models in the application of ICT, such as teaching students ritual versus academic use. In the same way, teachers are also role models for the use of social media in an ethical manner. Some studies have suggested students evaluate the participation of teachers in social media and their level of motivation, affective learning and classroom climate (see e.g., Mazer, Murphy, & Simonds, 2009). Few, if any studies have investigated the role of ethical reasoning among teacher students and their actual participation in social media. A pilot study recently conducted in Australia among teacher education students (Morris, 2010) investigated the ethical implications of SNS for pre-service teachers. This project "Ethics, Social media and Teacher Education" has developed as a result of international collaboration with

Monash University, Melbourne, Australia (<http://www.monash.edu.au/>). Therefore the current study parallels the research of Morris (2010) and provides information from a Norwegian context with aim to increase understanding of the role of ethics in the decision to participate in social media as a teacher student.

Method

The sample consisted of Norwegian pre-service secondary teachers in their third and fourth years of study. The survey investigated the attitudes towards acceptable behaviour for student-teacher interactions as in Morris' (2010) study, the perceived adequacy of ethical and professional training in the degree and the current usage of social media (e.g. Facebook).

Results and Discussion

Media reports indicate that teacher use/misuse of social media is of public interest. The results of the current study provide an interesting insight into the issues and ethical implications for pre-service teachers in Norway who are soon to become teachers themselves. The adequacy of ethical training and the degree to which teacher education students employ privacy and security settings for their personal profiles are outlined. Recommendations for the inclusion of training on the ethical use of social media in the pre-service teacher curriculum are made. Future directions of the study include a more detailed cross-cultural comparison with an Australian sample of pre-service teachers.

THEMATIC POSTER

Cooperative learning

To be open and committed - Forming a model of mission education

Elina Kuusisto, University of Helsinki, Finland

The purpose of this study is to explore the structure, goals and methods of mission education in order to educate people to be openly committed to one's own religion and to be open to encounter religious otherness. Mission education is examined within the main religion in Finland. The research context is a Lutheran student association. The empirical data consists of the interviews of the all 25 former chairpersons. The data is analysed by qualitative and quantitative content analysis. Situational learning (Lave & Wenger 1991) and the criteria of meaningful learning (Jonassen 1995) are utilized as theoretical frameworks. Definitions of intentionality and purposiveness (Kansanen et al.'s 2000) are applied as complimentary tools to examine educational goals.

The key result of the study is a model of mission education. The model has three educational components: values, goals and methods. The gist of the model is formed by the goals. The main goal is to arouse and strengthen of the mission interest. Four subgoals create the horizontal, societal, and vertical, religious, dimensions of the model. The subgoals are goals in their own right but their role is also to support the realisation of the main goal. Therefore mission education seems to have explicitly multidisciplinary nature. The model can be utilized as an evaluative instrument in reflecting the focuses of the religion education.

In order to realise the criteria of meaningful learning better more conscious efforts are needed to attain intentional and reflective learning.

This study examines the problem of how to be openly committed to one's own religion and to be open to encounter religious otherness at the same time. This question has long been in the focus of the missionary workers (see Franz  n 1986). However, in the globalizing world every representative of any religion faces this challenge in everyday life. For these reasons this study combines two disciplines: religious education and missiology. Mission education is applied as a linking concept. The purpose of this study is to explore the structure, goals and methods of mission education.

Mission education is examined within the main religion in Finland, Lutheran Christianity. The research context is a Lutheran student association *Opiskelijain L  hetysliitto* (OL), which is Finnish successor of the Student Volunteer Movement. The OL was chosen, because the activities of the OL are reminiscent of the activities of the mission of the congregations of the Finnish Evangelical Lutheran Church. However, the biggest difference is that all OL participants are young adults, the age group that is the greatest challenge to the Church.

The study is empirical despite having a historical and retrospective view since the OL is explored during the period 1972–2000. The data consists of the interviews of all 25 former chairpersons. The data is analysed by qualitative and quantitative content analysis in a partly inductive and partly deductive manner. *Atlas.ti* and *Excel*-programme are utilised.

Lave and Wenger's (1991) theory of situated learning is applied to understand the holistic nature of learning through participation in a community of practice. Kansanen et al.'s (2000) definitions of intentionality and purposiveness are utilised as complimentary tools to examine educational goals within the community of practice. Jonassen's (1995) criteria for meaningful learning are applied as a deductive guideline to evaluate the methods.

The key result of the study is a model of mission education. The model has three educational components: values, goals and methods. The OL's values are described in terms of a postmodern ethos, which appears as ecumenical Christianity and a holistic idea of mission.

The gist of the model is formed by the goals. The main goal is to arouse and strengthen of the mission interest, which has affective, cognitive and practical aspects. The main goal has four subgoals that create the horizontal and vertical dimensions of the model. The horizontal subgoals include socialisation into one's own community of practice as well as into the global world. The vertical subgoals include developing Christian spirituality and learning to encounter other religious traditions such as learning to be ecumenical and to practice religious dialog.

It is noticed that the subgoals are goals in their own right but their role is also to support the realisation of the main goal. Mission education seems to have therefore explicitly multidisciplinary nature, which reflects the structure of missiology (see Jongeneel 1995). The hierarchy of the goals can be seen as empirical examples of missionary dimension and intention, which are mostly discussed within the discipline of systematic theology and mission theology (see Ott 2001; Bosch 1984, Gensichen 1971; Newbigin 1958). Empirical findings suggest that different societal and religious themes can contain mission dimension, when these are understood as preparatory elements to fulfil the mission intention.

Authenticity and transfer were found to be the most exploited criteria of meaningful learning. Authenticity refers for example to supporting missionary work in many concrete ways. Learning about mission in different cultures and religious contexts was reported to take place mainly through lectures by experts who were mostly missionaries. In order to better execute the criteria it is needed to develop a better awareness of the goals of mission education among OL participants, volunteer workers and visiting experts, and also more conscious efforts are needed to scaffold the reflection of the studied topics.

The model is proposed to describe the characteristics of mission education more generally than in the OL only. The study suggests that the model can be utilised as an evaluative instrument in reflecting the focuses of the religion education especially within Finnish Evangelical Lutheran Church. Still, the model is to be tested in other contexts in order to develop it more and find out its broader relevance in theorizing mission education as part of the discipline of religious education.

Prediction of cooperative teamwork success in secondary students

J. Reinaldo Martinez-Fernandez, Universidad Autonoma De Barcelona, Spain; Carles Monereo, Universitat Autonoma de Barcelona, Spain; Montserrat Castello, Universitat Ramon Llull, Spain; Calixto Gutierrez-Braojos, Facultad de Ciencias de la Educacion. Universidad de Granada, Spain

In this work we analyzed the effect of a set of social learning variables related to teamwork in a specific learning task (integration of ideas in a writing task) in a sample of secondary students. Our aim was to analyze the effect of group gender composition, group skills organization, interaction, group task goal, social support inside the group, and the perception of effective work time at a level of success in a specific learning writing task. The relevance of our research is that we concluded in an approach model to know the effects of these variables in a best integration of ideas in a writing task with interesting results regarding theoretical, methodological and practical implications. In this sense, we found that the atmosphere of the group and the perception of the effective use of time are the factors that better explain success in the final task. Likewise, some interesting results on differences according group gender composition are discussed.

Overall quality and scientific originality

The study is original for the form of compilation of the information because it has been developed across a task and in an authentic classroom context. The procedure followed allows observing the students during the whole work process, their form of interaction, the conversations, decision making, and the sequence followed in the composition of the final text. From the point of view of the analyses, in this study an analysis of equation structural model is applied that puts as a whole a series of variables defined theoretically relevant for the collaborative work.

Nutrition as prerequisite for optimal school performance

Renate de Groot, Open University of the Netherlands, Netherlands; Carolijn Ouweland, VU University, Netherlands; Jelle Jolles, VU University, Netherlands

Nutrition might play a role in cognitive functioning and school performance. Fish consumption has shown its benefits for cognitive functioning in the elderly or children with disorders (e.g., autism, ADHD), but has rarely been investigated in relation to cognitive performance and school performance of adolescents.

Therefore we executed an observational study in 700 healthy Dutch high school students aged 12-18 years. Data with respect to fish consumption were collected, as well as end term grades to determine school performance, scores on the Amsterdam Vocabulary Test, and scores on the Youth Self-Report.

Results revealed that 13.6% of the Dutch adolescents never ate fish, 6.4% met national guidelines, 16.9% reached half of the norm, and 63.1% did eat fish but too little to meet at least half of the norm. Analysis of variance, controlled for age, gender, educational track, and LPE, showed significant differences between the four fish consumption groups in vocabulary ($p = 0.05$). A trend for significance was found for end term grades ($p = 0.07$). Contrast analyses demonstrated significant quadratic associations between fish consumption and vocabulary ($p = 0.01$) and end term grades ($p = 0.01$), respectively, indicating that higher fish intake was associated with more advanced vocabulary as well as higher end term grades. However, eating more fish than the described norm seemed no longer beneficial.

In conclusion, fish intake among adolescents may provide benefits in vocabulary and school performance. We advise to consume fish twice a week, but not more than that.

Introduction

Nutrition might play an important role in brain function. Fish consumption is often associated with better cognitive performance in the elderly. Up till now it was almost neglected what the role of fish consumption is in the period of adolescence. To our knowledge, there are only two studies, which highlight the effect of fish intake on cognitive functioning during adolescence. Kim (2010) showed that 15-years old adolescents who consumed regularly fish had significant better school performance than their non- or less fish consuming counterparts. Aberg (2009) et al. demonstrated in boys that high fish consumption at age 15 was associated with better cognitive performance at age 18.

In the current study, we endeavor to extend these recent findings in a Dutch high school population with a broader age range, including boys and girls! In addition to school performance, it is our aim to investigate whether fish consumption is associated with current cognitive performance measured with a vocabulary test and self-report attention. By means of this study, we add information about the role of fish consumption for cognitive development during healthy adolescence, a developmental period seldom studied in this field up till now.

Methods

Design and participants

An observational study, approved by the Ethical Committee of the VU University Amsterdam, in 700 healthy Dutch high school students (grade 7-12) was executed. Exclusion criteria: suffering from any learning, psychiatric or developmental disorders, using cognitive function influencing medication, skipping school regularly, and/or taking fish oil supplements.

Measures

Fish consumption was measured by a validated self-report questionnaire (De Groot et al., 2009). According to the Dutch 'guidelines for healthy food', the participants were divided in four groups: (1) never eats fish, (2) fish intake of less than half of the norm, (3) more than half of the norm, but less than the norm, and (4) norm or more.

Vocabulary of four types of words was assessed with the Amsterdam Vocabulary Test.

Regarding attention, adolescents filled in the attention subscale of the Dutch version of the Youth Self-Report (Verhulst & Van der Ende, 2004).

End of term grades for the three core school subjects Dutch, English and Mathematics were used as proxy for school performance. Since schools may have differed in grading policies, standardized z-scores were used.

Gender, age, and level of parental education were included as background variables.

Statistical analyses

To examine whether the four fish consumption groups differed in attention, vocabulary and/or school performance while controlling for age, sex, educational track, and LPE, Analyses of covariance (ANCOVA) were used. Covariates were tested for the assumption of linearity with the dependent variables. Assumptions of normality were tested within each fish consumption group for each dependent variable separately. Since the four fish consumption groups differed in sample sizes, we corrected for unequal cell sizes while analyzing. P-value was set at p-values <0.05.

Results

Participants

The final sample consisted of 700 adolescents (394 girls, 306 boys) with a mean age of 15.0 (SD=1.8).

Fish consumption

13.7% of the Dutch adolescents never ate any fish, only 6.4% met the national guidelines. In addition, 16.9% reached at least half of the norm, while the majority of the adolescents (63.0%) did eat fish, but rather irregularly or too little to meet at least half of the norm. Fish consumption did not differ between boys and girls, $\chi^2(3)=2.95$, ns, and educational track, $\chi^2(3)=1.00$, ns, neither was it associated with age, $F(3,696)=.39$, ns, nor with parental level of education, $F(3,694)=.96$, ns.

Attention

No significant differences between the fish consumption groups regarding attention problems, $F(3,681)=0.94$, $p=.42$. Of the covariates, only age was significant, $F(1,681)=6.49$, $p=.01$, $\eta^2=.01$. With increasing age more attention problems were reported.

Vocabulary

Significant differences were found between the four fish consumption groups, $F(3,624)=2.50$, $p=.05$, $\eta^2=.02$, even after controlling for the significant effects of the covariates age, $F(1,624)=329.65$, $p<.001$, $\eta^2=.35$, sex, $F(1,624)=3.75$,

$p=.05$, $\eta^2=.01$, and educational track, $F(1,624)=55.54$, $p<.001$, $\eta^2=.08$. Polynomial contrast analyses were performed and showed that the relation between fish consumption and vocabulary was quadratic, contrast $=-0.59$, $p=.01$. A higher average DHA/EPA intake per week was associated with more advanced vocabulary. However, eating more fish than the described norm seemed no longer to be beneficial. The model explained 40% of the variance in vocabulary.

School performance

Similar differences between the four fish consumption groups were found regarding school performance, $F(3,639)=2.35$, $p=.07$, $\eta^2=.01$. In this model, the covariates sex, $F(1,639)=11.39$, $p=.001$, $\eta^2=.02$, educational track, $F(1,639)=41.08$, $p<.001$, $\eta^2=.06$, and LPE, $F(1,639)=11.57$, $p=.001$, $\eta^2=.02$, were significant, whereas age was not, $F(1,639)=2.43$, $p=.12$. Polynomial contrast analyses demonstrated a significant quadratic association between fish consumption and school performance, contrast $=-0.20$, $p=.01$. School performance increased with a higher DHA/EPA intake, but it did no longer for the group with the highest fish consumption. The model explained 12% of the variance in school performance.

Discussion

Higher fish intake was proposed as being associated with higher cognitive performance as well as higher school performance. Our results demonstrated that after correction for age, sex, and educational track higher fish intake was associated with higher scores on the Amsterdam vocabulary Test. In addition, also school performance, measured as the average end term scores of the subjects Dutch, English, and mathematics, was higher when more fish was consumed. This implicates that the more fish was consumed by the adolescents, the better school performance, as well as vocabulary scores were. However, we did find quadratic associations, meaning that as soon as the adolescents in our population consumed more fish than the recommended amount this was associated with significantly lower scores on school performance and vocabulary.

Although fish consumption is only a proxy for the actual fatty acid status, our observations indicate that the association between fish consumption and school performance as well as vocabulary scores consists of an inverted U-shape in adolescents aged 12-18 years. Further prospective observational studies are required to confirm our findings, but ultimately intervention studies are required to proof the causality of this association. In the meantime, it seems prudent to advise adolescents to consume fish twice a week, but no more than that.

Can Buying Make a Difference? – Consumer's Responsibility from Adolescents' Perspective

Silke Speidel, University of Leipzig, Germany

Education for Sustainable Development (ESD), an important part of education in the global networked society, aims to enable pupils to recognise and accept the challenge of their personal responsibility for humankind and the environment, which also concerns their patterns of consumption. Therefore this study seeks to find out how pupils handle sustainable consumption decisions: Do pupils recognise any personal responsibility for humankind and the environment when asked about consumption decisions and if so, which consequences do they draw from this? Do they consider diverse interests and frameworks in their reasoning and if yes, which and to which extent? How do pupils deal with the competing logics of economy and moral? Do pupils' self-efficacy and belief in a just world influence the way they handle decisions on sustainable consumption and if yes, in which way? Using a qualitative approach, pupils of Year 10 and 11 were interviewed individually with a hypothetical decision situation and a set of predefined questions. Preliminary results indicate that although pupils recognise personal responsibilities for humankind and the environment, they also find reasons not to accept the challenge of this responsibility. Different structures of making a sustainable consumption decision become apparent. The result of these analyses shall be used to deduce implications for the design of lessons on sustainable decision-making.

Education for Sustainable Development (ESD) is an important part of education in the global networked society of the 21st century, underlined by the "UN Decade of Education for Sustainable Development" (2005-2014). One focus of ESD is sustainable consumption. Although sustainable consumption has been studied from different perspectives, including marketing, political sciences and sociology, an educational perspective with a sound theoretical foundation is lacking and would be a necessary complement the existing practical resources. Pupils' decision-making competencies with regards to sustainable development have been studied from a didactical perspective (e.g. Eggert & Bßgeholz 2009), but pupils' competencies in moral reasoning have been studied mostly separately from that (e.g. Lind 2008). Decisions of sustainable consumption are influenced by the competing logics of economy and moral. Whereas (neoclassical) economic logic dictates that consumers should look for their own advantage and maximize their own utility, moral expectations are that people do not only decide egoistically but comprise other perspectives and/or universal principles in their decisions.

According to the German Cross-Curricular Framework in the Context of Education for Sustainable Development (Appelt & Siege 2007), pupils are expected to "recognise areas of personal responsibility for humankind and the environment" on the basis of "critical reflection on globalisation and development issues" and the personal evaluation of development aid measures "taking diverse interests and frameworks into account" (Appelt & Siege 2007, 61). It thus aims at making pupils able to integrate the competing logics. As sustainability issues usually are highly complex due to interrelated variables on which no comprehensive reliable basis of information can be obtained, pupils have to reduce the complexity of the situation to remain capable of decision-making. On the other hand, they have to avoid over-simplifications that lead to misunderstandings and wrong predictions. How well pupils manage to integrate the competing logics in decision situations of sustainable consumption might depend on the efficacy they ascribe to the actions in question and thus also on their self-efficacy. Furthermore their belief in a just world can probably influence the decision in two directions: Whereas in situations of lower complexity, it can promote pro-social behaviour, it leads to justifying judgments in situations of higher complexity which renders pro-social behaviour unlikely (Hallitzky 2008). This study tries to answer how pupils handle the task of making sustainable consumption decisions: Do pupils recognise any personal responsibility for humankind and the environment when asked about consumption decisions and if so, which consequences do they draw from this? Do they consider diverse interests and frameworks and if yes, which and to which extent? How do pupils deal with the competing logics of economy and moral? Do pupils' self-efficacy and belief in a just world influence the way in which they handle decisions on sustainable consumption and if yes, in which way?

To answer these questions, pupils of Year 10 and 11 (aged 16 and 17) are interviewed individually with a hypothetical decision situation concerning sustainable consumption and a set of predefined questions. The interview is similar to a classic dilemma interview yet more open as the different possibilities of action have to be developed by the interviewee. The protagonist in the described situation desires a product which to his/her knowledge has been or could have been produced in a problematic way. The problems addressed include child labour, working conditions in Least-Developed Countries, and endangered species as well as precarious working conditions in Germany. The situation was presented by orally explaining the circumstances of the decision situation and handing out cards with information the protagonist was said to possess. After the initial advice to the protagonist, for which the pupils had to give reasons, they were asked about the assumed perspectives of different stakeholders mentioned on the cards, on hypothetical situations of every consumer acting the same way and on possible solutions for the addressed problems. As a qualitative approach is used, the number of pupils interviewed and of interviews analysed depends on when theoretical saturation is reached. The analysis draws on the balance theory of wisdom by Sternberg (1998), research on prosocial moral reasoning as well as complex problem solving and the influence of self-efficacy and belief in a just world on sustainable judgments and behaviour by Hallitzky (2008).

Preliminary results indicate that although pupils recognise personal responsibilities for humankind and the environment, they also find reasons not to take up the challenge of this responsibility. Different structures of making a sustainable consumption decision become apparent. So might e.g. the disregard of human rights be an issue of its own or only perceived as moral cost of the consumer. Different rights as well as their disregard seem either to be seen as negotiable and thus a field of trade-offs or to be seen as absolute, a disregard thus leading to a cut-off.

The result of these analyses shall be used to define different levels of competence in the field of sustainable decision-making and to deduce implications for the design of lessons on sustainable decision-making.

Cooperative learning and student preferences

Michal Nachshon, Ministry Of Education; Technion, Israel; Amira Rom, the Open University of Israel, Israel

The basic premise in co-operative learning is that it motivates active learning by students, encourages group processing of information, and strengthens meta-cognitive. The present research examines the preferences of "Science for All" students for co-operative learning as opposed to individual learning, and their perception of the co-operative learning process. The research sampling consisted of 283 11th–12th grade students. They created a portfolio reflecting two school years, which invited individual and co-operative learning and included an educational game based on scientific knowledge. The research tools in this study were: (a) A structured model of planning stages for developing the educational game; (b) A Questionnaire of personal achievements, filled by students at the end of the process. The research findings indicate a preference for group work, mainly due to its experiential nature and deeper learning of the collaborative process. Those who favored individual learning, indicate its lack of dependence on other person, and its simpler organization. These reasons related particularly to its level of feasibility, and emphasized individuality. Analysis of the findings indicates more diverse reasons and higher thinking levels amongst students preferring group work than those preferring individual work. Possibly the reservations against group work can be explained by a lack of ability or desire to contend with conflicting opinions. Apparently students capable of coping with conflicts of opinion, prefer group work, while students incapable of coping with conflicting opinions and lack of equality prevalent in group work, emphasize the disadvantages of group work.

Cooperative learning and student preferences

Cooperative learning in instructional and learning processes has some advantages: it provides in-depth learning, leads to diverse learning methods and social interaction. This integrative method increases interest in learning, leading to comprehension of content and successful learning. The basic premise in cooperative learning is that it motivates active learning by students, encourages group processing of information, and strengthens meta-cognitive activities (Lazarowitz & Hertz-Lazarowitz, 1998). The present research examines the preferences of "Science for All" students for cooperative learning as opposed to individual learning, and their perception of the cooperative learning process. "Science for All" is a multidisciplinary approach, a combination of scientific, technological and social aspects. Its purpose is to instill scientific literacy integrated with basic scientific knowledge, thinking skills necessary for the future, and standpoints on science and technology (Shwartz, Stern, 2006). Its educational aim is to acquire knowledge and understanding, in order to make informative decisions on social issues involving scientific and technological aspects (Hofstein & Yager, 1982). The study goals were:

to examine the methods students prefer using – cooperative or individual learning and to identify the reasons for their preferences.

to characterize the cooperative learning advantages and disadvantages expressed by students.

Procedure

The research sampling consisted of 283 11th–12th grade students. They created a portfolio reflecting two school years, which invited individual and cooperative learning and included an educational game based on scientific knowledge. The research tools used in this study were: (a) A structured model of planning stages for developing the educational game (Rom & Nachshon, 2009); (b) A Questionnaire of personal achievements, filled by students at the end of the process. The research approach is ethnographic –characterized by the assumption that a quality environment is inclusive, and that examining it will open a window on the social and learning world of the students.

Findings

Data were treated with qualitative and quantitative analysis. Most of the students preferred cooperative learning, while 39% preferred individual work. Three clusters of reasons reflecting preferences for cooperative learning were identified (see Figure 1): (1) The main preferences stemmed from the experiential aspect of group work. (2) The second group included these criteria: division of work, multiplicity of opinions for enrichment of knowledge and enriching each other (3). The group with the lowest frequency included criteria such as level of activity, greater efficiency in learning and paying more attention to opinions of others. In test a-parametric (Chi-Square=160.5, d.f=6, p=0.000) significant differences were found amongst the criteria. Two distinct clusters of reasons reflecting a preference for individual learning (see Figure 2): (1) The Main preferences include two equivalent aspects: Non-dependence on opinions of others and simpler organization; (2) The group of reasons included the criteria: gaining satisfaction, high level of activity and efficiency of learning. In test a-parametric (p=0.000, d.f=4, Chi-Square=56.5) (significant differences were found amongst the criteria. The students raised 481 reasons for the advantages of group work. In order to identify main trends, the reasons were grouped into 3 main categories (with significant differences amongst them). It was found that about half the criteria for choosing cooperative learning related to cooperation, 1/3 to the value of in-depth learning during cooperative learning, and 1/5 to the enjoyment aspect. The students raised

307 reasons indicating disadvantages of cooperative learning. The students' reasons were grouped into categories (whose differences were significant): more than half of the reasons for reservations to group work related to conflicts of opinion, 40% related to inequality within the groups, and a few related to technical problems.

Discussion and conclusions

The basic assumption of cooperative learning is that it motivates students to active learning, encourages group processing of information and reinforces meta-cognitive activity. "Science for All" adopted the method of cooperative learning as a unique tool to express the abovementioned components. During their studies, students experienced various individual and cooperative instruction methods. We assume that cooperative activities may contribute to the development of academic achievement when carried out in a suitable learning environment, (Lazarowitz, Hertz-Lazarowitz, 1998). The findings support researches that show a significant connection between the degree of satisfaction and the division of labor in groups, and the amount of work load imposed on the individual, and indicate that students who prefer cooperative learning identify the experiential advantages as well as the instructional/learning processes (Burdett & Hastie, 2009). This model of learning reinforces interest in studying, leads to understanding of the content and to success. An analysis of the reasons presented by students' preferring individual work indicates the individualistic aspects which were expressed. These conclusions relating to advantages and disadvantages raise the assumption that students who are capable of coping with conflicts of opinion prefer group work, while those who are not able to cope with conflicting opinions and inequality in cooperative activity overemphasize the disadvantages of cooperative learning. The importance of this research lies in the development of a teaching/learning method, which integrates multidisciplinary scientific content knowledge with modes of learning which together may foster academic achievement. This approach is likely to increase public awareness to the ways of training the future citizens in different ways of work (individual and cooperative) in respect to their future needs.

Fostering Gifted Students - A Pilot Project at the interface between School and University

Jutta Moehringer, Technische Universität München, Germany; Manfred Prenzel, TUM School of Education, Germany

In the whole of Europe the promotion of young talent in the field of natural sciences is in the focus of interest. Since 2009 the Technical University of Munich (TUM) has been running a pilot project on special tuition for students interested in and talented for mathematics, IT, sciences and technology (MINT). In a distinct upper secondary level track at the Otto-von-Taube-Gymnasium (ordinary state grammar school) 30 selected students, both male and female, are involved in a demanding advancement program based on the principles of acceleration and enrichment. The program itself differs from others in that it enhances the interconnection between school and university by taking into account whatever the institutions may require in terms of organisation, personnel and contents. The study aims at the evaluation of the special tuition regarding its processes and effects upon students, teachers, and university lecturers. The evaluation concept is based on the CIPP model with its focus on context, input, process, and product. The study-design is that of an explorative study collecting process data, thus using qualitative methods. At the same time and despite small samples only, quantitative methods are applied and set against data derived from large-scale studies such as PISA. First findings show that the TUMKolleg students are capable of handling scientific methods and that neither their performance motivation nor their extra-curricular activities are affected by the heavy workload they are facing. Teachers and university lecturers profit from this interexchange.

Background

The shortage of qualified young people talented for mathematics, IT, sciences and technology (MINT) not only in Germany, but all over Europe, gave rise to frequent initiatives aiming at sparking the young students' interest in the sciences (Ley, 2002). This is why the TUM started a pilot project together with a grammar school, focusing on MINT and directed at highly gifted students. At the beginning of the school year 2009/10 the Otto-von-Taube-Gymnasium (OvTG), an ordinary state grammar school not far from Munich, started introducing a distinct upper secondary level track. 30 students at the TUMKolleg are given the chance to take part in a special tuition program developed exclusively for their purposes. The tuition program itself is based on the principles of both enrichment and acceleration. Enrichment implies widening the curriculum by adding learning facilities. Acceleration means providing measures to achieve utmost efficiency by shortening the learning process (Southern et al, 1993). In the TUMKolleg enrichment comprises school and university. The school provides curricular contents in an all-encompassing and more profound manner and offers a way of teaching that leaves enough flexibility for inductive and independent acquisition. At the university the students are made acquainted with scientific work and given the opportunity to specialise in individual small research projects. Acceleration in this case implies that the students are given some ECTS credits for their future studies, provided they have succeeded in working on their tasks. They are equally enabled to minimise their phase of orientation, once they are immatriculated. The independence of TUMKolleg in terms of structure and organisation allows students to be weekly guaranteed a whole day reserved for getting used to doing their research on campus. Unlike other initiatives aiming at the tuition given to the students in the field of MINT, the TUMKolleg pilot project has the advantage of resting upon two institutions, the grammar school on the one hand and the university on the other. This helps to smoothen the processes at school and university and helps to alleviate the interconnection between lessons at school and research at university.

Aims

The study aims at the evaluation of the special tuition regarding its processes and effects upon students, teacher and university lecturers. The evaluation concept is based on the CIPP model as developed by Stufflebeam (2007) with its focus on context, input, process, and product. The leading questions are: 1. To what extent can students acquire scientific methods? 2. How have the students improved their command of mathematics, natural sciences and problem solving approaches? 3. Which development concerning non-cognitive personal attributes (achievement motivation, coping with stress and interests) can be recognised? 4. What effect does the interexchange between teachers and university lecturers have upon teachers' professional development and upon lecturers' awareness and accessibility to school students.

Methodology

The study-design is that of an explorative study and therefore comprises various qualitative methods including the individual steps of learning and process data. As the CIPP-model demands, the elements of evaluation are the following: The context is represented by the regular state grammar school OvTG and the particular target group of gifted students. The decisive elements regarding the particular target group are the following: A questionnaire with questions regarding the respective students' biographical background, motivation and interest. Furthermore there is a written pre-test assessing competence in mathematics, natural sciences and problem solving (Prenzel et al, 2004). The input implies the special tuition program with its particular offers at both grammar school and university. For the evaluation of the process the students are asked to keep structured diaries in which questions like those on achievement motivation, interest, and coping with stress must be answered. Apart from that, standardised questionnaires help to make explicit how lesson plans and teaching are experienced by teachers and lecturers and how students perceive their lessons (Seidel & Prenzel et al, 2006). The product evaluation at the end of the TUMKolleg is done by means of semi-structured interviews directed at lecturers, students, teachers, parents and student mentors. The results achieved through individual research projects reflect how well science methods have been learned and dealt with. A written post-test measures the progress regarding competence in mathematics, natural sciences and problem solving (Prenzel et al, 2004).

Findings

A part of the data collection has already been made and interpreted. The data collection of the first group of students will be finished in June 2011. Its results will be available in August 2011 at the latest. First findings show that the students of the TUMKolleg are capable of handling scientific methods and that neither their performance motivation nor their extra-curricular activities have been affected by the heavy workload they are facing. Teachers and university lecturers profit from this interexchange. Significance for theory, policy, and practice Research on highly gifted students has shown that only a minor part of tuition programs offered to students has been evaluated (Vock, 2007). At this stage the TUMKolleg is the only tuition project regarding MINT in Germany and therefore the only one with special attention to the institutionalisation of the co-operation between school and university. The unique significance of this project given, there is an unquestionable value of the evaluation results for theory and education, the more so, when it comes to applying the model of TUMKolleg to other schools.

THEMATIC POSTER SESSION

Educational Attainment and Effectiveness

Multitasking: does autonomous vs controlled motivation influence performance?

Marie-Paul Senecaut, K.U.Leuven Campus Kortrijk, Belgium; Joke Coens, Katholieke Universiteit Leuven, Belgium; Geraldine Clarebout, Katholieke Universiteit Leuven, Belgium

Mobile learning is gaining importance in education. Learning no longer binds students to one place. Studying 'anytime and anywhere' (Maag, 2006; Motiwalla, 2007) allows students to learn while performing another activity (Laing & Wootton, 2007), which leads to multitasking. Psychological research done mainly in artificial settings, suggests that performance will decline. Results in recent more ecological tests, where learning with a mobile device is secondary to another task, do not always follow this pattern (Doolittle & Mariano, 2008; Clarebout, Coens, & Elen, 2008; Coens, Clarebout & Reynvoet, 2009b). Among several possible explanations motivation could possibly influence performance. Checking this is the aim of this experiment.

We will determine participants' autonomous vs controlled motivation (Self-Determination Theory, Deci & Ryan, 1985) for learning Spanish words and for driving in a simulator using an adaptation of the Academic Regulation Scale (Ryan & Connell, 1989) as found in Vansteenkiste, Sierens, Soenens, Luyckx, & Lens (2009). We expect that participants who are highly autonomously motivated and lowly controlled motivated will show the best performance. Tests are scheduled for November till December 2010, so results will be available by Spring of 2011.

As young people multitask more and more, it would be of great value if we could find what influences their performance when multitasking. This knowledge may help educators in their search for more efficient learning.

Multitasking: does autonomous vs controlled motivation influence performance?

Marie-Paul Senecaut, Joke Coens, Geraldine Clarebout, K.U.Leuven Campus Kortrijk, Belgium;

Mobile learning leads to multitasking.

The "mobile revolution" with people increasingly connected, using mobile technologies in social practice and education is still in full expansion (Wagner, 2005, Alexander, 2004, Rideout, Foehr, & Roberts, 2010). Some even claim that within five years all K12 students in the United States will be using a mobile learning device (Norris & Soloway, 2010). The use of mobile phones and other portable devices is definitely putting its stamp on how learning takes place in many disciplines (Kukulka-Hulme, 2009). Typically mobile learning can be done "anywhere and anytime", meaning students can use the time spent waiting for a bus or riding a train to study (Maag, 2006, Motiwalla, 2007). In doing so, people are often multitasking. Multitasking has been studied elaborately in psychology, yet few researchers report on studies done in a more ecological setting. So far, most results show that multitasking leads to a lesser performance.

Results & expected pattern.

Doolittle and Mariano (2008) reported on learning with a mobile device while performing a second task and they found that stationary students watching an instructional podcast outperformed their colleagues watching the same instructional video on an iPod while walking down a hallway. Theory of divided attention (Craik, Govoni, Naveh-Benjamin & Anderson, 1996; Baddeley, Lewis, Eldridge & Thomson, 1984) explains this effect: when attention is divided during the learning phase of a task (walking down the hallway and watching the video), performance declines. Results of Doolittle's research were confirmed in Clarebout's (Clarebout, Coens & Elen, 2008) study where participants were asked to watch some study material on an iPod while cycling on an exercise bike at a speed of over 10 km/h. Cycling participants scored significantly lower than their friends watching the same movie on an iPod, sitting at a desk.

However, Coens, Clarebout & Reynvoet (2009b) asked participants to screw nuts on bolts while studying with an iPod. Some students were told studying was more important, for others screwing the bolts was to be given priority. Results were not completely as expected. Only one significant difference was found: students in the control group (not multitasking) did significantly better than students who had been told to combine the learning with the screwing of the bolts giving priority to the screwing of the bolts. Although the other groups showed a difference in result, it was not significant.

Several explanations are possible. We could mention among others: perception of importance (Levy & Pashler, 2008, Coens, 2008), working memory capacity (Doolittle & Mariano, 2008) and difficulty level of task (Cherng, Liang, Hwang & Chen, 2007). In this experiment we want to check whether maybe motivation for one of the tasks lies at the core of the differences in results.

A possible explanation

The multidimensional view of motivation, used in Self-Determination Theory (Deci & Ryan, 1985), distinguishes the quantity from the quality of motivation. SDT suggests that higher levels of motivation do not necessarily yield more desirable outcomes if the motivation is of a poor quality. Motivation of a poor quality means controlled rather than autonomous motivation (Ryan & Deci, 2000; Vansteenkiste, Lens, & Deci, 2006).

SDT divides motivation in autonomous vs controlled motivation. Autonomous motivation being an experience of volition and choice, such as in intrinsic motivation and identified extrinsic motivation as opposed to controlled motivation, which involves the experience of being pressured or coerced, corresponding with poorly internalized forms of extrinsic motivation (Deci & Ryan, 1985). When mobile learning, motivation could play a role. Applied to Doolittle & Mariano's experiment, we could suggest that students could have been highly autonomously motivated to walk down the hall and not so highly autonomously or highly controlled motivated to watch the instructional video, obviously resulting in a lesser performance. For Clarebout's study we might say that students could have been highly autonomously motivated to ride the bike and lowly autonomously motivated or highly controlled motivated to watch the study material on an iPod, explaining their poor performance. In Coens' experiment it could have been that learners were more or less as motivated to screw the bolts and nuts as they were to study the educational podcast, showing only slight non-significant differences in performance.

Does motivation play a part, does motivation influence performance?

The experiment

We will invite about 120 university students to learn Spanish vocabulary using an iPod, while driving in a simulator. We will ask them, for each task, to fill out an adapted version of the Academic Self-Regulation Scale (Ryan & Connell, 1989), which has been successfully used in previous work (e.g., Vansteenkiste, Zhou, et al., 2005). The 16-item scale, contains 4 items per regulation (intrinsic, identified, introjected and extrinsic motivation). This Dutch version, used by e.g. Vansteenkiste, Sierens, Soenens, Luyckx, & Lens (2009) has been validated.

As done in previous studies (e.g. Vansteenkiste, Lens, De Witte & Deci, 2004; Vansteenkiste, Zhou, Lens & Soenens, 2005; Vansteenkiste et al., 2009) we will create an autonomous motivation composite by averaging the scores for identified and intrinsic motivation and a controlled motivation composite by averaging the scores for external and introjected regulation. We expect four clusters to emerge: a high quantity motivation group (high autonomous, high controlled), a low quantity motivation group (low autonomous, low controlled), a good quality motivation group (high autonomous, low controlled), and a poor quality motivation group (low autonomous, high controlled).

If motivation (autonomous or controlled) is at the basis of the results of the experiment, then we should find the following pattern for each of the tasks. The experiments are scheduled to take place in November and December 2010, so results will be available by Spring 2011. As young people multitask more and more, it would be of great value if we could find what influences their performance when multitasking. This knowledge may help educators in their search for more efficient learning.

Associations Between Classroom Environment and Affective Outcomes in Queensland Secondary Schools

Jeffrey Dorman, Monash University, Australia

This research investigated associations between classroom environment and student affective outcomes in Australian secondary schools. The What Is Happening In this Class (WIHIC) questionnaire was used to assess 7 classroom environment dimensions: student cohesiveness, teacher support, involvement, investigation, task orientation, cooperation, and equity. Three student outcomes were also assessed: academic efficacy, attitude to subject, and attitude to computer use. The sample consisted of 1,256 year 11 and 12 students nested in 61 classes from 10

secondary schools in Queensland, Australia. Multilevel analyses with the 7 WIHIC scales as explanatory variables and the 3 outcome scales as response variables were conducted. The one significant classroom environment dimension that was common to all three models was task orientation. Keeping students engaged in the specific tasks at hand and completing meaningful activities is important to affective outcomes. Overall, this study has shown that students' perceptions of the classroom environment are related significantly and positively to affective outcomes. Teachers should ensure that positive environments exist in all classrooms.

Research on the psychosocial dimensions of classroom environments has made substantial progress during the past 40 years (Fraser, 2007). This research has focused mainly the atmosphere or climate that pervades the classroom. The strong tradition of classroom environment research has been to conceptualise environments in terms of Murray's (1938) beta press – the perceptions of the milieu inhabitants – with instruments assessing particular dimensions of the environment (e.g. teacher support).

The focus of much classroom environment research has been on associations between classroom environment and cognitive and affective outcomes. Ex post facto research designs with correlational data techniques have been the most common approach to environment – outcome studies. Most studies have used either the student as the unit of analysis and ignored class membership or aggregated at the class level and used the class as the unit of analysis. The present study preserves the nested nature of the data by employing multilevel analysis. It has three affective outcomes: academic efficacy, attitude to subject, and attitude to computer use.

Aims

- To validate scales of the What Is Happening In this Class (WIHIC) questionnaire;
- To validate scales to assess academic efficacy, attitude to subject, and attitude to computer use; and
- To use multilevel analysis to identify classroom environment dimensions that predict academic efficacy, attitude to subject, and attitude to computer use.

Methodology

Sample

The sample consisted of 1256 year 11 and 12 students nested in 61 classes from 10 secondary schools in Queensland, Australia. Of these students, 656 were male and 606 female.

Instrumentation

The WIHIC was used to assess 7 classroom environment dimensions: student cohesiveness, teacher support, involvement, investigation, task orientation, cooperation, and equity. Three student outcomes were also assessed: academic efficacy, attitude to the subject, and attitude to computer use.

Data Analysis

WIHIC and outcomes scales were validated using confirmatory factor analysis (CFA) and classical test theory procedures. Multilevel analyses with the 7 WIHIC scales as explanatory variables and the three outcome scales as response variables were conducted.

Findings

Reliability coefficients (Cronbach coefficient alpha) were computed for each scale. These results show that all scales had very good internal consistency reliability. Indices ranged from .88 for involvement to .94 for equity. CFA supported the WIHIC's structure.

Initial variance components models were used to partition variance in all variables across student, class and school. Results indicated only a small amount of variance in response and explanatory variables at the school level.

Subsequent regression modelling with backward elimination was conducted with variance partitioned at two levels: student and class (see Table 1). For example, academic efficacy was predicted by student cohesiveness, involvement, task orientation, investigation and cooperation. The -2loglikelihood ratio test statistic was used to report whether differences between null and regression models were statistically significant. From Table 1, the Δ -2loglikelihood statistic for academic efficacy is 1046.1. As $\chi^2(7, N = 1256) = 20.52, p = .001$, there is a statistically significant difference between the null and regression models.

Educational Significance

This study has demonstrated the use of multilevel analysis in classroom environment research. Because students are nested in classrooms, researchers should employ multilevel analysis when analysing classroom environment data. The above results show that classroom environment is a significant contributor to the sources of academic efficacy. Furthermore, it is possible that academic efficacy influences the environment. Bandura's (1997) triadic reciprocity theorises that personal factors influence, and are influenced by, environment and behaviours. Individuals are

producers and products of their own environment and social systems (Pajares, 1996). The results reveal that classroom environment was a much stronger predictor of attitude to subject than attitude to computer use with only 7.37% of variance in attitude to computer use scores attributed to the three predictor variables (task orientation, investigation and equity). More work is needed in integrating computer into the classroom environment.

The one significant classroom environment dimension that was common to all three models is task orientation. Keeping students engaged in the specific tasks at hand and completing meaningful activities is important to affective outcomes. This accords with much recent research (see, e.g. Dorman, Fisher, & Waldrup, 2006). Accordingly it would seem that the fields of student engagement and classroom psychosocial environment have much in common and research on the relationship between engagement and classroom environment should be undertaken.

Overall, this study has shown that students' perceptions of the classroom environment are related significantly and positively to affective outcomes. Teachers should ensure that positive environments exist in all classrooms.

Effects of rubric: Focusing on values of test, learning motivation and strategy

Masayuki Suzuki, the university of tokyo, Japan

In the present study, we investigated the effects of instruction about the test's grading standards and purpose by presenting a rubric to students. 101 eighth-grade students were randomly assigned to 1 of 3 classrooms, each of which corresponded to an experimental condition. The participants studied mathematics for 5 sessions: at the end of each session, the teacher gave a test of that day's lecture. The feedback methods of their test results varied according to each classroom's experimental condition: (1) the rubric condition in which participants received the rubric; (2) the rubric plus comment condition in which participants received the rubric and comments by the teacher; or (3) the comment-only condition in which participants received only comments by the teacher and not the rubric. The results showed that students who received the rubric were more likely to regard the test's purpose as improvement, had higher intrinsic motivation, used more deep-processing strategies and fewer surface-processing strategies and achieved higher scores than those who did not receive the rubric. The results also revealed that comments by the teacher had no effect on the dependent variables. In addition, the results of a path analysis suggested that the rubric influenced motivation, strategy and test score via values of test. The results of this study suggested that the rubric is helpful in informing students about the test's purpose of improvement, and the test's effects on students depend on the students' perception of the test's purpose or role.

Background and purpose of study

Considering the decline of scholastic ability in Japan, attention is being paid to tests. For example, an admission system based on recommendation that does not need for an academic achievement test has been reviewed. The expectations from an academic achievement test are that it would promote the zeal for achievement and encourage learning among students; however, it is possible that a test may adversely affect the learning motivation and strategy of students (e.g. Gipps, 1994). Therefore, it is important to examine the procedure of conducting tests. In recent years, researchers have examined students' perspectives on testing or assessment and shown that students' view of the test's values or purposes is related to their learning motivation and strategy (e.g. Brown, et al., 2009; Suzuki, 2009). For example, Suzuki (2009) defined values of test as the students' perception of the test's purposes and roles, and the scale comprises four sub-scales: improvement (e.g. test helps me understand the extent of my own learning), pacemaker (e.g. test supports the creation of a learning programme), comparison (e.g. test's purpose is to select excellent students) and enforcement (e.g. test's purpose is to enforce learning). The aspects of a test that help in improving learning and encouraging planning are related to high learning motivation or deep-processing strategy. On the other hand, the aspects that enforce learning and enable selecting excellent students are related to low learning motivation or surface-processing strategy (Suzuki, 2009). These results suggest that tests have a negative effect on students because they regard the test's purpose as comparison or enforcement. Therefore, as suggested in some studies that it is important to inform students about the test's purpose or grading standards (e.g. Murayama, 2006;

Spratt, 2005), it is considered essential that when teachers conduct tests they emphasise the purpose as improvement or pacemaker. If students understand that teachers do not use tests to enforce learning, but to help students improve, their learning motivation can be positively affected and they can be encouraged to use an effective learning strategy. A rubric can be useful for informing students about the test's purpose or grading standards. Although educators tend to define rubrics in slightly different ways, a commonly accepted definition is that it is a document that articulates the expectations from an assignment by listing the criteria, or aspects that count, and describes the levels of quality (Andrade, et al., 2009). Thus, a rubric enables students to understand the test's grading standards, judge their level of understanding and determine the best approaches for correcting mistakes and improving performance (e.g. Weaver, 2006). Therefore, in the present study, we investigated the effects of instruction about the test's grading standards and purpose by presenting a rubric.

Methods

Participants? The participants were 101 eighth-grade students from public junior high schools in two wards of Tokyo and a junior high school affiliated with the University of Tokyo. They voluntarily participated in the study. They were randomly assigned to 1 of 3 classrooms, each of which corresponded to an experimental condition. **Procedure?** The experimental classes were organised and provided at the University of Tokyo for 5 days during the summer of 2009. **Classes?** Mathematics classes on linear equations with two unknowns were conducted. During days 2–4, lessons consisted of the previous day's test review (10–15 min), a lecture on word problems (25 min) and a test on that day's lecture (10 min). On the first day, a pretest and lecture about methods of calculation were conducted. On the last day, participants reviewed the test that they took on the fourth day, and took post-test. **Feedback methods** The feedback methods of their test results varied according to each classroom's experimental condition: (1) the rubric condition in which participants received the rubric; (2) the rubric plus comment condition in which participants received the rubric and comments by the teacher; or (3) the comment-only condition in which participants received only comments by the teacher and not the rubric. All participants received correctness feedback and model answers. **Dependent variables** Values of test, intrinsic motivation and learning strategies were measured through questionnaires, and performance was measured by the post-test. The post-test consisted of three isomorphic problems and two challenging problems.

Results

Contrast analysis was used to test the effects of the rubric, and two orthogonal contrasts were constructed. The first tested for differences between two rubric conditions and the comment-only condition (rubric contrast: rubric [1], rubric plus comment [1], comment-only [-2]). The second tested for differences between the rubric condition and the rubric plus comment condition (comment in rubric contrast: rubric [-1], rubric plus comment [1], comment-only [0]). The results showed that students who received the rubric were more likely to regard the purpose of the test as improvement, had higher intrinsic motivation, used more deep-processing strategies and fewer surface-processing strategies and achieved higher scores than those who did not receive the rubric. The results also revealed that comments by the teacher had no effect on the dependent variables. In addition, the results of a path analysis suggested that the rubric influenced learning motivation, learning strategy and test score via values of test (Figure 1). The model provided a satisfactory fit to the data: $\chi^2(17) = 17.346$, AGFI = .882, CFI = .998, RMSEA = .017, SRMR = .066.

Discussion

The results of this study suggested that students' view of the test's values or purposes influenced their learning motivation, learning strategy and performance. Therefore, the test's effects on students depend on the students' perception of the test's purpose or role. In addition, the rubric proved to be helpful in informing students about the test's purpose of improvement, possibly because students can understand the test's grading standards and their achievement within those standards; hence, they can determine the best approaches for correcting mistakes and improving performance. However, because there was no difference in their enforcement score among conditions, more effective interventions must be developed.

Evaluation of the Model for Competence-Based Vocational Education

Lidwien Sturing, Wageningen University, Netherlands; Harm Biemans, Wageningen University, Netherlands;
Martin Mulder, Wageningen University, Netherlands; Elly De Bruijn, Utrecht University, Netherlands

The model for competence-based vocational education (CBE-model) consists of eight CBE-principles elaborated for four implementation levels and assess the actual and desired competentiveness of vocational study programmes (Wesselink, Biemans, Mulder and Van den Elsen, 2007a). This article presents the result of a study on the necessary adjustments of the CBE-model according to teachers in order to apply the model as a valid instrument to assess the actual and desired competentiveness of their study programmes. In study A 57 teachers evaluated the model during

group sessions resulting in a revised CBE-model including 10 principles for five levels of implementation. In study B 151 teachers completed a questionnaire to evaluate the comprehensibility of the revised model. The study showed that teachers understood and interpreted the revised model as intended, were able to position their study program by using the revised model and that the content validity and reliability of the revised model was satisfactory.

Introduction

The concept of competence has taken a central position in the curriculum reforms that are currently sweeping across the world (Arguelles & Gonczi, 2000; Brockmann, Clarke, Méehaut & Winch, 2008; Clarke & Winch, 2007; Weigel, Mulder & Collins, 2007). According to Velde (1999) competence-based education (CBE) enables students to prepare themselves to be competent professionals and citizens in this current society. Per August 2011 vocational study programmes in the Netherlands should be completely based upon a competence-based qualification structure following governmental policy.

The transformation to CBE has not gone smoothly. First the underlying principles of CBE were not clear in the first place. Furthermore, there were no sufficient guidelines or instructions provided by the government to implement CBE. Only a competence-based qualification structure is obliged by law. As a consequence of this situation the implementation of CBE resulted in putting new competence-related labels on old practices, as a result of which hardly anything changed in educational practice.

Therefore Dutch researchers constructed the model for competence-based vocational education which consists of eight crucial CBE design principles elaborated for four implementation levels (referred to as 'not', 'starting to be', 'partially' and 'completely' competence-based). It assesses the actual and desired competentiveness of vocational study programmes. Competentiveness refers to the extent to which study programmes are competence-based (Wesselink, Biemans, Mulder & Van den Elsen, 2007a).

Further research on the CBE-model appeared to be necessary. A study of Wesselink, Mulder and Biemans (2007b) showed that the CBE-model was perceived as comprehensive and useful by teachers, but that adjustments were necessary because some parts of the instrument could be interpreted differently. It is also unclear whether the results of Wesselink et al. (2007b) who evaluated this model only in the agricultural sector of vocational education and training (VET) with a small number of teachers can be generalized to other sectors.

The current study was initiated to fulfil two objectives. First to examine which adjustments of the CBE-model were necessary according to teachers in order to apply the model in educational practice. And second to examine the content validity of the revised model.

Methodology

In this study a multi-method approach was used. Two studies were conducted. Enrolled in both studies were teachers who were working in Dutch VET. In study A 57 teachers participated. A group session was held in which teachers in couples systematically examined which adjustments to the model were necessary. Preceding the sessions teachers filled out an individual questionnaire. Content analysis and descriptive statistics were used to analyze the data. Suggestions for adjustments were accepted if 20% or more of the teachers suggested the same adjustment. Based on study A the CBE-model was revised.

In study B 151 teachers completed the questionnaire. The questionnaire was based on the revised CBE-model. Teachers had to indicate for each CBE principle the competentiveness of their own vocational course by selecting a level and had to support their answer by giving an example. The supportive argumentations provided by the teachers were used to investigate whether the teachers understood the content of the model. The teachers were also requested to give their opinion on the importance of the various principles of CBE on a three-point scale (not essential; useful, but not essential; essential). Descriptive statistics were used to analyse the questionnaire. The validity was estimated by using the content validation approach of Lawshe (1975). Content analysis was used to analyze the supportive argumentations.

Results

The individual questionnaire showed that 87% of the teachers agreed with the principles of CBE as defined if they compared them with their own key words of CBE. According to 10% of the teachers 'flexibility of study programmes' missed in the model. The results showed that 40% of the teachers were not satisfied with the levels, because they experienced a gap between the last two levels. Least satisfied were teachers with the readability of the principles. Some definitions, sentences or single words were not always clear to the teachers and some parts of the model could be interpreted differently. During the group sessions teachers gave concrete suggestions to improve the readability. Another remark teachers made concerned principle 6 (self responsibility and self-reflection). Teachers didn't agree to

combine two aspects in one principle. During study B teachers were asked to rate the importance of each CBE-principle. The content validity ratio (CVR) was calculated by means of the percentage essential for each principle. All principles showed high CVRs which indicated that at least more than half of the teachers considered the principle essential. The lowest CVR was ,32 and the highest scored ,81. The model as a whole also had a good content validity (,61). The CBE-model also has a good reliability ($\alpha = 0,83$).

Conclusion and discussion

In the introduction two objectives were formulated for this study. The first objective was to examine which adjustments of the CBE-model were necessary. It can be concluded that several adjustments are necessary. Besides making various detailed semantic adjustments, one new principle (flexibility of study programmes) and a fifth level of implementation were included in the revised CBE-model. Principle 6 was divided into two separate principles. The second objective was to examine the validity of the revised model. The results show that the revised model has a good content validity. The teachers were able to position their study program on the model and they understood and interpreted the model as intended. With the help of the CBE-model teachers can grasp the meaning of the underpinnings of CBE and the way instruction should take place. The revised CBE-model offers teachers in an instrument to assess their own practice and see which aspects they have to work on in order to fully realize the main principles of CBE in actual teaching and learning processes. However more research is needed to investigate whether teacher teams can really work with the CBE-model and to examine whether students and teachers perceive the competiveness of their study programme similarly. This article indicates that so far the CBE-model can be seen as a useful instrument in the process and implementation of CBE by teachers.

To Agree Or Not To Agree: Establishing criteria for expert decisions using the resampling technique

Hendrik Lohse-Bossenz, Goethe-University, Germany; Mareike Kunter, Goethe-University, Institute of Psychology, Germany; Olga Kunina-Habenicht, Goethe-University Frankfurt, Germany; Juergen Daebritz, Humboldt-University Berlin, Germany; Daniel Zschaetzsch, Humboldt-University Berlin, Germany; Hanno Strang, Humboldt-University Berlin, Germany

In educational research and practice, standardized tests are widely used, often in high-stakes situations such as school transition or student admission. However, although expert panels are widely used in the process of test development, particularly in the field of student achievement testing, the quality of expert decisions has rarely been systematically investigated. The aim of this study is to investigate measures describing the quality of expert panels and their decisions, in order to establish guidelines for panel selection procedures. Besides the widely used measure of group agreement, it is argued that tools designed to measure the person-dependence of group decisions add incremental value to inferences about group homogeneity.

Using a resampling approach on two non-interacting expert samples ($N_1=48$ and $N_2=40$) from different contexts (teacher education and quality management), results show that despite agreements in both samples, the degree of person-dependence differs – indicating the sensitivity of the approach to differences in group homogeneity. The results are discussed with respect to practical applications such as estimation of optimal panel size or criteria for expert selection.

Introduction

In educational research and practice, standardized tests are widely used, often in high stakes situations such as school transition or student admission. Given the increasing importance of standardized testing, there is an equally increasing call to report evidence for construct validity of the implemented tests (APA, & NCME, 1999). In order to evaluate the usefulness and interpretability of test scores in a certain domain, researchers often rely on persons with high expertise in the domain of interest. For instance, in high-stakes testing experts are recruited to establish cut-off scores for minimal competence of students in the context of standard-setting procedures, or to evaluate the alignment of test procedures with established educational standards (Hambleton & Pitoniak, 2006; Kane, 1994). However, although expert panels are widely used in the process of test development, particularly in the field of student achievement testing, the quality of expert decisions has rarely been systematically investigated.

What remains unclear is whether decisions are based on a real consensus or whether they are merely a compromise between divergent opinions. Other unanswered aspects are panel size and panel selection criteria. How can researchers be sure to have chosen the "right" experts, or could it be that different people would not have reached a different, possibly contrasting, decision?

The aim of the study is to investigate measures describing the quality of expert panels and their decisions in order to establish guidelines for panel selection procedures. As within-group agreement is problematically influenced by group size (small groups tend to agree more easily), it is argued, that tools to measure the person-dependence of group decisions add incremental value to inferences about the validity of expert ratings. To test the sensitivity of this approach, we examined two different samples – one homogeneous (Sample 1) and one heterogeneous (Sample 2).

Method

Samples

Sample 1 included 48 experts from the field of teacher education who participated in a study aimed at developing a test to measure teacher candidates' educational knowledge. Experts rated 852 of topics on their importance to teaching on a 3-point scale. Sample 2 included 40 experts involved in adolescent talent development in sports, who participated in a study on quality criteria for sport schools. Experts rated 120 items regarding their usefulness for athletic and academic development on a 4-point scale. In each case, experts did not interact.

Procedure of Analysis

Using the empirical data from the expert ratings, subgroups of different size (3-47/39) were randomly formed using a resampling procedure (Efron & Tibshirani, 1993). For each group size the mean of all expert ratings and agreement within the group were calculated for 1000 repetitions (using the statistical software R (Bliese, 2009)).

Agreement

Within-group agreement was measured by the Average Deviation Index (ADM, Burke, Finkelstein, & Dusig, 1999), which was calculated by summing up the amount of distance of each participant from the group center. Lower values are indicative for higher agreement.

Person-dependence

The measure of person-dependence was estimated by calculating the standard deviation of the means for 1000 repetitions within each group size. This measure can be used as an indicator for the variation of groups' decisions depending on the random composition of groups. Higher values are indicative for higher person-dependence of the outcome.

Results

Results show that in both samples small groups – though randomly selected – achieve better agreement values (e.g. $ADM(S1;N=3)=0.31$ vs. $ADM(S1;N=20)=0.47$ for Sample 1 and $ADM(S2;N=3)=0.37$ vs. $ADM(S2;N=20)=0.52$ for Sample 2). The ADM values increase asymptotically with group size, indicating lower agreement in larger groups. However, regarding person-dependence of group decisions a reverse trend was observed, showing the larger the group, the less the decisions were dependent on specific group composition (e.g. $SD(S1;N=3)=0.18$ vs. $SD(S1;N=20)=0.02$ and $SD(S2;N=3)=0.20$ vs. $SD(S2;N=20)=0.06$).

Plots for both samples are presented in figure 1 (see attachment). Whereas in Sample 1 the curves for agreement and person-independence are lower and flatten very fast, Sample 2 shows larger values and only a near-linear decrease of person-dependence.

Discussion

The approach here presented used a resampling procedure to evaluate the quality of decisions in expert groups used in test development procedures. Following the analyses presented, Sample 1 seems to be homogeneous. Statistical procedures for group decision are appropriate. Sample 2, however, revealed a higher degree of person-dependence and despite sufficient agreement values, researchers should be cautious not to simply calculate a mean decision. Efforts should be directed to the identification of subgroups at least for reduction of systematic effects. Furthermore, this case requires an extension of panel size to increase accuracy.

The descriptive approach using within-group agreement and person-dependence measures is a useful tool for post-hoc evaluations of selected expert panels in order to support inferences drawn from experts' judgments. Besides further theoretical foundation, the resampling procedure can be used to answer practical educational questions like criteria for expert selection, size of expert panels or instructional contexts producing optimal expert decisions.

Comparison of the Impact of Input and Context Variables on Mathematics Performances in Grade 6 and 8

Sarah Gielen, Katholieke Universiteit Leuven, Belgium; Lien Willem, KULeuven, Belgium; Kaat Van Dessel, K.U.Leuven, Belgium; Daniel Van Nijlen, KULeuven, Belgium; Rianne Janssen, K.U. Leuven, Belgium

This study compares the outcomes of national assessments of mathematics at three different levels: grade 6 (primary education) and the A-track (pre-academic) and B-track (pre-vocational) of grade 8 in secondary education in Flanders-Belgium. It finds substantial differences in the amount of school variation. Furthermore, several pupil characteristics that have a negative effect on mathematics performance in the A-track have a stronger effect in the B-track, and are even more pronounced in grade 6. SES is more advantageous in the A-track, while the cultural capital is more important for B-track pupils, and both have more discriminating power in primary education. Finally, the negative impact found in secondary education of attending schools with more disadvantaged children is remarkably smaller in primary education.

It is common practice in educational effectiveness research to correct for input and context variables, in order to get a clear view on the value added of schools. This practice, however, may hide some parts of our educational system are more effective in leveling out the impact of these background characteristics of pupils than others, and thus realize more equal opportunities for all pupils. We examine the difference between the various educational levels in the amount of school variation and its distribution. Furthermore we compare the effect size of several input and context variables ('net models') on pupil performance in various levels of our educational system, and the amount of school variance explained.

The current study uses the outcomes of three national assessments of mathematics in Flanders, respectively at the end of primary education (grade 6, N=6438) and in the A-track (pre-academic) (N=3184) and B-track (pre-vocational) (N=4044) of grade 8 in secondary education. Both test results for mathematics and information from background questionnaires were used. The distribution of the variance is examined in multilevel null models by means of the intragroup correlation coefficient. Then 'net models' (controlling for gender, age, home language, cultural capital, SES, learning disabilities, educational network and proportion of disadvantaged pupils in the school) are constructed in which the effect sizes and significance of the different covariates are examined and compared across projects, as well as the proportion of explained variance.

The B-track of grade 8 shows the smallest amount of school variation and the largest amount of pupil variation, then comes grade 6 in primary education and then finally the A-track of grade 8. The variables of our net model explain about two third of the variance at the school level for both primary education and the A-track of grade 8. In the B-track, this is only 50%. At the pupil level, only 4 to 5 % of the differences are explained by the net model in grade 8, while in grade 6, these net variables account for on average almost 1/5th of the pupil differences.

A comparison of the effect of the covariates between the two tracks in grade 8 reveals that pupil characteristics (e.g. gender, grade repetition, different home language, learning disabilities) with a negative effect on math performance even have a stronger effect in the B-track. On the other hand, also the effect of two 'advantageous' characteristics differs: the number of books at home (cultural capital) has a more positive effect in the B-track, while the measure for

SES only has a significant (positive) effect in the A-track. Finally, after control for the already mentioned pupil characteristics, pupils in the A-track experience a stronger negative influence of being in a school with more disadvantaged pupils than pupils in the B-track.

A comparison with primary education learns us that most effects are even more pronounced in grade 6. The effect of repeating a year, of a different home language and of learning disabilities is stronger in negative sense. In the opposite direction, also the advantageous variables (SES and cultural capital) have a stronger positive effect in primary education. Finally, and on the contrary, the negative impact found in secondary education of attending schools with more disadvantage children is remarkably smaller in primary education.

With a focus on the (undesirable) school variation after correction for the net model, we conclude that the B-track does a fairly good job (only 5% of differences remain unexplained at the school level), the A-track does somewhat worse (13% remaining) and primary education lies in between (average 7% remaining). On the other hand, the impact of 'disadvantageous' pupil characteristics is the smallest in the A-track, and the largest in primary education. Is here a lesson to take – from the perspective of equal opportunities - for research and policy concerning the use of 'net models' that 'pardon' schools and school systems for the effects of some 'input and context' characteristics of pupils and schools?

THEMATIC POSTER SESSION

Culture and Education

Cultural Capital in the Early Childhood

Katharina Kluczniok, Otto-Friedrich-University of Bamberg, Germany; Michael Mudiappa, Otto-Friedrich-University of Bamberg, Germany

Studies have shown that cultural capital at the parental home is a strong predictor of school success. However there are criticisms in the measurement of cultural capital because focus lies on high cultural capital of the parents. Therefore there is less research concerning cultural capital in the early childhood. To meet the criticism an interdisciplinary approach of the sociological concept of cultural capital from Bourdieu and the educational concept of quality in family settings is suggested. The paper deals with activities in cultural and educational fields (e.g. visiting museums) in the early childhood. Based on these activities cultural capital is imparted by the parents to their children. Furthermore it can be assumed that structural aspects (e.g. socioeconomic status) and belief factors (e.g. aspirations) influence the participation of cultural educational activities. Data base is the German panel study BiKS-3-10 (N=554). The following research questions should be answered: 1. Which cultural educational activities take place in families with preschoolers before school enrolment? 2. Which cultural, structural and belief factors have an impact on the participation of these activities? Results of descriptive and multivariate analyses show a wide range of cultural educational activities which takes place in families with preschoolers. Relevant factors for the participation of cultural educational activities are reading to children, high cultural resources and educational beliefs of the parents. The results will be discussed regarding opportunities of activation and involvement of parents.

Studies have shown that cultural capital in families is a strong predictor of school success and educational chances. Therewith related educational inequality is the result of a conditional class effect. This effect is passed on by allocation, transfer and transformation of cultural capital over the life course. Cultural practices, investments in and accumulation of cultural capital and its transfer are influenced by the priority of education, by the parental educational level as well as by the family as a social context and by economical resources.

However, in the literature there is some criticism on the measurement of cultural capital. The main criticism is that the focus lies on high cultural capital of the parents. Therefore there is less research concerning cultural capital in the early childhood. As a consequence of this in the research is no consideration of social and cultural learning, no integration of home learning environment during preschool and there are less factors of parent-child-interaction. Referring to Pierre Bourdieu the acquirement of cultural capital and skills starts in the early childhood by active and passive transfers. Parent-child-interaction, parental cultural behavior and home learning environment are important for the transfer of cultural praxis and orientation, aspiration, habitus and their impact on the educational career. Encouraging cultural educational activities (e.g. reading to the child, visits of concerts and museums) is particularly relevant in this process. On the one hand, the child will acquire cultural skills and praxis which is assumed to have a positive impact on school success. On the other hand, investments in levels of cultural encouragements are indicators of the parental status achievement and educational aspiration. Indeed, it is this criticism that provides a major motivation for your study. To meet the criticism and to consider the acquirement of cultural capital in the early

childhood an interdisciplinary approach of the educational concept of educational quality in home learning settings and the sociological concept of cultural capital from Pierre Bourdieu is suggested. Against the background of both approaches the paper presents an interdisciplinary access, which combines sociological and educational factors to get more explanatory power for the impact of cultural capital in the early childhood. The integration is also an expansion of the concept of cultural capital and fulfills the criticism of the measurement of cultural capital.

The paper deals with activities in cultural and educational fields (e.g. visiting museums) in the early childhood. These activities take place outside the household by visiting cultural and learning places and are assumed to have an impact on educational success by better competencies, school performance, job training and the position on the labor market. Furthermore it can be assumed that structural aspects (e.g. socioeconomic status) and belief factors (e.g. aspirations) influence the participation of cultural educational activities. Data base is the German panel study BiKS-3-10. The longitudinal study BiKS-3-10 focuses on the formation of educational decisions concerning the transition from preschool to elementary school as well as the development of cognitive competencies. Starting in fall 2005 a random selection of 554 children and their families in two federal states (Bavaria and Hesse) are followed from the beginning of preschool until the end of elementary school.

The following research questions should be answered: 1. Which cultural educational activities take place in families with preschoolers before school enrolment? 2. Which cultural, structural and belief factors have an impact on the participation of these activities?

For the analysis descriptive and multivariate methods were used. Descriptive results show a wide range of cultural educational activities which takes place during the socialization. Multivariate regression analyses come to the result that factors of both theoretical concepts have a significant impact on participation of cultural educational activities. Relevant factors are reading to children, high cultural resources and educational beliefs of parents. Parents who are reading to their children, who have available more cultural resources and who have higher idealistic aspirations, do more frequently activities in cultural and educational fields. Surprisingly activities in cultural and educational fields are independent of the financial situation of the families.

The results will be discussed regarding opportunities of activation and involvement of parents. In praxis parental and institutional consciousness has to be reinforced. Based on the assumption that cultural capital of parents will be imparted from the parents to the children, aspirations and cultural activities will be passed down to the children as well. This means, that there should be more investments in parental education to underline the importance of cultural activities. This investment could be a booster of the starting conditions of the educational career. On the one side institutions such as museums and libraries should offer low-threshold services, which are easily accessible for the families. On the other side institutions have to integrate parents more in their educational program. Especially the preschool as learning environment next to the family has to integrate parents more in their educational program and provide information about cultural and educational activities in the neighborhood.

Relation between learning activities and intercultural competence

Hans Gruber, University of Regensburg, Germany; Regina Mulder, Universitaet Regensburg, Germany

Internationalization and globalization processes increasingly cause multicultural teamwork in several work areas. In consultancies this leads to cultural diverse work teams or work with clients with different cultural backgrounds. Therefore, consultants need to develop intercultural competence to successfully work with members of different cultures. This contribution reports a study which deals with the research question what learning activities are related to intercultural competence. Thereby formal and informal learning aspects are taken into account. In this study intercultural competence is measured through a combination of a video based case analysis and a structured interview. The learning background and demographic aspects are collected through a standardised questionnaire. 50 consultants – partly with formal learning experience, partly with no formal learning experiences – participated in the study.

Results of the study show no significant relation between formal learning and intercultural competence, no significant relation between experience based learning and intercultural competence, but a significant relation between professional experience and the affective dimension of intercultural competence. Internationalization and globalization processes increasingly cause multicultural teamwork in several work areas. In consultancies this leads to cultural diverse work teams. Therefore, consultants need to develop intercultural competence to successfully work with members of different cultures.

Theoretical framework

Dealing with people from different cultures can cause intercultural conflicts. These conflicts are caused by the reason that two or more people with different cultural orientation systems converge and have different expectations on the behavior of their counterpart. The concept of intercultural competence describes the specific ability to interact reflectively and productively with people from different cultures (Stahl, 1998). Intercultural competence is developed as a special skill based on general human communication abilities, acquired knowledge about cultural differences and practical experience in intercultural situations (Thomas, 2003). There has been lots of research in the past decades focusing on the effect of formal learning activities e.g. intercultural trainings on intercultural competence (Littrell, Salas, Hess, Paley & Riedel, 2006; Zakaira, 2000) but almost no research on the relation of informal learning activities. In our study we focused on the relation between formal and informal learning activities and intercultural competence. Concerning informal intercultural learning we distinguished between experience based learning and professional experience. Experience based learning is a special form of informal learning and describes how somebody is able to reflect upon his/her own experiences and how somebody is able to learn from his/her experiences. In contrast, professional experience describes the learning experiences which develop through challenging situations at work (McCauley et al., 1994).

Results of training evaluations indicate that pure knowledge transfer is not enough to prepare the learner for intercultural conflict situations (Kammhuber, 2000). Moreover, it is suggested that different learning aspects are connected with different aspects of intercultural competence. Intercultural competence is defined as a three-dimensional construct (see Figure 1), which consists of a cognitive, an affective and a conative dimension. Each dimension contains several items which describe parts of intercultural competence: e.g. cognitive aspects like cultural awareness, change of perspectives etc., affective aspects like openness and empathy etc. and the conative aspects like tolerance of ambiguity, communication skills etc.. It is assumed that the acquisition of intercultural knowledge can lead to a higher intercultural sensitization on the cognitive dimension of intercultural competence. Further assumptions of our study are that learning from experiences has a positive relation to the affective dimension of intercultural competence and professional experience is positively related to the conative dimension of intercultural competence.

Research questions

The research questions of our study were: Is there a connection between formal learning experiences and intercultural competence? Is there a connection between learning from experiences and intercultural competence? Is there a connection between professional experience and intercultural competence?

Method

Design

To investigate these research questions several research methods were combined: a video based case analysis in combination with a structured interview and a standardized questionnaire.

Sample

50 internationally experienced consultants participated. They were members of consulting companies with different size (big to small). Besides they were working in different consulting domains, such as IT, strategy consulting, HR consulting etc.. 30 of them had participated in intercultural formal learning activities, 20 of them never participated in formal learning activities.

Measures

For the measurement of intercultural competence a video based case analysis in combination with a structured interview was designed. This method has the advantage that the measured results are based on the cognitive behavior of the subjects instead of their self-assessment. The case analysis consists of three different intercultural conflict situations between Germans and members of other cultures (India, Spain, USA). These conflicts are based on training material which was taken out of culture assimilators. The conflict cases were filmed and during the realization of the study the subjects were confronted with all three video clips. After viewing one scene they were asked to analyze the situation. Therefore a standardized interview guideline was used. The interview questions were constructed in a way that the questions were aimed at reflecting the three dimensions of intercultural competence. Examples of the questions were:

"Which behaviours in this situation do you trace back to culture or cultural differences?" (Cognitive dimension)

"Which behaviours of the persons lead to this conflict situation?" (Conative Dimension)

"What do you think, how these persons feel in this situation?" (Affective Dimension)

For the measurement of the learning aspects a standardized questionnaire was used which consisted of scales on formal learning, learning from experiences, professional experience and demographic aspects.

Analysis

For the analysis of the interview data, we used thematic analysis. Here, we used the aspects which were included in the intercultural competence model as categories. All interviews were double coded according to the guidelines in the coding manual. Doublings in the content were only rated once to avoid high scores caused by repetition. To check the interrater-reliability of the coded data, the intra-class coefficient (ICC) was analysed for all categories. For further quantitative analysis with SPSS we combined the quantitative interview data with the quantitative data from the questionnaire and computed Spearman's rank correlation coefficient.

Results

Results are shown in Table 1. They show no significant relation between the learning experience of the subjects and their score in intercultural competence. The correlations are even quite small, except of the correlation between professional experience and intercultural competence. Looking at the correlations between the learning experiences and the dimensions of intercultural competence, only one significant correlation was found: between professional experience and the affective dimension.

Conclusions

It can be concluded that the connection between formal and informal learning experiences and the development of intercultural competence is not that direct then expected. There are several reasons which might have had an influence on the outcomes of our study: small sample size, limited measurement of aspects that influence intercultural competence. Main limitation of our study is, that we could only measure intercultural competence through a cognitive analysis and not "real" intercultural behaviour.

Building mathematics knowledge through blogs in the engineering university classroom

Jazmin Juarez, Escuela Superior de Computo, Mexico; Jose Chamoso, Facultad de Educacion, Spain; Maria Teresa Gonzalez, Universidad de Salamanca, Spain; Laura Hernandez, Universidad de Salamanca, Spain

In recent years, university teachers have experienced alternative methods of teach mathematics, some of them in order to develop classroom activities that incorporate the use of learning environments that contain asynchronous communication tools, to promote the collaborative process in which meaning is negotiated and knowledge is co-constructed. Blogs are often used in educational settings to foster collaboration and enhance interaction between students and teachers; however there is little evidence about the study of collaborative processes developed with the blogs use. The aim of this study was to analyze the knowledge building process carried out when engineering students use blogs as communication tools in a mathematics course.

The participants were 31 systems engineering students, from the Superior School of Computer Sciences in Mexico City. Students organized into 6 groups developed a project that consisted in design a blog to show problems of real phenomena solved by first order ordinary differential equations. Each group used a blog to post proposed problems, and as communication tool to select just two problems considering the representation of dynamic systems by initial value problems.

We analyzed students' messages using a sequential model of knowledge building phases proposed by Gunawardena, Lowe & Anderson (1997). The results showed high incidence in the first phase and low incidence in high phases of the knowledge building process: students just exchange and compare information to develop a task together; however the interaction between students through blogs can be an effective way to achieve results in relation to the acquisition of knowledge.

An important component in the growth and development of teaching and learning mathematics at university level has been the emergence of Web-based applications designed for the creation of spaces for teaching and learning (Engelbrecht & Harding, 2005). Success in learning to use Web-based environments depends on how these resources support collaboration, encourage participation and interaction among students (Fisher, 2000; Lee, 2001). Asynchronous communication transforms the teaching-learning process, enabling a group discussion and access to other participants for socialization and communication (Cabero, 2004; Silva & Gros, 2007; Kim, 2008). By participating in an activity mediated by asynchronous tools, students not only learn mathematical skills and procedures also explain and justify their own thoughts and discuss their findings on the use of mathematics in different problem-solving situations (H yrme & J rvel , 2005).

In the study of asynchronous interactions, some studies have focused on the level of discussion, considering the interactions as opportunities to promote knowledge and learning (Henri, 1991, Gunawardena et al., 1997). Asynchronous communication supports constructivist learning principles because it allows students to articulate, read

and reflect on the concepts (Hara, Bonk & Angeli, 2000). There have been recent attempts to describe the messages in online forums, to study the construction of knowledge in these communication spaces. However, although other asynchronous tools such as blogs can be used in various disciplines in higher education (Williams & Jacobs, 2004), and providing educational opportunities that support the learning process, still have limited use in teaching mathematics at university level.

In this respect, and considering that the communication has the potential to transform education by creating learning environments focused on students, the aim of this paper is analyze the knowledge building that take place when engineering students use blogs as contexts of debate to develop a task in a Mathematics course.

2. Method

We carried out a study in the School of Computing in Mexico City with a group of 31 students enrolled in the course of Differential Equations for the period January to June 2010. This course is taught in the second semester of Computer Systems Engineering and aims to formulate models and to solve engineering problems using ODE. The course was organized through a Web platform in the content management system open educational MOODLE, that the school offers teachers to develop courses. The implementation of the platform on the subject aimed to foster collaboration, reporting on aspects of the course, manage the distribution of documentation and the work to be done by students, and generate an efficient and flexible communication between teacher and students or among students themselves.

In this experience the students developed a project, in the first part of the project students investigated individually and resolved a problem of application of the first order ODE to represent an everyday situation, and then organized into groups, they designed a blog with the proposed problem for each member in the team. Since individual messages, students selected two proposals together, considering criteria identified by the teacher in the theoretical session. Each team restructured his blog including only the selected problems together and presents it in the classroom.

To collect data, we used the students' messages. We categorized the messages according to the model of building knowledge of Gunawardena et al. (1997), in the following phases: Phase I (Exchange and comparison of information), Phase 2 (Discovery and exploration of dissonance or inconsistency among ideas, concepts or statements), Phase III (Negotiation of meaning and / or co -construction of knowledge), Phase IV (Testing and modification of proposed synthesis or co-construction), and Phase V (Declarations of agreements and implementation of newly constructed meaning). The coefficient of reliability of the instrument of Gunawardena et al (1997) has been reported in some studies that have used this coding system (Schellens & Valcke, 2005; Veerman, Veldhuis & Diermanse, 2001).

Taking each complete message as the unit of analysis, 83 messages were classified in some phases of the model, according to the most appropriate description of the processes of building knowledge in the message. The contributions of two or more ideas or comments different phase were categorized into hierarchically superior. Phase 0 was allocated for those comments not related to the topic.

3. Results

By observing the amount of classified messages in each of the phases, it appears that the largest number of contributions (64%) corresponds to Phase I, which indicates that most students delivered remarks showed agreements, and requested or clarifications made. The percentage of messages in Phases II and III, Discover and explore dissonance and inconsistencies of ideas and knowledge to negotiate and build are very similar (14 % and 13 % respectively). An important observation is that the students focused on the development of the task to complete. Students reached agreement to jointly select a problem as indicated by posts categorized in Phase V: State agreements (7%), however, despite reaching an agreement, students rarely tested the foreground, contrasting with the theoretical information and personal experience, as the lower incidence (1%), was detected in stage IV: Evaluate and modify ideas. Only one message was categorized in phase 0.

In relation to the collaborative construction of knowledge, we detected that the knowledge gained by the students were allowed to restructure its initial work and convey their knowledge to classmates to present their work in the classroom. We also observed that the interaction in the discussion groups stays task-oriented, but didn't reflect high levels in knowledge building.

4. Discussion

The study shows that blogs provide new forms of collaborative work and spaces to discuss in which students can express themselves and build learning communities. We concluded that the building of new knowledge process is further developed when students share and compare their observations and understandings with others. The learning process was transformed from a personal activity to a social activity when they compared their own meanings through

interaction with the members of the group. We got new information to understand the knowledge building process when blogs are used and thus exploit their potential in math courses.

Level groups as approach to foster student achievement in a heterogeneous and multicultural context

Jeannette Wick, PHTG, Switzerland; Annelies Kreis, University of Teacher Education Thurgau, Switzerland

An increase in heterogeneity regarding students' cultural and linguistic background has become a widespread condition for teaching. Internal differentiation is asked for but demanding to practice in highly heterogeneous classes. As an approach to this problem two primary schools started to teach two out of six weekly German lessons in level groups with grades 4-6 that are smaller and more homogeneous. However, studies about the relationship between class size and learning gains show that smaller class sizes do not automatically result in higher achievement (e.g. Graue & Rauscher, 2009). In a multi-method comparative panel study we examined differences between teaching activities in level groups and in regular German classes in two intervention schools (8 classes, 145 students). In a comparison school (8 classes, 169 students) with similar conditions, German lessons are taught in regular classes without level groups. The two groups are compared with respect to teaching activities in regular classes gained from the perspective of students and achievements in reading comprehension competencies. For the assessment of content specific teaching activities in German lessons we developed a theory based questionnaire in expert workshops. Reading comprehension competences were assessed with a standardized, computer-based instrument (ELFE, see Lenhard & Schneider, 2006). Comparison of teaching activities in regular classes and level groups indicate that there is less internal differentiation in smaller and more homogeneous level groups than in regular classes. Regarding the achievement in reading comprehension there are no significant differences between the conditions with and without level groups.

Theoretical framework and aims

Multi-culturally constituted classes have become a widespread condition for teaching and a prevalent feature is increased heterogeneity of classes regarding students' cultural and linguistic background. As language competences are crucial for school success (e.g. Ditton et al., 2005) their fostering is essential. From a constructivist perspective, different previous knowledge of learners calls for a differentiation of learning environments. However, in highly heterogeneous multi-cultural classrooms internal differentiation comes to its limits. One way of adapting learning environments is to partly teach students in level groups with respect to linguistic previous knowledge. In 2001 two Swiss primary schools (grades 4-6) started to teach two out of six weekly German lessons in three different level groups. The aim of this shift was to improve the fostering of students' language competences in German under the condition of (a) a high proportion of students who come from non-German speaking families (52.6%, 8 languages, e.g. Albanian, Serbo-Croatian, Turkish) and (b) a large number of students with a German speaking middle-class background who are all taught in the same classes. Level groups are smaller and more homogeneous than regular classes. Several studies show that a reduced class size does not forthrightly result in higher learning gains (e.g. Graue & Rauscher, 2009). One explanation for this seems to be, that teachers do not adapt their activities when they teach smaller groups (Im Brahm, 2006). We therefore examined in a multi-method comparative panel study whether teaching activities in level groups are different from those in regular German classes. We furthermore compared intervention schools with two schools which are similar with respect to multi-cultural and socio-economic variables but in which all German lessons are taught in regular classes. Schools were compared with respect to (a) teaching activities in regular classes from the students' point of view and (b) learning gains of students (reading comprehension). The study firstly aims to evaluate whether there are differences between teaching activities during German lessons taught in smaller and more homogeneous level groups and in regular German classes in the intervention school. Secondly it examines whether there are differences between control and intervention group with respect to teaching activities in regular classes. Thirdly student achievement regarding reading comprehension is compared between conditions with/without level groups.

Methodology and design

We could not draw on proved questionnaire for the assessment of content specific teaching activities in German lessons by students and developed a new instrument. In two expert workshops and based on theory about teaching second languages (Cummins, 2000) we collected items that describe teaching activities and structured scales. These scales were validated with a pilot group of 97 students (grades 4-6). Seven scales (30 items) can be regarded as reliable: use of standard language (4 items, $\alpha=.55$), transparent learning goals (4 items, $\alpha=.73$), internal differentiation (4 items, $\alpha=.52$), stimulating search for information (3 items, $\alpha=.50$), stimulating meta-cognition and feedback (6 items, $\alpha=.80$), stimulating reading on differentiated levels (5 items, $\alpha=.78$) and stimulating reading-motivation and frequency (4 items, $\alpha=.5$). To assess students' reading comprehension competences a computer-based diagnostic program for grades 1-6 called ELFE was used (Lenhard & Schneider, 2006). ELFE analyses reading comprehension competencies on

four levels: word comprehension, velocity of reading, sentence comprehension and text comprehension. The scales for content specific teaching activities and data about reading comprehension competencies have been analyzed using T-Test (2-tailed) for dependent and independent means. Data was collected in 16 classes (NIG = 8, NCG = 8) with 314 students (NIG = 145, NCG = 169) for two different measuring points (t1 = beginning of the 4./5. grade, t2 = end of the 5./6. grade) with the same students. FindingsThe comparison of teaching activities in German lessons between level groups (LG) and regular classes (RC) shows that at the first measuring point (t1) the scale use of standard language was rated significantly higher for level groups than for regular classes ($p = .04$). Four further scales show significant differences with higher values for teaching activities in regular classes: internal differentiation ($p = .003$), stimulating search for information ($p = .006$), stimulating reading on differentiated levels ($p = .007$) and stimulating reading-motivation and frequency ($p = .000$). At t2 only transparent learning goals was rated significantly higher for level groups ($p = .000$). Five other scales differ significantly in favour of regular classes: internal differentiation ($p = .000$), stimulating search for information ($p = .000$), stimulating meta-cognition and feedback ($p = .000$), stimulating reading in differentiated levels ($p = .007$) and stimulation of reading-motivation and frequency ($p = .000$). Regarding differences between intervention und control group there are neither significant differences in the assessment of teaching activities nor regarding students' reading comprehension competencies at the first measuring point (t1) Two years later (t2) one teaching activity scale differs significantly in favour of the control group (stimulating reading-motivation and frequency, $p = .040$). Comparison of students' reading comprehension competencies between t1 and t2 shows a significant increase under both conditions without significant differences between conditions. Theoretical and educational significanceOne outcome of this project is a proved instrument which allows assessing content specific German teaching activities. Results indicate that German language teaching activities in smaller and more homogeneous groups are different to those in regular classes. However, modifications are not in a theoretically desirable direction: in comparison with regular classes internal differentiation is reduced in level groups and they do not result in higher reading comprehension competencies. We conclude that smaller and more heterogeneous level groups can unburden teacher workload but do not result in the desired student achievement.

Exploring reciprocal expectations of academic staff and international students in higher education

Mairin Hennebry, Newcastle University, United Kingdom

Internationalisation of higher education is a fast growing field of interest for research and Higher Education Institutions. In the year 2007/2008 international students contributed over £1.88 billion to the UK economy. However, external competition is increasing and there is an imperative to ensure that the needs of international students are met and that their experience of study in the UK is a positive one. This small scale study aims to contribute to current research on the experience of international students at Higher Education Institutions by examining the relationship between these students and academic staff. The study focuses on the relationship between each party's expectations and understanding of their own role and that of the other, with a key aspect of the study being the exploration of the role that culture has to play in both sets of expectations and understandings. The paper reports findings from two stages- the first being questionnaires and interviews administered to staff and international postgraduate students in an Education Department of a Higher Education Institution in the UK; the second an exploratory session with each set of participants to examine their reactions to the understandings and expectations of the other. Departing from Vygotsky's theoretical tradition of identity formation and Bernstein's framing theory, the data allows for an exploration of the potential for a better understanding of each others' roles and perceptions to influence behaviour and expectations.

Aims

This small scale study aims to contribute to current research on the experience of international students at Higher Education Institutions by examining the relationship between these students and academic staff. Particularly the study focuses on the relationship between each party's expectations and understanding of their own role and that of the other. A key aspect of the study is the exploration of the role that culture has to play in both sets of expectations and understandings.

Methodology

Questionnaires administered to all international postgraduate students in a School of Education at a Higher Education Institution in the United Kingdom. Semi-structured follow-up interviews with five students leading to a deeper exploration of the cultural nature of the students' perceptions and expectations. Semi-structured interviews with five members of the academic staff examining their own understandings of the role of academic staff and international students and the role of culture in these perceptions. Interview data from each set of participants would then be shared anonymously with the other set (student responses shared with teachers; teachers' responses shared with students) in order to explore reactions. This process would provide data as to whether a better understanding of each others' roles and perceptions has the potential of influencing their own behaviour and expectations.

Findings

Data collection is being carried out over the course of this academic year so findings are not yet available. Theoretical and educational significance of the research The internationalisation of higher education is a fast growing field of interest for research and Higher Education Institutions. In the year 2007/2008 international students contributed over £1.88 billion to the UK economy. The widespread recognition of English as a global language is no doubt a contributory factor in the increase of applications from international students to UK institutions, given that North America and Australia have experienced similar rises. However, Whilst English is unlikely to lose its status as a global language, it is not inconceivable that fast expanding economies may question the need for a qualification in an Anglophone country. Indeed universities in China and other Asian countries are actively recruiting international staff and students of their own, and in some cases setting up university courses entirely in English. Thus there is an imperative to ensure that the needs of international students are met and that their experience of study in the UK is a positive one. Research to date has considered various aspects of international students' experience of studying in higher education institutions, such as psychological and social adaptation to living and studying in a foreign country (Spencer-Oatey & Xiong, 2006; Maley & Gu, 2008), linguistic challenges of undertaking study in a second language (Edwards et al., 2007; Low et al., 2008), internationalisation of the curriculum (Clifford, 2009) and students' cultural awareness (Bodenhorn, 2005). The focus of much of the existing research has been on the students, with a handful of studies focussing rather on academic staff. Very few studies, however, have investigated the existence of any common ground among expectations of the two groups or sought to create sharing of understandings. Much of the research on internationalisation implicitly adopts a more simplistic view of identity by either grouping participants in the categories of 'home student' and 'international student' or according to their individual nationalities. Anecdotal evidence suggests that academic staff do similarly, whether consciously or unconsciously. If this is the case then it is conceivable that this cultural categorisation brings with it assumptions about what students might expect, what they may be used to, how they may behave. It is equally conceivable that the same is true in students' thinking about academic staff. The present study will create an opportunity to observe the impact that engagement between students and staff might have on the continuing construction of their respective identities and to examine whether some identities (e.g. cultural, academic, individual etc.) are more flexible than others. By creating channels of communication between staff and students such that misunderstandings or misconceptions can be unpacked and problematized. The findings and process of this study could contribute a valuable insight into ways of making the academic experiences of international students a positive one, while also having a beneficial impact on the professional development of academic staff. The theoretical basis for investigating shared understandings lies in Vygotsky's theoretical tradition and sociocultural theory, which hold that identity is shaped through participation in community, that we hold multiple identities and that these are continually being reconstructed through engagement with others. This study will seek to examine the impact that engagement with the other can have on professional identity formation of both staff and students. By using Bernstein's theory of framing, this study hopes to examine student and staff perceptions of the degree of control they have over the pedagogical relationship and the extent to which the level of framing promotes or inhibits opportunities for the development of identity.

Learning about slavery heritage in multicultural classrooms: students' entrance narratives

Geerte Savenije, Erasmus University Rotterdam, Netherlands; Carla Van Boxtel, University of Amsterdam, Netherlands; Maria Grever, Erasmus University Rotterdam, Netherlands

Both in and outside school students learn about heritage related to the history of the country they live in. Heritage education in a multicultural society and a globalising world should offer students of diverse backgrounds and with different frames of reference the opportunity to give meaning to heritage. This study aims at a better understanding of students' entrance narratives on sensitive heritage and the way students transform these narratives during a heritage education project. The entrance narratives we look at comprise interest in the subject and knowledge and opinions about it (Doering & Pekarik 1996). We expect that multicultural classrooms show a variety of entrance

narratives, and that students can enrich their knowledge and ideas on the significance of heritage by sharing and negotiating meanings. We conducted a multiple case-study with two multicultural classrooms in secondary education that participated in a heritage education project on transatlantic slave trade. The project consisted of a preparatory and closing lesson at school and a visit to a museum and a monument. Sources are questionnaires, student interviews (pre- and post), observations, transcribed videotapes of student interactions, and student products. Our preliminary analysis shows that students' entrance narratives comprise different types of significance: historical, societal and personal. Further analysis will focus on students' interest, emotions and first impressions during the museum lesson and the negotiation and appropriation of different perspectives on the significance of slavery heritage.

Aims and theoretical and educational significance

The last decades attention for cultural heritage, cultural identity and common ground has grown rapidly throughout the Western world. Globalisation and the movement towards increasingly multicultural societies have led to a renewed interest in national identity and a desire for national cohesion. History and heritage education are often thought of as ideal subjects to provide for this common ground in future generations (Symcox & Wilschut 2009). However, it is stated as well that in order to appeal to all students and to do justice to different historical interpretations one needs to address a plurality of narratives (Grever 2007). In line with this, a large part of the Dutch heritage institutions has expressed the need to consider the increasing multicultural character of school classes that attend their programmes. Students enter a learning process with 'entrance narratives', which comprise knowledge, perspectives and personal experiences, memories and feelings (Doering & Pekarik 1996). These may be more or less shared within multicultural classrooms. Previous studies show that students' representations of the past often reflect collective memory and the grand narratives that are part of it (e.g. VanSledright 2008). On the other hand, researchers emphasise that students in multicultural classrooms have different ideas about historical significance (e.g. Seixas 1993) and tell different stories about the past (e.g. Epstein 2000). Especially regarding sensitive heritage we expect students to bring in a diversity of narratives. For a dynamic approach of heritage it is important to stimulate students to express their ideas on its significance (Barton & Levstik 1998). Empirical research on the learning processes and learning outcomes of heritage education is still very scarce. This study aims to explore what occurs in classrooms during heritage education activities in and outside school to add profoundness to the debate on affordances and constraints of heritage education in the history school curriculum. Our research question is: How do students in multicultural classrooms negotiate, generate and share their entrance narratives and ideas on the significance of heritage during a heritage education project on sensitive heritage of topics from the history curriculum?

Method

We conducted a multiple case-study with two multicultural, urban classrooms in secondary education in the Netherlands. We selected a heritage education project that includes a preparatory lesson, a museum lesson and a closing lesson. The project discusses the transatlantic slave trade and includes a visit to the National Institute Dutch Slavery Past and Heritage as well as to the national slavery monument. Both classes engaged in the same project. In each case study we conducted four questionnaires and two interviews, we observed two triads at school and in the museum doing group tasks and we analysed student products. In general, each case covered a period of two weeks, of which the heritage project itself took one. The classes showed a variety of cultural and ethnic backgrounds and included native Dutch students as well. Participants were students aged 13-14 of higher general education which is the mid level preparing for higher vocational education. History was a compulsory subject of two hours per week. We composed two triads of students with diverse entrance narratives based on the results of a questionnaire. These six students we interviewed individually before and after the heritage project. The pre and post questionnaires were used to examine the students' entrance narratives by questioning their knowledge, their interests, their memories and experiences and their ideas on the meaning and significance of heritage and the related history. After each lesson we monitored students' emotions, interests and first impressions with a short questionnaire. For the third lesson this short questionnaire was integrated within the post questionnaire. The interviews focused on clarification of students' answers on the questionnaires as well as on students' experiences in the triads during the heritage project. In the observations of the triads we focused on their negotiation, generation and sharing of their entrance narratives and ideas on the significance of heritage. For the closing lesson we designed a group task on the significance of heritage which provoked student verbalization and student interaction. These conversations are coded for structural patterns, explanatory engagement, content emphasis (Fienberg & Leinhardt 2002), the negotiation of ideas on significance, the use of multiple perspectives, and historical thinking (Van Drie & Van Boxtel 2008).

Results and discussion

Our preliminary analysis shows that students' entrance narratives comprise different types of significance: historical, societal and personal. We expect that multicultural classrooms show a variety of entrance narratives on heritage related to transatlantic slave trade. Further analysis will focus on students' interest, emotions and first impressions during the museum lesson and the negotiation and appropriation of different perspectives on the significance of slavery heritage. We expect that students can enrich their knowledge and ideas on the significance of heritage by sharing and negotiating meanings. We analyse for the reciprocal influence of this process and the students' entrance narratives.

THEMATIC POSTER SESSION

Mathematics Education

Mathematical Word Problem Solving in Children Engaged in Computer-Based Metacognitive Support: A Lon

Hidetsugu Tajika, Kobe Shinwa Women's University, Japan; Narao Nakatsu, Aichi University of Education, Japan; Ewald Neumann, University of Canterbury, New Zealand; Hisae Kato, Hyogo University of Education, Japan; Tomoko Fujitani, Mukogawa Women's University, Japan; Chie Hotta, Aichi Gakusen University, Japan; Hironari Nozaki, Aichi University of Education, Japan

The purpose of the study was to examine how self-explanation known as a metacognitive strategy helps elementary school children solve mathematical word problems through computer-based support over one year. Research on computer-based support for self-explanation has been mainly carried on by using high school students and university students as participants. We developed a computer-based support program that helps elementary school children self-explain solution steps to worked-out examples. One hundred and twelve fifth grade students participated in the study. At the start of the study they were all given a word problem pretest. The students then solved two or three worked-out examples for thirty minutes once a week in a three-week training session. The students had three three-week training sessions up until June 2010. Students had a word problem test a week after each training session. In addition, we used sixty-eight fifth-grade students as the control group who did not self-explain the solution steps. The results show that all of the students gradually solved more word problems correctly than before. We further classified students in the self-explanation group according to their test scores, the upper group, the rising group, and the lower group, respectively. The upper group, whose students had consistently higher scores on the tests, self-explained their solution processes using inferences. The rising group, whose students were not good at the pretest but were gradually increasing their scores on each word problem test, gradually self-explained their solution processes using inferences and elaborated explanations. The lower group, whose students had consistently low scores on the tests, only took notes on the results of their past records about solution steps.

The purpose of the study was to examine how self-explanation known as a metacognitive strategy helps elementary school children solve mathematical word problems through computer-based support over one year. Recent research has shown that self-explanation is an effective metacognitive strategy across a wide range of task domains. Research on self-explanation has shown that most students including undergraduate students do not spontaneously self-

explain. However, it is also known that students start self-explaining when they are supported by guidance or prompts with feedback (e.g., Aleven & Koedinger, 2002; Atkinson, Renkl, & Merrill, 2003). Our framework for self-explanation was designed to provide computer-based support to self-explanation by providing solution steps for worked-out examples.

Within the realm of computer-based self-explanation support systems, for example, Aleven and Koedinger (2002) used geometry problems to compare self-explanations emphasizing computer-based instructional environments to instructional methods that did not emphasize self-explanations. The results showed that 10th grade students who explained their solution steps during problem-solving practice in computer-based instructional environments learned with greater understanding compared with students who did not explain their solution steps (see also Atkinson et al., 2003).

Research on computer-based support for self-explanation has been mainly carried on by using high school students and university students as participants. We developed a computer-based support program that helps elementary school children self-explain solution steps to worked-out examples. Tajika, Nakatsu, Nozaki, Neumann, and Maruno (2007) had sixth grade students self-explain each solution step to the worked-out examples using paper and pencil that showed the effectiveness of support for self-explanation. To develop effective computer-based support for self-explanation, we broke the solution steps into many simpler solution steps, which elementary school students could self-explain more easily. Worked-out examples consisted of six to ten solution steps to worked-out examples. Worked-out examples were word problems which consisted of ratio word problems, elimination problems, decimal problems, and so on. Students self-explained and/or solved each solution step when it was presented by a computer. The students selected the right explanation and/or solution to each solution step from the reference table on the computer. The computer included the provision of feedback for correctness on the students' self-explanations and/or solutions. It displayed error messages in response to the students' errors. It also required that a student got the self-explanation and/or solution right before moving on to the next worked-out problem. The students' correct explanations and/or solutions were exhibited on the display of the computer. After the students solved and/or self-explained all solution steps, they took notes to self-explain their solution processes to the worked-examples.

One hundred and twelve fifth grade students (fifty-four girls and fifty-eight boys with a mean age of 11 years 6 months when the study began) participated in the study. At the start of the study they were all given a word problem pretest. The students then solved two or three worked-out examples for thirty minutes once a week in a three-week training session. The students had three three-week training sessions up until June 2010 (i.e., last November, this February, and this June). Students had a word problem test (which depended on worked-out examples presented on the computer) a week after each training session. In addition, we used sixty-eight fifth-grade students as the control group who did not self-explain the solution steps. They had only the pretest and the word problem tests.

The results of two three-week training sessions (as of February 2010) show that all of the students gradually solved more word problems correctly than before. However, when we compare the Februarys' test scores for the students using computer-based self-explanation support with those of the students in the control group, the students using computer-based self-explanation support solved a little many more word problems compared to those of the control group.

We further classified students in the self-explanation group according to their test scores. The first group is called the upper group, whose students had consistently higher scores on the pretest and each word problem test. The second group was the rising group, whose students were not good at the pretest but were gradually increasing their scores on the word problem tests. The third group was called the lower group, whose students had consistently low scores on the pretest and word problem tests. As a result, many students in the upper group self-explained their solution processes using inferences. It was also shown that some of the students in the rising group gradually self-explained their solution processes using inferences and elaborated explanations. Most students in the lower group only took notes on the results of their past records about solution steps.

The study demonstrates that effective self-explanation can be achieved in a computer-based support approach and that some of the elementary students were gradually better able to solve word problems. The study also shows that support for self-explanation, while solving worked-out examples, can improve learning of domain-specific knowledge for some students.

Authenticity level of mathematic word problems solved by Spanish Primary education students.

Santiago Vicente, University of Salamanca, Spain; Jose Orrantia, University of Salamanca, Spain; Eva Manchado, University of Salamanca, Spain

Children's low achievement in mathematics has usually been related to the existing gap between the problems children are used to solving in the classroom, and the situations in which they are involved in their everyday life (INECSE, 2006). However, the length and the nature of this gap are still undetermined. In order to bridge this gap, a framework was posed by Palm (2001). This model holds that by analyzing certain aspects of word problem solving activity in school, the level of authenticity of this activity can be measured. These aspects are the following: a) event described by the problem; b) question asked by the problem; c) existence, realism and specificity of the data; d) presentation mode (oral, written...); e) availability of external tools; f) solution requirements; and g) purpose of the problem solving activity. In order to know the level of authenticity of the problems that Spanish children usually solve in mathematics classrooms, and considering the theoretical frame posed by Palm, all the word problems included in 1st to 6th grade mathematics textbooks from two Spanish textbook publishers were analyzed. The mathematical structure and the level of challenge involved for children were also analyzed for each problem. Results showed that although most of the aspects from Palm's model were well simulated in a high percentage of the problems analyzed, the aspects "purpose" and "specificity of data" still need further improvement. Furthermore, we found, in line with previous studies, that problems included by textbooks were highly stereotyped. Educational implications are discussed.

Children's low achievement in mathematics has usually been related to the existing gap between the problems children are used to solving in the classroom, and the situations in which they are involved in their everyday life (INECSE, 2006). However, the length and the nature of this gap are still undetermined. In order to bridge the gap, a new framework was posed by Palm (2001). This model holds that by analyzing certain aspects of word problem solving activity in school, the level of authenticity of this activity can be determined. These aspects are the following: a) event described by the problem; b) question asked by the problem; c) existence, realism and specificity of the data; d) presentation mode (oral, written...); e) availability of external tools; f) solution requirements; and g) purpose of the problem solving activity. Taking this theoretical frame into account, a continuum between authentic tasks and non-authentic tasks can be established. Furthermore, the aspects that characterize some tasks as "non-authentic tasks" might be improved to increase the authenticity of these tasks. An example of this issue is the research conducted by Palm and Burman (2009): they analyzed the task-reality concordance in Finnish and Swedish national assessment tests by assigning each problem to a category depending on whether the task simulated the aspects defined by Palm's model or not. Their results showed that: firstly, in most of the problems (more than 90%), only the aspect "event" could be considered as an authentic aspect; and secondly, the rest of the aspects could be considered as authentic aspects in no more than 50% of the problems. However, Depaepe, De Corte and Verschaffel (2009) analyzed how two 6th grade teachers approached word problems in a Flemish school during seven months. They found that certain additional aspects other than those pointed out by Palm and Burman could be considered as authentic in most of the problems (e.g., existence, specificity and realism of the data, solution strategies and requirements). The goal of this study was to analyze every problem included in textbooks and complementary materials of two main textbook publishers. We did so following a categorization based on Palm and Burman's proposal together with some of Depaepe et al's proposals about including an intermediate category between "authentic" and "non-authentic" in some of the aspects. We also wanted to update and extend previous research on this topic, developed by Orrantia, González and Vicente (2005), who found that word problems included in Spanish textbooks were highly stereotyped because the problems belong to the easiest mathematical structures. In addition, they found that challenging problems (i.e., those problems that included irrelevant information, or that lacked the information necessary to solve the problem and consequently the problem solvers had to infer this information) were very scarce. MeasuresAll activities from mathematics textbooks for the 1st to 6th grades belonging to the most recent editions of two of the most important publishers in Spain were classified into routine exercises and word problems. The proportion of word problems related to the whole number of activities was calculated. Then, the analysis focused on word problems, by examining: a) problem type by mathematical structure (additive, multiplicative and their respective sub-categories); b) problems' level of authenticity; and c) proportion of challenging problems (e.g., problems with irrelevant information or missing information that problem solvers must infer from their prior knowledge, problem posing activities, or realistic problems).

Method

The analysis of the word problems included in the textbooks was done by comparing them with the real life situations indicated in their figurative contexts. In order to categorize language use, availability of solution strategies, external tools, guidance, and solution requirements, two categories were defined depending on whether the task reasonably simulated each specific aspect (category 1) or not (category 2). For the aspects Event, Question, Existence, Realism and Specificity of information and Purpose, three classification categories were attached, and they were classified in category 2 when these aspects were partly simulated and in category 3 when it was judged as not being reasonably simulated.

Results

Results showed that only 20.45 percent of the analyzed activities in the Spanish textbooks were word problems. Most of them belonged to the easiest mathematical structure (i.e., in additive word problems only 18 percent could be considered as difficult, following the categorization from Riley, Greeno and Heller, 1983), and only 4.03 percent could be considered as challenging problems. Regarding the authenticity of the problems, results were closer to those of Depaepe et al. than to Palm and Burman's, since the main aspects of the problems (event, question and existence of information) were well simulated in most of the problems (91, 86 and 77 percent, respectively), and other aspects, such as external tools, data realism and language use, were also well simulated in more than 75 percent of the problems. However, the categories "specificity of the data" and, especially, "purpose" might clearly be improved because no more than 50 percent of the problems simulated the first category correctly whereas the second one was simulated in no more than 10 percent of the problems. In fact, according to Palm (2001), roughly 2.26 percent of the word problems could be considered as authentic tasks.

Conclusions and educational implications

Our results show that Spanish textbooks contained many more routine exercises than word problems. Furthermore, word problems were highly stereotyped, easy and non-challenging. In addition, although the main aspects related to the authenticity of the problems were well simulated in most of the problems, aspects like "purpose" and "specificity of information" must be improved. This issue is important because recent research on word problem comprehension (Orrantia et al, in press) showed how tasks with intentional information or goals should be easier to solve. Similarly it is also known that problems with specific information (especially, information related to problem solver) are easier to solve. By improving these two aspects of word problems we can increase the authenticity of the problems and help children to solve them more easily.

Differences in problem solving process and external representations' use at primary school mathematics

Johannes Grosse, University of Koblenz-Landau, Germany

The positive effects of representations on the problem solving process have already been shown in studies. Yet, studies on the configuration of problem solving process and the use of representations on complex story problems are scarce. That is especially unfavourable, because the constructive effects of complex story problems on learners' problem solving competences have already been proven. By closing this gap in research, an effort is made to help students in their struggles with problem solving in mathematics. The underlying study is analyzing the structure of the problem solving processes of primary school students when working on complex story problems and their external representations in the solution process. There are 17 students of 2nd and 10 students of 4th grade participated in the study. Different influencing factors on the processes of problem solving were explored (e.g. cognitive ability, self-efficacy, intelligence). In up to 40 minutes, the students worked on five complex story problems. They were allowed to use different auxiliary material. The students were videotaped individually during the solution process. The problem solving processes were analysed according to a newly developed system of categories for this study. ANOVA is conducted to compare the different class levels. Preliminary findings showed that the ability groups differed in terms of representations they used as well as the time they needed to solve the problems. Also, the quantity of solved word problems differed among the ability groups.

Introduction

The term "complex story problems" specifies a group of tasks that are different from "regular story problems". These tasks are based on very challenging mathematical structures and cannot be solved by arithmetic operation models that students are usually familiar with (Winter, 1992). To convince didacts of complex story problems' advantages, further research on the use of complex story problems in primary schools is needed.

The theoretical framework of this study bases on two models: first, the "student-problem-solver" (Reusser, 1992), second the „cognitive-metacognitive model of mathematical problem solving" (Montague, 1993). The reanalysis of

these two models lead a new system of categories that offers the opportunity to analyse the problem solving processes in primary school mathematics. This system (Groß, Hohn, Telli, Rasch & Schnotz, 2010) consists of 9 categories and 30 facets which can be used to analyse the configuration of the problem solving processes and the use of different external representations while working on complex story problems.

A representation is an object which stands for something else. Yet, studies on the configuration of problem solving process and the use of different external representations on complex story problems are scarce. That is especially unfavourable, because the conductive effects of complex story problems on learners' problem solving competences in primary school classes have already been shown in studies (Rasch, 2001). By closing this gap in research, an effort is made to help students in their struggles with problem solving in mathematics at school in this study.

Questions

- 1) What are the differences in the persistence and the quantity of solved word problems (total word problem score) among the ability groups in both class levels?
- 2) What are the differences in the usage of different external representations among the ability groups in both class levels?
- 3) What are the differences in the connection between the different stages of the problem solving process and the external representations among the ability groups in both class levels?

Methods

A total number of 27 students from a primary school participated in the study in April 2010. There are 17 pupils at 2nd (M=8.53 years, SD=.61) and 10 pupils at 4th grade (M=10.31 years, SD=.60). Different influencing factors on the processes of problem solving were explored: First verbal and visual spatial intelligence were measured by scales from cognitive abilities test (KFT) (Heller & Geisler, 1983; Heller, Schön-Gaedike & Weinläder, 1976). Second, scales from the project for the analysis of learning and achievement in mathematics (Pekrun, Götz, Zirngibl, v. Hofe & Blum, 2002) were used to assess students' mathematical self-efficacy as well as their mathematical self-concept. Lastly, students were asked to solve the complex word problems. In our study, students were successively given five tasks which were arranged in Latin Square Design. Students solved the problems on their own and got auxiliary material. They were videotaped during the solution process.

The participants were divided in both class levels into the two groups' higher math competence (HMC) and lower math competence (LMC) according to their results the KFT. At the 2nd grade, there were 9 students in the LMC-group and 8 students in the HMC-group. At 4th grade there were 5 students in both ability groups. Their solutions were analysed according to the aforementioned category system (Groß, et al., 2010). ANOVA is conducted to compare the different ability groups.

Outcomes

Question 1

Table 1 shows the differences in the persistence and the quantity of solved word problems. On average, students of the HMC-group in both class levels needed less time to solve the story problems than their peers at the LMC-group. At both class levels, students of the HMC-group achieved a higher quantity of solved word problems than students of the LMC-group.

Question 2

Analysis of students' solutions applied in the problem solving process and their external representations were given in Table 2 and 3 for both class levels. At the 2nd grade students of both ability groups did not use the "realistic pictures". Additionally, only members of the HMC-groups used "fingers" and "logical pictures".

At the 4th grade all kinds of external representation were used in the LMC-group. In the HMC-group the external representations "working materials" and "fingers" were not used.

Perspective

The design and development of the system of categories is completed. Using this system the remaining research question will be answered. Results of the analysis will be presented at the 14th Biennial Conference Earli 2011.

Investigating the consistency and extraneous effects when solving math word problems

Meng-Lung Lai, National Chiayi University, Taiwan; Meng-Jung Tsai, National Taiwan University of Science & Technology, Taiwan; Fang-Ying Yang, National Taiwan Normal University, Taiwan; Chin-Chung Tsai, National Taiwan University of Science and Technology, Taiwan.

Arithmetic word problems containing relational statements are difficult for students to solve, especially when the arithmetic operation required to solve the problem is inconsistent with the relational term (e.g., subtraction required yet the term more used; consistency effect). Extraneous information provided in problem statements may also have influences on students' problem solving (relevance effect). The authors investigated the consistency effect and relevance effect on students' arithmetic word problem solving process in this study. Thirty two college students participated in this study. They were asked to solve eight arithmetic problems which were designed based on four (2x2) combinations of consistency and relevance effects (consistency v.s. inconsistency; relevance v.s. irrelevance). Students' eye fixations and sequences of fixations on the problem statements were recorded by eye tracker FaceLab 4.5. Accuracy results showed that 9 students correctly answered all the problems while 10 of them made more than two errors. Students performed the worst in the inconsistent problems with extraneous information, followed by the inconsistent-only problems and the extraneous-only problems respectively. The eye movement data showed that the high-accuracy participants spent much more time than the low-accuracy participants in the integration phase but not the translation phase for each problem, especially for the inconsistent problems with extraneous information. Much more mental efforts were needed for students to solve the problems with both negative effects. Finally, high-accuracy participants reread the keywords in problem statements much more carefully than did the low-accuracy participants. More details and discussions will be presented in the conference.

Previous studies (e.g., Hegarty et al., 1992, Schoot, et al., 2009) have consistently demonstrated that mathematics word problems are widely regarded by students as very difficult, especially for those problems containing relational statements comparing the quantities of different variables (i.e., compare problems). The same holds even true when the required arithmetic operation to solve the problem is inconsistent with the relational term (e.g., addition required but the term less is used or subtraction required yet the term more is used; consistency effect). In addition, the existence of irrelevance information also significantly increases the difficulty of solving mathematics word problems (i.e., relevancy effect). Specifically, most students find it difficult to discriminate relevant from irrelevant facts when solving mathematics word problems, probably because they hold the misconception that all the numbers and information in a word problem must be used (e.g., Muth, 1992).

In this study, the authors investigated the consistency effect and relevancy effect on college students' mathematics problem solving process. Our participants were asked to solve eight arithmetic word problems which were designed based on four (2 x 2: consistency vs. inconsistency; non-irrelevancy vs. irrelevancy) combinations of consistency and relevancy effects (i.e., two trials for each combination). The materials were presented using GAZETRACKER 8.0 on a computer, situated approximately 0.70m from the participant. The authors partitioned the participants into three groups based on their accuracy rate on solving these problems. Participants' eye fixations (e.g., numbers of fixations and fixation duration) and sequences of fixations on these problems were recorded using an eye tracker (FaceLab4.5) that sampled the position of the participant's eye fixation every 16ms. The problem solving processes, namely translation (initial reading from the appearance of a problem to last line of the problem for the first time), integration (across-sentence comprehension excluding translation), planning (developing a plan for solving the problem), and

finally selecting an appropriate answer, were used to analyze participants' step-by-step thought and to identify the locus of difficulty on solving mathematics word problems.

Thirty two college students, half science-related majors and the other half, liberal art majors, participated in the study. Nine of them correctly answered all the problems and ten of them made more than two errors. The inconsistent problem with extraneous information was, as predicted, performed the worst, followed by the inconsistent-only one and the one with extraneous information respectively. Interestingly, participants were more bothered by the extraneous information than the inconsistent relational term.

The eye movement data showed that the high-accuracy participants spent much more time than the low-accuracy participants in the integration but not the translation phase for each problem, especially in the inconsistent one with extraneous information. Much more mental efforts needed to put forward to solve the problem with two negative effects presented. High-accuracy participants reread keywords much more carefully than their low-accuracy counterparts.

The major findings are threefold. First, college students, science-related major and non science-related major, performed similarly on the mathematics word problems and some of them even answered incorrectly on more than two problems. The compare problems still bother undergraduate students no matter for those receiving more logical training (science majors) or not (liberal art majors). Second, based on the eye fixations data, after the initial reading, the participants started to read different variables first and read the numbers soon afterwards, in which the former can be seen as the integration phase and the latter, the planning phase. It appears that we can identify the integration and planning phase that were considered difficult to disentangle by previous studies. Third, most higher accuracy participants read the problem from the first word to the last word before trying to solve problems while the pattern is not found for most of lower accuracy participants. More details and discussions will be presented in the conference.

Illusion of linearity in multiple choice problems: magnitude of geometric shape's size change

Vesna Vlahovic-Stetic, Faculty of Philosophy, University of Zagreb, Croatia; Valentin Lapaine, University of Zagreb, Croatia

This study is related to illusion of linearity, the tendency to apply properties of linear or proportional relations even in situations where it is not appropriate. It is investigated whether an offered linear solution affects the success of solving non-linear problems. It is also investigated whether the success of solving non-linear problems is affected by the magnitude of geometric shapes' size change. Finally, the relation between correctness of a solution and participants' degree of certainty is investigated. Pupils of third grades of two high schools participated in the research (N=201). They solved five linear and five non-linear word problems. There were four groups of non-linear problems. The difference between them were in whether a linear solution was among the offered solutions and in the magnitude of geometric shapes' size change (2, 3, 4, or 200, 300, 400) Participants solved linear problems very successfully and non-linear problems much worst. Participants who did not have linear solution offered solved significantly more non-linear problems than other group. Participants whose problems contained lesser magnitudes of geometric shapes' size change solved significantly more non-linear problems than group with greater magnitudes of change. The interaction of mentioned variables was also significant. Participants in all groups were equally certain in their correct solutions of non-linear problems. Participants who did not have linear solution offered were significantly less certain in their incorrect solutions of non-linear problems, and participants whose problems also contained lesser magnitudes of geometric shapes' size change were the least certain.

Student's tendency to use linear reasoning in non-linear problems is described in many areas of mathematics, such as arithmetic, algebra, probability, geometry and measurement. They fail to solve the given non-linear problems because of a very strong tendency to always apply linear solution methods and that error is called „illusion of linearity". This study is related to some aspects of illusion of linearity, the tendency to apply properties of linear or proportional relations even in situations where it is not appropriate. In geometry, illusion of linearity entails thinking that a geometric shape's area or a geometric solid's volume is going to be reduced or enlarged k times if its length is reduced or enlarged k times (in fact, areas are reduced or enlarged k^2 times and volumes k^3 times). It is investigated whether an offered solution which corresponds to the illusion of linearity (i.e. linear solution) affects the success of solving problems for which is it not appropriate to apply the linear model (i.e. non-linear problems). It is also investigated whether the success of solving non-linear problems is affected by the magnitude of geometric shapes' size change. Finally, the relation between correctness of a solution and participants' degree of certainty for groups with and without offered linear solutions and for groups with lesser and greater magnitudes of geometric shapes' size change is investigated.

Pupils of third grades of two high schools participated in the research (N=201). Each of them solved five word problems for which it was appropriate to apply the linear model (i.e. linear problems), each of which had five offered solutions. Each participant also solved five non-linear word problems, each of which also contained five offered solutions.

For the requirements of this study five lists of mathematical problems were constructed. In the Form A there were five classical proportionality problems that did not include any enlargement of areas of volumes, but only a linear enlargement.

Form B and C contained five non-linear problems, and for every problem five answers were offered. Among these five answers, one solution could be obtained if the participant is liable to the illusion of linearity; one was a correct solution, while the remaining answers served to reduce the probability of guessing. In form B were problems with lesser magnitude of geometric shapes' size change (2, 3 or 4 times enlargement or reduction). In form C were problems with greater magnitude of geometric shapes' size change (200, 300 or 400 times enlargement or reduction). Form D and F also contained five non-linear problems, and for every problem five answers were offered but without offered linear solutions. In form D were problems with lesser magnitude of geometric shapes' size change (2, 3 or 4 times enlargement or reduction). In form F were problems with greater magnitude of geometric shapes' size change (200, 300 or 400 times enlargement or reduction).

Distracting solutions in all forms were selected in such a way that they could not be obtained by simple linear combinations nor with the simple multiplication or division of the numbers in the problem.

Participants solved linear problems very successfully and they solved non-linear problems much worst. Participants who did not have linear solution offered solved significantly more non-linear problems than other group (with offered linear solution) ($F(1,177) = 36,18$). In addition, participants whose problems contained lesser magnitudes of geometric shapes' size change solved significantly more non-linear problems than other group (with greater magnitudes of change) ($F(1,177) = 30,100$). The interaction of mentioned variables was also significant ($F(1,177) = 21,34$). Participants without offered linear solutions in nonlinear problems were more successful and that difference was greater between groups with lesser magnitude of geometric shapes' size change.

Participants in all experimental groups were equally certain in their correct solutions of non-linear problems. Participants who did not have linear solution offered were significantly less certain in their incorrect solutions of non-linear problems, and participants whose problems also contained lesser magnitudes of geometric shapes' size change were the least certain.

Stimulating Creativity In Mathematics Classrooms: Increasing Engagement And Understanding

Gaye Williams, Deakin University, Australia

A theoretically developed and empirically grounded framework for considering conditions necessary (but not necessarily sufficient) for nurturing creative thinking in mathematics lessons is presented. This theoretical framework integrates socio-cognitive theory (Schwarz, Dreyfus, & Hershkowitz, 2009), theory linking positive affective with learning (Csikszentmihalyi, 1992), and psychological theory linking orientations to successes and failures to subsequent actions (Seligman, 1995). Flow (Csikszentmihalyi, 1992) is a state of high positive affect during creative activity that can occur during mathematical problem solving where students discover mathematical complexities that were not evident at the start of a task, and spontaneously decide to explore them (Williams, 2009). During the process of discovering complexity, groups spontaneously create 'Zones of Proximal Development' (Vygotsky, 1933/1966) with the potential to support new learning. Students' perceived successes resulting from mathematical insights developed during flow situations can build optimism (Seligman, 1995) (resilience) over time and this can increase student inclination to explore new ideas in the future. The Engaged to Learn Pedagogical Approach (Williams, in press) to mathematical problem solving is based upon this theoretical framework. Using illustrations drawn from elementary and secondary school classes, the complexity of this approach is illuminated by identifying key features that encourage and sustain creative mathematical thinking in mainstream elementary and secondary classes: including situations that theory suggests should build optimism. These illustrations demonstrate the deep mathematical understandings, and student engagement, that the Engaged to Learn Pedagogical Approach can nurture. Implications for teaching and learning associated with using approaches that nurture creative thinking are discussed.

The benefits of drawing upon approaches that encourage creative mathematical thinking in mathematics lessons in mainstream classes are elaborated. The Engaged to Learn Pedagogical Approach is used as a vehicle to discuss complexities associated with teaching and learning intended to achieve this. This approach is based upon a theoretical

framework that illuminates these complexities. This framework (Williams, in press) was developed through synthesis of aspects of several learning models and theories (Schwarz, Dreyfus, & Hershkowitz, 2009; Krutetskii, 1976; Csikszentmihalyi, 1992; Vygotsky, 1933/1966; Seligman, 1995). Within this framework, creative student thinking is represented through the 'observable cognitive elements': 'recognising', 'building-with', 'constructing' and 'consolidating' (Schwarz, Dreyfus, & Hershkowitz, 2009). Building-with and constructing are subcategorised using Krutetskii's (1976) 'mental activities' ('analysis', 'synthetic-analysis', 'evaluative-analysis' within building-with; and 'synthesis' and 'evaluation' within constructing). Social interactions that contribute to the creative development of new mathematical knowledge are represented using Schwarz, Dreyfus, and Hershkowitz's (2009) social elements: control, elaboration, explanation, query, agreement, and attention. Conditions for flow (Csikszentmihalyi, 1992) include: a) spontaneous intellectual mathematical challenges; and b) working beyond present skills level (Csikszentmihalyi, 1992) and conceptual level (Williams, 2009). These conditions are operationalised through students exploring unfamiliar mathematical complexities by spontaneously asking and pursuing questions that assist this exploration (Williams, 2009), and the spontaneously created ZPDs (Vygotsky, 1933/1966) associated with these spontaneous questions that can be examined through the nature of the insights developed. These mathematical insights represent deep and connected mathematical understandings that are articulated by groups as they share their findings with others at intervals during their problem solving activity. High positive affect becomes apparent through student exclamations in groups, excited communication to the class, and body language indicating intense focus on the task and/or communication of these findings to others. Similarly, the disinclination of some students to engage in solving unfamiliar problems is evidenced through their lack of engagement with the task and their group. This disinclination is frequently related to absence of optimism (Seligman, 1995). The Engaged to Learn Approach includes: a) tasks containing many opportunities to discover complexities; b) groups with similar paces of thinking to increase their likelihood of remaining in flow together; c) teacher questioning to elicit more complex student thinking; and d) an organisational structure (small group brainstorming/whole class feedback cycles) that provides opportunities to amplify the successes students achieve as other groups exclaim about group findings, or use them in their subsequent group activity. Developing and sustaining creative student thinking for the purpose of developing deep mathematical understandings is a complex process. This complexity is illustrated through activity within the Engaged to Learn Approach in upper elementary, and upper secondary classes, and through the spontaneous activity of optimistic Year 8 students within the Learners' Perspective Study who manoeuvred the conditions for flow and undertook creative mathematical thinking when such activity was not the explicit intention of their teacher. Lesson video and video-stimulated post-lesson student interviews within and beyond the Learners' Perspective Study (Shimizu, Kaur, Huang, & Clarke, 2010) provided access to the activity illustrated. It is hoped this elaboration of an approach that stimulates frequent creative mathematical thinking by students in diverse mainstream mathematics classroom settings (and the associated theoretical framework), will be of assistance to others exploring this research area. It is also hoped that these illustrations will raise awareness of the need to increase the frequency of such activity in classrooms internationally, and that they will illuminate subtle differences between teacher 'moves' that support and inhibit such activity.

THEMATIC POSTER SESSION

Motivational, Social and Affective Processes

Cooperation, Competition Behaviour of Children between 4-18 and Effect of Parent Resources on Them

Laszlo Kasik, University of Szeged, Hungary; Edit Toth, University of Szeged, Hungary

The aim of the research was to describe the developmental level of cooperation and competition abilities at the age of 4, 8, 12, 15 and 18 (N=945), and to examine mothers' opinion about their financial, intellectual and relationship resources in connection with children's cooperation and competition behaviour (N=855). A factor-wise study of these abilities was assessed with a Likert-type questionnaire. Besides children's own evaluations, teachers and mothers also evaluated the functioning of abilities. The mothers' views were assessed with another questionnaire developed by ourselves.

The relationship between the values of children and parents are the strongest in all age groups, and teachers and parents evaluate the most divergently the functioning of ability factors. Based on the total values, the competition factors show increasing tendency with age, contrary to most of the cooperation factors. Gender differences can be found especially among children between 12 and 18.

In all age groups, parents have different opinions about cooperation and competition abilities according to their age, financial status and level of education. The functioning of factors is influenced by parents' opinions less about relational and the least about financial resources. The parents of 15- and 18-year-old children assign a smaller role to themselves in the development of behaviour forms. The change in the ability factors is not always reinforced by parents' opinions, e.g. the frequency of competition increases with age but the parents of older students find it less important that children should see an appropriate example for competition in their environment.

Background

International surveys agree that the functioning of cooperation and competition abilities is very important for both individuals' inner balance and a satisfactory social co-existence (Fýlþp, 2009). One of the basic conditions of developing abilities in kindergartens and schools is having at the same time many evaluators' opinion about the functioning of psychic components to be developed. It is also crucial to take into consideration the characteristics of families and institutions influencing significantly the functioning of abilities lying behind different behaviour forms (Grusec and Hastings, 2007). Therefore, their improvement is a major task of institutionalized education (Schneider, 1993).

Aims

The aim of the research was to describe the developmental level of cooperation and competition abilities on the basis of children's, teachers' and parents' evaluation; to examine the parents' opinion about cooperation and competition; to describe the parents' views about financial, intellectual and relationship resources in connection with these behaviour forms; and to investigate the correlation between parental resources and the functioning of abilities.

Methods

Sample and data collection

Subjects were 945 children (at the ages of 4, 8, 12, 15 and 18), 855 mothers (only a few fathers sent back the questionnaire) and 46 teachers. The size of subsamples was approximately the same. Data collection took place in Spring 2010.

Instruments

The functioning of cooperation and competition abilities was assessed a Likert-type questionnaire developed by ourselves (Cronbach-a: 0.83–0.92). Besides children's own evaluations, teachers and mothers also evaluated the functioning of abilities. Based on the theoretical background (socio-anthropological, human ethological, social psychological), we had defined some dimensions in the abilities. On the basis of the factor analysis, the dimensions form many factors (e.g. interest, relation between give and take, time of competition, instruments of competition, winner).

The parental questionnaire (Cronbach-a: 0.81–0.95) consists of four sections: the influence of mothers and public education on behaviour forms; the influence of parents' financial, intellectual, relational resources on the development of the behaviour forms. Furthermore, we had a list of background variables about all participants (e.g. mothers' educational level; family type; net income).

Results

Development of cooperation and competition factors

The three raters rate the social factors very differently, the correlation values being between 0.22 and 0.68. In all age groups, the correlation between children and parents are the strongest, and teachers and parents evaluate the functioning of abilities the most divergently.

Based on the total values (mean of the three raters), we found for example that 15- and 18-year-old children want to realise more often their own interest in groups. They think more often that the distribution of awards depends on the work done (there is no equal share). The older children use lots of instruments (positive and negative) to win. The younger children (4, 8, 12) are more impatient if they have to wait for the result of the competition, and they think that they must defeat their partners. Gender differences can be found especially among children between 12 and 18, e.g. boys realise more their own interest in groups; girls exhibit a more dominant tendency toward help in a group.

Cooperation, competition and parental resources

In all age groups, the examined mothers' opinions about the two behaviour forms differ significantly: they think that their children's cooperative behaviour depends mostly on family education while competition should be acquired in schools.

Independently of the age of children, mothers' rejection is significant in the case of competition, it is considered as a really negative behaviour form. The change in the ability factors is not always reinforced by mothers' opinions. It is a very important result that the frequencies of most factors of competition increase with age but the mothers of older students (15, 18) find it less important that children should see an appropriate example for competition in their environment. On the contrary, most of the cooperation factors show decreasing tendency with age and the mothers of older children think that a good example for development of cooperation is very important.

In families where more money are spent on children, behaviour forms are more likely to be awarded by money; however, there is no significant difference between the quantity of money and the behaviour form awarded by money. It is very important for mothers, independently of age, to talk about behaviour forms and that they give examples (the two forms of intellectual resources); however, mothers of 15- and 18-year-old children think more that their influence is smaller than that of peers and media at this point. They think that children should see lots of good examples for cooperation in the family, and not many for competition. On the basis of the analysis of relational resources, mothers uniformly do not ask for help from anyone in order that children should get into situations where they have more possibilities to cooperate and to compete.

Some connections between the examined aspects

From the environment variables, mothers' educational level, family type and mothers' opinions about intellectual resources influence the most the development of social abilities. However, their effects are different by factors, and they are nearly of the same extent at a given factor in the age groups. The net income is the environment variable that has the smallest effect on the assessed factors of abilities.

Conclusion

Results are to be used as the basis for a complex development programme. The results unequivocally strengthen the international research experience that family factors have to be taken into consideration more than so far when elaborating a specific development program. Nevertheless it has to be taken into consideration that respondents were mothers. Numerous surveys show that mothers' opinions about cooperation and competition are different from those of fathers.

How Young People Respond To Change And Challenge: The Role Of Adaptability

Andrew J Martin, University of Sydney, Australia; Arief Liem, University of Sydney, Australia; Susan Colmar, University of Sydney, Australia; HARRY NEJAD, UNIVERSITY OF SYDNEY, Australia

Abstract

This study focuses on a relatively understudied construct, academic adaptability, defined as students' capacity to adaptively regulate cognition, affective, and behaviour in response to new, changing, and/or challenging conditions. It

seeks to examine the relationships between adaptability and its antecedents (age, gender, language background, literacy and numeracy) and well-being outcomes (general self-esteem, life-satisfaction, and emotional stability) in an integrative structural equation model (SEM), the conceptual scope of adaptability, and the validity and reliability of a set of hypothesised adaptability measures. The data were collected using a set of psycho-educational measures administered to 2,145 Australian high school students (mean age=14.01, 45% females). Preliminary analysis showed that participants' responses to the measures were normally distributed (i.e., relatively low skewness and kurtosis), internally consistent (i.e. $\alpha > .80$), and fit well to the hypothesized measurement models (i.e., excellent fit indices; item factor loadings $> .70$; invariant factor structures across gender and age groups). The SEM indicated that literacy and numeracy achievement scores significantly predicted adaptability (both $bs = .16$, $pb = .55$, $b = .51$, and $b = .31$, respectively, p

Extended Summary

Background. Both academic and non-academic challenges and changes are a reality of young people's everyday life (Martin & Marsh, 2006, 2008). It is argued that young people who are able to regulate their personal resources can effectively adapt to their challenging and changing circumstances and, further, attain a desirable state of well-being. This study focuses on a relatively understudied construct, adaptability, which is defined as young people's capacity to adaptively regulate cognition, affective, and behaviour in response to new, changing, and/or challenging conditions. Significant components in this research include adaptability, life effectiveness, self-confidence, and engagement – constructs that are all aligned with the National Goals for Schooling outlined in the Adelaide Declaration (1999) which hold implications for social and cultural development in Australia (MCEETYA, 1999) and beyond.

Aims. The present study was set with both measurement and substantive goals. As a measurement goal, the study aims to examine psychometric properties of a recently developed measure, the Adaptability Scale. To this end, we aim to assess the scale's descriptive statistics (mean, standard deviation), distributional properties (skewness, kurtosis), and internal consistency reliability, as well as first- and second-order confirmatory factor structure (CFA) factor structures (fit indices, factor loadings, measurement invariance across gender and age groups). As a substantive goal, the study aims to test a hypothesized model predicting the effects of socio-demographic factors (i.e., age, gender, language background) and academic abilities on adaptability and the effects of adaptability on key well-being outcomes (i.e., general self-esteem, life satisfaction, and emotional stability) in an integrative structural equation modelling (SEM).

Method. Data were collected using a set of psycho-educational measures administered to 2,145 Australian high school students. Of the total sample, 259 (12.1%) students were in grade 7, 567 (26.4%) students in grade 8, 509 (23.7%) students in grade 9, 491 (22.9%) students in grade 10, 267 (12.4%) students in grade 11, and 48 (2.2%) students in grade 12. This sample was drawn from seven schools that are broadly representative of school types in Australia (i.e., independent and government schools; single-sex and co-educational schools). The mean age of the sample is 14.01 years and 45% of them are females.

A set of items probing students' demographic information (e.g., age, gender, and language background), adaptability, and key well-being outcomes were used. As indicators of academic abilities, students' literacy and numeracy scores from nationally standardized achievement tests were used. Students' capacity to adapt in new, changing, and/or challenging situations was assessed by the Adaptability Scale developed for the purpose of this study. The scale is a 21-item self-report instrument that measures three proposed dimensions of adaptability, namely the cognitive dimension (e.g., I am able to change the way I think about new situations to help me deal with them better), the affective dimension (e.g., I am able to reduce negative emotions, such as fear, to help me deal with challenging or uncertain situations), and the behavioural dimension (e.g., I am able to adjust my behaviour e.g., work harder or longer, to help me deal with challenging or difficult situations.). Well-being outcomes were measured by pre-existing instruments, including the Satisfaction with Life Scale (Diener et al., 1985) and the Emotional Stability and General Self-Esteem Scales from the SDQ-II (Marsh et al., 1999). Items of these scales are rated on a 7-point scale ranging from 1 (strongly disagree) to 7 (strongly agree).

Results. Preliminary analysis showed that participants' responses to the measures, including the Adaptability Scale, were normally distributed (i.e., relatively low skewness and kurtosis) and internally consistent (i.e. α s $> .80$). Following recommendations on establishing model fit (e.g., Marsh, Hau, & Wen, 2004), the Comparative Fit Index (CFI), the Non-Normed Fit Index (NNFI), the Root Mean Square Error of Approximation (RMSEA), and an evaluation of

parameter estimates, were used to assess CFA and SEM models. CFA showed that each of the scales used evinced a robust factor structure (CFI>.90, NNFI>.90, RMSEA.60; Marsh et al., 2004) and invariance across gender and age groups (Delta CFI). Although fit indices suggested that responses to the adaptability items can be represented by both first- and higher-order factor models, for parsimony purposes, the higher-order factor model was used in addressing the substantive goal of the study. SEM indicated that students' literacy and numeracy achievement scores significantly predicted adaptability (both β s=.16, p =.55, β =.51, and β =.31, respectively, p

Conclusions. The study provides preliminary psychometric evidence of the Adaptability Scale. The study has also shown adaptability predicts general self-esteem, life satisfaction, and emotional stability – whilst adaptability is predicted by academic ability, but not gender, age, or language background. Taken together, the findings of the present investigation are relevant for school personnel and parents/caregivers seeking to enhance students' well-being that relies very much on the extent to which students are capable to adapt to challenging and changing circumstances. The findings also hold substantive and methodological implications for researchers studying issues related to adaptability in students' academic and non-academic lives.

Changes in Motivational and Self-regulated Learning Components: A multilevel growth curve modeling

Ridwan Maulana, GION - University of Groningen, Netherlands; Marie-Christine Opdenakker, University of Groningen, Netherlands; Roel Bosker, University of Groningen, Netherlands

The present study examined the developmental changes of and the link between motivational and self-regulated learning components of 566 first-year secondary education students from 10 Mathematics and 10 EFL classes in the Netherlands. A set of self-report measures of student motivational and self-regulated learning components was administered in five different occasions across the school year. Multivariate multilevel growth curve modeling (MMGCM) was applied and attention was paid to the general development and the deviation to this development at class and student level. Results revealed differences between classes and students within classes with regard to the level and growth of the motivational and self-regulated learning components. Self-efficacy, intrinsic value and autonomous motivation decreased significantly over time, whilst test anxiety and controlled motivation increased significantly over time. Moreover, self-regulation, delay of gratification, effort regulation and academic engagement decreased significantly over time, while procrastination increased significantly over time. In addition, the link between several motivational and self-regulated learning components over time was found. Class type and student gender could explain developmental differences of several components across the school year. The role of both determinants was discussed.

Introduction and framework

Research suggests that motivational and self-regulated learning components are important factors in education because they play the critical role in students' development, academic performance and behavior (Bandura, 1986; Bembenuddy & Karabenick, 1996; Hoffman & Spataru, 2008). However, positive achievement-related motivational and self-regulated learning components tend to decrease across age of schooling (Opdenakker & Maulana, 2010; Wigfield & Eccles, 2000). Particularly, problems regarding absenteeism, school drop out and misbehavior in the early years of secondary education are often associated with the drastic changes occurring in everyday's life of students during the critical transition from primary to secondary school (Eccles & Midgley, 1989; Hargreaves, Earl & Ryan, 1996).

Students experiencing a transitional year display poor motivation and low engagement in learning because transitions seem to facilitate stressful, yet excited moments for them (Johnstone, 2002). In effect, students' level of anxiety, emotional stability, confusion and disengagement during this transition may boost to a great extent (Howard & Johnson, 2004). In this study, we aimed at investigating the developmental changes of and the link between motivational and self-regulated learning components of the first year secondary students by incorporating expectancy-value and self-determination theories as underlying frameworks.

Research questions

- (1) How do motivational and self-regulated learning components (MSL) of first grade secondary students develop across the school year? What are the role of class type, subject taught, teacher gender and student gender on these changes?
- (2) How are the three motivational components linked with the self-regulated learning components across the school year?

Method

Participants

The sample included 566 students from 20 mathematics and EFL classes of secondary schools in the Netherlands. Surveys were administered five times across the school year.

Measures

Students responded to a questionnaire provided on a 5-point Likert scale. Measures of motivational components were adapted from the existing instruments including self-efficacy, intrinsic value, test anxiety and controlled and autonomous motivation. Self-regulated components included self-regulation, delay of gratification, effort regulation, procrastination and academic engagement. All measures showed satisfactory reliabilities: Cronbach's alpha between .70 and .90.

Data analysis

Multivariate multilevel growth curve modeling (Rasbash et al., 2005) was applied to answer the research questions.

Findings

1. Development of the MSL components over time

Results of multilevel growth curve analyses reveal differences between classes, between students within classes and differences across the school year with respect to changes in motivational components (Table 1). Results show that self-efficacy, intrinsic value and autonomous motivation decline systematically, while test anxiety and autonomous motivation increase over time (see Table 2; Figure 1). Differences in the development of several motivational components between classes over time are found and can be explained partly by class type and student gender (Table 3).

With respect to the self-regulated learning components, results show that differences between classes, between students within classes and differences over time with regard to changes in self-regulation, delay of gratification, effort regulation, procrastination and academic engagement are found (see Table 4). All self-regulated learning components except procrastination decrease over time (Table 5, Figure 2). The results suggest that there are large differences in the growth changes of degree of gratification, effort regulation and academic engagement over time and these differences can be partially explained by class type, student gender and teacher gender (Table 6). Polynomial developmental trends are found for both the motivational and self-regulated learning components.

2. Relations between the MSL components over time

Across the school year, higher degree of self-efficacy, intrinsic value, controlled motivation and autonomous motivation are correlated with higher degree of self-regulation. Similarly, higher levels of self-efficacy, intrinsic value and autonomous motivation are associated with higher levels of degree of gratification. In line with these findings, self-efficacy, intrinsic value and autonomous motivation are positively correlated with effort regulation. Likewise, higher levels of self-efficacy, intrinsic value and autonomous motivation are related with higher levels of academic engagement. In contrast, self-efficacy, intrinsic value and autonomous motivation are negatively correlated with procrastination. Test anxiety is negatively related with effort regulation and is positively associated with procrastination. Interestingly, test anxiety is positively associated with self-regulation (Table 7).

Significance of research

This study provides an empirical base for the elaboration of differences in motivational and self-regulated learning components across the first year of secondary education. The study revealed that all positive motivational and self-regulated learning components decreased significantly over time, while negative components of both constructs increased significantly over time. These findings may verify the problematic nature of the transitional period between primary and secondary education that need further attention.

The present study represents an important movement beyond static assessment of motivational and self-regulated learning components across the first year of secondary school. The results offer ecologically valid empirical evidence to the knowledge base in terms of the developmental changes of and link between various motivational and self-regulated learning elements and suggest cues to pay attention to the transitional context of schooling to enhance the quality of learning and instruction. Moreover, a sophisticated and highly promoted approach was used: The constructs were studied within a longitudinal multilevel design paying attention to changes over time and to differences between classes and students within classes.

Comparing self-report and teacher assessment of reading motivation

Jeannette Bergsma, Utrecht University of Applied Sciences, Netherlands; Wim van de Grift, Groningen University, Netherlands; Thonia Houtveen, University of Applied Sciences, Netherlands

There is increasing interest in research on reading motivation, since we know that affective components of reading strongly correlate with reading development. So far, in the Netherlands we failed to develop a reliable instrument to measure reading motivation in very young children. We developed an instrument to measure reading motivation based on two separate and relatively well-established indicators of reading motivation: Competence beliefs and goal orientations. In this paper we present two versions of a questionnaire; a self report scale and a teacher version of the scale.

Background:

There is growing concern about the low level of literacy in the Netherlands (Struiksmā, 2003, Dutch Inspectorate of Education, 2007). The absence of proficient reading skills is a considerable risk factor, associated not only with academic failure and school dropout, but with unemployment and even adjudication (Werner, 1993). Much research on reading has focused on the cognitive processes of reading (Watkins & Coffey Young, 2004) and prevention of reading difficulties (Carnine e.o., 2006). Based on a substantial increase of knowledge about the process of learning to read and the factors influencing this process, researchers are optimistic about the possibilities of teaching almost every pupil basic reading skills. Many reading problems could be prevented by early identification of children at risk of reading failure and more intensive interventions for pupils who do not respond sufficiently to effective classroom instruction alone (Snow, Burns & Griffin, 1998, Simmons & Kameenui, 1998, Pearson, 1999, Rand National Reading Panel, 2000; Collins Block & Pressley (eds.), 2002; Farstrup & Samuels (eds.), 2002). At the same time research results indicate that engagement is essential to long-term achievement. Many more children could attain high levels of reading achievement if efforts are made to increase engagement. To engage young readers, teachers need to offer a coordinated emphasis on competence and motivation in their reading instruction. Both skill and will are important ingredients (Baker, Dreher & Guthrie, 2000; Oka & Paris, 1986). As Guthrie and Wigfield (2000), put it "motivation activates behavior, the most able students will not be able to read if they are not motivated".

There is increasing interest in research on reading motivation, since it is known that affective components of reading strongly correlate with reading development (Guthrie & Wigfield, 1997). Theorists assume a variety of constructs to explain reading motivation and how these constructs may affect reading (Wigfield, Egges & Rodriguez, 1998). So far, in the Netherlands we failed to develop a reliable instrument to measure reading motivation in young children.

Aims:

This study is aimed at the following:

the development of an instrument to measure reading motivation for primary school pupils?

researching the relationship between reading motivation, reading competence and reading achievement

researching the relationship between classroom environment, including teacher behavior and reading motivation, reading competence and reading achievement?
In this paper we answer the first question.

Method:

Based on the study from Morgan and Fuchs (2007) we search for studies, including instruments, for children in primary education based on two relatively distinct and well-established indicators of reading motivation: competency beliefs and goal orientations. These two indicators are increasingly linked within dynamic models of reading motivation (e.g., Lepola et al., 2005; Nurmi & Aunola, 2005). We selected 18 instruments including 565 items. We asked an expert group of 5 teachers to place the items in several categories: competence beliefs and goal orientations (task orientation, social dependence orientation and ego defensive orientation). Items placed in the same category by every teacher were selected for further instrument-construction. We developed a teacher rating scale and a self report scale for children (4-12 year). The 47-item version of the scale was field-tested in May 2009 in 16 schools, by 52 teachers and 861 children. Teachers were asked to score the instrument on reading, math and creativity. Children only rated the items for reading. We also asked teachers to provide pupil information (e.g. age, gender, years of reading, test scores) and information about the reading environment (e.g. text books, children's' books in the classroom, time spend on reading). On the basis of item-test correlations, 27 items were eliminated. We used the 20-item teacher rating scale for 3000 children.

Results:

The reliability of the 20-item version of the teacher rating scale is .92. The subscales were also sufficient reliable (task orientation: Cronbach's alpha = .85, social dependence orientation: Cronbach's alpha = .79, ego-defensive orientation: Cronbach's alpha= .75 and competency beliefs : Cronbach's alpha= .79).

For the construct validity we used a LISREL model (Jöreskog & Sörbom, 1985), which shows the interrelationships of the subscales. We found a positive fit for the model.

We also asked the teachers to rate the motivation for reading of each individual child. We found a high correlation for preschool children (.84) and a bit lower, but still satisfying correlation for older children (.52).

The reliability for the total 20-item self rating scale for children was good (.76), but for the subscales it was insufficient (.62; .76; .66; and .57).

Significant correlations were found between teacher en self report scales.

Educational and theoretical significance:

Theorists assume a variety of constructs to explain reading motivation and how these constructs may affect reading. The results of this study may contribute to the knowledge base on which factors of reading motivation contribute to reading achievement. Educational significance lies in the applicability of the developed instruments in the classroom practice. If the claim that promoting reading engagement requires a coordinated emphasis on competence and motivation in reading instruction is taken seriously, teachers need tests not only for measuring reading achievement, but for motivation as well to design their classroom practice.

Teacher Perceptions and Student Explanations of Engagement in Learning

Andrea Christensen, University of Notre Dame, United States

This study examined the relationship between middle school students' perceptions of the instructional activities in their classrooms and students' self-reported engagement. In addition, this study examined the types of information teachers use to assess students' engagement. Participants were 106 students and eight teachers at a mostly rural middle school in northern Indiana. Findings showed that teachers' engagement predicted teachers' perceptions of their students' engagement, but that there was no relationship between teachers' perception of students' engagement and students' self-reported engagement. Students' reports of meaningfulness during instruction predicted students' engagement. The lack of relationship between students' engagement and teachers' perceptions of students' engagement suggested that students and teachers use different criteria to assess engagement. Observation notes revealed that teachers tend to overestimate students' engagement in learning activities. Teacher and student interviews confirmed that teachers and students assess engagement differently. Teachers view compliance and on-task behaviors as indicators of engagement, whereas students feel engaged when they are involved in interesting, active, social activities during which they can think deeply and apply what they have learned. This mismatch in definitions and expectations for engagement can have negative consequences for students' learning because this may mean that teachers are less likely to provide a learning environment that is consistent with students' needs.

Aims

The first goal of this study was to determine which instructional activities influence students' engagement in learning in eight middle school classrooms over one school year. A secondary goal was to determine what information teachers use to assess their students' engagement in learning.

Methodology

Eight teachers at a mostly rural middle school in northern Indiana, USA, participated in a year-long intervention designed to enhance student engagement. All teachers' classrooms were observed 12 times throughout the year. At the end of each observed class, surveys were administered to teachers (N=8) and students (N=106) using a variant of the Experience Sampling Method (Csikszentmihalyi & Larson, 1987). Responses on each Experience Sampling Form (ESF) reflected experiences during the observed class session. Teacher ESFs measured teacher's self-reported engagement, teacher's perception of students' engagement, and teacher's efficacy. Student ESFs measured students' engagement, and students' feelings of competence, belongingness, autonomy and meaningfulness. In order to understand how teachers and students think about engagement, teachers and students were interviewed regarding how they interpreted survey items from the engagement subscales on the ESFs. Observer notes were used to assess types of learning activities done in each classroom on days when students' reports of engagement and teachers' perceptions of their students' engagement differed.

Findings

Regression analysis of the student data revealed that students' reports of meaningfulness in their classroom predicted students' self-reported engagement ($b = .596$, $p = .002$). This suggests that students are most engaged in learning when they think that what they are doing is interesting, relevant and appropriately challenging. Regression analysis revealed that teachers' perception of students' engagement was predicted by teachers' own self-reported engagement ($b = .786$, $p = .006$), but it was not predicted by the student self-reports. This suggests that when teachers feel engaged in what they are teaching, they are more likely to perceive that their students are also engaged in learning. Additionally, the lack of relationship among teachers' perceptions of student engagement and any of the student self-reports, particularly students' self-reported engagement, suggests that teachers and students use different criteria to assess engagement. In order to further examine the lack of relationship between teachers' and students' ESF reports of student engagement, teachers' and students' average engagement ratings for each observed class were plotted on a 5 x 5 grid (not at all, a little, sort of, pretty much, very much) such that teachers' and students' ratings could be plotted together in the same cell. These plots provided two types of information. First, they revealed the general trend that teachers tend to overestimate their students' engagement in learning. Second, they exposed which class sessions resulted in the largest discrepancies between teachers' and students' reports of student engagement. Observation notes for each of these class sessions were examined for trends. In general, the learning activities on these days did not offer challenge, and teachers did not press for deeper understanding of concepts nor require students to think more deeply about their answers. This was true regardless of the type of activity. Thus, this demonstrates that students reported low levels of meaningfulness and engagement on the days when teachers estimated their students' engagement in learning as high. Teacher interviews provided additional insight into why they may overestimate students' engagement. Teachers tend to use behavioral indicators, such as compliance and time on-task, to assess their students' engagement. For example, teachers stated that students seem interested "if they're doing the task and staying on task" and if "they are doing what I ask them to do." Since compliance is valued in American schools, many students may behave this way despite boredom or lack of interest. Student interviews supported the finding that perceived meaningfulness predicted students' engagement. In general, students commented that they feel engaged when they are doing fun, active, social activities during which they can apply what they have learned, "see it in action," and talk about the material with their fellow students. Students said that they are interested in learning when they can do "group activities with [their] friends" during which they can "think about [their] answers, justify and defend [their] thoughts, and get help from friends." They also mentioned that they value hands-on activities because "you're doing the stuff not just hearing someone tell you about it" and that with these types of activities "something happens when we put all that work in, with the [worksheets] we just get a grade." Additionally, students contradicted teachers' assertions that students "don't want to do the hard stuff" by saying that "it's ok to do a lot of work when you get something out of it."

Theoretical and educational significance

This research demonstrates that teachers and students define student engagement differently, and thus, interpret survey items assessing engagement differently. Teachers' definition of engagement was consistent with definitions of behavioral engagement, whereas, students' definition of engagement tended to be consistent with definitions of cognitive and emotional engagement (Fredericks, Blumenfeld, and Paris, 2004). This mismatch in definitions and expectations for engagement can have repercussions for students' learning. When teachers misunderstand students' signals, teachers are less likely to provide a learning environment that is consistent with students' needs (Hargreaves, 2000). When students' needs are not met, students' learning can be compromised. Additionally, within the American

educational system where students move from class to class and teachers feel substantial pressure to cover the curriculum and address a large number of state standards, teachers may not be able to take the time to form relationships with students. Without these relationships, teachers may continue to misunderstand students' signals and learning needs (Gutierrez, 2000). Also, under these circumstances, teachers may feel compelled to prioritize curriculum coverage over learning goals and student engagement. Thus, teachers may continue to be satisfied with compliance because they are not able to offer the kinds of activities that students report are most engaging.

The Role of Instructional Opportunities in Motivational Processes that Predict Student Engagement

Hayal Kackar, University of Notre Dame, United States; Julianne Turner, U. of Notre Dame, United States

The goals were to 1) investigate the relationship between middle school students' perceived engagement in instructional activities, and students' perceptions of meaningfulness, competence and autonomy, and 2) to examine how these relationships were affected by the quality of instructional opportunities offered by the task and taken up by the students. Participants were 69 students nested in eight classrooms of a middle school. Data were collected using a variant of the experience sampling method and real-time classroom observations. Results revealed that motivational processes (meaningfulness, autonomy, and competence) and instructional opportunity variables (i.e., the extent to which an open-ended task requires students to connect ideas, and the extent to which students take up opportunities provided by the task) affected students' engagement in unique ways. When it was only the task/instructions that afforded strong opportunities for students to work on content (i.e., without students taking up these opportunities), the relationship between meaningfulness and engagement decreased, and a similar decreasing pattern was observed for competence as well. It was only when students actively took up opportunities to work on content provided by the task, that the relationship between meaningfulness and engagement, and competence and engagement increased significantly. Results supported the theoretical and practical significance of the premise that engaged learning is a product of integrating motivation and instruction. Indeed, instructional opportunities alone were not significant predictors of engagement. Once the motivational processes were taken into account, however, the instructional opportunity variables contributed to the relationship between motivational processes and engagement in meaningful ways.

Aims

The goals were to 1) investigate the relationship between middle school students' perceived levels of engagement in instructional activities, and students' perceptions of meaningfulness, competence and autonomy, and 2) to examine how these relationships were affected by the quality of instructional opportunities offered by the task and taken up by the students.

Methodology

Data and Participants

Data were collected as part of a professional development intervention designed to help middle school teachers understand and implement instructional practices that foster student engagement and achievement. Analyses in this study focus on data collected during one semester from 69 students (47% 6th, 20% 7th, and 33% 8th graders), in eight classrooms (42% in mathematics, 25% in science, 16% in language arts, and 17% in social studies), in a middle school in the midwestern United States.

Procedure Students completed a variant of the Experience Sampling Method (ESM, Csikszentmihalyi & Larson, 1987) in which they responded to a survey (i.e., the Experience Sampling Form, ESF) six times per semester, during the last 8 minutes of class. The ESF contained multiple Likert-scale items ranging from 1 (not at all) to 5 (very much). Classroom observations were conducted six times per semester in the classes where students responded to ESFs. The observation instrument captured teachers' use of instructional practices and the extent to which students take up the opportunities provided by the task.

Measures The items on the ESF were first aggregated and then used to construct the following measures. Engagement was constructed by taking the mean of 9 items (e.g., I was enthusiastic in class, I was interested in class; $\alpha=.88$, $M=3.53$, $SD=.75$). Meaningfulness was constructed by taking the mean of 4 items (e.g., What I learned in class is important to me, I learned information I can use outside of school; $\alpha=.85$, $M=3.37$, $SD=.88$). Competence was constructed by taking the mean of 4 items (e.g., I am satisfied with my work in class, I feel good about how well I could do the work; $\alpha=.74$, $M=4.06$, $SD=.58$). Autonomy was constructed by taking the mean of 5 items (I made decisions about what I did in class today, I worked to reach my own goals; $\alpha=.78$, $M=3.80$, $SD=.71$). Instructional opportunities to work on content was adapted from Gresalfi, 2004, and included in the observation instrument. It was rated on two dimensions: task/instructions ($M=1.87$, $SD=.53$) and students ($M=1.42$, $SD=.38$) (See Table 1 in Appendix).

Analyses

As the data are nested (students nested within classrooms), Hierarchical Linear Modeling (HLM, Raudenbush & Bryk, 2002) was used to test the relationships between the motivational variables and engagement, and the effect of instructional opportunities on these relationships.

Findings

As seen in Table 2 (in Appendix), perceived meaningfulness ($b_{10} = .29$, $p_{30} = .38$, p The instructional opportunity variables contributed to the relationship between motivational variables and engagement in expected ways. When it was only the task/instructions that afforded strong opportunities for students to work on content (i.e., without students taking up these opportunities), the relationship between meaningfulness and engagement decreased ($\gamma_{11} = -1.09$, $p_{11} = -2.34$, $p_{12} = 1.20$, $p_{22} = 3.02$, p These patterns worked differently for autonomy: when task/instructions afforded strong opportunities to work on content, the relationship between perceived autonomy and engagement increased significantly ($\gamma_{31} = 1.61$, $p_{32} = -1.35$, $p > .05$). This finding was not surprising and suggested that the nature of the task being open-ended and requiring students to connect ideas on their own instantly awakened students' feelings of autonomy in relation to engagement. Theoretical and Educational

Significance

Fostering student engagement during instructional activities continues to be a challenging endeavor to educators (Marks, 2000). A large body of motivation research has consistently linked engaged learning to the extent to which teachers provide instructional opportunities that support students' feelings of competence (Urdan & Turner, 2005) and autonomy (e.g., Assor, Kaplan & Roth, 2002), and that enhance the value and meaning students attach to their content learning (Brophy 2008; Marks, 2000). Along the same lines, Brophy (2008) posited that feelings of meaningfulness, competence and autonomy are important factors in the degree to which students value what they are learning, but that beyond theoretical predictors, we know little about classroom situations that afford opportunities for students to develop an appreciation of their learning. Drawing upon these theoretical perspectives, this study found that the three motivational process variables (meaningfulness, autonomy, and competence) and two instructional opportunity variables (i.e., the extent to which an open-ended task requires students to connect ideas, and the extent to which students take up opportunities provided by the task) affected students' engagement in unique ways. Brophy (2008) argued that students are more likely to develop an appreciation of the content when teachers offer "'minds-on' learning opportunities that allow students to develop and discuss content-related opinions and explanations" (p. 141). Our results supported this argument revealing that strong perceptions of meaningfulness and competence in relation to engagement emerged only as a result of students being actively engaged in the task (i.e., by offering explanations, asking questions, drawing connections between ideas) rather than just being presented with the task. Results of this study also supported the theoretical and practical significance of the premise that engaged learning is a product of integrating motivation and instruction (Stipek, Givven, Salmon, & MacGyvers, 1998). Indeed, instructional opportunities alone were not significant predictors of engagement as indicated by the nonsignificant predictors of the intercept, $\gamma_{01} = -.17$, $p > .05$, and $\gamma_{31} = .45$, $p > .05$, respectively (see Table 2 in Appendix). Once the motivational processes were taken into account, however, the instructional opportunity variables contributed to the relationship between motivational processes and engagement in meaningful ways.

THEMATIC POSTER SESSION

Motivational and Social Processes

Observing teaching behaviour associated with a social-emotional intervention programme.

Mary Sheard, University of York, United Kingdom

A new observation tool was developed for use in a longitudinal randomised evaluation of Together 4 All (T4A), a social and emotional intervention programme based on the PATHS (Promoting Alternative Thinking Strategies) prevention curriculum. T4A was recently introduced into six Primary Schools in Craigavon, an area of religious, cultural, social and economic diversity in Northern Ireland. Given the turbulent history of Northern Ireland, a major goal in adopting the programme was to inculcate in this generation of children positive attitudes toward citizenship, respect for others, and recognizing and expressing feelings. The main aim of the evaluation is to find out what are the impacts of the programme on teachers' pedagogic behaviours and on children's pro-social behaviour, mutual respect and understanding, and emotional and social development. Using a 4-point rating scale for recording observations of 15 minute intervals, the observational tool aims to capture the complexity of the teaching behaviours and the subtlety of changes that might occur in these behaviours as a result of programme implementation. Findings analysing classroom observations of teaching behaviour after 6 months of implementation suggested superior teaching behaviour in the intervention classes on 10 out of 11 pedagogical items associated with the T4A programme for schools, while after

eighteen months of programme implementation, findings were equivocal for intervention and control groups. The poster presents a visual model of the interrelationships of teaching behaviours associated with the intervention programme.

Background

A new observation tool was developed for use in a longitudinal randomised evaluation of Together 4 All (T4A), a social and emotional intervention programme based on the PATHS (Promoting Alternative Thinking Strategies) prevention curriculum. T4A was recently introduced into six Primary Schools in Craigavon, an area of religious, cultural, social and economic diversity in Northern Ireland. Given the turbulent history of Northern Ireland, a major goal in adopting the programme was to inculcate in this generation of children positive attitudes toward citizenship, respect for others, and recognizing and expressing feelings. The main aim of the evaluation is to find out what are the impacts of the programme on teachers' pedagogic behaviours and on children's pro-social behaviour, mutual respect and understanding, and emotional and social development. Using a 4-point rating scale for recording observations of 15 minute intervals, the observational tool aims to capture the complexity of the teaching behaviours and the subtlety of changes that might occur in these behaviours as a result of programme implementation. Findings analysing classroom observations of teaching behaviour after 6 months of implementation suggested superior teaching behaviour in the intervention classes on 10 out of 11 pedagogical items associated with the T4A programme for schools, while after eighteen months of programme implementation, findings were equivocal for intervention and control groups. The poster presents a visual model of the interrelationships of teaching behaviours associated with the intervention programme.

Theoretical Framework

The study adopts a socio-cultural perspective. As an intervention programme to enhance social emotional learning, mutual respect and understanding and pro-social behaviour, the T4A programme is an agent of cultural change and social action based on knowledge and understanding of cultural practices, meanings, belief systems and value systems. Central to this is the view that, because communities organise themselves through conflict as well as through co-operation, individuals are often prevented from learning to see the world as others do, and may even be led to believe that there is only one way of seeing or doing and that that is the best way (2). Such has been an issue historically and presently still is in Northern Ireland. From this socio-cultural perspective, teachers, parents and other significant adults are more experienced social partners from whom children learn the social practices and cultural conventions of social interactions. The evaluation study of T4A seeks to identify how the programme impacts on the pedagogic behaviours of teachers as pupils' social partners and agents of cultural change. Identifying changes in teaching behaviours is central to evaluating programme effects on children's social interaction and pro-social behaviours in and out of the classroom.

Methodology: Observing and rating teaching behaviours As part of a mixed methods approach, observation measures were developed to capture the range of teaching and pupil behaviours associated with the programme's emphasis on promoting social emotional development and mutual respect and understanding. Eleven specific teaching behaviours are represented under four headings: Managing Behaviour and Problems, Supporting Emotional Development, Facilitating Peer Interactions, and Supporting Mutual Respect and Understanding. The following 4-point rating scale is used for recording observations of 15 minute intervals: 0 = Not applicable (used when the classroom events preclude the behaviour from occurring) 1 = Not seen 2 = Rarely/Occasionally (1 or 2 instances) 3 = Frequently (pervasive/salient within the observation interval). The frequency or saliency of the targeted behaviour (Factor 1) and the duration of the targeted behaviour (Factor 2) inform the rating. The frequency or saliency factor permits recognition that there are likely to be some teaching situations where a behaviour is precluded from occurring during all or part of the 15 minute observation interval. The duration of the target behaviour is the length of the active time interval, defined as the period during which the target behaviour could occur. Observers combine both factors to arrive at a rating.

Findings Analysis of baseline classroom observations of teaching behaviour undertaken after 6 months of implementation suggested superior teaching behaviour in the intervention classes on 10 out of 11 items, as follows: Positive behaviour management · Positive behaviour modelling · Provision of interpersonal support · Emotion modelling · Promoting social awareness · Encouraging social problem solving · Supporting peer interaction · Providing feedback on peer interaction · Engaging pupils' attention. Emotion regulation was observed more in control classes. Analysis of baseline classroom observations of pupil behaviour after 6 months of implementation suggests superior pupil behaviours in the intervention classes in: Showing mutual respect and understanding · Positive coping strategies · Self expression of feelings · Identifying feelings of others. Directional advantage for the control group was found in co-operative learning. Analysis did not reveal strong patterns in pupils' playtime behaviour. Directional advantage included less physically aggressive behaviour in the

intervention group and more turn-taking in the control group. Using the same observational measures after eighteen months of programme implementation, findings were equivocal for intervention and control groups.

Educational Significance

As PATHS did not use observations, this new observation measure presents an important development for evaluating teaching and pupil behaviours associated with the implementation of programmes to develop social-emotional learning and mutual respect and understanding. The educational significance of the observational measure is as an indicator of the educational effectiveness of social-emotional intervention programmes at early and later stages of implementation. In particular, the measure usefully highlights issues around the sustainability of programme effects.

Effects of intervention based on process of interests' development

Etsuko Tanaka, University of Tokyo, Japan

This study tested effects of intervention based on process of interests' development on learner's perception of practical values at science lesson for junior high school students. "Perception of practical values" is defined as recognition that learning contents is useful to analyze phenomenon caused in our daily life or related to our daily life. In Experiment 1, scientific experiments related to contents student will learn was displayed as introduction of a class and students were informed that they can account for experimental results if they understand this lesson. That let students have positive emotion at start of classes. Only in doing so, intervention to encourage students to perceive values of learning contents will become effective. Experiment 2 examined whether the effect of intervention depends on individuals' learning beliefs and tested effects of intervention that get students solve the problem related to daily life. The result suggests that students who have understanding focused belief can perceive value even without solving daily life problem, but students who have that belief can't. And if teacher have effectual introduction, not only take a mundane example related to learning contents but also emphasize that there are many other mundane examples and get students solve the problem related to daily life, they can enhance learner's perception of practical values effectively.

Background and purpose

We recognize importance of interests in learning contexts, however, very few concrete ways to increase them has been proposed (Hidi & Harackiewicz, 2000). These days, teachers try to please students by using PC or colourful text. But, interests caused by that ways will just be temporary. We have to find the way to encourage substantial and developed interest. This study especially looks at science class, because a large number of students don't like science in Japan. In the Hidi and Renninger (2006) model, interest development is influenced by positive emotion in relation to an activity and by perceiving value and developing knowledge in a domain. Developed interest contains not only positive effect but also stored value and knowledge. In learning contexts, we have to continue to learn even if we have something challenging. So, encouraging students to perceive values of task is important. However, it isn't effective to emphasize its value without interest and knowledge about the task (Durik & Harackiewicz, 2007). At first, teachers have to encourage students to learn actively. In this study, scientific experiments related to contents student will learn was displayed as introduction of a class. Because Harada (1998) showed that even students who dislike science like scientific experiments. In addition, students were informed that they can account for experimental results if they understand this lesson. That will let students have a concrete goal and willingly try to understand contents. Only in doing so, we can encourage them to perceive values of task.

Magara(1991) insists that it is effective to take a mundane example in order to encourage students to perceive practical values, but it is insufficiency. To perceive values of overall learning contents, recognizing that not only examples taken by teacher but also all learning contents are related to phenomenon happening around us is very important. It's expected that they can realize that only when teacher emphasize that there are many other mundane examples related to learning contents.

Experiment 1

Methods The experimental classes were organised and provided at the University of Tokyo for 5 days (day1, 5 for measurement and from day2 to day5 for lesson) during the summer of 2009. The participants were 101 eighth-grade students from junior high schools in Tokyo. They voluntarily participated in the study. They were randomly assigned to 1 of 3 classrooms, each of which corresponded to an experimental condition. 1) Intro + Emphasize group 2) Intro group 3) Emphasize group. Intro + Emphasize group were encouraged to have a concrete goal and willingly try to understand learning contents by displaying scientific experiments related to contents as introduction of a class. In addition to that, the teacher not only took a mundane example related to learning contents but also emphasized that there are many other mundane examples. Intro group had same introduction but the teacher just took a mundane example and didn't emphasize. In Emphasize group, the teacher took a mundane example and emphasize, but didn't have experiments as introduction. Instead, they were displayed at the end of a class.

Students were asked to answer questionnaires before lessons, during classes, after classes, and about a month later. The questionnaires include positive emotion and perception of practical values.

Results and discussion Covariance analysis with pre positive emotion as a covariate was used to test the effect of introduction on positive emotion at the start of the classes: "This class sounds like exciting." The result showed a significant difference among three groups (Day2 : $F(2,60)=5.46$, $pF(2,56)=3.90$, $pF(2,52)=4.74$, p . Multiple comparisons suggested that groups with Intro have higher positive emotion than Emphasize group.

Covariance analysis with pre practical values as a covariate was used to test the effect of interventions on practical values after classes: "Today's learning contents is useful in our daily lives." The result showed a significant difference among three groups (Day2 : $F(2,60)=4.12$, $pF(2,59)=5.07$, $pF(2,51)=3.18$, p . Multiple comparisons suggested that Intro + Emphasize group perceived higher practical values than Emphasize group. This result indicated that it is very important to trigger positive emotion at start of the class in order to encourage students to recognize practical values. On the other hand, multiple comparisons don't showed significant difference between Intro + Emphasize group and Intro group. And a month later practical values didn't have significant differences. These results found that these interventions are not doing enough to influent learner's perception of practical values. And it is possible that the effect of intervention varies between individuals. It can depend on their beliefs about learning. Here is the reason.

To perceive values, students need to realize how learning contents and daily life are connecting. So, students who have the belief that understanding is important in learning will realise how learning contents and daily life are connecting only by being taken a mundane example. On the other hand, students who have that belief won't. So, in experiment 2 tests whether the effect of intervention depends on individuals' learning beliefs. And new intervention that get students solve the problem related to dairy life is added.

Experiment 2

Methods Experiment 2 differs from Experiment 1 in the following respects. First, students were randomly assigned to 1 of 3 classrooms; 1) Intro + Emphasize + daily problem group 2) Intro + Emphasize 3) Intro group. Second, they also answered questionnaire about their understanding- focused belief.

Results and discussion Multiple regression analysis with contrast showed that interaction of daily problem-nondaily problem contrast and understanding- focused belief reached marginally significant ($t(62)=-1.68$, p). The result suggests that students who have understanding focused belief can perceive value even without solving daily life problem, but students who have that belief can't (Figure1). And if teacher have effectual introduction, not only take a mundane example related to learning contents but also emphasize that there are many other mundane examples and get students solve the problem related to dairy life, they can enhance learner's perception of practical values effectively.

Individual Vs Collaborative Learning: Affect, Goal Orientation, Engagement And Achievement

W. Marc Jackman, The University of Trinidad & Tobago, Trinidad and Tobago

This study examined the links between motivational factors such as achievement goals, self-efficacy, and affect within the context of individual versus collaborative learning among prospective teachers in two contrasting university courses: educational psychology and technology education. The psychology course was delivered in traditional teaching mode while the technology education course was technology based and conducted in a computer lab. Multiple regression analyses revealed that positive affect predicted group collaboration in both subject areas (re: educational psychology: $b = .62$, $R^2=.37$, p $b = .46$, $R^2=.39$, p Further regression analyses also revealed that mastery orientation also played a small role among those who chose group collaboration over individual study for technology education students. However, multiple regression analyses showed that individual study was predicted by negative affect (re: educational psychology: $b = .54$, $R^2=.30$, p $b = .45$, $R^2=.33$, p Additionally, stepwise regression analyses revealed that engagement predicted achievement outcomes for both courses with additional influences from group collaboration for the technology students (re: $b = .46$, $R^2=.23$, p

Introduction

Contemporary programmes of higher education (in areas such as engineering, education, medicine, statistics and) are undergoing considerable redesign to include more collaborative learning among students (Adams, Morehead & Sledge, 2008; Balasooriya, Hughes & Toohey, 2009; Delucchi, 2006). This is especially important in teacher education programmes where graduates are expected to play critical roles in building communities of learners (Adams, et. al., 2008). In this context, prospective teachers must have opportunities to engage in and experience the value of collaborative learning during their programmes of study. It is therefore important to assess the factors that facilitate

or impede collaborative learning in order to be better informed and guide the delivery of courses in teacher education programmes.

Given the preeminence of achievement goal orientation, task-engagement and, more recently, affective motivation factors in adaptive learning outcomes, this study explored the links among these factors and students' personal choices to engage in collaborative learning during the two contrasting courses of study. Further, relations among collaborative learning, motivational affect and achievement outcomes were also explored.

Literature Background

Achievement goal orientation is important because it predicts important and valued educational outcomes. This happens because students' reasons for engagement in the learning situation determine the use they make of appropriate cognitive strategies and the understanding, processing and retention of domain specific concepts in long-term memory (Anderman, Austin & Johnson, 2002). In effect, achievement goals direct the "energization and direction of competence-based affect, cognition and behaviour" (Elliot, 1999, p. 169). According to Elliot (1999), the seminal work of researchers Dweck and Nicholls in support of the mastery-performance dichotomy was so compelling and impressive that it laid the foundation for "this framework to become the dominant theoretical approach in the contemporary achievement motivation literature" (p. 170). According to Elliot (1999), mastery and performance-approach may be construed as approach orientations since they both entail approaching success while performance-avoidance is seen as an avoidance orientation with largely negative antecedents and effects. Additionally, the importance of self-efficacy to engagement, affect and learning outcomes was not overlooked in this study.

Consequences of Adopting Mastery Goals

The general consensus in the extant literature is that mastery goals prompt a wide range of adaptive processes and outcomes (Ames, 1992; Dweck & Leggett, 1988; Harackiewicz, Barron & Elliot, 1998; Pintrich & Schunk, 1996; Urdan, 1997). These positive processes and outcomes can be defined as motivational, cognitive, affective, behavioural. However, mastery goals have not been unequivocally associated with positive achievement outcomes in terms of grades (most researchers posit that this is due to the superficiality of examination questions relative to the depth of learning that mastery orientation engenders).

Consequences of Adopting Performance-approach Goals

Concerning affective outcomes, Elliot (1999) found that performance-approach goals show positive relations with desires for challenge during study and calmness under assessment conditions once adequate preparation had occurred. However, in some circumstances performance goals have been related to stress and anxiety under evaluation conditions (Urdan, Midgley and Anderman, 1998). Performance-approach goals have also been curiously associated with positive achievement outcomes.

Consequences of Adopting Performance-avoidance Goals

Performance-avoidance students are posited to be sensitive to negativity in the learning environment. It is also argued that student with this goal orientation also show greater self-preservation concerns and experience considerably less pleasure during task activity (Covington, 1984; Jagacinski & Nicholls, 1990). Elliot and McGregor (1999) also found that performance-avoidance positively predicted test anxiety in examination settings.

Academic Self-efficacy & Its Consequences

Bandura and his colleagues argue that self-efficacy is the foundation of human agency and "unless people believe that they can produce desired effects by their actions they have little incentive to act" (Bandura, Barbaranelli, Capara & Pastorelli, 1996, p. 1206). Although self-efficacy has been assessed as a general measure, Bandura et al. (1996) found that domain specific self-efficacy yielded results that afforded greater predictive and explanatory power.

Essentially, the study explored the extent to which achievement goals (mastery, performance-approach and performance-avoidance), task engagement, self-efficacy and positive and negative affect are associated with or can predict collaborative learning. Further, the extent to which collaborative group study or individual learning figures in achievement outcomes of the two courses mentioned were also examined.

Research Questions included:

Which motivational and affective factors predict collaborative and individual learning for the contrasting subject areas?

Which motivational and affective factors predict academic engagement for the contrasting subject areas?

Which motivational, affective or learning factors predict achievement outcomes for the contrasting subject areas?

Method

Participants

Seventy-five (75) first year B. Ed students participated in the study. The majority, 93%, was female, (i.e. a representative sample of this particular school of education). The study took place at the end of the semester after participants had completed course requirements for the two particular courses study (i.e. psychology of learning and technology education). Participation was voluntary and the questionnaire administration took place in a large lecture hall.

Measures

Students were asked to take a retrospective view of the semester just completed and fill in questionnaires regarding their motivation, affect, and choice of engagement with course content or assignments (individual or group study) and to allow access to their grades for these courses. The PALS (2000 version) motivational questionnaire was used and an retrospective version developed for the study. Questionnaires were also developed to measure collaborative and individual learning preferences as well as engagement factors for the two subject domains.

Analyses

Multiple and stepwise regression analyses were then conducted to establish the predictive relationships among specific variables. More specifically, personal and classroom goal orientation factors and affective factors were entered as independent variables to predict collaborative and individual learning. Then affective and goal orientation factors were entered as independent variables to predict engagement. Stepwise regression analyses were used to determine which factors predicted achievement outcomes for each subject domain. Pearson product-moment correlations were used to identify associations among the variables in the study.

Preliminary Results & Theoretical Implications

Preliminary results revealed that mastery goals were associated with a host of adaptive variables but not achievement outcomes. Engagement factors showed a greater tendency to be related to achievement outcomes. Regression analyses showed differences between the predictive engagement and achievement factors for the two subjects as well as factors that facilitate collaborative and individual study. Surprisingly, only students who experienced positive affect sought to work collaboratively with their peers.

Further, positive affect was also predicted engagement by in one course but not in the other. The differences seen between the two courses were unique and have implications for our understanding of motivation, affect and collaborative learning in higher education settings.

The role of competence beliefs, task value, and achievement goals in predicting mathematics anxiety

Daria Rovani, Faculty of Humanities and Social Sciences, Zagreb, Croatia; Nina Pavlin-Bernardic, Faculty of Humanities and Social Sciences, Croatia; Vesna Vlahovic-Stetic, Faculty of Philosophy, University of Zagreb, Croatia

This paper analyzes the role of competence beliefs, subjective value, and achievement goals in the prediction of elementary school students' mathematics anxiety, considering students' gender, grade and previous mathematics achievement. A sample of 297 fifth to eight-grade students from two elementary schools in Zagreb, Croatia participated in the study. Students answered a questionnaire on motivational beliefs and anxiety in mathematics at the end of school year. Results showed that mastery-avoidance goal was the strongest predictor of mathematics anxiety followed by competence beliefs, interest and attainment value. Motivational beliefs predicted mathematics anxiety above and beyond previous mathematics achievement. Students pursuing mastery-avoidance goals were more prone to mathematics anxiety. In addition, students who had stronger competence beliefs, higher interest in mathematics and higher attainment value were less likely to show mathematics anxiety. This research advances our understanding of how individual differences in motivational beliefs may influence mathematics anxiety. Understanding the motivational background of mathematics anxiety, teachers can make easier to the children to overcome this problem.

Achievement emotions, such as anxiety, play a very important role in teaching and learning (Pekrun, 2006). Mathematics anxiety is commonly defined as a feeling of tension, or fear brought upon by the presentation of mathematical problems that interferes with math performance irrespective of student's true ability (Ashcraft, 2002; Hoffman, 2010). Previous studies of mathematics anxiety were mainly oriented to investigating detrimental effects that mathematics anxiety has on mathematics achievement (e.g. Ma, 1999). Therefore, very little research has examined potential antecedents of mathematics anxiety (e.g. Jain & Dowson, 2009). At the same time, there is an increasingly large number of studies exploring the links between academic emotions and students' motivational beliefs. Contemporary motivational theories tend to emphasize competence beliefs, subjective values and achievement goals as central constructs explaining motivational process. Previous research findings suggest that

achievement goals can predict achievement emotions (Linnenbrink & Pintich, 2002; Pekrun et al, 2006, 2009), as well as competence beliefs (e.g. Hoffman, 2010; Jain & Dowson, 2009) and subjective value (e.g. Pekrun et al., 2002). The aim of present research is to analyze the role of competence beliefs, subjective value, and achievement goals in the prediction of elementary school students' mathematics anxiety, considering students' gender, grade and previous mathematics achievement.

A sample of 297 fifth- to eight-grade students (160 males, 137 females) from two elementary schools in Zagreb, Croatia participated in the study. Students answered a questionnaire on motivational beliefs and anxiety in mathematics at the end of school year. Participants were administered the Mathematics Anxiety Scale for Children (Chiu & Henry, 1990; adapted by Arambasic et al., 2005), Achievement Goals Questionnaire (AGQ; Elliot & McGregor, 2001) and Motivational Beliefs Questionnaire (Rovan et al., 2010) consisting of competence beliefs, interest, attainment value and utility scale.

Hierarchical multiple regression analysis was conducted to predict students' mathematics anxiety. First, demographic variables (gender and grade) were entered to serve as controls. Second, we tested a regression model that only included students' gender, grade and previous mathematics achievement. Third, to evaluate the effects of competence and subjective value beliefs, we tested a regression model that included these measures in addition to previously mentioned measures. Finally, we tested a regression model that also included achievement goals measures: mastery-approach, mastery-avoidance, performance-approach, performance-avoidance and work avoidance.

Results of hierarchical regression analysis revealed that the demographic variables did not account for a significant amount of explained variance ($R^2 = 0.01$). Previous mathematics achievement added significantly to the prediction of mathematics anxiety ($\Delta R^2 = 0.13$, $p < 0.05$), $\Delta R^2 = 0.19$, $p < 0.05$ and $\Delta R^2 = 0.13$, $p < 0.05$.

Interestingly, these results also suggest that students with mathematics anxiety are much more concerned with the possibility of not thoroughly understanding mathematics (mastery-avoidance goals), than with possibility of performing worse than other students (performance-avoidance goals). This research advances our understanding of how individual differences in motivational beliefs may influence mathematics anxiety. This can have important implications for practitioners. Understanding the motivational background of mathematics anxiety, teachers can make it easier for the children to overcome this problem. For example, mathematics teachers could focus on helping students to feel competent, emphasizing task value and supporting students' autonomy.

Development of Preventive Measures to Prevent School Absenteeism in Twente

Annette Van Liere, ROC van Twente, Netherlands; Henk Ritzen, Applied University Edith Stein, Netherlands; Saskia Brand-Gruwel, Open University, Netherlands

This research studies the relationship between school policy regarding school-absenteeism of pre-vocational education schools and pupil's self-experiences regarding school and school-absenteeism. School-absenteeism is a big problem for pupils, as well as for the school and the environment. It is an indicator for early school leaving and is also related to risky behavior. Initially schools took measures by addressing school management and tackling disciplinary problems. Yet, often personal factors like physical/psychological/cognitive problems and negative self-experiences are important factors related to school-absenteeism that are left unaddressed. This research aims at developing more knowledge on the way schools execute their policies regarding school-absenteeism and how pupils respond to these policies. From 10 pre-vocational education schools in the east of Netherlands the school policy concerning absenteeism was measured using a questionnaire. Furthermore, self-experiences of 700 pupils of 3 selected pre-vocational education schools was also measured using a questionnaire. The results of this research will be translated to preventive measures which will be used to further improve their policies and practices to prevent school-absenteeism.

Introduction and hypotheses

School-absenteeism is a very obstinate problem for youngsters, schools, and society. Currently, school-absenteeism is regarded an important indicator for early-school-leaving and risky behavior (Teasley, 2004). Twelve pre-vocational education schools, two secondary vocational education schools and four local municipalities in the Netherlands have committed themselves to investigate these problems and subsequently take measures that aim at a fitting, personalised and just-in-time approach of school-absenteeism. Often schools take measures to tackle problems through school policies and disciplinary actions. Only when a pupil's school-absenteeism becomes frequent or chronic, schools will look at the underlying problems. The chance of absenteeism increases when pupils are experiencing

background problems, negative self-experiences regarding school of when they feel disengaged to school (Kearney, 2008; Reid, 2005; Vuijk, Heyne, & Noll, 2008). Little is known of the effectiveness of certain measures. Moreover research results are inconsistent (Reid, 2005).

This research aims at developing more knowledge on the way schools execute their policies regarding school-absenteeism and how pupils respond to these policies. The following hypotheses will be studied: Pre-vocational education pupils with positive self-experiences toward school are less absent than pupils with negative self-experiences. Schools that attribute school-absenteeism to pupil's behavior contribute to the negative self-experiences towards school and to absenteeism of pupils. Moreover, schools that attribute school-absenteeism to the curriculum contribute positive to the self-experiences towards school and absenteeism of pupils.

Theoretical framework

Each year the amount of youngsters not attending school becomes larger and larger. Several factors, categorized in the pupil himself, school and the social environment, are related to school-absenteeism (Teasley, 2004; Kearney, 2008). Self-experience is an important personal factor to school-absenteeism. Reasons for negative self-experience regarding school, are by example: not feeling engaged, losing interest, boredom or unhappiness, fear for social or assessment situations, looking for attention, being attracted to activities outside school (Vuijk, Heyne, & Noll, 2008). With regard to pupils with negative self-experiences, school-absenteeism will increase, whereas motivation, efforts to do homework and school engagement becomes less, until in the end the pupil leaves school too early. School-absence can be caused by underlying problems like learning-, behavioral or physical/psychological problems (Teasley, 2004). School factors like school-size and location, academic- and social-climate, school-policies and disciplinary measures, the quality and effectiveness of the staff, relationship between school-parents, teacher-pupil, influence absenteeism. Also a pupil's social environment like his/her socioeconomic status (SES), the family structure, parent-child relationship and parental-involvement with school are related to absenteeism (Teasley, 2004). School and pupils think different about school-absenteeism, school tends to attribute school-absenteeism to pupil-related factors, as pupils to school-factors (Reid, 2003). Schools measures regarding school-absenteeism by addressing school management and tackling disciplinary problems leads to a procedure of preventive policies, early detection, administration and interventions when a pupil already starts being absent. Punitive programs and zero-tolerance policies do not curb school-absenteeism. Poor school-climate is related to school-absenteeism and linked to harsh and inflexible disciplinary practices and rigid regulations regarding school reintegration. Activities regarding pro-social preventive measures like improving relationships and relevant, alternative curriculum schemes can reduce school-absenteeism (Reid, 2003; Vuijk, et al., 2008).

Method

Two questionnaires will be used, one to measure school policy of 10 pre-vocational education schools and a questionnaire to measure self-experiences of 700 pupils of 3 selected pre-vocational education schools in the region Twente (Netherlands). In March 2010 the questionnaire "School-policies" has been conducted on 10 pre-vocational education schools, in the region Twente (which is located in the east of the Netherlands) (Ritzen & Liere, 2010). In December 2010 the questionnaire "Self-experiences" will be conducted to 700 pupils of 3 of the ten pre-vocational education schools. For the questionnaire "School-policies", a theoretical study has been performed, leading to common questions and questions grouped in 5 subscales: measures related to school-absenteeism (alpha .87); realized measures (alpha .74); preventive measures (alpha .81); no problem (alpha .88); bottleneck (alpha .88). The questionnaire "Self-experiences" is composed by the Dutch version (Vuijk et al., 2008) of Kearney's Refusal Assessment Scale-Revised (SRAS-R), called SRAS-R-NL; and Ritzen's (2004) version of the Self-experience questionnaire initially developed by Stoel (1982). The SRAS-R-NL contains 32 scale-items 7 point Likert-scale, grouped in four subscales: avoiding school-related stimuli that call negatively affect (alpha .68), avoiding social or evaluative situations at school which one dislikes (alpha .60), the pursuit of attention from significant others (alpha .81), the pursuit of tangible amplifiers outside the school setting (alpha .65). Ritzen's (2004) version of the Self-experience questionnaire contains 60 scale-items 4 point Likert-scale, grouped in 8 subscales, self-experience of: school in general (alpha .75), curriculum (alpha .66), relationship with teacher as didactic (alpha .82), teacher as a person (11 items, alpha .85), occupational training (alpha .70), relationship with classmates (alpha .69), school-organization (alpha .74), academic self-concept (Alpha .70).

Preliminary results

Results of the questionnaire "School-policies", shows that organizational and procedural activities like having a clear vision, using a central administration system, informing the mentor and parents, and supervision are implemented, not imbedded in a organizational quality procedure; evaluation of the activities, clear rules, having a personal conversation, comes in second place. Activities to engage and motivate pupils like improving curricula, an flexible

scheme, special activities, are less. Schools believe that clear rules, powerful school-policy, following-up activities and a good relationship with parents are most effective in reducing school-absenteeism, not disciplinary measures.

The rest of the results will be presented during the Earli conference in Exeter in 2011.

The difference of perceived instrumentality and study strategy use across major and non-major course

Wonsik Kim, Arizona State University, United States; Jenefer Husman, Arizona State University, United States

The purpose of this study to examine how students will differently develop perception of instrumentality between major and non-major courses and how this difference in perceived instrumentality affect their use of study strategies in the class. 231 college students majoring in mechanical and aerospace engineering (MAE) participated in this study. Participants took a survey for the major (MAE) course and a survey for the non-major (HU/SB) at same semester. Two types of instrumentality and study strategies such as collaboration and knowledge building were measured using online surveys. Multivariate analysis of variance method (MANOVA) was used to examine the difference in perception of instrumentality and the use of self-regulated study strategies between major course and non-major course at college level. The study results showed that students had significantly higher perception of instrumentality and were more willing to use self-regulated study strategies when they were taking a major course than taking a non-major course.

Theoretical framework

Faculty and academic advisor ask students to take a range of courses reflective of many traditional academic disciplines because these courses will help students possess basic skills and knowledge in the major areas of study (Husman & Hillpert, 2007). However, it is not unusual to see students who seemed to be disengaged from their course works in college or university level because of low level of perceived instrumentality. According to expectancy x value theories, increasing utility value about current learning activity should result in higher motivation and better learning. In addition, it has suggested that perceiving a current task as instrumental in attaining future goals enhances not only student motivation but also subsequent performance (Vansteenkiste et al., 2004; Wigfield & Eccles, 2002). Perceptions of instrumentality are the connection between completing a present task and reaching a long term future goal (Husman & Hillpert, 2007). Husman and Lens (1999) examined people's perceptions of the connection between current activities and their outcomes. Because it is proximal in definition, instrumentality is situated within one's distal or general future time perspective. It is dependent on both a specific activity and a person's general view of the future (Husman & Hillpert, 2007). Malka and Covington (2005) found that perception of instrumentality accounted for a significant amount of variance in academic achievement of postsecondary students. Students' perception of instrumentality was related to their classroom behaviors that lead to high achievement (Husman & Hillpert, 2007). Previous research has demonstrated the importance of self-regulate study strategies such as knowledge building and collaboration for better performance in school (Weinstein, Husman, & Dierking, 2000). Purposes of studyThe purpose of this study to examine how students will differently develop perception of instrumentality depending on different course type like a major and non-major course and how this difference in perception of instrumentality will affect their use of study strategies related to students' achievement in the class.

Method

Participants

In the study, 231 undergraduate students were recruited from Mechanical and Aerospace Engineering (MAE) courses at a large public university in the southwestern United States. The participants were enrolled in 24 different courses – one 100 Level course; seven 200 Level courses; ten 300 Level courses; and nine 400 Level course. 18.4% of the sample were women and all of the participants were engineering major. ProcedureData for the current study were collected from the fall semester of 2008 to the spring semester of 2010 via an online survey. Research assistants visited the classroom of each approved course section and informed the students about the research opportunity. Participants were asked to complete the survey for one MAE course and one Humanities and Social Sciences (HU/SB) course which they were taking at the semester. Students were offered cash incentive (\$10) for the completion of the survey each semester. Data were downloaded and entered into Excel, and then recoded and analyzed in SPSS. MeasuresPerceptions of Instrumentality (PI). The PI scale was administered to determine perceived instrumentality of a particular college course selected by the participant. Endogenous perceived instrumentality was measured using 4 items that evaluated the perceived instrumentality of learning from the course, such as, "I will use the information I learn in this class in other classes I will take in the future." The 4-item exogenous perceived instrumentality assessed perceived instrumentality of the grade earned in the course, such as "The grade I get in this class will not affect my ability to continue on with my education." Participants responded to a 5 point Likert-type scale ranging from 1 (strongly disagree) to 5 (strongly agree). Students Perceptions of Classroom Knowledge-Building (SPOCK). Two subscales from SPOCK were administered in this study: Knowledge building and collaboration (Shell et al., 2005). Knowledge building focused on classroom knowledge building. This 7-item subscale assessed students' tendencies to make meaning from and construct their own understanding of classroom material, such as "In this class, I try to fully explore the new information I am learning." The 5-item collaboration subscale assessed the level of collaborative learning at the classroom level, such as "My classmates and I actively work together to complete assignments in this class."Participants responded on a 5-point Likert-type scale ranging from 1 (almost never) to 5 (almost always). These were classroom-specific and participants were asked to focus the course which they were taking.

Analysis

For each participant, we created subscale scores for Perception of instrumentality, collaboration, knowledge building, and self-efficacy by calculating a mean score from the related survey items. Coefficient alpha (Cronbach, 1951) was computed on each subscale to obtain reliability evidence. Descriptive statistics for all variable subscales were computed and analyzed. Multivariate analysis of variance (MANOVA) method was then used to evaluate the difference in PI and study strategies use between major (MAE) and non-major (HU/SB) course.

Results

Descriptive statistics for our variables of interest are displayed in Table 1. Multivariate analysis of variance (MANOVA) result showed that there was statistically significant difference between MAE and HU/SB course on the dependent measures, Wilks's Λ ; = .53, $F(4,457) = 101.30$, $p = .00$. The multivariate η^2 based on Wilks's Λ ; was .47. Analyses of variances (ANOVA) on the dependent variables were conducted as follow-up tests to the MANOVA. Using the Bonferroni method, each ANOVA was tested at the .00125 level. The ANOVA on endogenous PI was significant, $F(1,460) = 260.05$, $p = .00$, $\eta^2 = .36$, on exogenous PI was significant, $F(1,460) = 165.50$, $p = .00$, $\eta^2 = .27$, on collaboration was significant, $F(1,460) = 67.61$, $p = .00$, $\eta^2 = .13$, and on knowledge building was significant, $F(1,460) = 28.42$, $p = .00$, $\eta^2 = .06$. DiscussionThe results of study suggested that students had more perception of instrumentality in major course than non- major course. In addition, they were more likely to use study strategies like collaboration and knowledge building when they were taking major course than taking non- major course at college level. According to the study results, instrumentality as a value factor in expectancy x value theory will increase motivation to use study strategies. However, it is a limitation not to examine the actual effect of instrumentality and study strategies on achievement like a course grade. In addition, it is necessary to add expectancy factor like self-efficacy to see the effect of expectancy x value on motivation and achievement.

THEMATIC POSTER SESSION

Reading, Writing and Talking

Reading on the World Wide Web: A Theoretical Framework

Johan van Strien, Open University of the Netherlands, Netherlands; Saskia Brand-Gruwel, Open University, Netherlands; Els Boshuizen, Open University, Netherlands

In contemporary education, students not only read printed text, they frequently use the Internet to search for information and read hypertext as well. In contrast to printed (linear) text, which is usually read from top to bottom in a fixed order, the Internet is made up of multiple hypertext (nonlinear) documents. Through hyperlinks, readers can easily choose their own reading paths across multiple documents. However, little is still known of how hypertext

reading comprehension occurs and which processes are involved. Although research on traditional text processing is abundant and provides useful insights on the processing of single and multiple linear text, a clear framework of nonlinear text processing, including hypertext reading, is still lacking. The aim of this poster is to arrive at a theoretical model that gives an extensive overview of the reader, text, and task factors as well as the processes involved in multiple-document and hypertext reading, based on insights from reading and educational research. The resulting model will function as a starting point for a series of empirical studies focussing on the factors and processes identified.

Texts are crucial for conveying and for acquiring new information (McNamara & Kintsch, 1996). It is therefore not surprising that much of the learning that takes place in and out of schools is based on successful comprehension of texts (Kendeou & van den Broek, 2005; Rouet, Britt, Mason, & Perfetti, 1996). In contemporary education, students not only read printed text, they frequently use the Internet to search for information and read hypertext as well. In contrast to printed (linear) text, which is usually read from top to bottom in a fixed order, the Internet is made up of multiple hypertext (nonlinear) documents. Through hyperlinks, readers can easily choose their own reading paths across multiple documents. However, little is still known of how hypertext reading comprehension occurs. Although research on traditional text processing is abundant and provides useful insights on the processing of single and multiple linear text, a clear framework of nonlinear text processing, including hypertext reading, is still lacking.

Research Problem and Aim The central questions to be addressed in the poster are (1) which factors and processes are involved in reading multiple text documents, most notably in the context of reading hypertext documents on the World Wide Web, and (2) how can research on hypertext reading be extended? The aim is to arrive at a theoretical model that gives an extensive overview of the factors and processes involved in multiple-document and hypertext reading, by combining insights from reading and educational research, and to set a research agenda. The resulting model will function as a starting point for a series of empirical studies focussing on the factors and processes identified.

Factors Involved in Reading The factors that are involved in reading will be subdivided into three categories: Reader, text, and task characteristics, based on previous work (e.g., Fox, 2009; Rouet, 2006).

Reader characteristics. Reader characteristics entail both cognitive and motivational factors. Influential cognitive factors include readers' prior knowledge (e.g., Shapiro, 2004), reading skills (e.g., Voss & Silfies, 1996), and working memory capacity (e.g., Burton & Daneman, 2007). In the context of multiple-text learning, readers' epistemological beliefs have been found to be an influential factor as well. Epistemological beliefs are beliefs about the nature of knowledge and knowing (Hofer & Pintrich, 1997). These may include beliefs about the certainty, the source, the justification, the acquisition, and the structure of knowledge (Duell & Schommer-Aikins, 2001). Epistemological beliefs are positively related multiple-text comprehension (Strömsö & Bråten, 2009) and self-regulation of learning (Dahl, Bals, & Turi, 2005; Pieschl, Stahl, & Bromme, 2008). Self-regulation and metacognition skills in turn are important in hypermedia learning (Bannert & Mengelkamp, 2008). Finally, multiple-text reading requires metatextual knowledge, i.e., knowledge about texts, documents, and search tools, as well as sourcing skills; Readers must be capable of integrating information from different, conflicting sources (Rouet, 2006). There is also an increasing amount of attention paid to motivational factors, such as motivation and interest. Hypertext research suggests that learners selecting hyperlinks based solely on their personal interest generally perform more poorly than learners who select links that are semantically related to one another (Salmerón, Kintsch, & Cañas, 2006). In reading research, on the other hand, interest has been associated with positively to comprehension of and learning from text (e.g., Hidi, 2001; Schiefele & Krapp, 1996). These apparent contradictions warrant a closer look.

Text characteristics. Texts differ in their degree of coherence, i.e., the degree to which a text enables readers to make appropriate, meaningful connections between elements of text and the reader's prior knowledge (Rapp, van den Broek, McMaster, Kendeou, & Espin, 2007). The influence of coherence on learning has been found to depend on readers' prior knowledge: High-knowledge readers learn more from low-coherence texts, whereas low-knowledge readers benefit from high-coherence (McNamara, Kintsch, Songer, & Kintsch, 1996).

Task characteristics. Different tasks may lead to different outcomes of multiple-text learning, often depending on reader characteristics. For instance, argumentative tasks may be more suitable for high-knowledge learners, whereas less knowledgeable learners may benefit more from summarization tasks (Gil, Bråten, Vidal-Abarca, & Strömsö, 2010).

Processes Involved in Reading Processes and strategic behaviours taking place during (single-text) reading include cognitive strategies (e.g., rehearsal, elaboration, organization), metacognitive and regulatory behaviour (e.g., planning and monitoring), and motivational processes, such as persistence and maintaining interest (Dermitzaki, Andreou, & Paraskeva, 2008). With respect to multiple-document and hypertext reading, it has been argued that reading multiple documents generally involves the same processes as reading single documents (e.g., Strömsö, Bråten, & Samuelstuen, 2008). Successful reading of hypertext requires readers to select information, self-monitor the comprehension process, activate prior knowledge in order to integrate information from multiple texts (Coiro & Dobler, 2007; Stadtler & Bromme, 2007), but in addition requires them to gain knowledge about the quality and trustworthiness of sources (Stadtler & Bromme, 2007) and to deal with conflicting information (Britt & Gabrys, 2002).

Extension of Research on Hypertext Reading The factors involved in and the processes taking place during hypertext reading are not well-documented yet. Existing models of multiple-document reading are incomplete

as these do not consider motivational variables and other relevant variables, such as epistemological beliefs (cf. Rouet, 2006). Studies on the processes involved in hypertext reading have focused on small samples of highly skilled readers (Coiro & Dobler, 2007). As the Internet is made up of numerous hypertext documents, hypertext research is an important knowledge base. However, hypertext research has been more concerned with how texts can be used rather than how they are processed. Also, it has been argued that hypertext research had a technical rather than conceptual focus, and was promotional rather than empirical (Perfetti, 1996). Therefore, findings from hypertext studies will be augmented with insights from reading research to make the link between hypertext learning and learning from traditional text (Shapiro & Niederhauser, 2004). This synthesis of insights from different fields of research will lead to a more complete model. By shifting the focus to from reading multiple linear texts to reading of nonlinear hypertext documents, the literature on reading comprehension will be expanded as well.

Online collaborative writing: Understanding the evolution of a group artifact using CORDTRA

Andri Ioannou, Technology University of Cyprus, Cyprus

CORDTRA (Chronologically-Oriented Representations of Discourse and Tool-related Activity) provides "an innovative representation for analyzing the evolution of discourse and tool-related activity across time" (Hmelo-Silver, Chernobitsky, & Nagarajan, 2009, p. 3). This paper discusses how the CORDTRA methodology helped understand the process of collaborative writing and the evolution of a group artifact in an online collaborative writing activity. The analysis focused on a 4-member group. Group members were asked to work in distance to analyze a case and produce a consensus plan suggesting a solution to the embedded problem. Students discussed ideas, reached consensus, and produced a solution together, using a threaded discussion board and a GoogleDoc to facilitate their collaboration. Results show how the task (i.e., the problem at hand, scoring rubric, and collaboration script), mediating technologies (threaded discussion and GoogleDocs), and most importantly the interaction of individual and group understandings are all interwoven in the collaborative writing process.

Background

Researchers in the field of computer-supported collaborative learning ((CS)CL) tend to concur that collaborative knowledge construction cannot be understood by focusing solely on the individuals as group members, or on the characteristics (affordances) of the technology, or on the cognitive processes apparent in the learning environment (Arnseth & Ludvigsen, 2006; Stahl, 2006; Strijbos, Kirschner, & Martens, 2004). Instead, they focus on the complex interactions among collaborators (i.e., the interaction of individual and group understandings) and the (technologically mediated) environment that enable learning to occur socially. Knowledge, then, is constructed collaboratively, as group and personal perspectives are brought together (Stahl, 2006); successful collaboration requires group members to contribute information, ideas, solutions, and opinions that need to be evaluated to construct and maintain a shared understanding. CL does not just entail sharing a workload or individual knowledge with one another (i.e., cooperation), but rather negotiating multiple interpretations and solutions to establish meaning (Cognition and Technology Group at Vanderbilt, 1993; Scardamalia, & Bereiter, 1996). According to Stahl (2006), for CL to take place, ... the group must engage in thinking together about a problem or task and produce a knowledge artifact, such as a verbal problem clarification, a textual solution proposal, or a more developed theoretical inscription, that integrates their different perspectives on the topic and represents a shared group result that they have negotiated. (Stahl, 2006, p. 2, emphasis added).

As the theme of EARLI 2011 suggests, the study of CL warrants particular attention in our global network society – a society in which today's learners (and tomorrow's professionals) are called upon to work together in geographically separated settings to solve problems (Dede, 2005). Yet, the study of CSCL is not a trivial task. The CSCL community has been calling for methodologies and tools that will help us obtain an understanding of CL (and collaborative writing) without oversimplifying the phenomena observable in the interactions among collaborators (Chi, 1997; Hmelo-Silver et al., 2009; Kulikowich & Young, 2001; Stahl, 2006; Suthers, 2006).

Research Question

The overarching goal of this work is to provide a comprehensive account of the process of collaborative writing and the evolution of a group artifact in an online collaborative activity. The present paper focuses on how the CORDTRA (Chronologically-Oriented Representations of Discourse and Tool-related Activity) methodology helped understand these processes. CORDTRA provides "an innovative representation for analyzing the evolution of discourse and tool-related activity across time" (Hmelo-Silver et al., 2009, p. 3).

Theoretical Framework

Activity Theory (AT; Engeström & Miettinen, 1999a, 1999b) provides a useful theoretical lens for understanding CL in complex learning environments, and thus, it is used here for the study of collaborative writing. According to AT, activities are always motivated by and oriented towards an object and the need to transform this object into an outcome (Engeström & Miettinen, 1999). The object evolves as people pursue it with diverse cultural tools (e.g., discourse, technologies) and under different conditions (rules, type of community, and division of labor). Figure 1 presents the Activity System of the study.

Methodology

Participants and Procedures

Data was collected from 16 graduate students enrolled in a fully online, learning theories course at a large public University in the Northeast USA. During weeks 13 and 14 of the 16-week course students (in 4-member groups) collaborated on case study analysis, online. Groups discussed a case scenario and produced a consensus plan suggesting a solution to the problem embedded in the case scenario. They were provided with a scoring rubric to guide the development of their plan, and a script regarding the expectations for collaboration and coming to a consensus. Details about the case study, scoring rubric, and collaboration script will be included in the final paper. Groups were asked to use the WebCT's threaded discussion board (licensed by the school) and a GoogleDoc to support their collaboration. Data included: (a) logs of online activity (including discourse) archived on the threaded discussion board and the GoogleDoc history, and (b) group artifacts (consensus plans).

Analysis and Results

This paper examines the case of one particular group which presented interesting patterns of online collaboration and writing. Student interactions during the collaborative writing process (i.e., discussion of ideas, consensus building, and production of a group solution) was first analyzed using a coding-and-counting approach to Computer-Mediated Discourse Analysis (CMDA) as described in Herring (2004). More details about this methodological toolkit, the unit of analysis (i.e., the event), and the coding scheme of the study will be discussed in the final paper.

Subsequently, the CORDTRA analysis tool was utilized. This illustrative technique allowed the investigator to go beyond coding-and-counting to carefully examine the complex interactions among collaborators, the task (i.e., problem at hand, scoring rubric, and collaboration script), and the mediating technologies (threaded discussion and GoogleDocs) during the collaborative writing process (Hmelo-Silver et al., 2009). Figure 2 presents the CORDTRA for the group of interest. Briefly, the time of contribution runs at the top of the CORDTRA in chronological order. Each time-point on a CORDTRA diagram represents a collaborator, a coding category (i.e., the event), and the mediating technology used at the time. The CORDTRA serves as a pointer to the online activity. The researcher can zoom in on the areas of the diagram where interesting patterns exist to explore the phenomenon deeper, by going back and forth between the CORDTRA and the recorded data (Hmelo-Silver et. al, 2009).

Within an Activity Theory framework, the CORDTRA helped understand the process of collaborative writing deeper and the evolution of the group artifact during the online activity. The CORDTRA analysis explored how students contributed information, ideas, solutions, and opinions, evaluated those to construct a shared understanding, and built a consensus solution for the case. Results revealed how the task, mediating technologies, and most importantly the interaction of individual and group understandings are all interwoven in the collaborative writing process.

Understanding the process of online collaborative writing and collaborative knowledge construction is not trivial. It is time for innovative methodologies, such as CORDTRA, to shed some light on how collaborators approach the challenge of collaborative writing and learning together online.

Scaffolding student problem solving through classroom discourse

Javier Rosales Pardo, Universidad de Salamanca, Spain; Santiago Vicente, University of Salamanca, Spain; Jose Chamoso, Facultad de Educacion, Spain; David Munez, University of Salamanca, Spain; Jose Orrantia, University of Salamanca, Spain

Research on educational intervention in word problem solving has documented different kinds of instruction that allow the students to perform better. Less is known about how classroom interaction is organized according to the cognitive processes embedded in word problem solving. The aim of this work is to analyse the classroom interaction when teacher and pupils solve arithmetic word problems together. The focus is on how teachers promote these cognitive processes involved in problem solving. The participants were 10 Primary Education teachers with more than 10 years' experience. Five of them taught 6-8-year-old students (G1), and five teachers taught 10-12-year-old students (G2). Each teacher was audio-taped when teaching students how to solve two different arithmetic problems. An analysis of the interaction was required at different levels: 1) The interaction was broken down into episodes; 2) The episodes were broken down into interaction cycles; 3) The content made public was identified; and 4) The

instructional aids embedded in discourse were identified (from here on "instructional aids") No significant differences were found when comparing instructional aids that are addressed to the mathematical, metacognitive and situational content, between G1 and G2. However, significant differences were found between the percentages of instructional aids devoted to mathematical, metacognitive and situational contents made public, within groups. In addition, different levels of autonomy for each academic level are indicated.

Introduction

Word problem solving implies the translation of the problem statement into a mental model of the situation described in the problem. Specifically, word problem solving can be split into two main stages: comprehension and resolution. In the comprehension stage the problem solver must use the relevant information to solve the problem. In the resolution stage, (s)he is ready to plan the arithmetic computations needed to solve the problem. At the same time, these processes interact with other intrinsic mechanisms known as metacomponents. These higher-order executive processes are instrumental in planning, monitoring, and evaluating academic tasks. In addition, to solve arithmetic problems is necessary: firstly, mathematical knowledge in order to select the numerical data and the arithmetic operation (Briars & Larkin, 1984; Riley, Greeno & Heller, 1983); and secondly, situational knowledge in order to create a situational context in which the mathematical information must be embedded (Reusser, 1988; Kintsch, 1988, 1998) It is well documented that the promotion of these processes in the educational intervention leads children to a higher level of development in their mathematical performance when compared to more classical learning experiences in traditional classroom settings (Assink & Verloop, 1977; De Corte & Verschaffel, 1980; Fuson & Willis, 1989; Jitendra, Griffin, McGoey, Gardill, Bhat & Riley, 1998; Jitendra, Hoff & Beck, 1999; Lewis, 1989; Willis & Fuson, 1988; Wolters, 1983; Xin & Jitendra, 1999; Zwerts, 1984; Verschaffel & De Corte, 1997) Despite the theoretical significance of these studies and the consistency of the results, there are few studies in which mathematics classes are described on the basis of an analysis of the cognitive processes that are triggered when an arithmetic problem is solved jointly. If teachers provide guidance for accomplishing the learning goals and to move from a position of shared responsibility to one in which the student takes control of learning goals and processes (Turner, Meyer, Cox, Logan, Di Cintio & Thomas, 1998), this knowledge about the cognitive processes should have greater importance. In the present study, the verbal utterances of two groups of teachers and their students when solving several arithmetical word problems together were audio taped, transcribed and analysed in order to identify: firstly, the presence of those processes mentioned; and secondly, the responsibility assumed by teachers and students to achieve the learning goals.

Method

The participants were 10 primary education teachers with more than 10 years' experience. Five of them taught 6-8-years-old students (G1), and five teachers taught 10-12-year-old students (G2). Each teacher was audio-taped when teaching students how to solve two different arithmetic problems. The number of students in each classroom varied from 25 to 30, and the sessions were approximately 3-15 minutes long. All of the participants were audio-taped in their ordinary classrooms and during the time normally devoted to this type of work. The analysis of the interaction required 4 different levels: 1) the interaction was broken down into episodes. An episode was defined as a set of activities that presents: a) a recognizable objective or goal, b) a regular structure of participation, and c) a recognizable sequence of routines. In the present work we distinguish four types of episodes; 2) the episodes were broken down into interaction cycles. Basically, an interaction cycle starts with an initial question/order and it finishes when that question/order is completed; 3) the content made public was identified. For each interaction cycle we extracted the content that was made public, identifying all the propositions it contained and categorized as mathematical, situational or metacognitive; 4) each interaction cycle was analysed according to the number of instructional aids and kind of support provided by the teachers. Consequently, each interaction cycle showed a certain level of autonomy: 1) teachers are responsible for the content made public without students' participation; 2) teachers offer one or more invasive instructional aids (i.e., those that include part of the answer, either in the question or feedback given to students); 3) teachers offer both invasive and non-invasive instructional aids; 4) teachers only offer non-invasive instructional aids (i.e., those that do not include part of the answer in the question or feedback given to students); 5) students are responsible for the content made public without teachers' participation.

Measures

Two types of measures were used: 1) Percentage of aids that was addressed to each public content (mathematical, situational, and metacognitive); and 2) Level of autonomy per interaction cycle for every academic level.

Results

Overall, no significant differences were found when comparing instructional aids that are addressed to the mathematical, metacognitive and situational content, between G1 and G2 (see Fig. 1). However, in both the academic levels, significant differences were found between the percentages of instructional aids devoted to mathematical, metacognitive and situational contents made public: $G1, \chi^2(2, N=100) = 60.56, p$ Regarding the level of autonomy

that was allowed during the interaction, both groups showed low levels (see Fig. 2): G1, ($M = 1.89$, $SD = .81$); G2, ($M = 2.11$, $SD = .88$). In addition, differences approached significance when comparing level of autonomy between G1 and G2, $t(198) = 1.82$, $p = .07$. The findings of the present study reveal the type of cognitive processes that were supported by the teachers. We found no differences between the two educational levels. However, as we can see (Fig. 1) most of the instructional aids were related to the mathematical information, whereas metacognitive and situational information received far less instructional aids. On the other hand we found differences regarding the level of autonomy assumed by the teachers and students. Despite both educational levels showed low levels, G2 allowed a higher level of autonomy.

Educative implications

Knowing what teachers usually do in their classrooms in their interaction with children is important because it will allow us to make proposals for change or enrichment for teachers' instructional practices, that being not very remote of which already it is being made, could be integrated in their daily activities.

Peer writings as modeling examples and instructional support in writing

Olga Firssova, Open University of the Netherlands, Netherlands; Monique Bijker, Open University the Netherlands, Netherlands; Saskia Brand-Gruwel, Open University, Netherlands; Els Boshuizen, Open University, Netherlands

As demonstrated in research in different cognitive domains, instruction based on modeling examples stimulates cognitive modeling of task solution and development of own strategies of tackling complex tasks. The aim of this study is to examine how instructional support designed according to principles of cognitive modeling and example-based learning affects the quality of writing produced by advanced level university students. A selection of peer writings accompanied by expert explanations and elicitations that focus attention on the salient text aspects is used as modeling examples of expected task performance. These examples are analysed by students prior to engaging in a complex writing task. We expect this learning activity to positively affect the way students engage in writing and the quality of produced writings. The study is based on between-groups control group design and is embedded in a ongoing masters' programme. Results are expected in the spring of 2011.

Performing complex tasks, such as writing academic papers, articles and theses is known to present a challenge for university students in spite of years of training and practice in writing at school and undergraduate level (Castelló, Ióesta, & Monereo, 2009, Torrance, Thomas & Robbins, 1994). University practice, particularly at advanced levels, is based on the 'tried and true' method of learning by doing, in this case by writing as the prevailing form of the writing skill development (Kellogg, 2008). Available case studies and descriptions of incidents of practice, evidence from research studies indicate that instructional support with a modeling component as an exposure to expert writing strategies with a subsequent discussion, or a training in generative 'getting started' activities, is both needed and appreciated (Rijlaarsdam, 2003; Torrance, Thomas & Robbins, 1993). The aim of this study is to determine the effects of instructional support for writing for graduate level students that is based on the principles of example-based learning and cognitive modeling (Van Merriënboer & Kirschner, 2007). Example-based research conducted in a variety of domains and at different expertise levels convincingly demonstrates that eliciting the process of task solution supports active processing of new knowledge and fosters task performance (Atkinson, Derry, Renkl, & Wortham, 2000, Van Gog, Paas & Van Merriënboer, 2004). Instruction based on worked or modeling examples (i.e., examples with process of task solution information) stimulates cognitive modeling of task solution and development of own strategies of tackling complex tasks (Van Merriënboer & Kirschner, 2007). In theory, available 'good practice' examples of peer work can serve as modeling examples of task performance as they demonstrate a range of possibilities of reaching the task goals within the learner's zone of proximal development. Analyzing a set of such examples will help the learner to get grip of the underlying task model, affecting activities the learner will engage in performing the task and the task performance. However, such examples do not make the process of decision-making explicit, this information will have to be inferred from the text or to be provided. As demonstrated in studies of learning argumentation, information given in the modeling text-based examples is better processed by learners when such examples are accompanied by elicitations that focus attention on particular aspects of the text or steps in the argumentation building process (Schworn & Renkl, 2007). The presented study addresses the question how analyzing examples based on peer work affects performing complex writing tasks and the quality of task performance, i.e. the produced writing. We hypothesise that analyzing peer writings accompanied by elicitations and explanatory information is a good starting point in performing a complex writing task, a better form of preparation for complex writing tasks than learning by writing alone. In the presented study this hypothesis is tested in the real settings of an advanced level university course in which students perform a series of a complex writing tasks.

Method

Participants Participants are graduate students in Educational Sciences with a professional teacher education background. Females prevail (75%) and the age range is 30-55 years. All students enrolled a selected core curriculum course of 4, 3 EC in 2010-2011 academic year are included in the sample (target n = 75).

Materials and procedure

A between-groups control group design with counterbalanced treatments is used, with the independent variable (type of task) at three levels: a preparatory conventional writing task (control condition), an example-based preparatory task with explanatory teacher comments embedded in the text and an example-based task without comments. Selection of examples and teacher explanations are provided by a teacher expert. Participants in the two experimental conditions analyse two pieces of peer writing either accompanied by elicitations and explanatory remarks or only labelled as good practice examples. The control group performs a preparatory writing task of approximately the same study load. Upon completion of the preparatory task all participants perform two writing tasks in the same genre as the studied examples. Participants will provide an indication of knowledge of the task topic, an estimate of time invested in preparation of the topic and the writing task and of the task difficulty (control variables). Effectiveness of this form of support will be measured through the quality of produced texts (the quality of task performance) based on the Structure of Observed Learning Outcomes (SOLO) taxonomy (Biggs & Collis, 1992). Construct validity of the SOLO-based quality scale will be tested in the RASCH model (Bond & Fox, 2001). The effect of the intervention on task performance will be measured by analysis of variance (one-way ANOVA). Repeated measures ANOVA will be used to examine development over time. Results are expected in the spring of 2011.

Teachers, Children and Picture Books: Teaching and Learning in a Visual Age

Petros Panaou, University of Nicosia, Cyprus; Charalambos Vrasidas, CARDET - University of Nicosia, Cyprus

The European Picture Book Collection II project has been an effort to join the European and international community of scholars, authors, educators, and librarians who believe that what happens in one language and literature can no longer be studied and taught in isolation from the rest of Europe and the world. For the purposes of EPBC II, educators and students approached literary texts from various EU states, bringing them into dialogue with each other, and exploring their cultural backgrounds with a particular focus on the role of visuals. Participants discussed the diverse stories within the collection in a comparative manner, identifying similarities and differences, and pondering on issues of difference, identity, and diversity. The pictorial part of the stories was expected to facilitate intercultural communication. The paper evaluates and analyzes the results of the pilots and implementation of this European project in seven different EU countries (Austria, Cyprus, Estonia, Greece, UK, Poland, and Romania).

The European Picture Book Collection II project has been an effort to join the European and international community of scholars, authors, educators, and librarians who believe that what happens in one language and literature can no longer be studied and taught in isolation from the rest of Europe and the world. The first European Picture Book Collection (EPBC) was created by European scholars and educators working in the fields of children's literature and teacher education, and purported to bring to children across Europe at least one picture book from each member

state of the European Union. In 1997, EPBC received the award of "Innovative Reading Promotion in Europe" from the European Committee of the International Reading Association. EPBC II is a project that built on and extended the logic and scope of the original EPBC. A Comenius Multilateral project initiated in 2009, it resulted in the compilation of a new collection of picture books and the development of accompanying educational material. EPBC II addressed three educational areas (second language learning, literature, and culture) so that each area increased the learning motivation and opportunities in the other two. Because the entire process was conducted via attractive visual stories and enhanced educational technology (www.epbcii.org), students were expected to view literature, multiculturalism, and second language learning in a more positive manner. For the purposes of EPBC II, educators and students approached literary texts from various EU states, bringing them into dialogue with each other, and exploring their cultural backgrounds. Participants discussed the diverse stories within the collection in a comparative manner, identifying similarities and differences, and pondering on issues of difference, identity, and diversity. The pictorial part of the stories was expected to facilitate intercultural communication. Picture books, through their dynamic combination of image and text, were also considered as ideal for second language learning. The power of stories was viewed as a powerful motive for second language acquisition. Teachers implemented pedagogical tools that encouraged children to observe and analyze each language and the way it is written, read and structured, in relation to other languages. Innovative ICT tools were developed in order to make use of the picture books' visual nature, turning them into e-books and enabling interactive activities that were expected to bring the e-books in dialogue with each other and engage students in comparative processes. For the purpose of implementing the project, students were introduced to several new foreign languages and/or developed their knowledge of languages they were already familiar with. Through comparative and creative approaches, they were expected to develop positive attitude and basic linguistic and metalinguistic skills, especially in reading and comprehending texts written in their birth languages as well as in foreign languages. Since all educational activities were built around literary texts (European picture books) more emphasis was placed on reading and writing skills, without excluding, of course, the two other basic skills (listening and speaking). Students read engaging visual stories in an interactive environment, and, through comparative and creative approaches, were expected to identify and explore different genres, their characteristics and building blocks. Learning to "read the picture" and interpret the gap between word and image was also central. Finally, students explored the manners in which cultures are reflected in stories and engaged in comparative and creative activities that were expected to encourage them to celebrate pluralism. Equal emphasis was placed on extending their knowledge around specific areas of diverse European cultures (art, history, religion, geography, tradition, etc.). The paper evaluates and analyzes the results of the EPBC II piloting and implementation in seven different EU countries (Austria, Cyprus, Estonia, Greece, UK, Poland, and Romania). The questions guiding the research reported here were:- To what extent were the educational objectives achieved? - What were the strengths and weaknesses of using picture books in teaching and learning? - Which were the most effective teaching practices with regards to the use of picture books in teaching and learning? Qualitative methods of data collection and analysis--such as tools that evaluated the achievement of learning objectives, reflection journals by teachers, interviews of students, and focus group discussions--are used to answer the above-mentioned questions. In addition, experts reviewed the picture books that were used and rated the books according to criteria which were derived from the findings of this research. The conclusions guide future research and educational practice towards a specific direction.

Epistemic Cognition and Multiple-Documents Literacy: An Intervention Study

Leila Eve Ferguson, University of Oslo, Norway; Ivar Braten, University of Oslo, Norway; Oistein Anmarkrud, Department of Educational Research, Norway; Helge Stromso, University of Oslo, Norway

While it can be expected on the basis of theory and correlational studies that more advanced epistemic cognition, for example realizing that diverse sources must be compared to check knowledge claims, may facilitate multiple-documents literacy, there is no experimental evidence to support this view. We therefore designed an intervention where students read multiple documents presenting opposing views on a social-scientific issue and examined possible changes in their epistemic cognition after reading, as well as the relationship between those changes and multiple-documents comprehension. Given the working memory demands of the complex reading task, we also entertained the possibility that the effects of the intervention might depend on students' working memory capacity. Preliminary results from a pilot study involving four 10th graders suggest that the intervention may be effective in changing epistemic cognition. However, whereas the participants changed in the direction of what seemed to be more adaptive beliefs concerning justification for knowing, they, at the same time, seemed to change their beliefs about the stability of knowledge in the direction of what has traditionally been considered more naïve beliefs. Because a control condition was not included in the pilot study, it was not possible to explore whether observed changes in epistemic changes were unique to the intervention condition or whether such changes were associated with good performance on the comprehension measures relative to controls. A complete data set for 140 participants randomly assigned to intervention and control conditions is under collection and analyses of those data are presented at the conference.

Aims

To examine whether a short-term intervention targeting epistemic cognition may promote multiple-documents literacy and, moreover, whether any intervention effects may be moderated by working memory capacity.

Theoretical framework

In today's information society, multiple documents-literacy, that is, the ability to locate, evaluate, and use diverse sources of information for the purpose of constructing and communicating an integrated, meaningful representation of a particular issue, subject, or situation (Bråten & Strömsö, 2010), is required both in and out of school. When faced with literacy tasks that involve using multiple information sources to solve problems or understand complex issues of personal, social, or educational relevance, people have to make judgements regarding what counts as knowledge, the nature of that knowledge, and how to justify knowledge claims, with the term epistemic cognition used to describe such judgements in current literature (e.g., Greene, et al., 2008). It can therefore be expected that more advanced epistemic cognition, for example, realizing that diverse sources must be compared to check knowledge claims or judging knowledge to be tentative and fallible, may facilitate multiple-documents literacy (Bråten et al., in press). Thus far, however, experimental evidence to support this view is essentially lacking. Still, a few studies (Kienhues et al., 2008, in press; Valanides & Angeli, 2005) suggest that even brief encounters with multiple information sources on an ill-structured topic may further the development of more adaptive epistemic cognition. In the present study, we built on those studies and designed an intervention where students read multiple documents presenting opposing views on a social-scientific issue and examined possible changes in their epistemic cognition after reading, as well as the relationship between those changes and multiple-documents comprehension. Given the considerable working memory demands of the complex reading task, we also entertained the possibility that the effects of the intervention might depend on students' working memory capacity.

Methodology

Participants were 140 10th-grade students from four lower-secondary schools in southeast Norway. Before reading, all students' domain- and topic-specific epistemic cognition was assessed, as well as their working memory and knowledge about the topic of the documents. The domain-specific measure of epistemic cognition focused on beliefs about the justification of knowledge claims in science (Greene et al., 2008), and the topic-specific measure of epistemic cognition focused on the stability of knowledge concerning the issue discussed in the documents (Kienhues et al., in press).

Those in the intervention condition read five authentic documents providing conflicting information on the effects of sun exposure for the purpose of giving a presentation on "How sun exposure affects our health." The first document was a neutral, informative text about UV-index and -radiation, whereas two of the documents presented the view that sunrays may protect against cancer and two of the documents presented the view that sunrays may cause cancer. For the participants in the control condition, two of the documents were modified so that they only encountered the viewpoint that sunrays may cause cancer but still encountered the same concepts as those in the intervention group. Participants were randomly assigned to condition and all read the five documents on a computer using the software Read&Answer (Vidal-Abarca et al., in press).

After reading, all participants were again administered the epistemic cognition measures and the knowledge measure. In addition, multiple-documents comprehension was assessed by means of a coherence measure capturing the perceived relatedness of concepts across documents (Ozgungor & Guthrie, 2004) and short-essay, integrative questions capturing the integration of ideas across documents (Rukavina & Daneman, 1996).

Preliminary results and conclusion

The results of four female 10th graders who participated in a pilot study indicated that three of the students changed their domain-specific epistemic cognition concerning the justification of knowledge claims after the intervention, with three of the students putting more emphasis on the need to justify knowledge claims in science by considering multiple sources of information (on a 10-point scale, pre-tests scores were 7.2, 4.5, and 6.0, respectively; post-test-scores were 9.2, 10.0, and 7.7, respectively) and one of the students viewing external authority as a less reliable source for justifying knowledge claims (on a 10-point scale, pre-test score was 7.5: post-test score was 5.8). Three of the students also changed their topic-specific epistemic cognition after the intervention, surprisingly viewing knowledge about the issue to be more certain than before (on a 10-point scale, pre-tests scores were 5.0, 3.1, and 6.9, respectively; post-test-scores were 6.9, 5.0, and 8.4, respectively). Thus, whereas the participants changed their personal epistemology in the direction of what seem to be more adaptive beliefs concerning justification for knowing, they, at the same time, seemed to change their beliefs about the stability of knowledge in the direction of what has traditionally been considered more naïve beliefs. Because the control condition was not included in the pilot study, it

was not possible to explore whether observed changes in epistemic changes were unique to the intervention condition or whether such changes were associated with knowledge gain and good performance on the comprehension measures relative to controls. A complete data set for all 140 participants is under collection at this time point and analyses of the data set that address those issues will be presented at the conference.

THEMATIC POSTER SESSION

Learning and Instructional Technology

Piloting electronic peer-assisted learning with multicultural university students

Cheryl Foxcroft, Nelson Mandela Metropolitan University, South Africa; Liesl Smith, Nelson Mandela Metropolitan University, South Africa; Celeste Barker, Nelson Mandela Metropolitan University, South Africa

Nelson Mandela Metropolitan University (NMMU) has prioritised peer assisted learning as a key strategy to improve the success and graduation rates of its culturally diverse student body. In addition to strengthening existing peer assisted programmes (Supplemental Instruction, tutorials, mentoring), a pilot Electronic Peer Assisted Learning (e-PAL) project was implemented in 2010. e-PAL involves the use of senior students trained as e-PAL facilitators to electronically facilitate learning and learning support, which is embedded in and accessible to all students in a module. e-PAL facilitators work closely with lecturers and professional support staff. Two factors necessitated the introduction of e-PAL. Firstly, most NMMU students are Y-generation learners who want information instantly and use technology extensively to network and communicate. e-PAL involves a blended learning strategy, which combines traditional and technology-enabled learning opportunities. Secondly, traditional peer assisted learning cannot reach all students due to timetable constraints and clashes and the availability of small group lecture venues. e-PAL is less constrained by the timetable as the group can be facilitated at any time that is convenient and students only need access to the internet. The work of theorists that focus on Social Interdependence Theory (e.g., Geertz, Vygotsky, Bakhtin, Doyle, and Erickson) and research conducted on Y-Generation learners, blended learning and peer-assisted learning informed the conceptualisation of e-PAL. The pilot project has been continuously evaluated by gathering qualitative and quantitative data including pass rates, contact data, records of facilitated sessions, student survey feedback, and facilitator online feedback. The findings and lessons learned will be discussed.

South African student success and graduation rates are a source of concern and the Department of Higher Education and Training has tasked higher education institutions to implement improvement strategies. Of the 25 500 student that The Nelson Mandela Metropolitan University (NMMU) enrolls, only 50% finally graduate and 25% graduate in the minimum time period. NMMU has thus prioritised peer assisted learning as a key strategy to address the differential success rates of its culturally diverse student body and improve graduation rates. With its roots in Social Interdependence Theory, peer assisted learning's positive impact on knowledge construction, cognitive development and the stimulation of independent learning has been researched by numerous theorists including Geertz, Vygotsky,

Bakhtin, Doyle, and Erickson. Other advantages include: a. Learning activities are facilitated in such a way that students are actively and collaboratively engaged in learning. b. As students are placed in small groups in SI and mentorship programmes, and sometimes in tutorials and laboratory practicals, they develop a sense of community in this smaller group, which complements the more impersonal large group lectures. c. Students learn to take increasing responsibility for their own learning and learn how to learn. d. The peer facilitators (normally senior students) learn how to facilitate learning; how learning takes place, which enhances their own learning; what resources are available to enhance learning while they also develop their communication, presentation, leadership and interpersonal skills and become more confident and self-assured when working with groups. e. Peer facilitators can be used in medium- to large-sized lectures to assist lecturers to employ small group and active learning strategies that engage students in active and collaborative learning. Internationally, many of the leading teaching and learning universities use peer facilitators to achieve more favourable lecturer/student ratios, which have a positive impact on student success and their learning experience. In addition to existing peer assisted programmes (Supplemental Instruction, tutorials, mentoring) at NMMU, a pilot Electronic Peer Assisted Learning (e-PAL) project was implemented in August 2010 in 8 modules. 9 e-PAL Facilitators each offered a 2-hour session once a week where students could get additional support online with regards to the learning material covered in lectures during that week. The overall strategic objective of NMMU's Electronic Peer-Assisted Learning Project (e-PAL) is to implement an expanded project in which learning support is embedded in a module, accessible to all students, and facilitated electronically by trained e-PAL facilitators working closely with lecturers and professional support staff acting as e-PAL coordinators in order to enhance student retention and success. Two factors necessitated the introduction of e-PAL. Firstly, most NMMU students are Y-generation learners who want information instantly and use technology extensively to network and communicate. e-PAL supports a blended learning strategy, which combines traditional and technology-enabled learning opportunities (Bersin:2003; Tarrison:2004). Secondly, traditional peer assisted learning cannot reach all students due to constraints such as timeslots available on timetables, timetable clashes, and available small group lecture venues. e-PAL is less constrained by the timetable as the group can be facilitated at any time that is convenient and students only need access to the internet. Research conducted on Y-Generation learners indicates that they are most influenced by their peers and that they find more interactive learning environments less intimidating (McCrindle and Wolfinger:2010; Coates:2007; Weiler:2004; Christie:2004). This supports the NMMU notion of creating an interactive peer learning environment that incorporates the Y-generation learner's need for visual stimulation and preference for electronic communication. Furthermore, the decision to design a structured facilitated programme was based on research that has shown that instead of simply placing learning support material online, it is much more effective to have an online PAL facilitator who can facilitate learning through intentionally structured e-tivities (Salmon:2003). Supplemental Instruction statistics have shown that most peer-assisted learning programmes cannot function as a once off "quick-fix" before tests and exams. Comparative analysis on students with similar entry profiles has shown that students who attend sessions regularly throughout the semester are more likely to improve their academic performance, whereas those who only attended once or twice have shown little or no improvement. The e-PAL project is also aligned to NMMU's recently approved Vision 2020 Strategic Planning Framework that has been operationalised in terms of eight strategic priorities. One of the key strategic priorities related to NMMU's core academic functions is to create and sustain a responsive learning environment conducive to excellence in teaching and learning and fostering holistic student success. Among the various strategic goals and objectives identified to address this strategic priority the e-PAL project is aligned to the following: a. Setting high expectations for student success while also providing high support. (ePAL offered an additional 220 hours of support in the 5 month pilot project in 2010) b. Expanding the use of active and collaborative learning strategies to engage students more actively in learning. (e-PAL complements face-to-face peer facilitated sessions) c. Significantly expanding the use of electronic/blended learning so that this becomes an integral part of how learning is facilitated at NMMU. (e-PAL is easy to use and therefore an ideal way to introduce students to an online learning environment) d. Providing complementary learning experiences outside of the classroom to develop students holistically. (Students can access e-PAL from any location as long as they have access to the internet) The pilot project has been continuously evaluated by gathering qualitative and quantitative data including pass rates, contact data, records of facilitated sessions, student survey feedback, and facilitator online feedback. Preliminary findings are that 526 students registered voluntarily on the 8 module sites to access the sessions and learning material. An estimated 2100 students are registered in these 8 modules, 25% of whom made use of e-PAL. Research indicates that a third of learners might participate in voluntary programmes. 25% is thus fair attendance considering that e-PAL has been running for two months. Online questionnaires conducted in September 2010 indicated that 85% of participants enjoyed the e-PAL environment and found it interesting, whilst 100% of participants found the platform easy to use. Findings and lessons learnt will be discussed.

Writing Wiki-Articles as Follow-Up Course Work: How can we support our Students?

Tatjana Hilbert, University of Mainz, Germany

The Wiki-technology enables Internet users to not only read contents but also to edit existing articles and to write about new topics. In a recent study, students from six university courses (N = 167) were advised to use a Wiki in a virtual learning platform for follow-up course-work. All students had to write at least one article about a topic discussed during the university course. Participants in two courses were only given technical support (n = 51). Two courses additionally were given a checklist on minimum standards for the articles (n = 59). In the remaining two courses, new articles additionally were read and discussed in the course (n = 57). The Wiki articles in each course were analysed according to their length, quality, and structuredness. Learning outcome was measured by a multiple choice test at the end of the semester. On the whole, the analysis showed that the quality of articles was better in courses where students discussed their fellow students' articles. Learning outcome was best for students in the minimum standards condition. For using the Wiki-technology for follow-up course work, results indicate that more support helps students to write high-quality articles. However, this may not lead to a good learning outcome.

Apprentices' and supervisors' perceptions of a paper vs mobile and online tool for learning journals

Jessica Dehler Zufferey, University of Fribourg, Switzerland; Laetitia Mauroux, University of Fribourg, Switzerland; Jean-Luc Gurtner, Dept of education, Switzerland

Learning journals (LJ) are used more and more in educational research and practice. They support reflection and articulation of experiences, knowledge and performances. Despite their high potential for vocational education and training (VET), they have only started to be used in several professions in Switzerland, as all newer ordinances make a learning journal mandatory. We worked with baker and pastry cook apprentices since they will have to elaborate a learning journal from 2011 on. We developed a mobile and online tool as instrument of the learning journal for these apprentices. This study compares the mobile and online tool with a paper-based instrument in order to evaluate apprentices' experiences with both instruments. Two classes of apprentices used each one of the two learning journal instruments. We analyzed the ease of use and the usefulness attributed by apprentices and supervisors. Results indicate that apprentices do encounter problems of usability with both instruments. Nevertheless they identify potential usefulness of the learning journal, particularly when they use the mobile and online tool. Supervisors perceive the usefulness of the LJ somewhat differently than apprentices. The findings show that apprentices are not very much willing to use any learning journal. However, when they are forced to choose they prefer the technological version. Preferences of supervisors are less univocal.

Introduction

Learning journals (LJ) are becoming a reality for apprentices in VET in Switzerland. Recent ordinances stipulate the introduction of a LJ. Few specifications are prescribed on how to implement the LJ. Therefore, information about experiences with different implementations of LJs is necessary to inform decisions and shape emerging practices.

Learning journals

Learners use LJ to document their learning processes, outcomes, and progress by means of reflective texts, pictures, figures etc. LJs support the reflection on prior experiences and performance and help learners to recall important information. LJs are used in a multitude of educational contexts, for example in medical education (e.g., Driessen, et al., 2005). Research on LJs in vocational training is, however, rare and shows potentials as well as limitations (Kicken, Brand-Gruwel, van Merriënboer, & Slot, 2009). In the present project, a mobile and online tool (MOT; see Figure 1) was developed and tested which allows apprentices to collect pictures of workplace experiences by means of a mobile device and send them to an online repository and develop their LJ on the basis of the pictures. Specifically, the LJ provides text fields for reflection, self-evaluation, evaluation by the supervisor, comments from supervisors. Prompts in the text fields guide the reflection on learning achievements, learning needs and planning of next learning steps (adapted from Kicken et al., 2009). The current study compares the MOT (developed for a specific profession) with a paper instrument that is proposed to all professions in Switzerland (SDBB, 2009). The paper instrument is a two-pages form with four categories for apprentices' notes (description of work process, remarks, sketches/photos, and competences).

Context

Participants were baker and pastry cook apprentices and their supervisors within the Swiss dual VET system. Apprentices in this field already have to create a recipe book and the new ordinance will include as of 2011 a LJ. The MOT we developed for this profession includes both the recipe book and the LJ.

Research questions

This study adopted the technology acceptance model (Davis, 1989) which states that perceived ease of use and perceived usefulness influence whether or not an instrument will actually be accepted and used. Our research questions are:

1. How do apprentices and supervisors perceive the ease of use of the two instruments?
2. How do apprentices and supervisors perceive the usefulness of the two instruments?
3. Would apprentices and supervisors intend to use the two instruments?
4. Which LJ instrument would apprentices and supervisors prefer to use?

Method

Design and sample. One class (16 apprentices and supervisors) used the paper LJ while a second class (8 apprentices and supervisors) used the MOT.

Measures. Apprentices and supervisors filled in a questionnaire which measured the:

- o perceived ease of use (6 items) (6 items, see Davis, 1989),
- o perceived usefulness for their learning (11 items; e.g., "The learning journal helps to collect and document experiences from the workplace."),
- o intention to use the instrument (1 item)
- o preference (1 item: "If I had to elaborate a learning journal like the apprentices from 2011 on, I would prefer to use ..." with the response options "paper version" and "technological version").

All items except the preference item were rated on a 7-point Likert scale from -3 ("I do not at all agree") to +3 ("I totally agree").

Procedure. The pedagogical rationale and the functionality of the LJ instruments were introduced to apprentices and their supervisors. For the six-week long test phase, apprentices were instructed to document their experiences for at least six recipes with the respective LJ instrument. At the end of the test phase, a debriefing (via questionnaires and plenary discussion) session was organized.

Results

Due to the small and unbalanced sample sizes, we present the quantitative data in a descriptive rather than inferential way.

Perceived ease of use. Overall, apprentices did not perceive any of the instruments to be easy to use. This was found for the MOT ($M=0.00$, $SD=1.59$) as well as the paper LJ ($M=0.65$, $SD=1.51$). Overall ratings from supervisors (who were less actively involved in the use of the LJ than apprentices) were higher as well in the MOT condition ($M=0.90$, $SD=0.92$) as in the paper condition ($M=1.46$, $SD=1.47$).

Perceived usefulness. Apprentices evaluated the usefulness of the LJ for their learning as moderately positive. The overall score in the MOT condition ($M=1.81$, $SD=0.83$) was slightly higher than in the paper condition ($M=1.30$, $SD=1.33$) as were all items separately. In contrast, supervisors rated the usefulness of the LJ higher in the paper condition ($M=2.51$, $SD=0.41$) than in the MOT condition ($M=1.91$, $SD=0.62$). Interestingly, supervisors overall rated the usefulness of a LJ higher than apprentices.

Intention to use and preference. Apprentices in the paper condition reported that they would rather not use the instrument if they had the opportunity ($M=-0.94$, $SD=2.21$) while apprentices using the MOT were slightly more positive about its usage ($M=0.38$, $SD=1.85$). Supervisors expressed an intention to use the LJ to a comparable extent in the MOT ($M=0.50$, $SD=0.55$) and in the paper condition ($M=0.67$, $SD=2.34$).

Ongoing analyses on different process and outcome variables (such as the content of LJ or supervisors' comments on their apprentices' LJ) complement these results and will be presented at the conference.

Personal Learning Environments for Networked Adult Learners in Work-Based Context

Erika Tanhua-Piironen, University of Tampere, Finland; Johanna Sommers-Piironen, University of Tampere, Finland

New social software applications have changed the way people are communicating, participating and working in various informal and formal contexts. Networked learning has expanded and the working life requires employees to continuously update their competences. Lifelong learning is an important but challenging part of the professional development. One promising approach is the idea of Personal Learning Environments (PLE). The main focus of the concept is on the learners' control and management of their own learning. Another concept in this study is a model of a networked adult learner in workplace. This will be further developed and tested during the ongoing research.

The study is based on design research, which is carried out in educational corporate life context. It consists of pilot cases in which social software applications are chosen and introduced to traditional personnel training programs. The data is collected by questionnaires, interviews and monitoring the learning activities of the pilot groups in the chosen social software environments. The design process itself is also in focus and reflections concerning this process constitute a part of the data. The first tentative findings about design process and the initialization of social software show that the instructor has a significant role in the process: in implementing new ways of learning and knowledge sharing with social software and in encouraging learners to take control of their learning.

Introduction

New technologies, including wikis, blogs, social networking and media sharing tools have changed the way people are communicating, participating and working in various informal and formal contexts. Networked learning has expanded and adult learning is strongly moving from classrooms to open learning environments and networks. Furthermore, the working life requires employees to continuously update their competences, making lifelong learning an important but challenging part of professional development. A promising approach to smoothly connect learning and working is the idea of Personal Learning Environments (PLE).

Our aims are to find out how the concept of PLE can be applied to educational work-based contexts and to elaborate the idea of a networked working adult learner. This study belongs to a two-year research project, Future Space for Shared and Personal Learning (F-SHAPE), between two Finnish universities and participating companies. The project targets to design novel concepts for flexible learning to serve the needs of adult learners and working life in particular.

Framework

Although the definitions of Personal Learning Environment (PLE) have varied from the descriptions of technological solutions to more pedagogical approaches (Fiedler & Valjataga 2010), the main focus has constantly been on the learners' control and management of their own learning. As a new approach to the use of Web 2.0 technologies for shared and personal life-wide learning (Attwell 2007), PLEs can be described as interactive, collaborative and communicative spaces in which learning takes place and collective know-how is developed (Attwell 2010). The affordances of social software - connectivity and social rapport, collaborative information discovery and sharing or content creation and modification (McLoughlin & Lee 2007) - offer interesting potential for learning in the 21st century.

The features to consider when designing work-related learning environments (like the PLEs in this case) include among others support for individual reflection and social interaction, integration of theoretical knowledge with learners' practical experience - i.e. informal and formal learning - and tools for collaboration and knowledge exchange (Tynjälä & Hakkinen 2005). As the present and constantly changing working life requires shared expertise, knowledge management and diverse communicative skills as well, PLE appears to be a promising approach to the learning of working life context.

Another encouraging concept in this study is the model of the Networked Student (Drexler 2010) based on constructivism and connectivism. In that model social software and RSS technology are used to support knowledge exploring and construction, social connections, reflections and communication. Concerning a networked adult learner in workplace, this model needs to be further developed and tested.

Methodology

This study is based on design research which is characterized as iteratively developing theory and practice in close collaboration with the research subjects and contexts (Barab & Squire 2004). The empirical part is carried out in educational corporate life context. It consists of pilot cases in which social software applications are chosen and introduced to traditional personnel training programs. The data is collected by questionnaires, interviews and monitoring the learning activities and discussions of the pilot groups in the chosen social software environments. The design process itself is also in focus and reflections concerning this process constitute a part of the data.

Research tasks are focused on questions:

- How to design social software based learning activities in educational working life contexts?
- What kind of features of social software tools will prove useful for these purposes?
- What kind of challenges or barriers may appear when including new elements in traditional learning environments and how these barriers can be addressed?

With these research questions the model of the networked adult learner in working life context will be defined further. The first pilot case is a three-month training for the workplace instructors of apprenticeship students actualised in three groups of approximately 15 employees in financial and insurance business. The main interest is in the use of social software to support discussion and sharing of experiences as well as peer scaffolding in disjointed working groups. The second pilot case is a fifteen-month expert training for 15 specialists in insurance business with the focus on individual and collective reflection (blogs and chat), shared expertise and collaborative content creation (wikis).

Findings

As the first pilot training started in October 2010, solely tentative findings about design process itself and the initialization of social software are described here. Some challenges both in the designing and implementing of new learning environments can be already observed. First of all, the instructors have stated the importance of accurate planning when designing learning activities with Web 2.0-tools. Secondly, both the learners and the instructors need pedagogical and technological scaffolding and guidance with these new learning tools even though some of those are already familiar from informal contexts. Similarly, motivational aspects and additional value of the participation in the learning communities need to be considered because of learners' competing duties and interests. In conclusion, it seems obvious that the instructor has a significant role in implementing new ways of learning and knowledge sharing with social software and in encouraging working learners to take control of their learning.

Possibilities of social media in HE guidance

Sakari Saukkonen, University of Jyväskylä, Finland; Jaana Kettunen, University of Jyväskylä, Finland; Liisi Suurnakki, University of Jyväskylä, Finland; Liisi Suurnakki, University of Jyväskylä, Finland

Several innovations have emerged to supplement traditional guidance practice. One such innovation is the use of ICT in HE guidance. The usage of social media in guidance may improve learning outcomes as learning is a collaborative and collective construction of new knowledge on the basis of past experience and current understanding. In this presentation we give an overview of the research project Social media in Higher Education guidance. In the beginning we supposed that 1) social media is may not yet be extensively used by HE organizations, 2) the HE students are probably quite skilful users of net and they spontaneously use quite a wide range of different social media

applications, and 3) not all potentials of social media and/or web 2.0 applications are put in good use in HE guidance. Our preliminary findings are: 1) Finnish HE institutions are using the Internet in guidance in a very traditional fashion – social media applications are not widely used, 2) Student's every day technology practices may not be directly applicable to academic tasks – the Internet is seen as a place of entertainment and personal communication, and 3) From the students' point of view studying, learning, academic advising and guidance are mostly separated from the net. Empirically we are going to gather more survey data of the use of the Internet in HE guidance. Theoretically we need to understand more profoundly the nature of both study and career guidance in HE in order to evaluate the true potentials and benefits of social media.

Study counselling and guidance in Higher Education (HE) generally involves face-to-face interaction and additional interaction through telephone, letters, emails or the Internet. Traditionally most important of all has been the one-to-one interaction between a study counsellor and HE student. Decision making, and a student's direction and progress towards learning and professional goals play a crucial role in the development of individual identity and purpose, as well as positive self-esteem and interpersonal functioning. EU Council resolution on integrating guidance to lifelong learning strategies 21.11.2008 emphasizes how citizens' lives are increasingly characterized by multiple transitions: one of them being from higher education to employment. Guidance plays a decisive role in the major decisions individuals have to take throughout their lives. In this respect, it can contribute to empowering individuals to manage their own career paths in a more secure way, and to achieve a better balance between their personal and professional lives. Several innovations have emerged to supplement traditional guidance practice (Vuorinen 2006). One such innovation is the use of Information and Communication Technology (ICT) in HE guidance. Beginning with access to traditional study and career information, ICT in guidance has evolved to include a wide variety of information sources as well as facilitating interaction among clients and guidance professionals. Watts (2002) identifies four phases in the general development of ICT in guidance: 1) the mainframe phase (1960 to late 1970s), 2) the microcomputer phase (1980s to mid-1990s), 3) the web phase (1990s to early 2000s) and 4) the current digital phase. He also identifies trends that can be seen across the phases: increased accessibility, increased interactivity, and more diffused origination - the trend towards more diverse content creating.

Social media is one of the most promising features of ICT in guidance. The usage of social media in guidance may improve learning outcomes as learning is a collaborative and collective construction of new knowledge on the basis of past experience and current understanding. Social media can facilitate a shift from traditional, individually centered teaching to collective learning of shared understanding (Wells & Ball, 2008). ICT and social media especially may also be helpful in learning from peers, sharing information, and reaching towards different communities inside & outside HE. Web 2.0 has not yet been recognized by institutional actors while the users of web, including many HE students are moving towards web 3.0. The rich connectionism is probably just starting to change the way we communicate and use the web in our social life and also in the use of different services, like career guidance services in HE. Recent report by UK Commission for Employment and Skills reveals that nowadays the Internet is still generally used with the same scheme as in the use of previous printed materials (UKCES 2010). The Internet adds value especially in obtaining educational and labour market information. However the Internet is not used to support transition learning.

According to Vuorinen (2006), effectiveness in the use of the Internet is likely to be improved by providing professional support for users who need it, by systematically integrating web-sites to existing services, by ongoing re-evaluation of standards of practice, by awareness of ethical issues and standards in designing services and by conducting research and evaluation to appropriately guide the evolution of Internet-based career resources and services (see also Sampson 2002).

Our aim is to give an overview of the research project "Social media in Higher Education guidance" which is part of the ESF-funded project "Development of Guidance and Generic Skills in Higher Education" conducted at the University of Jyväskylä, Finland. At the beginning of the project our working hypothesis was that Internet-based guidance environments will play a significant role on HE students study and career guidance. One reason for this assumption has been the growing popularity of social media solutions and applications. In the beginning of the project we supposed that 1) social media may not yet be extensively used by HE organizations, 2) the HE students are probably quite skilful users of the Internet and they spontaneously use quite a wide range of different social media applications, and 3) not all potentials of social media and/or web 2.0 applications are put in good use in HE guidance.

We have been gathering data by examining the current Internet-based guidance services in the Finnish HE field, by conducting a survey directed to a representative sample of Finnish first year HE students, and we have also gathered a small data from HE career guidance staff asking their opinions of the use and usefulness of social media.

In a nutshell our research findings so far are:

Finnish HE institutions are using the Internet in guidance in a very traditional fashion – social media applications are not widely used
Guidance services in the Internet are hard to find, and lack consistency in terms of concepts and service delivery logics
Student's every day technology practices may not be directly applicable to academic tasks – the Internet is seen as a place of entertainment and personal communication
Net communities (like Facebook) are for creating and maintaining personal relationships
From the students' point of view studying, learning, academic advising and guidance are mostly separated from the net
In Finland we have the technology and we have the generation who masters it but we seem to lack people who are willing to do "serious business" over the Internet - like collaborative learning or guidance & counselling

Empirically we are going to gather more survey data of the use of the Internet in HE guidance. Also some data analysis from past surveys is still continuing. Theoretically we need to understand more profoundly the nature of both study and career guidance in HE in order to evaluate the true potentials and benefits of social media. This requires also more extensive understanding of the different features of various social media applications used in HE guidance.

Relationships between students' eye-movements and online search strategies

Meng-Jung Tsai, National Taiwan University of Science & Technology, Taiwan; Fang-Ying Yang, National Taiwan Normal University, Taiwan; Meng-Lung Lai, National Chiayi University, Taiwan

In order to understand the cognitive process of students' learning via online information searching, this study aimed at examining the relationships between students' eye-movements and their online search strategies. A total of forty university students participated in an eye-tracking experiment in which they were asked to answer a multiple-choice question about causes of landslides before and after an online searching task. Students' perceived search strategies were evaluated by a self-reported instrument, The Online Information Searching Strategy Inventory (OISSI), right after the searching task. During the searching task, not only the computer screens were captured but also students' eye-movements were tracked by a FaceLAB eye-tracker with GazeTracker software. Seven indices were obtained from the OISSI: Control, Disorientation, Trial & Error, Problem Solving, Purposeful Thinking, Select Main Ideas and Evaluation, indicating the seven aspects of online search strategies that had been utilized by each subject in this task. As for students' eye-movements, five indices were coded for both relevant and irrelevant areas of interest (AOIs) defined in all of visited web pages. Therefore, a total of 10 eye-tracking indices (5 for relevant AOIs and 5 for irrelevant AOIs) were coded for each subject. The five eye-tracking indices included average fixation numbers, average fixation durations, average regression numbers, average fixation frequency and total reading time. Correlation coefficients between the 7 search-strategy indices and the 10 eye-tracking indices were analyzed to examine their interrelationships. The preliminary results showed significant correlates existed between the two variables and will be presented in details at the conference.

Relationships between students' eye-movements and online search strategies

Purpose

Providing information about human's minds, eye-tracking experiments have been widely used in research about reading (Rayner, 1998) and human-computer interactions (Radach & Kennedy, 2004). Recently, researchers have attempted to use eye-tracking technology to explore students' learning in technology enhanced learning environments. Related research include using eye-tracking technology to analyze the process of multimedia learning

(van Gog & Scheiter, 2010), to examine the multimedia effects on conceptual learning (She & Chen, 2009; Cook, Wiebe & Carter, 2008), to explore computer game learning experience (Alkan & Cagiltay, 2007) and to investigate how graphic overviews facilitate or hinder hypertext comprehensions (Salmeron, Baccino, Canas, Madrid & Fajardo, 2009). Some pilot studies have attempted to explore how users read online information (Larigo, Pan, Hembrooke, Joachims, Granka & Gay, 2008; Matrai, Kosztyn & Sik-Lanyi, 2008). However, little study has been looking deeply into how students construct knowledge via Internet-based learning, especially how they select and interact with the huge amount of information provided on the Internet. In order to understand the cognitive process of students' learning via the Internet, this study aimed at examining the relationships between students' eye-movements and their online information search strategies by conducting an eye-tracking experiment with an online searching task.

Methodology

A total of sixty university students participated in an eye-tracking experiment in which they were asked to perform an online search task about "landslides." The subjects were randomly selected from three colleges of different domain expertise including social science, natural science and engineering backgrounds. Before and after the search task, students were prompted to answer a multiple-choice question about the causes of landslides. The material used for the multiple-choice question was an image with four pictures demonstrating four different contexts of relevant and irrelevant environmental conditions, for example, temperature and rainfall etc. During the search task, students' eye-movements with the computer screens were all tracked and captured by a FaceLAB 4.5 eye-tracker with GazeTracker 8.0 software. For each subject, it took about thirty to forty minutes to finish the whole search task including the calibrations and question answering. Right after the experiment, each subject was asked to answer a questionnaire including The Online Information Searching Strategy Inventory (OISSI) (Tsai, 2009) in order to collect data about students' perceived strategies for online information processing. A total of 54 subjects who successfully passed the calibrations and had completely collected data were included for data analyses in this study. A correlation analysis was used to examine the relationships between students' eye-tracking indices and search strategy indices. Seven indices obtained from the OISSI scale indicate students' Control, Disorientation, Trial & Error, Problem Solving, Purposeful Thinking, Select Main Ideas and Evaluation aspects of strategies perceived by students to use in the task. As for students' eye-movements, five indices were coded for both relevant and irrelevant areas of interest (AOIs) which had been defined in all visited web pages for each subject based on the screen-captured videos. Therefore, a total of 10 eye-tracking indices (5 for relevant AOIs and 5 for irrelevant AOIs) were coded for each subject. The five eye-tracking indices included average fixation numbers, average fixation durations, average regression numbers, average fixation frequencies and total reading time (Rayner, 1998; Radach & Kennedy, 2004). Correlation coefficients between the 7 strategy indices and the 10 eye-tracking indices were analyzed to examine the correlates.

Findings and Significances

A preliminary result showed that there were some significant correlations between the two sets of indices: OISSI indices and Eye-Tracking indices. This means that there was an intimate relationship between students' visual attentions and their online information search strategies. Since the search task in this study served as an opportunity for students to reconfirm or modify their prior knowledge, the search strategies assessed in this study in fact represented students' cognitive strategies for constructing their knowledge via an interaction with the information provided on the Internet. Therefore, this study provided eye-tracking evidences for students' perceived cognitive strategies for Internet-based learning. In addition, the preliminary result also showed that students with different backgrounds paid different attentions to relevant and irrelevant online information, suggesting a further examination is needed for future study. In conclusion, results of this study not only help researchers further understand the cognitive process of Internet-based learning but also provide suggestions for the developments of future Internet-enhanced learning environments.

THEMATIC POSTER SESSION

Learning disabilities

Working memory, logical reasoning, calculi and reading

Beatriz Vargas Dorneles, Universidade Federal do Rio Grande do Sul, Brazil; Luciana Corso, Universidade Federal do Rio Grande do Sul, Brazil

This study describes the different components of working memory to explain variations in children's arithmetic and reading performance. It involved 49 Brazilian students, between 9 and 11 years old, attending public schools. The students completed tasks designed to assess the three components of working memory: central executive, phonological and visual-spatial. They were also assessed in arithmetic, oral reading and logical reasoning performance. The results show a correlation between reading performance and phonological (digit span) and the central executive (digit span backwards). No correlation was found between these components of working memory and calculi. Furthermore, no correlation was found between the visual-spatial task and reading performance or arithmetic performance. However a correlation was identified between the visual-spatial component and the inverse relation between addition and subtraction. As expected, a correlation was found between the arithmetic task and inverse relation between addition and subtraction as well as additive composition.

Our findings confirm that research results in this area are still inconclusive and controversial, highlighting the need for more investigation. One implication of this research for education concerns the importance of refining the relationships between the different components of working memory and the learning of reading and calculi in order to prevent at-risk students from developing problems. Similarly, we could tackle the cognitive obstacles that prevent learning by carefully selecting teaching resources, contents and teaching appropriate learning strategies.

The study of the cognitive processes underlying learning difficulties in mathematics and reading has expanded significantly in recent years. The different cognitive abilities underlying learning have been defined. The importance of working memory (WM) has been highlighted, especially through the WM research-based model proposed by Baddeley and Hitch (1974). It consists of three constantly interacting components: the central executive (CE) in the center of the model and phonological loop (PL) and visuo-spatial (VS) sketchpad on the periphery. Andersson and Lyxel (found difficulties in the CE in children with learning disabilities. They suggested that the deficit would be more restricted to the simultaneous processing and storage of verbal and numerical information in children with difficulties in mathematics only. When these difficulties were associated with reading the deficit would be centered on the processing and storage of numerical and visual information. Research into learning disabilities in mathematics and reading is moving towards a more detailed characterization of the cognitive abilities of these children. Another recently highlighted aspect concerns the role of logical development as a predictor of mathematical performance. The study by Nunes et al. (2007) shows that logical development is critical in predicting children's performance in mathematics. This study did not assess skills linked to reading. Based on this study we chose three logical relations from logical reasoning: the inverse relation between addition and subtraction (IRBAS); additive composition (AC) and one-to-many correspondence (OC). The present work describes the different components of WM and logical reasoning in order to explain variations in children's calculi and reading performance.

Method

This is a cross-sectional quantitative study involving 49 Brazilian students, between 9 and 11 years old, attending public schools, with an IQ above 82 (WISC, 1991). The children completed tasks designed to assess the three components of WM (PICKERING; GATHERCOLE, 2001). The TDE-School Performance Test (STEIN, 1994) was used to assess arithmetic performance. An instrument comprising regular (RW), irregular (IW) and non-words (NW) (SALLES,

2001) assessed oral reading. The logical reasoning was assessed using three groups of six tasks each involving the IRBAS; AC and OC adapted from Nunes et al. (2007). Intergroup differences were analyzed using the Spearman's correlation at a significance level of p

Results and Discussion

Table 1 presents the results of the correlations between arithmetic and reading performance and the cognitive skills

The correlation between WM measures, logical reasoning and reading suggests internal consistency of the instruments used. The correlation between the PL (digit span task) and the RW and IW highlights the role that phonological memory plays in reading. However, our study shows no correlation between arithmetic performance and PL as some studies (GEARY et al., 2000). Contrary to our expectations, there was no correlation between the VS and reading and arithmetic maybe because our study evaluated simple arithmetic that requires conceptual and procedural skills that are more dependent on the language systems (PL) than the VS systems. The same may be true for reading, although the VS system supports the spatial organization and sequence of letters, the PL plays a prominent role in the early stages of reading. However, a correlation between the VS and the IRBAS was found, indicating that the early calculi need spatial parameters to be successful. The correlation found between the CE and RW, IW and NW confirms the results of research highlighting the CE as the one that plays an important role in reading. During reading the CE retrieves information on syntax, word meaning, phonological rules, while the PL retrieve words, phrases or sentences as they are being processed. Contrary to our expectations, our study showed no correlation between the CE and arithmetic. The correlation between the VS and IRBAS shows the importance of spatial aspects to calculi and the correlation between the arithmetic task and IRBAS and AC was expected as the algorithm must be the result of the understanding of these relations. Conclusion Our findings confirm that research results in this area are still inconclusive and controversial pointing out the need for more investigation. One implication of this study for education concerns the importance of refining the relationships between the different components of WM and learning of reading and calculi in order to prevent at-risk students from developing future problems. Similarly, we could tackle cognitive obstacles by carefully selecting teaching resources, contents and appropriate learning strategies.

Mathematical abilities of children with autism spectrum disorder.

Daisy Titeca, Ghent University, Belgium; Annemie Desoete, Ghent University, Belgium; Herbert Roeyers, Ghent University, Belgium; Stefanie Pieters, Ghent University, Belgium

Aim: The aim of this study was to investigate the arithmetic abilities of children with autism spectrum disorder (ASD) in comparison to children with mathematical learning disability (MLD) and age-matched control children without ASD and MLD.

Method: Twenty-two children with ASD, 22 children with MLD and 22 age-matched control children without ASD or mathematical problems participated in this study. All 66 children were at least of average intelligence and were assessed with a standardized test for number fact retrieval (TTR) and on some subtests of a functional diagnostic test of basic mathematical knowledge and skills (TEDI-MATH), more specifically the subtests tapping the different components of the Triple Code Model.

Results: ANOVA revealed that children with ASD and children with MLD obtained significantly lower scores than control children on number fact retrieval. Furthermore, a MANOVA conducted with the three subtests tapping the

Triple Code Model revealed a trend toward significance. Post-hoc analyses showed that ASD children did not significantly differ from the MLD or control group, while the MLD group performed worse than the control children. Discussion: Children with ASD show mathematical difficulties on the domain of number fact retrieval. However, children with ASD show a different profile of difficulties than children with MLD. These results have important educational implications and suggest that adjustments in educational techniques should be based on the specific needs of children with ASD. Future research should assess the mathematical abilities more extensively, and should investigate the underlying processes thoroughly.

1. Aims

Up till now, most research in children with autism spectrum disorder (ASD) has focused on the social-communicative deficits of these children. Although some researchers suggest that children with ASD are characterized by a profile of strengths and weaknesses in their cognitive and academic functioning, studies in this domain are relatively scarce, and results are inconsistent. According to recent estimations, approximately 70% of the children with ASD may have intellectual abilities in the normal range – and should therefore be able to follow a regular educational program (Chakrabarti & Fombonne, 2005). This seems however in contrast with the experience of practitioners. Regarding the field of arithmetics, many children with ASD seem to have difficulties with the mathematical techniques used in mainstream schools. In the current literature on children with ASD, the field of arithmetics remains a rather unexplored topic, which only a few studies have examined. A study by Chiang and Lin (2007) shows that – although they think the clinical significance of these results is limited – children and adolescents with autism have significantly lower scores on the Arithmetic subtest relative to the mean of their subtest scores on the WISC-III. Mayes and Calhoun (2003) report that 22% of the children with ASD have an arithmetic disability. The present study wants to elaborate on this theme, by examining to what extent children with ASD experience difficulties with arithmetics and what kind of mathematical problems can be detected. A better understanding of these mathematical difficulties is necessary to adjust the mathematical techniques that are currently used in mainstream schools, so as to minimize the problems that children with ASD experience.

2. Methodology

2.1. Subjects

Twenty-two children with ASD, 22 children with mathematical learning disability (MLD) and 22 control children without ASD or mathematical problems participated in this study. Children in the clinical groups had a clinical diagnosis of ASD or MLD that was previously made by a multidisciplinary reference centre or rehabilitation centre. All 66 children were at least of average intelligence ($M = 100.4$; $SD = 11.8$) and were between 6.9 and 12.5 years old ($M = 8.5$ years; $SD = 1.0$ years). The three groups of children were age-matched and did not differ on intelligence.

2.2. Instruments

In order to estimate the intellectual capacities, all children were assessed with the short version of the WISC-III (Similarities, Picture Arrangement, Block Design and Vocabulary). To examine the arithmetic abilities, all children were assessed on number fact retrieval (with the Arithmetic Number Facts Test; TTR) and on the different aspects of the Triple Code Model (visual identification of Arabic numbers, verbal processing of number words and quantity representation; with the TEDI-MATH).

3. Findings

Analysis of variance (ANOVA) comparing the three groups (ASD, MLD and control group) revealed that children with ASD and children with MLD obtained significantly lower scores on number fact retrieval in comparison with the control group (see Table 1). Furthermore, a multivariate analysis of variance (MANOVA) with the three subtest related to the Triple Code Model as dependent variables, revealed a trend at the multivariate level ($F(6, 122) = 1.91$, p

4. Discussion

Children with ASD show a problem with number fact retrieval that is comparable to that of children with MLD. This finding underscores the importance of following up the mathematical automatization abilities of this group of children. However, children with ASD show a different profile of difficulties than children with MLD: Whereas children with MLD seem to have difficulties with the number words component of the Triple Code Model, children with ASD do not fail these kind of tasks. The results of this study may have important educational implications. The findings suggest that adjustments in educational techniques should be based on a more profound analysis of the strengths and weaknesses in mathematics so as to meet the specific needs of children with ASD. These needs may be different from the needs of children with MLD, as they show a different profile of difficulties. A clear understanding of the specific mathematical difficulties of children with ASD also aims at the development of an appropriate STICORDI-advice (STImulation, Compensation, Remediation and Dispensation), for instance working with memory cards or the use of a calculator. Future research should assess the mathematical abilities of children with ASD more extensively, so that

more aspects of the arithmetic field are included in the assessment and more subtle problems can be detected as well. In addition, it will also be important to investigate the underlying processes thoroughly, so that specific modifications are possible. Such studies are currently being prepared.

Writing performance in students with dyslexia: beyond single word spelling difficulties

Vince Connelly, Oxford Brookes University, United Kingdom; Anna Barnett, Oxford Brookes University, United Kingdom; Emma Sumner, Oxford Brookes University, United Kingdom

Difficulties with reading and spelling are established characteristics of dyslexia. However, students with dyslexia repeatedly report writing as a persistent problem throughout education (Mortimore & Crozier, 2006). Models of writing development highlight the processes engaged when writing, and provide the theoretical framework for this research (Berninger & Swanson, 1994). This study directly examines the process of writing, and the product, across three cohorts (ages 8-25 years): individuals with dyslexia, typically-achieving age-matched peers and spelling-ability matched. The aim is to explore how difficulties with spelling may hinder writing development with regards to handwriting execution and the quality of compositions. Participants were screened through nonverbal reasoning, reading, and spelling ability; and completed measures assessing spelling, handwriting speed, vocabulary, working memory. Pause distributions within free writing were analysed using the Eye & Pen software and digital writing tablet. Since data collection is not yet complete, this presentation focuses on preliminary analyses of the performance of a single case-control. Initial analyses reveal interesting differences. In free writing the student with dyslexia produced five times as many spelling errors and half the amount of text composed by the control. The student with dyslexia paused more frequently and spent more time 'in-air'. Fewer words were produced during each execution burst, demonstrating a dysfluent writing profile. Results shall be explored in relation to current theoretical models of writing development; suggesting avenues for future research and appropriate intervention.

Literacy and writing skills are essential forms of expression throughout education, and writing tasks are incorporated into a large part of the school day. The established model of writing development by Berninger & Swanson (1994) recognises the importance of handwriting and spelling as transcription skills in developing writers. This model provides the theoretical framework for the direction of study. Working memory is illustrated as the storage and processing capacity governing low- (transcription) and high- (planning, translating, and reviewing) level processes (Berninger & Swanson, 1994). These processes are engaged concurrently while writing. It can be hypothesised that if one aspect of the writing process is impaired, or poorly developed, the coordination of the other processes are not managed effectively.

Spelling performance has consistently been found to be impaired in children and adults with dyslexia (Bernstein, 2009; Kemp et al, 2009). These difficulties, with both reading and spelling, persist despite adequate learning opportunities and educational instruction; this is true globally, in many different languages. Previous research has shown that children with dyslexia take longer than their age-matched peers in copying tasks (Sovik & Arntzen, 1986); and handwriting samples depict poor legibility (Martlew, 1992). In addition, handwriting speed has been distinguished as accounting for a significant amount of variance in the quality of text composition in students with dyslexia (Gregg et al, 2007). Students with dyslexia have also been found to use a smaller range of vocabulary in writing compared to typically achieving peers (Sterling et al, 1998).

The aim of this study is to explore spelling level, the handwriting profile and the quality of written compositions produced by individuals with dyslexia; and comparison control groups in order to differentiate level of performance. In particular, examining handwriting movements and pause distribution in a free writing task, in the hope of determining whether spelling is a factor constraining production for the dyslexic sample. One hypothesis is that poor spelling accounts for the slower handwriting and smaller lexical diversity often reported in writing produced by dyslexic samples. When writing, pausing before a word may allow for the retrieval of the correct grapheme representation from memory. Individuals with dyslexia are predicted to pause more frequently to decipher a spelling;

subsequently placing heavy demands on working memory, thus impeding handwriting performance by increasing motor execution time. This study breaks down writing performance and patterns in execution.

Methodology

There are two separate studies running, one consisting of children in primary schools across Oxfordshire, the other with students at Oxford Brookes University: spanning ages 8-25 years. Both studies have three defined cohorts: participants with dyslexia, and two control groups consisting of typically-achieving participants - the first matched by chronological age and the second by level of spelling ability. All groups consist of 25 participants. Participants with dyslexia were initially recognised by an Educational Psychologist or the Special Educational Needs Coordinator (SENco), as having a diagnosis of dyslexia and further screened to show a discrepancy between cognitive ability and reading/spelling performance. The typically-achieving groups showed no discrepancy, and age-appropriate literacy skills.

Participants complete a series of standardised measures of non-verbal cognitive ability, word and non-word reading, spelling, receptive and expressive vocabulary, handwriting speed, manual dexterity, and verbal/visual working memory. An experimental free writing task was designed to assess writing performance. The set topic asked participants to present their perspective on a current issue. Writing was recorded on a digital writing tablet (using Eye & Pen software) which records the XY coordinates of handwriting to a laptop for later analysis. This analysis gives an indication of pause distributions and durations. Pause duration groups have been established from current literature to attribute to, and define, low- and high- level writing processes. A detailed analysis of spelling errors will be performed across the spelling task and within writing.

Results and findings

As data collection is still underway, group data is not yet available to examine relationships between writing processes and product. Therefore, a preliminary analysis is presented in the form of a case-control comparison. A case study of two female university student, age-matched, both studying psychology, one with dyslexia (19.10 years) and the other typically-achieving (19 .8 yrs), highlights prominent differences. In the free writing task both participants spent approximately 20 minutes composing, the student with dyslexia wrote a total of 276 words and made 15 spelling errors, compared to the control who produced 498 words and only 3 spelling errors. Writing fluency for the student with dyslexia was 15.2 words per minute (wpm), compared to 25.7wpm by the control student; and the student with dyslexia spent 7.10 minutes pausing in-air, not physically composing on the paper, compared to 4.69 minutes respectively. In addition, the student with dyslexia was found to pause for >2 seconds more frequently, and produce fewer words during each execution bursts. Overall, these results reflect a dysfluent writing profile for the student with dyslexia when compared to the control, which may be the result of spelling/handwriting difficulties and/or working memory constraints. This point can be further elaborated with the group comparisons and the results from the supporting measures taken, such as working memory assessment.

The groups of participants will be compared across spelling, vocabulary, and handwriting measures using a general linear model analyses. ANOVA and MANOVA tests will be conducted to assess the relationship between variables concerning the processes and the written product.

Theoretical and Educational Implications

There is a growing need for research to encompass both writing processes and the product, in order to suggest appropriate intervention for these students and also teaching instruction. As little research has examined the quality of composition, level of handwriting fluency and vocabulary knowledge in this population, opportunities to provide substantial support are missed. The results from the measures included will develop our understanding of the cognitive and linguistic profile of this atypical population and highlight areas in need of appropriate further support. In addition, findings from the comparison groups will provide support towards the current models of typical writing development. The overall benefits of this study are long term with regards to the contribution to knowledge in developmental and specialized educational research.

Training written spelling in Italian children with dyslexia-dysorthographia

Barbara Arfe, Facolta di Scienze della Formazione, Italy; Elisa Cona, Centro Regionale Disturbi dell'Apprendimento-ULSS 20, Verona, Italy

The Study tested a spelling training designed to help Italian dyslexic children integrate phonological and visual-orthographical processing of orthographically complex words in writing. Three groups of children participated: a) a group of children with dyslexia (N=10), addressed to a phonological + visual-orthographical training (PhO), b) a group

of dyslexic children (N=10), addressed to a control phonological training (Ph), and c) a spelling age matched control group of young writers with typical development, addressed to the PhO training (PhO-TD). Results show greater improvements in spelling in the PhO groups than in the Ph group.

Developmental dyslexia is a persistent difficulty in learning to read and spell words (Bastien-Tonazzo, Stroumza, & Cavé, 2009). Dyslexic children's spelling problems are as severe as their reading problems and can have long term effects on their writing and compositional skills (Berninger et al., 2008; Connely et al., 2006). According to a widely accepted hypothesis, these difficulties are rooted in a phonological impairment, due to a speech perception deficits (Serniclaes et al., 2001), problems in temporal processing of auditory information (Tallal, 1980), or categorical perception deficits (Manis et al., 1997). An alternative hypothesis is that dyslexic children's difficulties are related to a visual-attention deficit (Spinelli et al., 2002; Valdois, 2004; Plaza & Cohen, 2006) or to a deficit in magnocellular visual processing (Stein & Walsh, 1997). Recently, a third hypothesis has emerged, which combines the two: an asynchrony in processing visual-orthographic and auditory-phonological information would cause the encoding, decoding and word recognition deficits of dyslexia (Breznitz & Misra, 2003). In synthesis, the integration of auditory-phonological and visual-orthographic information may result inadequate in dyslexic children.

In this Study we tested a spelling training designed to help Italian dyslexic children integrate phonological and visual-orthographic processing of orthographically complex words in writing. Italian is a shallow orthography; the majority of Italian letters have only one pronunciation, so that a child can write unerringly by using a phonetic strategy, or a one-to-one sound-letter conversion procedure. For this reason, phonological trainings and spelling under dictation generally succeed in developing spelling skills. However, Italian spelling-sound correspondences are not all equally simple. Some Italian spellings are less shallow than others. The letters c and g, for example, have different pronunciations depending on the letters that follow. Their written spelling is based on orthographic context-sensitive rules (Barca et al., 2007): e.g. the letter c correspond to the sound /k/ when followed by /a/, such as in /casa/house or /tS/, when followed by /i/, such as in /cielo/sky. Moreover, the same sound can correspond to two letters in some orthographic contexts: e.g. /k/ is converted in a grapheme of two letters /ch/ when /k/ is followed by /i/, like in chiesa/church. Italian children experience initial difficulties with this class of words (with context-sensitive orthography) and, this difficulty is particularly severe among young dyslexic children (Barca et al., 2006; Arfé et al., 2009): reading and spelling errors in this class of words result to be persistent, and little sensitive to instructional intervention. The Study investigated whether training Italian dyslexic children to integrate phonological and visual-orthographic processing of these orthographically complex words could improve their written spelling more than traditional interventions.

Three groups of children participated: a) a group of children with dyslexia-dysorthographia (N=10, 3rd to 5th graders), addressed to a phonological + visual-orthographical training (PhO), b) a group of dyslexic-dysorthographic children (N=10), matched by age and spelling skills to the PhO group, addressed to a control phonological training (Ph) (traditional intervention), and c) a control group of young writers with typical development (2nd to 3rd graders), matched to the PhO group by spelling scores and addressed to the PhO training (PhO-TD). Children in the PhO group were presented a written word and were asked to: a) carefully look at it and to read aloud, together with the examiner, the graphemic groups corresponding to the word syllables, b) close their eyes and read the word again silently from their memory, c) write down the word. The Ph training consisted of a traditional spelling under dictation task and games to stimulate phonological awareness. In both groups, children were invited to correct themselves their spelling errors. Pretest and posttest consisted of spelling under dictation a list of 42 four-syllabic words with complex (context-sensitive) orthographic rules; standardized word spelling, nonword spelling and spelling in text dictation tasks were also administered at pretest and posttest (Sartori et al., 2006).

The results show a significant effect of training condition. The PhO group showed significant improvement in real word [t(10)=5,05, p] and nonword [t(10)=2,95, p] spelling, in the spelling of words in text dictation [t(10)=2,91, p], and in the spelling of complex words (with context-sensitive graphemes) [t(10)=4,70, p]. The Ph group improved only in real word spelling [t(10)=2,68, p]. The PhO-TD group improved in real word spelling [t(10)=3,16, p], in spelling in text dictation [t(10)=3,71, p], and in the spelling of "context-sensitive" words [t(10)=4,22, p]. Theoretical and practical implications of these findings will be discussed with a focus on clinical and educational intervention.

Functional Deficits in Phonological Working Memory in Children With Intellectual Disabilities

Kirsten Schuchardt, University of Hildesheim, Germany; Claudia Maehler, Institute of Psychology, Germany; Marcus Hasselhorn, DIPF, Germany

Background.

Recent studies indicate that children with intellectual disabilities (ID) have functional limitations primarily in the phonological loop of working memory. These findings are indicative of a specific structural deficit. The aim of the present study was therefore to investigate various functions of phonological working memory in children with ID.

Method.

In a three-group design, specific subfunctions of phonological working memory were examined in students of the same mental age (one group of 15-year-olds with mild ID [IQ 50–69], one group of 10-year-olds with borderline ID [IQ 70–84], and one group of 7-year-olds of average intelligence [IQ 85–115]). The automatic activation of the subvocal rehearsal process was operationalized by the word-length effect; the size of the phonological store, by a task involving repetition of nonwords of differing syllable length; and accuracy of processing, by both the phonological similarity effect and the quality of acoustic presentation of the nonword repetition task (distorted vs. undistorted item presentation).

Results. The results revealed impairment of the phonological store only in terms of reduced storage capacity, and showed that this deficit increased with length of the item sequences to be remembered. However, this deficit was observed only in children with mild ID.

Conclusions. The findings are discussed in the context of the two-component model of the phonological loop. They indicate that deficits in storage capacity are associated with deficits in language development and thus seem to be one of the causes of cognitive impairment in individuals with mild ID.

Aims

Children and adolescents with intellectual disabilities (ID) are characterized by profound deficits in phonological memory functions (Henry, 2001; Schuchardt et al., 2010). However, the various studies did not find children with ID to underperform to the same extent on all types of phonological tasks, indicating that it is not the entire functioning of this component that is affected, but specific subfunctions. These findings raise the question of exactly which phonological subfunctions are impaired in children with ID. The present study was designed to address this question by experimentally varying specific aspects of phonological information processing. Relying on the model of Hasselhorn, Grube, and Mähler (2000), we conducted an experimental study examining the automatic activation of subvocal rehearsal processes in terms of the word-length effect, the capacity of the phonological store in terms of the syllable-length effect in nonword repetition tasks, and accuracy of processing in the phonological store in terms of the similarity effect and the distortion effect.

Method

Participants. A total of 63 students participated in the study. In a mental age comparison design, a group of 15-year-old students with mild intellectual disability (MID; IQ 50–69), a group of 10-year-old students with borderline intellectual disability (BID; IQ 70–84), and a control group of 7-year-olds with average intellectual abilities (C; IQ 93–115) were compared. The three groups were matched for mental age using scores on the Columbia Mental Maturity Scale (CMMS).

Tasks. The participating children were administered three different tasks assessing their memory span for words (phonologically dissimilar one-syllable words, phonologically dissimilar three-syllable words, and phonologically similar one-syllable words) as well as a nonword repetition task. Sequences of words of increasing length were presented acoustically at a rate of one word per second, starting with two and continuing up to a maximum of eight words. The phonologically dissimilar one- and three-syllable word span tasks used familiar German nouns that did not rhyme and were thus phonologically distinct. The phonologically similar word span tasks, in contrast, consisted of one-syllable rhyming nouns with a high level of phonological similarity.

In the nonword repetition task, a total of 24 meaningless nonwords with lengths of two, three, and four syllables, were presented acoustically and then had to be repeated correctly. Words of different syllable lengths were mixed for presentation. The capacity of the phonological store can be inferred from the length of the nonwords that participants are able to repeat relatively free of errors. The accuracy of processing in the store, which may be independent of its capacity, was assessed by varying the quality of acoustic presentation. To this end, half of the words were presented in distorted form, making their processing more difficult.

Results

Children with ID did not show any specific deficits in the rehearsal process. In all three groups, children showed higher memory span scores when reproducing series of one-syllable words compared to series of three-syllable words. In

other words, all three groups of children with a mental age of 7 years automatically activated the subvocal rehearsal process in the phonological loop—an ability that is fully developed by the age of 6 to 7 years in typical development. Likewise, we found no evidence for intelligence-related differences in the accuracy of processing as a functional characteristic of the phonological store: all three groups showed a significant similarity effect. Likewise, varying the quality of acoustic presentation (i.e., presenting half of the nonwords in acoustically distorted form) did not lead to differences in the groups' performance. Lower levels of intelligence thus evidently did not influence the accuracy of processing.

In contrast, the capacity of the phonological store was clearly limited in children with MID. These children performed at the same level as the younger control group children when asked to repeat two-syllable nonwords, but their performance on three- and four-syllable nonwords declined markedly. In contrast, the scores of children with BID were comparable with those of the average-intelligence control group.

Theoretical and educational significance of the research

Deficits in storage capacity can therefore be seen as a causal factor in ID (IQ

Issues surrounding the definition of developmental dyscalculia

Amy Devine, Centre for Neuroscience in Education, University of Cambridge, United Kingdom; Fruzsina Soltesz, University of Cambridge, United Kingdom; Alison Nobes, University of Cambridge, United Kingdom; Denes Szucs, University of Cambridge, United Kingdom

International research has indicated that developmental dyscalculia (DD) affects between 3 and 10% of the population. Despite the similar prevalence rate, research into DD has been relatively neglected compared to other learning disabilities such as reading disability (Hanich, Jordan, Kaplan, & Dick, 2001; Mazzocco & Myers, 2003). Consequently, there is no consensus as to how DD should be defined or measured; the selection criteria and tests used in different studies have varied greatly. This poster discusses the issues surrounding the different definitions of DD used in past prevalence studies, and also describes a recent large-scale investigation of the prevalence of DD in the UK. The effects of using different selection criteria for DD will be demonstrated on the data from the study sample.

As would be expected with standardized scores, the majority of points fall within 1 SD of the average score for both the reading and mathematics scores.

Although the distribution is somewhat linear there is a moderate amount of spread. In particular, there are some children who got high scores on one test with average scores on the other test. At the top central section of the scatter plot the number of children who gained high scores in reading, with average scores in mathematics can be seen. In the middle right region of the scatter plot the number of children who gained high scores on mathematics, with average scores in reading can be seen.

Also highlighted in the scatter plot is the group of interest: children with lower scores in mathematics, with average or above average reading scores. When low mathematics performance is defined using a cutoff of 1 SD below the average score, with reading performance at or above 1 SD below the average reading score, 5.40% of children fall within this group. The effects of using the different cutoff scores used in previous dyscalculia prevalence studies will be illustrated on the data set and the implications of using different cutoffs for the diagnosis of DD will be discussed.

THEMATIC POSTER SESSION

Teacher Education

Promoting Reflective Awareness of Teachers' Epistemological and Ontological Beliefs

Gregory Schraw, University of Nevada, United States; Lori Olafson, University of Nevada Las Vegas, United States; Michelle Vanderveldt, Cal State Fullerton, United States

We examined change in epistemological and ontological beliefs using pre-posttest surveys and end-of-semester interviews on a sample of 16 graduate students enrolled in an education class. Results indicated that approximately 63% of participants had consistent beliefs. Another 30% experienced minor changes, while only one experienced substantial change. We discuss the role of action research and corresponding active reflection as components of the

learning environment that enhanced awareness and development of beliefs, describing four ways that participatory action research promoted greater understanding of course information and personal beliefs. We concluded that while beliefs do not change during a 15-week course, educational experiences nevertheless helped teachers develop explicit awareness of their beliefs and use this awareness to make informed curricular and pedagogical choices in their classrooms.

Purpose and Research Predictions

This research examined whether teachers' epistemological and ontological beliefs changed during a 15-week graduate class and what role participatory action research played in critical reflection and change. Based on previous work (Brownlee, 2004; Marra, 2005; Olafson & Schraw, 2006) we expected most students to maintain consistent beliefs across the semester based on pre- and posttest measures, even though some students were expected to change. We also predicted that participation in an action research projects would heighten individuals' awareness of their beliefs and lead to beneficial reflection regarding the relationship between beliefs and teaching practices.

Theoretical Framework

A number of studies have examined teachers' epistemological and ontological beliefs. Epistemological beliefs refer to beliefs about the origin and acquisition of knowledge (Schommer-Aikins, 2002), while ontological beliefs refer to beliefs about the nature of reality (Ponterotto, 2005). Epistemological beliefs are related to classroom pedagogy and management strategies in several ways (Brownlee & Berthelsen, 2006; Hofer, 2001). Teachers who endorse relativist beliefs (i.e., a belief in complex, contextually sensitive knowledge) report using more teaching strategies, focus to a greater extent on student-based collaborative learning, and are less apt to adopt a teacher-directed management style compared to teachers who endorse strong realist beliefs (i.e., a belief in simple, unchanging knowledge).

Methods

16 graduate students enrolled in a The Study of Teaching class completed three self-report instruments at the beginning and end of the course, including the Four Quadrant Scale, the Teacher Belief Vignettes, and the Epistemological Beliefs Inventory (EBI) (Schraw & Olafson, 2008). The Four Quadrant Scale partitions epistemological and ontological beliefs along two separate dimensions, which yield four separate quadrants, including a relativist-relativist (quadrant 1), relativist-realist (quadrant 2), realist-realist (quadrant 3), and realist-relativist (quadrant 4) quadrant. The Teacher Belief Vignettes consist of three vignettes that portray realist, contextualist, and relativist views of teaching. The EBI includes 32 items rated on a 5-point Likert scale designed to elicit students' beliefs about knowledge (Schraw, Bendixen, & Dunkle, 2002). We also conducted individual, semi-structured interviews with each participant.

Results

Quantitative Means and standard deviations for scores are shown in Table 1. Dependent t-tests for quadrant placement and EBI variables showed no significant differences between the pre- and posttest. We also examined quadrant placement across time. Ten of 16 participants remained in the same cell. Three switched from cell 4 to 1, two switched from cell 1 to 4, and one switched from cell 1 to 3. The frequency of changes was not statistically significant, and in addition, all but one of the changes occurred between adjacent cells (e.g., cell 4 to cell 1). We also conducted a 2 (time: pretest, posttest) x 2 (type of belief: epistemological, ontological) repeated measures analysis of variance (ANOVA) to compare pre- and posttest means for the epistemological and ontological coordinate scores. The only test to reach significance was for the type of beliefs variable, $F(1, 15) = 31.23, p < .001$, $F(2, 30) = 21.83, p < .001$.

Qualitative Findings

Transcribed interviews yielded a coding scheme that consisted of 44 codes that were grouped together in a higher order of classification to form the resulting three themes summarized in Table 2.

Discussion

Our results highlight two findings. One is that most participants did not experience a substantial change in world views. This finding is consistent with previous research that did not report significant short-term change among in-service teachers, and that when change occurred, it did so in the context of classes that focused on constructivist instruction that emphasized the role of student cooperative discussion and reflection on personal beliefs (Brownlee, 2004; Marra, 2005). A second finding is that participants reported increased awareness of their beliefs due to classroom discussion and the action research project in particular. We identified under Theme 3 four ways that action research promoted great awareness, including opportunities to try new activities in a real-life context, a forum to examine beliefs, connecting theory to practice, and promoting reflection on beliefs and how beliefs are related to practice.

Summary of Three Main Themes from Interviews

Theme 1: Absence of Meaningful Change Most students did not change due to age and experience and a stable set of personal beliefs related to classroom practices. When change occurred, this change was primarily epistemological in nature, and related to a change in the perceived importance of helping student construct relevant knowledge.

Theme 2: The Development of Greater Awareness All participants expressed developing a greater awareness of their beliefs. Many described how their existing beliefs had been tacit, and that the format of the course allowed them opportunities to articulate their beliefs explicitly. Explicit awareness promoted greater reflection on the relationship between beliefs and practices.

Theme 3: Action Research Promotes Greater Awareness of Beliefs Students participated in an action research project that promoted greater awareness of beliefs in four ways. These included opportunities to implement a new practice in the classroom, a forum where participants were able to examine the relationship between their own beliefs and practices, facilitating connections between theory to practice, and promoting systematic reflection on epistemological and ontological beliefs.

The Wheel of Growth of Pre-service Teachers

Tsafi Timor, Kibbutzim College of Education, Israel

The principal aim of this study was to examine pre-service teachers' perceptions of their growth during one year of pedagogical instruction and practice teaching, with regard to three categories of knowledge: personal growth, the growth of pedagogical knowledge, and the growth of content knowledge. The study has focused on the following questions: The study focuses on two questions: 1. Are there any differences in pre-service teachers' perceptions of various dimensions of practice teaching and pedagogical instruction between the beginning of the year and its end? 2. What are the correlations between dimensions pertaining to personal growth, growth in pedagogical knowledge, and growth of content knowledge at the beginning of the year and at its end? The research tools included the "Wheel of Growth" from coaching models. Analysis was conducted by statistical analysis. Findings indicate significant changes in all dimensions of knowledge during the year, a fact which reflects a significant growth. Findings also yielded significant correlations among the three categories, a fact which indicates that the process has occurred simultaneously in all categories of knowledge. It is recommended that the research be replicated in further contexts.

Theoretical Significance

Reports from existing Teacher Training Programmes imply the need to ensure a balance between practical dimensions of training and theoretical knowledge (Vick, 2006). While some researchers see practice teaching as the highlight of the four years of teacher training, others argue that practice teaching is an artificial situation and does not provide a real teaching experience (Vassallo, 2000). Two decades ago Shulman (1987) identified three categories of knowledge essential to training programmes: content knowledge (of a specific domain), pedagogical knowledge (how to teach), pedagogical content knowledge (how to teach a specific domain). Studies indicate that pre-service teachers wish to improve their content knowledge, pedagogical knowledge, and pedagogical content knowledge. Pedagogical knowledge consists of class management, the use of problem-solving strategies, and motivation issues; Content knowledge include learning resources; Pedagogical content knowledge include lesson planning, establishing link between real-life situations and class materials, and problem-solving in specific areas (Jegede & Taplin, 2000). Researchers agree about the importance of personal growth alongside professional growth. (Coolahan, 2002). However, there is no mentioning of relationships between various categories of knowledge, which may be crucial to the creation of a balanced teachers' training programme. The Wheel of Growth from coaching models advocates a balance between the parts of the wheel, each of which representing another domain of life, so that the wheel can spin smoothly (Whitworth, Kimsey-House & Sandahl, 1998). This study has adopted the Wheel of Growth in order to examine pre-service teachers' perceptions of their process of growth during a year of practice teaching and pedagogical instruction, with regard to personal growth, growth of pedagogical knowledge, and growth of content knowledge. This overall goal is to consider necessary changes in the foci of pedagogical training programmes. The study focuses on two questions: 1. Are there any differences in pre-service teachers' perceptions of various dimensions of practice teaching and pedagogical instruction between the beginning of the year and its end? 2. What are the correlations between dimensions pertaining to personal growth, growth in pedagogical knowledge, and growth of content knowledge at the beginning of the year and at its end?

Methodology

Research population consists of 30 pre-service teachers in second year, aged 21-29, two male and 28 female. The "Wheel of Growth" questionnaire was divided into triangles which meet in the center, each of which represents a dimension of pedagogical training and practice teaching. The Wheel contains 9 circle lines numbered 0-10 whereas the midpoint of the Wheel indicates 0 and the outer circle line indicates 10 (Figure 1). It included 11 dimensions.

Course of study:1. The dimensions for the Wheel of Growth were determined by the participants in a class discussion followed by a discourse analysis. They were clustered into three categories:

A. Personal Growth includes the following dimensions: Creativity, Reaction to feedback, Self-Confidence, Team-work, Assertiveness;

B. Growth of Pedagogical Knowledge includes the following dimensions: Managing Time in Class, Managing Discipline in Class, Lesson Planning, Communicating with Learners, Reflecting on Teaching.

C. Growth in Content Knowledge includes the dimension of "Content knowledge".

Growth in "pedagogical content knowledge" was not included as a separate category because the participants pertained to a variety of content disciplines (e.g. Literature, Maths).2. The pre-service teachers ranked themselves for each dimension at the beginning of the year and at its end. The percentage of respondents was 85% and 82% respectively. 3. Analysis of the questionnaires was conducted in a quantitative way: analysis of the first research question was conducted by T-Test and by descriptive statistics. Analysis of the second research question was carried out by the Pearson Correlation Test to calculate correlations between dimensions and categories.

Findings

Research question 1: Findings have yielded significant differences between the beginning and the end of the year (Figure 2).The scores yielded at the beginning of the year ranged from $M=4.88$ ("Self-Confidence") to $M=6.80$ ("Communicating with Learners"). The scores yielded in the different dimensions at the end of the year ranged from $M=7.23$ ("Managing Time in Class") to $M=8.80$ ("Communicating with Learners"). The biggest leap has been perceived in "Lesson Planning" $t(29) = 9.54; p$

Research question 2: Below are examples of correlations between the three categories of knowledge: Growth in pedagogical knowledge: dimension of "Lesson planning": the highest correlation was observed between "Lesson planning" and "Self-confidence" at the beginning of the year ($r=0.79$; p Personal growth: dimension of "Assertiveness": the highest correlation was observed between "Assertiveness" and "Self-confidence" at the beginning of the year ($r=0.72$; p Growth in content knowledge: dimension of "Content knowledge": the highest correlation was observed between the dimensions "Content knowledge" and "Self-confidence" at the beginning of the year ($r=0.62$; p

Summary: 1. The net of correlations within the categories and among the three categories took different forms at the beginning of the year and at its end, indicating that changes have been occurring.2. Pre-service teachers perceived a simultaneous growth in the dimensions pertaining to the three categories of knowledge, mainly in the dimensions "Lesson planning", "Managing discipline in class" and "Content knowledge". The perceived simultaneity in the process might indicate that a certain balance was obtained during the year between the 3 bodies of knowledge.3. Their perceptions may point to the creation of an integrated body of knowledge between theory and practice, especially between pedagogical knowledge and personal growth.

Modeling the relationship between Cypriot teachers' conceptions and practices of assessment

Michalis Michaelides, University of Cyprus, Cyprus

The current project aimed toward the investigation and modeling of the conceptions Cypriot teachers hold about educational assessment and examine their relationships with their assessment practices. Brown's (2006) Conceptions of Assessment III Abridged Survey scale was adapted in Greek and administered to 249 teachers. Analysis of the data revealed that the most popular assessment practices reported were the use of teacher-designed assessments, and written assessments given in class. Teachers expressed strong agreement with the use of assessment for improving teaching and learning and endorsed conceptions of assessment for holding students accountable. Assessment for school accountability purposes found only slight support. Preliminary correlational analysis indicated that the conceptions teachers hold seem to relate to the practices of assessment they report, without any significant differences between demographic groups. Further analysis with structural equation models will attempt to model the relationship between conceptions and practices of assessment and will be presented in the final paper. The findings will contribute to the international discussion of how teachers think about assessment and will shed light on the relationship between beliefs and practices in educational assessment.

THEORETICAL BACKGROUND AND RESEARCH OBJECTIVES

Recent research in educational assessment has promoted the notion of assessment for learning in contrast to assessment of learning. Responding to policies that emphasize national standards and standardized testing in education, researchers have turned to new directions: e.g. the investigation of how teachers make use of formative assessment practices (e.g. Black et al., 2004), and the examination of how teachers conceive of assessment and its purposes (e.g. Brown, 2004, 2009).

Research has linked the conceptions of teachers about teaching and learning with their actual practices, and findings from psychology indicate that beliefs predict behavior. Moreover, the effectiveness of educational policies depends partly on teachers' conceptions and beliefs about these policies. Conceptions can be defined "as a more general mental structure, encompassing beliefs, meanings, concepts, propositions, rules, mental images, preferences, and the like" (Thompson, 1992, p.130); they "describe the organizing framework by which an individual understands, responds to, and interacts with a phenomenon... they appear to be multifaceted and interconnected" (Brown, 2004, p.303). Assessment conceptions have been found to be idiosyncratic (Cizek et al., 1995), inconsistent in the sense that teachers choose assessment practices based on previous experiences, their studies, traditional or modern teaching models, as well as culturally shared (van den Berg, 2002). Brown's (2004) framework describes four purpose-defined conceptions of assessment: (1) assessment can be used to hold schools accountable, (2) assessment as a means for making students accountable, (3) assessment improves educational practice, (4) assessment is irrelevant to education. Brown developed this framework in New Zealand. His findings highlight the importance of the context on conceptions and practices about assessment; local schooling practices and policies differ across countries, e.g. on the emphasis on standardized testing, on accountability matters, etc. Therefore, a cross national investigation of conceptions about assessment would reflect these differences.

The objectives of this study include the description and modeling of teachers' assessment conceptions and practices in Cyprus through a survey instrument adapted from Brown (2006).

METHODOLOGY

Developed in New Zealand, Brown's (2006) 27-item Conceptions of Assessment scale (CoA-IIIa) was adapted in Greek and administered to a country-wide sample of 249 educators together with a brief questionnaire about their assessment practices. The internal consistency for the CoA-IIIa items was satisfactory ($\alpha=.68$). The majority of the sample was female (75%), elementary school teachers (53%), regular classroom teachers (77%) and experienced (64% over 5 years of teaching).

RESULTS

Descriptive analysis of the survey data revealed that most of the teachers (80%) had not more than a brief seminar on educational assessment during their studies or professional careers. The most commonly employed assessment practices reported were teacher-designed assessments, and class written assessment, while the least frequently used were essay type questions and standardized tests or large-scale exam papers.

The agreement teachers expressed with each of the four conceptions on assessment was measured on a 1 to 6 scale. The conceptions of assessment for improving education was ranked the highest (mean=4.39, s.d.=0.57) and assessment as a means for student accountability followed (mean=4.27, s.d.=0.66). The belief that assessment can be used for school accountability received slight support (mean=3.83, s.d.=0.92) while assessment as an irrelevant educational practice received neutral ratings (mean=3.40, s.d.=0.68).

Excluding the irrelevance conception, all other conceptions were positively intercorrelated ($0.40 < r < 0.50$, all $p < 0.01$). This can be interpreted as having similar beliefs about assessment for and of learning simultaneously. A MANOVA test to examine differences on the four conceptions about assessment between gender, and years of experience groups revealed a significant main effect for years of experience (Wilks' $\lambda=.90$, $p < .05$), with univariate effects on the improvement conception and for student accountability. Further analysis will look into differences due to the level of education (elementary vs. secondary, and professional training in assessment).

To answer the question on the relationship between conceptions and practices on assessment, the significant correlation coefficients between the scores on each of the conceptions and the frequency of each practice are presented in the Appendix Table 1. The conceptions teachers hold seem to relate to the practices of assessment they report: The more they endorse assessment for improving education the more they use various forms of assessment. The same applies for the conception of assessment for school accountability, but to a lesser degree.

In the final poster, the data will be analyzed using structural equation modeling to describe more fully the interrelationships between assessment conceptions and practices.

THEORETICAL AND EDUCATIONAL SIGNIFICANCE OF THE STUDY

This paper describes the first attempt to study teachers' conceptions of assessment via a standardized instrument that has been used in various other cultures (New Zealand, Hong Kong, Spain, China, Brazil etc.) Therefore, the findings will contribute to the international discussion of how teachers think about assessment. Such empirical data constitute

valuable input for assessment specialists who recommend new directions in assessment practices. In fact, the Cyprus Ministry of Education is currently pursuing a wide-range educational reform that encompasses assessment methods. Finally, it will shed light on the relationship between beliefs and practices in educational assessment and inform policy-makers on the training and professional development needs.

The Who and the What: The linkage of theory and practice in mentoring-dialogues

Sandra Moroni, University of Teacher Education Fribourg, Germany; Alois Niggli, University of teacher education, Switzerland

The lack of connection between university-based teacher education courses and field experiences has been a perennial problem in traditional teacher education programs. For this reason a hybrid space was created to tie up university courses and field experience in internships more closely. Thus, learners will be faced with multiple contexts. Our approach is based on the cognitive flexibility theory. Knowledge was primarily acquired in case-based learning situations which dealt the subject of differentiated instruction. In a qualitative longitudinal study involving 25 advanced students, this issue was investigated in three distinct settings.

Preparatory setting 1: Internship discussion between university tutor and student with a primary focus on the scientific knowledge acquired at university.

Preparatory setting 2: Discussion of the same problem between the mentor-teacher and student with a focus on the knowledge acquired through practical experience.

Reflection setting 3: Study group discussion between student, mentor-teacher, and university tutor following a classroom observation session with a focus on both forms of knowledge.

In a first research stage two evaluation strategies to report our findings were used which were based on a qualitative text analysis: (1) ranks and percentages of meaning units of discourse in each of the three settings; (2) transsituational meaning units, produced by the same student in two or three settings. Professional success seems to be based on linking up these meaning units derived from theory or practice. Our study identifies the contents of teacher training programmes which should be paid particular attention to in this respect.

Numerous studies have demonstrated the obstacles to student teacher learning that are associated with the traditional loosely-planned model of field experiences (e.g. Arnold et al., 2011). Our study, aiming at a closer linkage between theory and practice, is based on two theoretical concepts:

First the concept of hybrid spaces (Zeichner, 2010) in pre-service teacher education is used to bring together both school- and university-based teacher educators and practitioners as well as academic knowledge in specific academic knowledge to enhance the learning of prospective teachers. The creation of hybrid spaces is connected with the idea of a third space in school-university partnerships. It implies a more egalitarian status for participants and thus a shift from an either/or-perspective to a both/also-point of view.

Secondly, regarding the learning processes of students we have drawn upon the cognitive flexibility theory by Spiro, Feltovich, Jacobson & Coulson (1991), claiming that complex knowledge is best acquired in case-based, multiple perspective learning environments. Such acquisition will take place if a given concept can be spotlighted at different times, in different contexts and according to different purposes. Thus students will experience a multi-faceted exposure to the concept, which can then be dealt with in varied episodes.

Our instructional steps, which will be described below, are based on these theoretical assumptions.

Subject: The concept focused on in varied contexts was constituted by the subject of differentiated or adaptive instruction, respectively, in the mathematics classroom.

First the conceptual basics of a university-course were discussed with the practitioners who had applied for an ensuing internship. They were then provided with suitable lesson-contents, which they were to work through with their pupils.

(a) In a preparatory setting 1 (internship interview between university tutor and student) a link is established primarily to the scientific knowledge acquired at university. The fundamentals of the course are to be adapted to some specific content, which rises from practice. The perspective of the course is focused on a specific case.

(b) In a preparatory setting 2 (discussion of the same problem between the mentor-teacher and student) a link is established primarily to the knowledge acquired through practical experience. The perspective is opened up to the general classroom situation, its dynamics, to the various backgrounds of individual learners, and to the view of the mentor-teacher.

(c) In a Reflection setting 3 (study group discussion between student, mentor-teacher and university tutor), following a classroom observation session a link is established between both forms of knowledge theory and practice. The focus is on the student's behaviour in the classroom and not only on its planning.

The following questions have been of interest to us:

(1) What: Which key aspects of the theory conveyed are relevant to practice?

(2) When: Does the relevance of these key aspects depend on the different episodes?

(3) Who: Which stakeholders initiate classroom discourse?

(4) Effect: How do teacher students rate the competences acquired?

Later studies are intended to focus on the question of "How", with a special emphasis on the design of the discourse between those stakeholders, who take on different perspectives.

Method

The discussions described above took place during the school years of 2009/2010 and 2010/2011 as part of a course in General Didactics with a focus on "instructional differentiation" at the Fribourg Teacher Training College. There was a vast majority of female students (21 out of 24), who are in their last year of their three-years' teacher education course for primary school teachers.

The discussions between the different participants were analyzed according to Mayring's (2002) Qualitative Content Analysis. There was a two-phased validation: a communicative validation of the first ten students among the workgroup was executed in the pilot study with a dialogic consensus-method. In the main study the codification-system will be monitored by the inter-rater reliability with the remaining 14 students, thus making allowances for the criteria of good practice in qualitative social studies.

According to the principle of triangulation the qualitative data collection was complemented by a quantitative analysis of a questionnaire, in which competences in the field of differentiated classroom instruction were assessed. These constructs were similar to those of the discussions.

Results

In the three discourse settings various aspects of differentiated instruction are addressed, which can be grouped into a macro-level (organisation of classroom teaching) and into a micro-level (methodological interaction in the classroom). During the first setting the focus is clearly on the macro-level, whereas in the third setting problems concerning the micro-level are more frequently raised. An increasing differentiation among the students can clearly be noticed. However, this does not seem to be true for all students to the same extent – there are also students who address organisational aspects during all three settings.

The findings also show a difference of the discourse topics depending on whether the talks took place with the tutor or the mentor. As the respective initiators of topics seem to be relevant this aspect needs special attention: first analyses show that - quite differently from conversations with their mentors - in their conversations with tutors it is especially students who initiate topics.

An appreciation of the competences shows that the students rated their own competences referring to various aspects of differentiated teaching higher at the end of the intervention than at its beginning. Between the final points of the intervention the competences may be temporarily rated lower, which might be explained by the fact that students assess themselves more strictly due to an increasing awareness of the problems of differentiated instruction. The present study makes a contribution to a practice-centred curriculum in teacher education. Its key aspects allow for a programme which can avoid the traditional separation between theoretical foundation of knowledge and its practical implementation. Teacher novices will furthermore be enabled to develop a set of key knowledge which is relevant to differentiated instruction. Ensuing studies will allow for assumptions about the "How" of discourse exchange between students, teacher educators, practitioners in hybrid settings. Moreover, statements about the development of competences and about empowerment in multiple contexts in teacher education will be theoretically meaningful.

Frictions and coherence in teachers' beliefs - Teachers' perceptions on themselves and pupils' role

Elsi Ahonen, University of Helsinki, Finland; Kirsi Pyhalto, Helsinki University, Finland; Janne Pietarinen, University of Eastern Finland, Finland

Research on teachers' professional beliefs has shown that there is a relationship between teachers' professional beliefs and professional practices carried out by them. However, this relationship is complex and dynamic rather than causal. (Bakkenes, Vermunt & Wubbels, 2009; Van Driel, Bulte, & Verloop, 2007.) Moreover, teachers' professional beliefs do not necessarily form a consistent professional world view (Rauste-von Wright, 1986; Van Driel et al. 2007). This means that a variety of complementary and sometimes contradictory professional belief systems may exist simultaneously, which is reflected in various ways in teachers' practices and thus on pupils' and school community's learning. This study aims to analyze the variation, context-dependency and coherence of teachers' professional beliefs about themselves and the pupils in the school's pedagogical practices. A selected group of 68 comprehensive school teachers were interviewed. The interviews were content analysed using an abductive strategy. Results showed that teachers' perceptions on themselves and pupils role vary from active learners to passive objects in different context of the school. There was also variation both between teachers and within the teacher's beliefs. Moreover teachers' perceptions were often highly context dependent. While some teachers emphasised knowledge transmission as a core of teaching, others perceived themselves and the pupils as active and collaborative learners in variety of school practices. Similar kind of inconsistency was characteristic for an individual teacher's perceptions. A teacher often, for instance, referred teaching both as knowledge transmission and as facilitation of pupil's active and collaborative learning. The challenge of promoting teachers' professional learning is discussed.

Research on teachers' professional beliefs has shown that there is a relationship between teachers' professional beliefs and professional practices carried out by them. However, this relationship is complex and dynamic rather than causal. (Bakkenes, Vermunt & Wubbels, 2010; Van Driel, Bulte, & Verloop, 2007.) Teacher's professional beliefs, for instance the way in which they perceive their role as teachers or the kinds of instructional methods they consider effective, are likely to affect their interpretations and instructional practices adopted in a classroom. Not only that, these professional beliefs effect the way teachers' act in their professional community for example how they collaborate and take a stand in curriculum development work and how they utilize other teachers' expertise in developing their own work and school. Hence teachers' professional beliefs guide their actions in pedagogical encounters with pupils and other members of the school community.

However, teachers' professional beliefs do not necessarily form a consistent professional world view (Rauste-von Wright, 1986; Van Driel et al. 2007). This means that a variety of complementary and sometimes contradictory professional belief systems may exist simultaneously, which is reflected in various ways in teachers' practices. These complementary or contradictory professional belief systems are constructed in parallel social contexts within the school community. Lack of a coherent and personally meaningful pedagogical theory upon which collective structures of activity and participation can be a reason, for instance, why shared aims and teachers' willingness to promote school development do not automatically transform into the everyday practices of school (Vermunt 2010). This study aims to analyze the variation, context-dependency and coherence of teachers' professional beliefs about themselves and the pupils in the school's pedagogical practices.

Methods

This study includes data collected from the teachers of nine case-schools around Finland. Altogether a selected group of 68 comprehensive school teachers, including both primary and secondary school teachers, were interviewed (Female: 42, Male: 26, Age: Mean = 44.6, Range = 31, Min./Max.= 30/61 years, Std. Deviation= 9.250). The teachers were selected for interviews on the basis of the open-ended responses to questionnaires collected previously from all the case-school teachers. The criteria for selecting the teachers were variation in the teachers' perceived professional orientation in terms of school development and their own role in it, their educational background, gender, work history and working experience. Teacher interviews were conducted in case-schools during spring 2006 by using teachers' professional landscape inventory developed by Soini, Pyhalto & Pietarinen 2010. The interviews were content analysed using an abductive strategy.

Results

The results showed that although the teachers recognized the importance of facilitating the pupils' active role in learning, they still often considered pupils' role passive and traditional in terms of school practices. The teachers mostly perceived the pupils as active educational participants in informal school settings, but not to the same extent in the core process of teaching and learning. At the same time teachers/ perceive themselves most often as passive

objects in the professional community. Only few teachers perceived themselves as facilitators of learning in their professional community. However, there was variation both between teachers and within the teacher's beliefs. Moreover teachers' perceptions were often highly context dependent. While some teachers emphasised knowledge transmission as a core of teaching, others perceive themselves and the pupils as active and collaborative learners in variety of school practices. Similar kind of inconsistency was characteristic for an individual teacher's perceptions. A teacher often, for instance, referred teaching both as knowledge transmission and facilitation of pupil's active and collaborative learning. There were also discontinuities in the teacher's perceptions about themselves as members of the professional community. A teacher for example reported that she just had to keep the wheel running even though they felt that the practices they performed in professional community were not as good as they could have been.

Discussion

Teachers' professional beliefs about themselves and the pupils form often inconsistent professional world view. Moreover these beliefs seem to vary within and between different contexts of teacher's work. This partial inconsistency and context-dependency of professional beliefs may provide a challenge for the teachers' professional learning and for the systematic use of novel pedagogical practices in the classroom and professional community.

However, we consider these findings quite encouraging especially in terms of developing the pupils' active agency in the school community: most teachers had already identified the need to promote the pupils' active role in school. The next challenge is to contribute to the teachers' professional agency to collaboratively develop instructional practices that promote the pupils' collaborative learning and sense of belonging in everyday classroom activities.

Tiered teaching: Making explicit our teacher education pedagogy

Rena Heap, The University of Auckland, New Zealand; Dawn Garbett, The University of Auckland, New Zealand

As experienced teachers with specific strengths in teaching science, we were confident in our own knowledge of the science education content and skilled in the ways of making this content accessible to students enrolled in a Graduate Diploma of Teaching (Primary) programme. Student teachers who graduate from this one-year programme have to be capable of teaching all curriculum areas to any children aged between 5 and 12. Therefore, they are keen to learn science content and the pragmatic, yet superficial, aspects of delivering information and organising successful experiments. Standard practice for lecturers in this science education methods course has been to model exemplary practice by demonstrating how to run well-organized and dynamic practical sessions. However, we propose that teacher education, globally, in any curriculum area needs to be more than modeling exemplary practice. We wanted our students to see "beneath the surface to the complex thinking and the wealth of experience so crucial in shaping pedagogically meaningful learning experiences" (Loughran and Russell, 2007, p. 218). Consequently we have developed a collaborative team-teaching model, 'tiered teaching'. In this presentation we discuss the impact of tiered teaching on making the complexity of pedagogy transparent when teaching science. Teaching classes together and researching our teaching has enabled us to reframe our assumptions and move beyond the simplistic and misleading idea that teacher education is the modeling of exemplary practice. This research has evolved over three years. We believe this collaborative teaching model is applicable globally to teacher education in any curriculum area.

Aim

The aim of this research was to examine the impact of tiered teaching on making our implicit practice explicit. Teaching classes together has enabled us to reframe assumptions that centre on the simplistic and misleading idea that teacher education is the modeling of exemplary practice.

Method

For over three years we have team-taught in combined classes. Content knowledge has remained a focus for the students and us; however, what was given more prominence through tiered teaching was the subtext (the deeper tier) of learning about teaching. This subtext was addressed by our having dual roles; lecturer and provocateur. The provocateur's role was to critique the lecturer's practice to the students to draw their attention to the complex and challenging craft of teaching. Different models of team-teaching can be identified in the literature. For example, Kirkwood-Tucker & Bleicher (2003) present team-teaching along a continuum comprised of three different models. To the far left lies the series model where lecturers present in a series one after the other. Planning, design and assessment of the course may be shared but the lecturers are not present in each other's sessions. At the center of the continuum is the alternating model where two or more lecturers alternate during the each session. To the far right is the interactive model. Here the lecturers are both present actively teaching as a side-by-side team. Other models parallel this continuum. Our tiered teaching style and purpose does not fit neatly into any of these models in that a) we taught together with alternating the dual roles and b) our model is underpinned by self-study methodology. LaBoskey (2004) identifies five methodological features as being important to self-study. They are that it: is improvement-aimed with evidence of reframed thinking and transformed practice; is collaborative; employs multiple, primarily qualitative methods; is self-initiated; and is made public. Multiple data sources were generated. We documented planning and debriefing discussions, held prior to and following each session. The provocateur kept a handwritten logbook of questions and ideas to draw the students' attention to during the session, as well as additional comments to discuss with one another after the session. We also gathered written data from the students at a mid- and end-point of each course. Data collection and data analysis did not happen linearly but was a hermeneutic, recursive process involving reading and re-reading the data, followed by discussion. Emergent themes became clear. Finally, the data was revisited to identify particular instances to support the themes that emerged (Lankshear & Knobel, 2004).

Findings

Several themes have emerged from the data analysis. The most significant were; the cost of tiered teaching; the shift in priority towards less science education but more teacher education; our own growth in expertise; and the transformation of our practice. In terms of cost, we found that with two of us planning, teaching and debriefing each session, we were investing heavily in the project emotionally, intellectually and in terms of time and energy. We acknowledged that we both felt more comfortable in the sanctuary of our own classrooms, behind a closed door, where each of us felt that we had more autonomy and control. A second theme to emerge was that the science content that we covered during our tiered teaching needed to be pared back so that we had more time to discuss the aspects of teacher education that we considered important and wanted to highlight. A number of successful content-based activities were omitted in favor drawing the students' attention to teaching decisions. The third theme that emerged was our growth in expertise; we developed more confidence and self-assurance in our teacher education practices as our study deepened our understanding of the complex challenges involved in teaching about teaching. An unexpected outcome of our tiered teaching together is that we have taken the intentions and skills of critiquing each other's practices into those classes we teach individually, and this has enabled us to teach on multiple levels even when on our own. Data and analysis to support each of these themes will be given in the presentation.

Theoretical and educational significance

By acting as the experienced eyes in each other's classes we have been able to make more explicit to the student teachers the teacherly decisions we were making in practice. We have been able to open student teachers' eyes to the complex skills that expert teachers bring into play in their wider practice. We have learned to make our thinking as teachers explicit to our students so that they can see how we deal with the myriad of dilemmas and challenges that arise in teaching. Tiered teaching was the impetus to change our pedagogical approach and transform our practice. Through this self-study we recognised that we teach our students on different meta-cognitive levels or tiers. Often several of these tiers are eclipsed by our drive to impart subject specific content and pedagogical knowledge as effectively as possible. At an even deeper tier, we see the practice of thinking critically and reflecting on our teaching - in front of the students; in discussion and in private - as being a means to expand our view of the world and our students' view of their profession. We believe this collaborative teaching model is applicable globally to teacher education in any curriculum area.

Conceptual change and Cognitive Skills

A Learning to Learn Approach to School Improvement in Italy

Chris Goldspink, Incept Labs, Australia; Cristina Stringher, INVALSI, Italy

The need to improve the quality of Italian public education, accounting for about 80% of the total number of schools, has been triggered by international comparative studies on student outcomes. The Italian education system, like those of many other Western Democracies has been subject to constant reform initiatives.

Two sets of ideas have influenced educational reform of OECD countries in the recent past: managerialism and market approaches (see Goldspink 2007 for a discussion). This paper examines how this has been manifest in Italy. The focus is on the influence of such change to the administration of school based education. The paper also explores the impact of this change on learning systems. It is argued that these approaches to reform have been based on philosophies and assumptions hostile to the achievement of improved learning and have delivered little real change wherever they have been applied, Italy included. A 'bottom up' or self-organisational model being pursued in the State of South Australia is examined as a possible alternative. Unlike the 'rationalist' management and economic approaches, this approach focuses on people, relationships and learning, rather than structures and centrally determined standards and conformance. We examine the potential for such an approach in Italy, including the likely barriers and adaptations needed for it to be effective.

This research reappraises the recent influences on Italian educational reform and propose an alternative direction. The argument for the alternative draws on empirical evidence as to the effectiveness of a reform being undertaken in the State of South Australia: a reform informed by learning rather than administrative theory. The potential benefits as well as the challenges associated with perusing a similar approach in Italy are identified.

A political reality in western democracies during the post-war period has been the need to do 'more with less' (Pollitt 1990; Self, 1993). In addition, the influence of neoclassical economic and neoliberal political thinking led to increasing calls for budgetary restraint, downsizing, privatization and deregulation (Wilenski, 1986; Osborne and Gaebler, 1993; Self, 1993; Davis, 1997). Goldspink (2007) has argued that these ideas have had a significant influence on educational policy and reform. This is particularly true in today's Italian educational policy, struggling to achieve better results in PISA studies on student outcomes while combating the lack of resources that has been emerging after the 2008 world crisis.

Despite these reform efforts (or we will argue at least in part due to their misdirected nature), education in the Western world has changed little over the last century (Sarason 1990; Evans 2001). The dominant approach has its origins with enlightenment (modernist) concepts of knowledge and assumptions about 'knowledge needs' derived from class based conceptions of social role (Goodson 1997; Sterling 2001), with Italy being no exception to this very broad developmental pattern. Governments have been motivated to improve effectiveness – focusing on the quality of outcomes for both individuals and the wider community/society – as well as with administrative efficiency. In Italy this is evident in all the principal reform documents of the past decade and has been underlined with the recent Gelmini Reform (MIUR 2002, 2003; Fioroni, 2005; MIUR 2007, 2010). However, while attempts to improve effectiveness have been informed by changing thinking about knowledge and alternative theories of learning, in most countries educational practice has drawn rather eclectically on such theories. Modernist (behaviourist) instrumental approaches are still evident while post-modern (constructivist) influences have also been increasingly embraced, at least at the level of policy (Boudourides 1998; Vanderstraeten and Biesta 2002).

In Italy, the land of positivist Maria Montessori, a similarly eclectic mix of behaviourist approaches and idealistic philosophies was evident in the major school reform of 1923 and still display their influence. During the republican era, school changes have been conducted primarily from a centralized administrative perspective (Vertecchi, 1996). More recently, reform attempts (with the exception perhaps of the Berlinguer reform of 2000 originally inspired by childrens' developmental stages) seem rooted primarily not on learning theories, but on even more general references to European education, postmodernism and globalization. An eminent Italian sociologist has recently pointed out the relative lack of studies dealing with the relations between globalization and education especially in

Italy (Cobalti, 2006). It is also worth noting that in 2007 the Eurydice network was unable to classify Italian school autonomy regulations as pertaining to any school of thought (Eurydice, 2007). In other words, these reforms have lacked any grounding in learning theory or philosophical or theoretical coherence.

If education has been increasingly informed by administrative ideas rather than a coherent understanding of learning, what can we say of this influence? Christopher Hood (2000) has argued that throughout the history of public administration, four broad 'styles' can be discerned. These are fatalist, hierarchist, individualist and egalitarian. The hierarchist (classical bureaucracy), individualist (neo-liberal) and egalitarian (social democratic) approaches are most relevant in Australia, Britain and other Western Democracies.

In Italy, a blend of the four approaches seems to have inspired the reform compromise in the republican era, with the hierarchist possibly prevailing and with recent neo-liberal mainstream propaganda focusing especially on school autonomy yet free from correspondent school evaluations, and on the managerialist idea of "meritocracy". (Eurydice 2007; Cobalti, 2006; MIUR 2003, 2005, 2007, 2010).

This paper examines the implications of these perspectives as they have been applied to education reform in Italy. It is argued that while each has brought some valuable insights and can be demonstrated to have led to some useful change – neither provides a basis for future improvement. Indeed, Italian student outcomes as measured by international comparative studies seem to show that if pursued further, these perspectives will diminish the quality and effectiveness of education. An alternative based on an internally consistent set of assumptions about learning is illustrated. This is based on research into an educational improvement program being undertaken in the public government school system in the State of South Australia. This practical and successful example is used to draw out the limitations of past approaches and provide a grounding point for the development of a set of principles to guide future reform. These principles draw on a well established set of ideas – that of educational systems as 'loosely coupled' – but draw also on recent advances in thinking about the application of complex systems to organisational design and management (Goldspink, C., 2007a, 2007b). Most importantly, however, they are grounded in and consistent with contemporary thinking about the nature of knowledge and learning. Indeed the change process was itself based around learning rather than instrumental and administrative process. The most recent learning theories are thus the third pillar to inform this set of reform principles. These ideas are examined for their relevance to the Italian context. Specific challenges particular to this context are examined to ascertain if the benefits associated with this approach may be able to be realised in Italy. The approach is important to Italian education policy as it offers an option to move beyond long standing ideological debates, political compromise and to allow empirical evidence to drive future innovation in the sector.

Students' cognitive operational stages and students' and teachers' cognitive preferences

Caesar Anton, Technion, Israel; Reuven Lazarowitz, Technion, Israel

The purpose of this study was to investigate the cognitive preferences of 11th grade students and (a) their cognitive operational stages, (b) teachers' cognitive preferences, and (c) students' gender. The study sample included 633, 11th grade biology students and 20 high school biology teachers. Two instruments were used: Biological Cognitive Preferences Inventory (BCPI) for assessing cognitive preferences of students and teachers and; Video–Tape Group Test (VTGT) for assessing cognitive operational stages. The instruments were administered by the researcher, at the 3rd trimester of the academic year. The statistical analysis of BCPI reveals that Principle (P) and Critical Questioning (Q) were the most preferred modes by students and teachers, while Recall (R) and Application (A) were the lowest preferred modes. Analysis of VTGT indicates that only 17% of 11th graders in biology classes have reached the formal operational stage, while 58% and 25% of the study sample have been found in the transitional and concrete stages. The cognitive preferences of students at the concrete stage were high in Recall (R) and Principle (P) modes, while students at the formal stage demonstrated higher level of preferences to Principle (P) and Critical questioning (Q) modes, which is similar to teachers' cognitive preferences. No relationship was found between students' preferences and gender. The results of this study may contribute information to the developers of curricula, textbooks writers and teachers on adapting learning material and instructional strategies to students' cognitive preferences and their cognitive operational stages.

New high school biology curriculum has increased emphasis on four domains: content knowledge, inquiry skills, and attitudes toward science and nature of science. Concepts and principles presented in this curriculum require students to operate on the formal cognitive stage, while studies have shown that only 40% of the high school students are at this operational stage (Adey & Shayer, 1990; Valanides, 1998). Teaching concepts which require formal reasoning from students who are not at this cognitive stage oblige teachers to adequately teach students according to their interests and cognitive preferences (Tamir, 1975), to obtain information on their students' cognitive stage, (Hofstein &

Mandler, 1985), and to develop educational material suited to heterogeneous students population (Witenoff & Lazarowitz, 1993). No studies on students' cognitive preferences and cognitive stages were carried out in the Arab high schools in Israel. This study fulfills this educational need. The construct of cognitive preferences was proposed by Heath (1964) and investigated by Tamir (1975, 1988) and Lazarowitz & Penso (1992) in their studies as a potentially new outcome variable in new science curricula. Heath (1964) suggested the following modes of cognitive preferences: (1) Recall (R): Acceptance of information without consideration of implications, applications or limitations. (2) Principles (P): Acceptance of information because it exemplifies or illuminates a fundamental scientific principle, concept, or relationship. (3) Questioning (Q): Critical questioning of information regarding its completeness, generalization, or limitations. (4) Application (A): Emphasis on the usefulness and applicability of information in a general, social, or scientific context. Research question The main question of this research: Is there a correlation between the cognitive preferences of 11th grade biology students learning according to the new biology curriculum and the following variables: (a) their teachers' cognitive preferences; (b) students' cognitive operational stages; (c) students' gender.

Method

The study was conducted in 18 Arab Israeli high schools during the last semester of the academic year (April ad May). Data was collected with instruments using quantitative approach. Sample In this study were involved 633, 11th grade students (boys, N=206; girls, N=427, 16 to 17 years old) from 18 Arab high schools in Israel. All students studied biology at the five points study level for matriculation exams according to the new biology curriculum. Furthermore 20 biology teachers participated in this study. Instruments Two instruments were used: 1. The Biology Cognitive Preferences Inventory (BCPI) included 28-items designed according to the blueprint of Heath (1964). Every item begins with an introductory statement that is followed by extension statements, each corresponding to one of the four modes described, and all of them are correct, but differ on their cognitive preference. Students are asked to rank the four statements within each item in order of their preference by assigning 4 to the most preferred, and 1 to the least preferred statement. 2. The Video-Tape group Test (VTGT), is based on 12 video-taped tasks designed by Shemesh & Lazarowitz (1988), and used for assessing students' reasoning stages. For each correct answer and explanation, students receive 2 points; for a wrong answer, but correct explanation, 1 point and 0 points for other possibilities.

Procedure

The two instruments were administered in each classroom by the researcher in the following mode: The VTGT was assessed at the first week of the third term of the academic year and the BCPI at the second week of the third term. The instruments answered by students and teachers were coded and analyzed in a non-parametric analysis.

Results

The statistical analysis of BCPI revealed that Principle P is the most preferred mode by students (and teachers), while Application, A is the lowest preferred mode. Analysis of VTGT indicate that only a small percentage of 11th students (17%) have reached the formal operational stage, while 58% and 25% of the sample have been categorized as transitional or concrete thinkers, respectively. It was found that there are differences in cognitive preferences between students which are in different operational stages. Students in concrete stages tend to prefer R () and A modes () while students in formal stage preferred P() and Q modes (). However, the biology teachers tend to prefer P() and Q modes () which is similar to the students' cognitive preferences of the formal operational stage ($F(12,1874) = 9.6, p=0.06$). No significant differences were found between males' and females' cognitive preferences ($F(4,628) = .34, p=n.s., \eta^2=.00$) or students performance on any of the six operational modes.

Detection of strategies to handle multiple choice questions by using an eye tracker

Gun-Brit Thoma, Leibniz-Institute for Science Education, Germany; Inger Marie Dalehefte, Leibniz-Institute for Science Education and Mathematics, Germany

Multiple choice tests play an important role in assessing knowledge, skills and abilities because they are less costly and easy to score, a more reliable measure of knowledge in a limited testing period and they allow greater efficiency than other test formats. However, theoretical perceptions as well as research findings indicate that people do not always use the same strategies to answer the questions in a test. It seems that especially experts and laypersons differ with regard to their strategies due to their different amount of prior knowledge. There is a lack of a systematic analysis of strategies to handle different kinds of questions such as multiple choice questions. The aim of the study is, therefore, to reconstruct the strategies that experts and laypersons use to solve multiple choice questions by using an eye tracker. A sample of different experts and laypersons (N=50) answered a computer-based multiple choice test while an eye tracker recorded their eye movement. We assume that laypersons who have little to no prior knowledge of a topic will probably guess the right answer. In contrast, experts can probably exclude some wrong answers or they can immediately name the correct answer because of their prior knowledge. Analyses of the eye movement are supposed to reinforce our hypotheses. This means the results of the study will reveal experts' and laypersons' strategies to deal with multiple choice questions as well as give in-depth insight into the relationship between processing strategies and eye movement.

Aims

In a number of research areas there is a need to assess knowledge, skills and abilities. One test format which plays an important role in assessment and which is used very often is the multiple choice test. Multiple choice test formats are often chosen because they are less costly and easy to score, a more reliable measure of knowledge in a limited testing period and they allow greater efficiency than other test formats (Bortz & Döring, 2006). This format also plays an important role in large scale studies such as TIMSS and PISA. Based on its popularity and broad acceptance in the test field it is of great importance to acquire more knowledge about the way people handle and process throughout a test. Theoretical assumptions as well as research findings indicate that people do not always use the same strategies to answer and solve questions. It seems that especially experts and laypersons differ with regard to their strategies due to their different amount of prior knowledge and experiences (Chi, 2006; Gruber, 2006). So far little is known about whether experts and laypersons differ in their strategies to answer multiple choice questions. We assume that laypersons who have little to no prior knowledge of a topic will be likely to guess the right answers (Attali & Bar-Hillel, 2003; Bortz & Döring, 2006; Burton, 2001; Burton & Miller, 1999). In contrast experts can possibly exclude some wrong answers or they can immediately name the correct answer because of their prior knowledge. Experts do not have to guess. Thus, there is a lack of systematic analysis of strategies to handle different kinds of questions and tasks. This study is a preliminary attempt to acquire insight into the strategies of experts and laypersons to solve a test by using eye tracking. The eye movements of a person are directly linked to her/his visual attention and can, therefore, give some indication of the strategies used and the extent of knowledge (Joos, Rötting & Velichkovsky, 2002; Funke & Spering, 2006). The aim of the study is to reconstruct the strategies and patterns that experts and laypersons use to answer and solve multiple choice questions using of an eye tracker. The study addresses two research questions:

- a) Which strategies can be identified while solving multiple choice questions?
- b) Which strategies do experts and laypersons use to solve the multiple choice questions?

Methodology

The sample (N=100) consists of persons with different level of knowledge about the topic "human brain". The expert group consists of psychology and medicine students whereas the layperson group consists of students of a topic peripheral discipline like history, business or law. Students fill in a questionnaire (paper-pencil) regarding their individual background. They then answer a computer-based multiple choice test about the topic "human brain". This test fits international standards, has 22 items about facts and functions of the human brain, and distinguishes between persons with different knowledge in this topic. Experts' and laypersons' eye movement are recorded with a stationary eye tracker while they answer multiple choice questions presented one after another. The difficulty of the items and the position of the right answers are varied systematically.

Findings and theoretical significance

This study revealed fundamental knowledge about what kind of strategies experts and laypersons use to solve multiple choice questions. The findings indicate that persons use different strategies based on their pre-knowledge. In summary, data show that experts use more efficient strategies than laypersons. Future research questions concern to what extent these findings can be replicated with other kinds of multiple choice formats. This attempt to explain strategies with respect to multiple choice data is highly relevant for research areas connected to item construction. This means, more knowledge about these strategies can, for instance, supply important information of how these strategies are influenced and what kind of role the position of item distracters plays.

What is the Effective way of Preparation? : Interaction with Beliefs about Learning.

Keita Shinogaya, Keio Advanced Research Center, Japan

This study examined the effect of monitoring activity on presented questions during preparation through experimental history classes. In Study 1, 86 Japanese junior-high school students were randomly assigned into the two conditional groups: question-only group, question and monitoring group. In Study 2, 76 junior-high school students were assigned into the three conditional groups: answering-only group, judgment-only group, answering and judgment group. As a result, there was a significant interaction with learners' beliefs about learning. Although some researches mentioned the effect of individual-difference factor on the effect of pre-questions, learners' information processing has never been revealed. The result of this study suggested not only the effect of learners' beliefs but important role of monitoring process. These findings are useful to make concrete suggestions to teachers about what and how to task students as preparation.

Introduction

This study focused on what effects preparation has and how the effect brings about. In daily life, students prepare for the next lecture at home beforehand. To make students' learning effective, we need to reveal the effective way of preparation. According to previous researches about advance organizer, learners can understand the relations between the main facts in the text when they read advance organizer (e.g., summary) beforehand, (Mayer, 1983; Titsworth & Kiewra, 2004). Indeed, the understanding of the causal relationship among the historical events deepened in history class if the learners read the textbook before the lecture (Shinogaya, 2008). But, there was no effect among learners who considered history learning as simply memorizing the historical events (the level of "meaningful learning belief[1]" is low). Therefore, the present studies examined the effective way of preparation for all learners through a series of experimental classes.

Study 1

Purpose According to the previous studies, given adjunct pre-questions enhanced learners' understanding of the text (e.g., Rickards & McCormick, 1988). These results suggest that it may be possible to direct learners' attention to the

causal relations between historical events when they take the lecture if they were given some questions beforehand (e.g., "why this event happened?"). However, taking other researches into account (Thiede et al. 2003), not only giving learners questions but also making them to monitor their current state to the goal is necessary to let the learners' attention to the materials. Therefore, Study 1 examined the effect of monitoring activity on presented questions during preparation. The monitoring activity in this study was to answer the presented questions and to judge their confidence in their answers (e.g., Chi et al., 2001).

Participants, Procedure, and Measures

86 Japanese junior-high school students were randomly assigned into the two conditional groups. Experimental history classes were conducted for 5 days. All participants did preparation with a textbook for 5 minutes, and then took a lecture for 45 minutes. In the lecture, the teacher presented more detailed information about historical events that weren't written in the textbook. During preparation time, participants in questions-only group were given questions that asked causes of historical events. On the other hand, participants in questions and monitoring group were asked to make answers to the questions and to judge their confidence in their answers. Before the 5 days lectures began, the students' beliefs about learning history (meaningful learning belief) were measured with 4 items used in the previous research (Ichikawa, Horino, & Kubo, 1998). Participants responded to each of the items (e.g., "To understand the relations between facts is important in learning history") on a 5-point scale. Mean score of 4 items were used as individual-difference variable. At the 5th day, two tests were conducted. One asked participants to recall the name of the historical events in textbook, and the other asked them to explain the cause of the historical events.

Results

As seen in Figure 1, there was the significant difference between two groups at the score of the causal relation tests ($F(1, 40) = 4.94$, $p(t(37)) = 2.07$, $p(b) = .38$, $p(b) = -.20$, n.s.).

Study 2

Purpose In study 1, the effects of answering to the presented questions and judging of confidence were confounding. Therefore, study 2 revealed the effect of each activity during preparation.

Participants and procedure 76 junior-high school students were randomly assigned into the three conditional groups: answering-only group, judgment-only group, answering and judgment group. During preparation, participants in answering-only group were presented questions and asked to make answers to them. Participants in judgment-only group were presented questions and judged their confidence on their own knowledge about the questions. Participants in answering and judgment group answered to the questions and judged their confidence on their answers. All other procedure was the same as study 1.

Results

As the results of comparison analysis, there was a main effect of answering to the presented questions ($F(2, 54) = 3.08$, $p = .05$). And as shown in Figure 3, there were the interaction with meaningful understanding belief. The belief impacted the test score in the answering-only group ($b = .46$, p

Discussion

Answering-only? judgment-only? answer and judgment meaningful learning belief This study revealed that answering to the given questions during preparation enhanced learners' understanding of the lecture. This finding supported the results of previous researches (Pressley et al., 1990). The result showed that judgment of confidence can direct learners' attention to the questions, and this finding also supported the previous researches about self-regulated learning (e.g., Thiede et al., 2003). Although some researches mentioned the effect of individual-difference factor on the effect of pre-questions (e.g., Ozgungor & Guthrie, 2004), learners' information processing has never been revealed. This study is significant because it suggests not only the effect of learners' beliefs but important role of monitoring process. These findings are useful to make concrete suggestions to teachers about what and how to task students as preparation. In presentation, I will show more detailed data (e.g., relations among learners' answers to the questions, judgment scores of confidence, and test performances) and propose a model of self-regulated learning, regarding the relationship between preparation and lecture. [1] sub category of beliefs about learning that put importance on understanding the relations among facts

Analysis of 1st year university students' personal epistemologies using scenario-based interviews

Jo Brownlee, QUT, Australia; Susan Walker, Queensland University of Technology, Australia; Beryl Exley, QUT, Australia; Sandra Lennox, Notre Dame University, Australia; Sharyn Pearce, QUT, Australia

Personal epistemological beliefs, or beliefs about knowing, provide a way in which to understand learning in a range of educational contexts because they are considered to act as filters for all other knowledge and beliefs, including the beliefs we hold about learning. However such beliefs often remain implicit and recent debate in the field has centred on how best to measure such beliefs. Using semi-structured scenario-based interviews, this study investigated the nature of beliefs about knowing and learning of 35 first year teacher education and creative writing students at a large metropolitan university in Australia. The scenarios drew on direct classroom teaching experiences in order to provide scaffolding for students who typically find questions about knowing and knowledge challenging to address. The focus of this paper is on examining the richness of data that emerged from the scenario-based interviews. The analysis indicated relationships existed between individuals' core beliefs about knowing and their beliefs about learning, suggesting that the scenarios were useful in eliciting core beliefs about knowing.

Introduction

Higher education, in particular the first year of university studies, can be an important time for effecting changes in thinking, particularly in relation to beliefs about learning and knowing (Chai, Khine, & Teo, 2006). Personal epistemological beliefs, or beliefs about knowing, provide a way in which to understand learning in a range of educational contexts because they are considered to act as filters for all other knowledge and beliefs, including the beliefs we hold about learning. However such beliefs often remain implicit and recent debate in the field has centred on how best to measure such beliefs. This paper reports on the effectiveness of using scenario-based interviews as a way to investigate the nature of beliefs about knowing and learning in first year teacher education and creative writing students.

Measuring personal epistemology with scenario based interviews

First year students from a large university in a metropolitan area in Australia were selected at random to participate in a scenario based interview about their beliefs about knowing and learning. Fifteen early childhood preservice teachers, 14 primary preservice teachers, and 6 creative writing students who were in the first year of their undergraduate degrees participated in the interview. An analysis of their scenario-based interview responses is the focus of this paper. The interviews, conducted by the research assistant, were semi-structured scenario-based, and took between 30 to 60 minutes each. The research assistant was trained in how to administer the interview including how to probe in a non-leading manner. Semi-structured interviews are a common method of investigating epistemological beliefs (e.g., Sutton, Cafarelli, Lund, Schurdell, & Bischel, 1996). However, for this study we used scenario-based interviews which were based on the original work of Stacey, Brownlee, Thorpe and Class EAB016 (2005). The scenario was designed to reflect actual classroom practice because it seems students are often challenged by the abstract topic of personal epistemology. Nist and Holschuch (2005) have also used such an approach to interviewing to help students to think about their personal epistemologies. Their research showed that the use of a scenario enabled research participants to be able to articulate their beliefs more clearly. The scenarios in the current study thus were aimed at helping students to reflect on a specific scenario with which they were familiar in their chosen field of study. We ensured that across early childhood, primary and creative writing students, the scenarios used reflected the sorts of experiences they might encounter in their professional experience. With each of the scenarios, the same interview questions were posed, for example: a) Sometimes people talk about there being "right answers" or "truth" in child care/ primary teaching/ creative writing. Do think that anybody's opinion is as good as another's? Do you trust the opinions of experts? b) How would you go about learning something that you needed to know that would help you to be a child care worker/ primary teacher/ creative writer?

Analysing the interviews

The interviews were carefully examined and interpreted using content analysis. As strong traditions of research regarding beliefs about knowing and beliefs about personal learning have provided well defined categories, a theory – driven approach was used to categorise the interview responses. In this study the categorisations used to analyse the data were referred to as objectivism, subjectivism and evaluativism (categories adapted from Kuhn & Weinstock, 2002). Within research regarding beliefs about learning, the categories described by Marton et al. (1993) as quantitative and qualitative have also appeared in many studies over time (e.g., Marton et al., 1993). The researchers used these broad categories as a rubric to analyse the data in this study. A perceived measure of success of the use of scenario- based interviews was the extent to which we would be able to observe these categories of knowing and learning in the interview data. That is, were the students able to articulate clearly what they believed about knowing and learning in order for us to apply these rubrics to the data. Findings from the scenario-based interviews We were able to clearly analyse the interviews using the rubrics described earlier. Data was rich and, for the most part, elaborated to such an extent that enabled us to make reasonably clear determinations on the categorisation of data. Specifically, the interview data revealed that core beliefs about knowing and beliefs about learning were related for these students. We noted patterns of thinking in which 1) evaluativistic beliefs tended to be associated with more qualitative conceptions of learning (sometimes with quantitative views included as part of the pattern) and 2)

subjectivist or objectivist beliefs were related more to quantitative beliefs about learning. ImplicationsThe focus of this paper was to assess the value of using scenario-based interviews as way to gather rich data for analysis of personal epistemologies. We argue that the methodological approach of using scenario-based interviews contributes to this explicit reflection on personal epistemologies. Being involved in such interview processes appears to support students in their explicit reflection on beliefs, particularly in the context of scenarios which provide a more concrete experience for students to reflect upon.

Examining Affordances and Constraints of Epistemic Development through a Vygotskian Lens

Suzanne H. Broughton, Utah State University, United States; LeAnn G. Putney, University of Nevada, Las Vegas, United States

Current research on students' epistemic beliefs relies on Piaget's view of development. This view may not take into consideration the role of experience prior to schooling as a mediating factor. This study examined students' epistemological beliefs through a Vygotskian (1987) perspective on learning and development, placing experience as an integral part of cognition, thus creating opportunities for learning that lead development. We examined small group discussions related to science beliefs in two demographically contrasted 6th grade classrooms. Discursive analytic results indicate a contrast in level of sophistication of student beliefs in the two cases. The primary deciding factor in level of epistemic belief development between these cases is prior experience with the information either within or beyond the schooled setting.

Researchers have studied students' epistemological beliefs by focusing on the fluidity or rigidity of their beliefs, the nature of the concepts being learned, the information source, and how well students can express an argument based on the information (See Hofer & Pintrich, 1997). Their view of development of these beliefs is often credited to Piagetian theory. However, these researchers may not take into consideration the role of experience prior to schooling as a mediating factor in epistemic development. Our aim was to examine students' epistemological beliefs through a Vygotskian perspective on learning and development. Vygotsky's (1978, 1987) work places experience and human activity as an integral part of cognition, which creates opportunities for learning that lead development.

The discourse practices children experience at home later become a means for participating in classroom activities (Hicks, 1995). Hicks further argued that children use this experiential knowledge for structuring school experiences. Children whose prior experiences and discourse practices are consonant with those found in formal classroom settings may learn academic discourses with ease, while if not, they may encounter difficulties.

Theoretical Framework

We examined student's epistemological beliefs from a Vygotskian perspective, rather than the more usually accepted work of Piaget. Vygotsky (1987) viewed use of signs and symbols as mediators of human cognition. Language becomes a tool for developing thought, while we develop language through thought. This interaction of thinking and speech results in experience for the learner, which Vygotsky viewed as a key factor in further impacting the relationship of thinking and speech. Learning and development are reciprocally related, thoroughly situated in culture, and individual development is "a process in which children grow into the intellectual life of those around them" (Vygotsky, 1978, p. 88). Vygotsky (1978, 1987) argued that, while learning systems may be similar among children, these systems cannot be identical for all children because of their differing social experiences.

Epistemological Beliefs

Epistemological beliefs are an individual's beliefs about the nature of knowledge and knowing (Hofer & Pintrich, 1997). Hofer (2000) proposed four independent dimensions of epistemological beliefs including certainty, simplicity of knowledge, source, and justification. Justification is often used by researchers who hold a Piagetian developmental view on epistemological beliefs (Kuhn 2005). In this study we targeted student's beliefs about the nature of science (NOS) because they are epistemic in nature.

Method

We incorporated a text-based intervention and small group discussion with a discursive method of analysis. The discursive analysis was based on the interactional ethnographic orienting theoretical approach (Castanheira, Crawford, Dixon & Green, 2001) to examine dialogic responses of students during small group discussions. While this study did not lend itself to a full ethnographic approach of observing over time, we used the orienting aspect of organizing the discourse accordingly as patterns of who participated in the small group discussions, in what ways, and with what outcomes and consequences related to their NOS beliefs. Discourse and componential cross-case analysis provided tools for uncovering student's NOS beliefs and affordances and/or constraints of prior experience on learning opportunities.

Participants

Students in two 6th grade classrooms participated in separate small group discussions. Students in Classroom 1 (n=23) attended a charter school, were primarily Hispanic (50%) and from lower-income families. Students in Classroom 2 (n=24) attended a private school, were primarily White (88%) and from upper-middle income families. Each discussion group consisted of five or six students, randomly selected from among their peers. Each discussion was led by the first author and lasted approximately 20 minutes.

Intervention

We used Questioning the Author (QtA) (Beck & McKeown, 2006) discussion format. QTA encourages critical analysis of text and encourages students to challenge authority related to text information. The text for this study described the scientific rationale for Pluto's reclassification.

Each discussion was audio taped and transcribed for analysis. From these we purposefully selected two groups as telling cases (Agar, 1994). We analyzed students NOS beliefs within and across the two classrooms.

Results

Sources of Knowledge

The analysis revealed a striking contrast between students in Classroom 1 and 2 regarding sources of knowledge (Table 1). Students in Classroom 1 relied solely upon text information for their answers. Students were typically restating ideas from the text such as "Pluto shares Neptune's orbit and Pluto's round shape."

In contrast, students in Classroom 2 either built upon or diverged from text information. For example, Ryan's answer was based upon an experience of attending an outside-of-school event. This suggests that students in Classroom 2 were relying upon experiences and knowledge gained outside of this particular opportunity for learning.

Challenging Authority

Differences emerged regarding student's NOS beliefs about authority (Table 2). Students in Classroom 1 typically viewed text as an authority source as evidenced by their sole reliance on the text for answering questions. In contrast, students in Classroom 2 commonly relied on prior knowledge and experiences to answer questions.

Students in Classroom 1 viewed scientists as the authority for science knowledge. However, no evidence of this authority belief was exhibited by students in Classroom 2. Rather, students in Classroom 2 were likely to challenge the scientists' decision to reclassify Pluto, suggesting that they do not view scientists as having final authority on science knowledge.

Further, each student in Classroom 2 argued that scientists make mistakes. This view was all but missing from students in Classroom 1, with the exception of one student. This provides further evidence students in Classroom 2 relied on their views that scientists make mistakes as justification for challenging scientists as the authority.

Conclusions

The two cases illustrate how differences in the sociocultural context could constrain opportunities for learning. Students in Classroom 1 relied on the text for answering questions while students in classroom 2 exclusively drew upon outside knowledge. Classroom 1 students may not have had opportunities for prior learning or learning

outside of the classroom that would have afforded them the epistemic beliefs for challenging authority. In contrast, students in Classroom 2 likely had opportunities for developing more sophisticated epistemic beliefs, including the belief that it is okay to challenge authorities. Given that the demographics of these two classrooms were radically different, and that neither teacher had previously taught the material, it appears that the deciding factor between these two is prior experience with the information.

THEMATIC POSTER

Science Education

Teachers' Emotions and Plausibility Perceptions of Human-induced Climate Change

Doug Lombardi, University of Nevada, Las Vegas, United States;

Gale Sinatra, University of Nevada, Las Vegas, United States

Topic emotions can have an appreciable impact on the learning process, particularly for controversial topics (Broughton, Sinatra, & Nussbaum, 2010; Griffith & Brem, 2003). Controversial topics may elicit strong emotions that could influence a plausibility judgment about the topic's message. Individuals—especially those who are not disposed to think deeply—may judge a message to be of lesser plausibility based on their emotions, and therefore, would not evaluate the quality of that message in comparison to their background knowledge (Chinn & Brewer, 2001). In such a case, individuals may not engage deeply in the topic and their learning would be reduced. This study examined the relationships among teachers' emotions about human-induced climate change, their plausibility perceptions, background knowledge of weather and climate distinctions (an important scientific principle related to understanding climate change), and needs for cognition and closure. Eighty-five teachers participated in the study and we found that topic emotions, specifically anger, shame, and hopelessness, were significant predictors of teachers' plausibility perceptions of human-induced climate change. More anger resulted in judgments of lesser plausibility, whereas greater shame and hopelessness resulted in greater plausibility. Need for cognition did not predict plausibility, but one subcomponent of need for closure—decisiveness—was significantly related, with greater decisiveness related to lesser plausibility perceptions of human-induced climate change.

Purpose of the Study

Strong emotions are associated with the topic of human-induced climate change (Moser, 2007) and teachers may have adverse feelings when teaching about climate change. In another controversial topic—biological evolution—teachers may experience appreciable anxiety when teaching. Because of their anxiety, teachers may avoid discussing sensitive aspects of evolutionary theory with their students (Griffith & Brem, 2004). Anxiety and other strong emotions could discourage teachers from promoting mastery-level learning in their students (Linnenbrink, 2007).

Emotions based on the instructional topic (e.g., human-induced climate change) may also interfere with cognitive processes (Pekrun, Frenzel, Goetz, & Perry, 2007). For example, individuals use plausibility judgments to evaluate the compatibility of incoming information (Chinn & Brewer, 2001) with their background knowledge (Connell & Keane, 2004). Therefore, when exposed to scientific evidence, individuals may evaluate data quality based on their plausibility perceptions. Strong topic emotions may either raise or lower plausibility perceptions and severely limit this evaluation. An individual's inclination toward a particular view of knowledge (e.g., seeking closure; Kruglanski, 1989) may enhance the effect of strong emotions on plausibility perceptions. However, this effect may be dampened by individuals who are epistemically disposed toward a high need for cognition (Cacioppo, Petty, Feinstein, & Jarvis, 1996).

The purpose of this study is to examine the relationship between background knowledge, needs for cognition and closure, topic emotions and plausibility perceptions. We specifically asked the question: how do background knowledge about weather and climate distinctions (an important conception related to climate change), need for cognition and closure, and topic emotions predict plausibility perceptions of human-induced climate change? We hypothesized that there would be a significant relationship between the predictors and plausibility perceptions.

Methods

Eighty-five teachers participated in the study. Forty were in-service science teachers from a school district in the southwestern United States, who were enrolled in professional development workshop. The remaining 45 were pre-service teachers from the same district enrolled in a local university's science methods course. Participants ranged in age from 24 to 60 ($M = 33.0$, $SD = 11.7$), with 0 to 35 years of teaching experience. The participants were predominantly female (75%) and white (76%).

Participants completed five questionnaires: (a) emotions about human-induced climate change (and teaching about climate change), (b) knowledge of weather and climate distinctions, (c) plausibility perceptions of human-induced climate change, and (d) needs for cognition and (e) closure. The participants completed the questionnaires prior to any instruction about climate change using an online electronic survey tool.

We created the Emotions about Teaching Human-Induced Climate Change questionnaire, containing five items. Participants read statements about human-induced climate change (the first three items) and teaching about the topic (the last two items), then rated how well ten different emotions reflected their intensity of feelings about the statement using a 5-point Likert-type scale (1 = strongly disagree to 5 = strongly agree). The ten emotions are anger, anxiety, boredom, curiosity, fear, frustration, happiness, hopelessness, shame, and surprise.

We used the 13-item Distinctions between Weather and Climate Measure (DWCM; Authors, 2010) to measure background knowledge. The DWCM has 13 statements that participants classified as being either “weather” or “climate.” To assess participant plausibility perceptions of human-induced climate change, we used the Plausibility Perceptions Measure (PPM; Authors, 2010). Participants rated the plausibility of eight statements about climate change culled from the latest report by a United Nations’ expert panel (Intergovernmental Panel on Climate Change, 2008). Participants rated each statement on a 10 level scale (0 = greatly implausible or even impossible and 10 = highly plausible).

Cacioppo et al. (1996) developed the Need for Cognition Scale, which has 18 items measuring the extent to which people engage in and enjoy effortful cognitive activities. Webster and Kruglanski (1994) created the Need for Closure Scale examining students’ “motivation with respect to information processing and judgment” (p. 1049). This instrument has 42 items where participants rate their need for—or desire to avoid—cognitive closure. The instrument includes five subscales measuring: (a) preference for order, (b) discomfort with ambiguity, (c) decisiveness in judgment, (d) affording predictability, and (e) close-mindedness.

Results

We conducted two multiple regression analyses to examine the relationship between the predictor variables (DWCM, needs for cognition and closure, and topic emotions) to PPM (the criterion variable). The first regression (Model 1) includes only topic emotions that individuals have about climate change (see Table 1, only key variables included for conciseness). There was a significant relationship between the predictors and PPM, $F(17,67) = 3.49$, $p < .001$, with $R^2 = .469$. Specifically, hopelessness and shame about human-induced climate change were significant predictors, where a higher intensity of emotion resulted in greater plausibility. In Model 1, background knowledge and needs for cognition and closure did not significantly contribute to prediction of plausibility.

Model 2 includes only emotions about teaching climate change (see Table 2, only key variables included for conciseness). There was a significant relationship between the predictor variables and PPM, $F(17,67) = 1.85$, $p < .039$, with $R^2 = .319$. Anger about teaching climate change and decisiveness (a need for closure subcomponent) were significant predictors, with greater anger and decisiveness resulting in lower plausibility judgments. In Model 2, background knowledge, and need for cognition did not significantly contribute to prediction of plausibility.

Importance of the Study

Earlier studies have shown a relationship between anxiety and teaching about biological evolution (Griffith & Brem, 2003). This study reveals a relationship between anger, shame, and hopelessness to the controversial topic of climate change, providing additional evidence for topic emotions that may impact instruction. As Broughton, Sinatra, and Nussbaum (2010) state, individuals can “exhibit overall enjoyment of science learning, [whereas] a specific topic, may unexpectedly trigger negative emotions” (p. 32). Furthermore establishing a relationship between topic emotions and plausibility perceptions may provide insight into how controversial topics are taught. That is, teachers may bring these negative emotions to the classroom when they teach about climate change. This research begins to shed light on how emotions may influence the teaching and learning of controversial topics.

Children as co-researchers: children’s views from collaborative science inquiries

Charles Max, University of Luxembourg, Luxembourg; Chris Siry, University of Luxembourg, Luxembourg

The aim of this research work is to analyse the process of 4 to 6 year-old children's learning of science by focusing on how these children document and comment their lived and co-elaborated experiences during and immediately after open science learning activities. Drawing from a longitudinal corpus of classroom interactions (200 h), this excerpt is part of a larger three-year study (2008 - 2011) conducted in five Luxembourg pre-school and elementary schools. The

research project is exploring the nature of young children's science learning as a social phenomenon that is interactively achieved, discursively bound and contextually mediated. Of particular interest are the multiple resources, which young learners bring from socio-cultural, institutional and historical contexts and, which they use to make meaning about water phenomena through interactive practices and multimodal talk-in-interaction. The poster will display the multi-dimensional framework of the study based on a thorough combination of sociocultural, interactional and micro-ethnographic perspectives in order to frame „doing science" in collaborative learning activities as a cultural enactment. The data for the study were collected in the spring semester of 2009-2010 academic year via participatory observation, video and document analysis, interviews with teachers and pupils. This research poster informs about the challenges, the process and the outcomes of involving young children as active researchers in the enquiry work of a project on early science learning in pre- and primary school.

Subject

Developing scientific literacy from young age on is the focus of numerous educational reforms internationally during the past decades. In order to shed light on the learning processes of children as they collaborate in early science, this study focuses on interactive practices of children when "doing science" in early childhood classrooms with a complex multilingual background. More specifically, the research analyses the mutual accomplishment of the particular learning context through children's joint acting with equipment and their multimodal interactions. We conceive science learning as an interactional achievement, one that encompasses the enactment of elementary science as culture and as a cultural accomplishment. This enactment unfolds through a dynamic, non-linear and creative combination of culturally given tools and the children's specific linguistic repertoires and discourse formats that they develop across multiple contexts.

Rationale

The rationale behind the present research is to explore the nature of young children's science learning as a social phenomenon that is interactively achieved, discursively bound and contextually mediated. A further issue concerns the multiple resources of young learners, they draw upon when making meaning about water phenomena through multimodal interactive practices. The following questions are guiding the research:

- How do 4 to 6 year-old children display their understanding about water phenomena?
- How does the multimodal nature of children's ways of doing, arguing, reasoning, imagining, re-presenting and talking about water phenomena allow construction of a collaborative framework for exploring the specific science phenomena?
- How does the context-sensitive organization of talk and multimodal interactions of the children shape promising opportunities for science learning in an early education class?

This poster presents challenges, processes and outcomes of the research's initiative to involve 4 – 8 year-old children as active researchers in this project on science learning in pre- and primary school. We understand students as co-researchers when they participate in collecting and analysing research data and inferring imaginable actions (Fielding, 2001). There is a growing body of research (Christensen & James, 2000; Mason & Urquhart 2001; Punch, 2002; Alderson & Morrow, 2004; Flutter & Ruddock, 2004), which involves children as participants and co-researchers and addresses the various ways, they might be actively involved (Darbyshire et al., 2005). Arguments to involve children actively as co-researchers in a multi-method framework are manifold as this allows to a) get a richer and multivoiced evidence, b) overcome unfocused and incomplete perspectives on the processes under inquiry, c) using a more appropriate way of talk as means to access children's views d) start a dialogue with participants in the study who get the chance to reply to data and intermediary findings from an external lens, d) empower the research participants in the area of enquiry (Kellet, 2009, 2010), e) broaden the unit of analysis while keeping the empirical part still manageable (Matusov, 2007).

Multi-method framework

The study is framed by a multi-dimensional approach based on a thorough combination of different research perspectives. In particular, these perspectives include cultural historical perspectives on human activity (Daniels et al., 2010), sociocultural approaches on learning as cultural enactment (Goodwin, 2007), conversational analytic perspectives on learning as an interactional achievement (Melander & Sahlström, 2009) and micro-ethnographical discourse analyses to conceptualizing "doing science" as a cultural accomplishment (e.g., Schlieben-Lange, 1983).

Our multi-method data gathering framework engages children actively in the research process. As we explore what children value in science activities, we acknowledge their voice in the learning process. This allows us to collect their unique insider-perspective on the joint learning process, and to get access to their understandings of the phenomena under scrutiny. Additionally, their own recordings allow us to analyse their discursive practices as enactments of elaborate science, demonstrating representations of science concepts but also the conditions of such science accomplishments.

Research design/ context

Drawing from a longitudinal corpus of classroom interactions (age 4-8), this excerpt is part of a larger three-year study (2008 - 2011) conducted in five schools. By working in collaboration with early childhood teachers, this project documents the emergence of practices through which children co-construct science as a discursive accomplishment, while simultaneously supporting teachers in implementing science activities and expanding inquiry-based approaches. Small handheld video cameras give the children the possibility to a) collect jointly relevant moments of their inquiry activities, b) to express their findings, insights or thoughts in multimodal ways during or immediately after joint science activities. This device gives the students freedom to record important moments without an adult filter and to talk by using own discursive formats.

All the recordings (200 hours) have been organised within a searchable database using Transana, an open-source software (Woods, 2007). They serve as the main data source for the current analytic work. Key episodes are being transcribed in relation to the core research questions. The transcripts serve to analyse the dynamics of speech while children interact (1) in small groups during inquiry activities, and (2) during classroom talk, teacher initiated.

Findings / Analysis

The project has generated tangible outcomes about the multimodal, and discursive ways of young children's enacting of knowledge and reasoning about science topics. In considering the ways children develop shared meanings, the initiative of involving multilingual children as co-researchers allows to considerably increase insights in the genuine features of knowledge building through participating in emerging multimodal and multilingual discourses. In our case, the spontaneous scientific discourse – featuring both specific conceptual content and scientific inquiring – and the children's extended comments on pictures, video clips... from their data collection allowed a richer understanding of their conceptual frameworks (understood as enrichment or reorganization processes) as enacted through discourse during multilayered interaction.

Analyzing and cognitive modelling of strategies in science education

Sascha Bernholt, IPN Leibniz-Institute for Science Education, Germany; Jan Lenk, University of Oldenburg, Germany; Claus Moebus, University of Oldenburg, Germany; Ilka Parchmann, IPN Kiel, Germany

The use of a specific language supports scientists to grasp their ideas, share their thoughts, and solve problems. For example, the application and interpretation of chemical formulae is crucial for chemists, but also one of the most difficult and unpopular topics in chemistry education. To develop successful didactical approaches, more insights in learning strategies and difficulties are required. We address this issue with an integrated approach involving educational research, neuroimaging, and cognitive modelling.

A computer-based learning environment was developed to answer the question, which strategies students develop to match different types of representations. Students from introductory chemistry courses (N=418) responded to tasks that required the matching of formulae with their respective names and appropriate particle models. They were asked for the strategies they used to identify the underlying rules of this symbolic language at specific time points within the learning environment (open-ended questions) and in additional interviews (N=8). The results show that students' strategy quality increased slightly, but significantly, over the course of the learning environment.

Further 63 students took part in a fMRI study, working on tasks about formulae, too. Based on the strategy questions and the interview results, different strategies were modelled using ACT-R. Comparing the strategy-dependent module-region correlations between measured and predicted BOLD-curves show mixed results. The modelled strategies differ in their implementation and need further revisions but the obtained results provide already a firm footing.

Theoretical background

The use of a specific language supports scientists to grasp their ideas, share their thoughts, and solve problems (Krajcik & Sutherland, 2010). For example, the application and interpretation of chemical formulae is crucial for chemists, but also one of the most difficult and unpopular topics in chemistry education for students and even freshman students, as numerous studies revealed (Schmidt, 1997). Problems are mainly referred back to difficulties in connecting different levels of representation (macroscopic, submicroscopic, symbolic/mathematical). However, these problems do not only pertain to the use of chemical formulae but to a large array of topics and concepts across the science domains (DeJong & Taber, 2007).

Research indicates that novices and experts apply different strategies when solving science problems (Williams & Noyes, 2007). Accordingly, strategy use is a major predictor for achievement in scientific problem solving situations (Taasobshirazi & Glynn, 2009). A model to explain complex behaviour in science domains is the Adaptive Control of Thought-Rational (ACT-R) theory (Anderson et al., 2004). This cognitive architecture can be used to quantify and visualise the relationships among cognitive variables involved in learning and problem solving. In addition, Anderson (2007) postulates a neurophysiological analogy between the cognitive architecture and particular brain regions. These regions are captured within ACT-R by a set of seven modules with specific functions. Assuming the viability of the brain mapping assumption, the modules predict BOLD signals for the corresponding brain regions, making it possible to compare BOLD signal predictions generated from strategy-specific ACT-R models with BOLD signals obtained from actual fMRI scans (Mßbus & Lenk, 2009; Mßbus et al., 2010).

Research questions and methods

In order to develop successful didactical approaches, more data and results about learning strategies and difficulties are required. We address this issue with an integrated approach involving educational research, neuroimaging studies, and cognitive modelling. We focused at first on students in introductory chemistry courses as complex problem solving activities require multiple strategies, leading to a large variety of individual pathways and solution methods. A computer-based learning environment was developed to answer the research question, which strategies students develop to match different levels of representation.

Students (aged 10 to 13 years; N=418) responded to tasks that required the matching of chemical formulae with their respective names and appropriate particle models (intervention time: 90 min). They were asked for their used strategies to identify the underlying rules of this symbolic language at specific time points within the learning environment (open-ended questions) and in additional interviews (N=8). Further 63 students took part in a fMRI study, working on tasks about formulae, too. Based on the strategy questions and the interview results, different strategies were modelled using ACT-R. With Bayesian identification analysis the problem solving strategies were matched to participants. Finally, the strategy-based predictions of BOLD-curves were compared to the obtained fMRI data.

Results

The results show that students without prior knowledge and training in chemistry classes are able to understand the basic characteristics of chemical formulae and simple particle models. The students expressed 25 procedures to match formula and names (partially combinations). These were categorized into six levels of strategy quality. Over the course of the learning environment, the strategy quality increased slightly, but significantly (one-way repeated-measures ANOVA, $e = .98$, $F(1.96, 777.9) = 108.54$, $p < .001$). In addition, the quality of the applied strategy correlates with the obtained scores ($r = .22$, $p < .001$).

Four different major strategies of the students were modelled using ACT-R. The individual BOLD curves for the trials were aggregated onto a trial template of 10 scans. Comparing the strategy-dependent module-region correlations between measured and predicted BOLD-curves for the 10-scan template shows mixed results. For six out of seven modules correlations between .73

The project design and results show that combinations of methods and data from different disciplines offer in-depth coverage of complex learning processes. These insights help to identify students' strategies when solving problems in a self-paced manner. However, the range of possible interpretations especially with regard to the results of neuroimaging studies is still limited. Further research is needed to bridge the gap between the different disciplines and to develop descriptive and prescriptive models of student learning (Mason, 2009).

Cognitive Processes for Solving Physics Tasks in Upper Secondary Education

Bettina Kreiter, Universität Duisburg Essen, Germany

The goal of this research project is to describe the cognitive processes that are needed for solving physics tasks in upper secondary education; this description would, in theory, help develop a model of competence, which does not yet exist for upper secondary education. The theoretical cognitive processes will be empirically validated by measuring students' cognitive processes, analyzing tasks and measuring competence. The use of this psychological knowledge is important to properly create a category system of cognitive processes for solving physics tasks in upper secondary education. Our main question, which is present at the moment, is how to validly measure and define the cognitive processes that students use while solving physics tasks.

Fostering representational competence considering students' preconceptions in ray optics

Rosa Hettmannsperger, University of Koblenz-Landau, Campus Landau, Germany; Wolfgang Schnotz, University of Landau, Germany; Andreas Mueller, University of Geneva, Switzerland; Jochen Kuhn, University of Landau, Germany; Wieland Mueller, University of Landau, Germany; Sibel Telli, Universität Koblenz-Landau, Campus Landau, Germany

It is a well-known fact in science education that creating multiple representations plays an essential part in understanding science. The special difficulty in physics stems from the fact that students already have developed physical concepts based on everyday experiences. Their common-sense understanding interacts with the new knowledge acquired in school. This research aims to implement instructions which take into consideration common misconceptions in order to support students in creating "scientifically appropriate" representations. The study was designed as pre-and post-test quasi-experimental design. Students of two classes of the 8th grade in one grammar-school formed real pictures by using a spherical concave mirror. As a result, there are some indications that instructions adapted to widespread misconceptions – while operating on representations – improves students' conceptual understanding more than encouraging the use of various representations alone.

1. Theoretical background

There is a broad consensus among science education researchers and cognitive scientists that students need to develop and understand multiple representations to deal with scientific concepts.

Representational competence means the ability to generate and use different representations in a skilled way and implies understanding how to co-ordinate and to translate different kinds of representations with equivalent meanings into another (Rost 2006).

The special difficulty in physics stems from the fact that students' former schemata are composed of physical concepts based on everyday experiences. Students' beliefs about how the world works are often in contrast to scientific explanations of physical phenomena (Wiesner 1992; Duit 1993).

Following recent research on conceptual change and cognitive science in physics education (Tyson, Venville, Harrison & Treagust 1997, diSessa 2008; Treagust & Duit 2008; Hubber, Tytler, & Haslam 2010), instructions were developed that take into consideration students' prior knowledge being reflected in external representations in order to support students in creating "scientifically appropriate" representations.

2. Research questions

- Are tasks, which demand overcoming common misconceptions by dealing with and operating on domain specific representations in order to be solved, useful to foster representational competences in ray optics?
- To what extent do these tasks help students to improve knowledge and problem-solving in ray optics?
- To what extent do these tasks help students to improve their conceptual understanding in ray optics?

3. Hypothesis

- Students whose prior knowledge about picture formation was taken into account will outperform students who have been taught the same issue, but whose prior knowledge was not addressed, in knowledge and problem solving concerning picture formation.
- Students whose prior knowledge about picture formation has been taken into account will outperform students who have been taught the same issue, but whose prior knowledge has not been addressed in their general conceptual understanding of ray optics.

4. Methods

In a quasi-experimental pre-and post-test study students of two classes of the 8th grade in a German grammar-school were taught by the same teacher to form real pictures produced by a spherical concave mirror. Both treatment and control condition included 3 lessons. Furthermore, pre- and post-tests demanded one class hour in each case. The sample ($n = 57$) included 24 boys and 33 girls.

The treatment condition included instructions adapted to common misconceptions about picture formation (Goldberg & McDermott 1987; Reiner, Slotta, Chi & Resnick 2000). In contrast, students' ideas about this issue were not addressed in the control condition. In both conditions students were encouraged to deal with various kinds of representations. Two tests were implemented before and after the lessons: a curricular valid achievement-test with regard to ray optics and a concept-test based on existing results on students' concepts in ray optics (Goldberg & McDermott 1987, Wiesner 1992)

5. Results

Students in both conditions improved significantly both in knowledge and problem-solving ($MTG_{pre} = 5.27$, $MTG_{post} = 10.24$, $MCG_{pre} = 8.25$, $MCG_{post} = 12.32$, see Figure 1, p $MTG_{pre} = 19.39$, $MTG_{post} = 30.22$, $MCG_{pre} = 21.5$, $MCG_{post} = 26.04$, see Figure 2, p p). We assumed that tasks in both conditions were useful to foster students' experimental competences in ray optics (see research question one). An ANCOVA revealed no significant differences between both groups in the post-achievement-test. As a consequence, the first hypothesis could not be verified. However, an ANOVA indicates that both groups differed in their augmentation of conceptual understanding measured in the concept-test ($p = .005$). Students in the treatment condition improved more than students in the control condition, ($F = 8.655$, $\omega^2 = .13$). For this reason, the second hypothesis was confirmed.

6. Discussion

The present study shows that a relatively short intervention taking into account widespread preconceptions can lead to a significant and practically important improvement of conceptual understanding.

A follow up study with a larger sample size ($n \approx 500$) will be performed in November 2010. The following additional variables will be collected: intelligence, motivation in physics lesson and former achievement in subjects, which could exert an influence on representational competences in ray optics, such as physics, mathematics and German language. Students' worksheets will be collected to analyze how students operate on self-developed and given external representations. Long-term effects will be checked by repeating the post-tests six months after the intervention. In addition, think aloud interviews will be conducted with a small part of the sample ($n \approx 30$) after the intervention and the post-test.

Changes in self-regulated learning in first-year students of a university of applied sciences

Barbara Otto, Institut of Psychology, Germany; Daria Mueller, University of Frankfurt, Germany

How does students' self-regulated learning (SRL) change during their first semester? Can features of the learning context predict the extent of SRL? And can students' academic achievement be predicted by students' SRL and learning context? The present study approached these research questions and surveyed 114 first-year students in the fields of architecture and civil engineering. Based on a process model of self-regulation a student questionnaire was developed to assess various components of SRL and features of the learning context. This instrument was applied at the very beginning (t0), at the end of the first semester (t1), and at the end of the second semester (t2). Additionally, at the pretest cognitive abilities were assessed as control variable by five subtests of WIT-2. Furthermore, data of students' academic achievement (grades, credit points) will be reported to us soon. Concerning the development of SRL during the first semester t-tests for dependent samples were conducted and revealed a significant gain in students' overall SRL. Additional linear regression analyses revealed that the perceived learning context accounts for 23% of students' SRL at t1, whereas it even accounts for 48% of students' SRL at t2. Further regression analyses are pending relating to the question whether SRL and the perceived learning context can predict academic achievement even after controlling cognitive abilities. Conclusions to be drawn in theory and practice will be discussed at the end of the presentation.

Objectives

Every person's life is a chain of learning processes. Being able to regulate one's own learning processes is seen to be the key to successful learning in school and beyond (Boekaerts, 1999). Thus, it is assumed, that self-regulated learning (SRL) significantly determines differences in academic achievement even beyond students' cognitive abilities. Accordingly, many empirical studies have already revealed that the extent of SRL is positive associated with academic achievement (e.g. Fuchs et al., 2003; Pintrich, 2003; Zimmerman & Martinez-Pons, 1986).

Especially critical academic phases, such as the transition to higher education, require the basic ability to learn in a self-regulated way but can also be seen as challenge to further develop these competencies. Only those students who can deal with the higher academic demands in a self-regulated way will persist in their field of study and finally graduate. Hence, if students lack in SRL competencies this might lead to an early drop out of their program at the university.

Actually, recent studies concerning the retention of students at German universities (HIS, Heublein et al., 2008, 2010) showed that about 30% of German students drop out of their bachelor program without a degree. This percentage is even higher at universities of applied sciences: Here, 39% of the enrolled students discontinue. This drop out particularly happens within the first two semesters before the first intermediate examinations are done. One reason of this discontinuity might be seen in a low level of SRL competencies at the beginning of first semester and/or in a lacking development of SRL competencies within the first semesters. As student retention is a key issue particularly at universities of applied sciences the examination of the extent and the development of first semester students' SRL competencies as well as the particular conditions which promote positive developments in SRL are of great interest. Speaking of these conditions in the present study the assumptions of self-determination theory (Deci & Ryan, 1985) can also apply for the development of SRL as SRL is always a self-determined action. Thus, it is presumed that the

perceived learning context plays an important role in students' SRL and consequently also in students' academic achievement.

Therefore, the following research questions are addressed in the present study:

1. How does students' SRL change during the first semester at a university of applied sciences?
2. Can features of the perceived learning context predict the extent of SRL?
3. Can students' academic achievement be predicted by students' SRL and perceived learning context even after controlling for their cognitive abilities?

Theory

Self-regulation

Based on a process model of self-regulation (Zimmerman, 2000) the learning process is divided into three consecutive phases: pre-action, action, and post-action. In pre-action the given assignment and the particular conditions in the learning environment initiate the beginning of the SRL processes by evoking certain motivational and emotional tendencies within the learner. If the learner is not intrinsically motivated or shows low self-efficacy he needs to apply self-motivating strategies. Under these conditions the student has to set goals for his learning. Moreover, the learner will have to plan the application of learning strategies as well as the time he is going to invest. Afterwards, the learner starts with learning (action). He will apply different learning strategies as well as volition strategies. In case the learner deviates from his planned learning behavior it is beneficial if he self-monitors his actual behavior. Finally, a learning outcome results. In post-action the student has to compare his actual result with his prior set goal. Hereby, he also has to evaluate whether the final result can be interpreted as success or failure. Furthermore, he will also reflect how he approached the given task. Consequently, certain emotions (e.g. satisfaction) will arise depending on whether the task was successfully solved or failed. These subsequent emotions and evaluations have an impact on future learning, as they can lead to modifications in planning strategies and time or in setting goals.

Learning context

SRL is always accomplished in a particular learning context. This learning context can be more or less supportive for the development of SRL. According to self-determination theory (Deci & Ryan, 1985) the maximum of self-determination and thus also of SRL can only be reached if the learning context satisfies three basic needs of a learner, namely the need for autonomy, the need for competence, and the need for relatedness. Usually, teaching staff at a university designs the learning context of the students. Therefore, the teaching staff is supposed to have a significant impact on students' SRL.

Method

To approach the research questions 114 first-year students in the fields of architecture and civil engineering of a university of applied sciences were surveyed. Their average age was 22.05 years ($SD=2.95$), and 65% of them were male. In order to assess the longitudinal data a student questionnaire was developed to assess SRL (63 items, $\alpha=.85$) and features of the perceived learning context (12 items, $\alpha=.68$). This instrument was applied at the very beginning (t_0) as well as at the end of the first (t_1) and second semester (t_2). Additionally, at the pretest cognitive abilities were assessed as control variable by five subtests of WIT-2. Furthermore, data of students' academic achievement (grades, credit points) at the end of the second semester will be reported to us by the university soon.

Results

Concerning the development of SRL during the first semester t-tests for dependent samples were conducted and revealed a significant gain in students' overall SRL ($T=2.21$, p Additional linear regression analyses controlling for cognitive abilities revealed that the perceived learning context accounts for 23% of the extent of students' SRL at the end of the first semester, whereas it even accounts for 48% of the variance in students' SRL at the end of the second semester. Further regression analyses are pending relating to the question whether SRL and the perceived learning context can predict academic achievement, even after controlling cognitive abilities. Conclusions to be drawn in theory and practice will be discussed at the end of the presentation.

THEMATIC POSTER

Social Aspects of Learning

Perception Of Relevance, Frequency, Impact And Seriousness Of Suffering And Wellbeing States

Daniela Raccanello, University of Verona, Italy; CAMILLA GOBBO, University of Padova, Italy

Considering the extant literature, it is possible to draw indications on how children represent physical or psychological suffering and wellbeing states from studies focused on themes such as memory of positive and negative events, concepts of health and illness, or ability to distinguish bodily and psychological domains. However, our knowledge on children's representation of internal states deriving from negative or positive experiences of different domains is still scarce. Therefore, we investigated how children and adults evaluate physical and psychological states of both valences on some dimensions, exploring the role of age and gender. The participants were 61 5/6-, 7/8- and 9/10-year-olds, and 20 college students. They evaluated a list of physical and psychological states of suffering and wellbeing according to their relevance, frequency, affective impact and seriousness, and justified their answers. Main results showed that wellbeing states were perceived as more relevant, less frequent and more positive than suffering states. In addition, physical states of suffering were evaluated as more relevant and serious than psychological states by 5/6-year-olds, while it was the opposite for adults. Finally, perception of relevance was positively correlated with perception of frequency and, only for suffering, with perception of seriousness. From an applied point of view, this knowledge could be helpful in devising an intervention for parents and teachers, aiming at improving adults' abilities to relate with children taking into account how they actually perceive and evaluate events with positive or negative repercussion on their lives.

Introduction.

Taking into account an educational perspective, it assumes particular relevance to understand the internal representation of positive and negative events characterizing children's daily life, exploring how and in which terms they form personal evaluations of dimensions such as relevance, affective impact, and seriousness. Considering the extant literature, it is possible to draw some indications on how children represent suffering and wellbeing states on the basis of studies focusing on themes such as memory of positive and negative events, concepts of health and illness, and ability to distinguish between bodily and psychological domains (e.g. Bibace, Wiehe, & Leeman, 2001; Carey, 1995; Fivush, Hazzard, McDermott Sales, Sarfati, & Brown, 2003; Gobbo & Raccanello, 2010; Schmidt & Fröhling, 2000; Wellman & Gelman, 1992). However, even if these studies suggest a growing interest towards this topic, our knowledge on children's representation of internal states relating to negative or positive experiences pertaining to the physical or psychological domain, is still scarce. Only recently, some data about narratives of personal events revealed that 9-year-olds' and their mothers' evaluations of seriousness often do not match (Gobbo, Zanon, Raccanello, & Tornatora, 2009). However, this study examined evaluation of only one dimension and concerned only negative events. Therefore, the main aim of the present work was to investigate how children and adults evaluate relevance, frequency, affective impact and seriousness relating to internal states of either domain and valence. First, we hypothesized higher relevance, frequency and more positive evaluations for wellbeing than for suffering states. Second, we examined whether level of state importance was related to the perceived frequency and, for suffering states, to seriousness. Third, analyzing children's and adults' justifications, we aimed at exploring the dimensions underlying children's and adults' evaluations and their relationships. Furthermore, we investigated whether perception of relevance, frequency, affective impact and seriousness of states changed at different ages; in particular, on the basis of previous findings (Gobbo & Raccanello, 2010), we hypothesized a lower relevance for physical suffering and higher relevance for psychological suffering at increasing ages. Finally, we explored the role played by gender.

Method.

The participants were 61 children: among them, there were 20 5/6-year-olds ($M = 5$ years, 10 months; 13 girls, 7 boys), 20 7/8-year-olds ($M = 7$ years, 11 months; 12 girls, 8 boys) and 21 9/10-year-olds ($M = 10$ years, 0 months; 10 girls, 11 boys). In addition, 20 college students ($M = 22$ years, 3 months; 13 girls, 7 boys) were involved. They were orally proposed a list of states related to physical (e.g. to have headache) and psychological (e.g. to be sad) suffering and physical (e.g. to be in shape) and psychological wellbeing (e.g. to be happy). For each state (5 for each type of suffering and wellbeing) we asked participants to evaluate their perception of relevance, frequency, affective impact and seriousness (the latter only for suffering states), by means of 5-point Likert-type scales, and to justify their answers (except for frequency). In a preliminary phase, children's understanding of each state was assessed and definitions were given when required.

Results and discussion.

Four repeated-measure ANOVAs were run, separately for each dimension, with Age and Gender as between-subjects factors and State (physical and psychological suffering, physical and psychological wellbeing) as within-subjects factor, using the Bonferroni correction for pair comparisons. As far as relevance is concerned, wellbeing states were perceived as more relevant than suffering ones (State: $F(3,219) = 110.17$, $p < .001$); in addition, only for suffering, the physical domain states were more relevant than the psychological for 5/6-year-olds, while it was the opposite for adults (Age X State: $F(9,219) = 3.49$, $p < .001$). Regarding frequency, wellbeing states were considered more frequent than suffering states (State: $F(3,219) = 109.19$, $p < .001$); moreover, for the 7-year-olds and adults physical suffering was perceived as less frequent than psychological suffering (Age X State: $F(9,219) =$

2.30, $p = .017$, $\eta^2 = .09$). Considering affective impact, as expected suffering states were evaluated more negatively than wellbeing states (State: $F(3,219) = 480.47$, $p < .001$); however, only for suffering, adults' evaluations were more negative than for all the other groups (Age X State: $F(9,219) = 2.25$, $p = .020$, $\eta^2 = .09$). Regarding seriousness, physical suffering was perceived as more serious than psychological suffering by the 5/6-year-olds, while it was the opposite for adults (Age X State: $F(3,73) = 3.85$, $p = .013$, $\eta^2 = .14$). Furthermore, we found significant correlations between perceptions of relevance and frequency for each kind of state (physical suffering: $r = .28$, $p = .011$; psychological suffering: $r = .45$, $p < .001$, $r = .43$, $p < .001$, $r = .41$, $p < .001$, $r = .54$, $p < .001$, $r = .60$, $p < .001$). In conclusion, our results showed that wellbeing states were perceived as more relevant, less frequent and more positive than suffering states. In addition, physical states of suffering were evaluated as more relevant and serious than psychological states by 5/6-year-olds, while it was the opposite for adults. Finally, a strong relationship between judgments of relevance and frequency of personal experiences of particular states in both children and adults suggests that the types of states that one has to face more often counts more in one's own daily life. From an applied point of view, this knowledge could be helpful in devising an intervention for parents and teachers taking into account how children actually perceive and evaluate events with negative or positive repercussion on their lives.

Quality of the home learning environment and the transition to school: An Australian Study.

Susan Walker, Queensland University of Technology, Australia; Donna Berthelsen, Queensland University of Technology, Australia

The quality of children's early home learning environment and early learning competencies appears to be instrumental to school adjustment and achievement. This poster reports data analyses from a nationally representative sample of children participating in Growing Up in Australia: The Longitudinal Study of Australian Children (LSAC). Three research questions are addressed: (1) Are early home learning experiences at age 4 years related to academic outcomes at 8 years? (2) Are differences in academic outcomes at age 8 accounted for by the level of children's language and emergent academic skills at age 4 years? (3) Are differences in academic outcomes explained by children's learning-related behaviours at age 6 years? The regression analyses use data from three data waves of LSAC, when children were age 4, 6 and 8 years. The sample group for the analyses were 3,643 children in the Kindergarten Cohort who were 4 years of age at recruitment into the study. Regression analyses controlled for a number of socio-demographic factors. Significant contributions to learning outcomes were: being read to daily by an adult in the home at age 4 years; children's approaches to learning at 6 years of age, and learning competencies at age 4 and 6 years.

There is increasing recognition of the importance of the early years of school in establishing the foundation for future academic achievement. The quality of children's early home learning environment and early learning competencies appears to be instrumental to school adjustment and achievement. Research indicates that early and subsequent engagement with school is contingent on developing early competencies in literacy skills; the ability to build positive relationships with peers and teachers; and self regulation (Pianta & Stuhlman, 2004). It has been found that the process of social and academic disengagement with school can begin as early as first grade (Alexander, Entwistle & Horsey, 1997; Hamre & Pianta, 2001; Jimerson, Egeland, Sproufe, & Carlson, 2000). However, in Australia, there have been no attempts to replicate findings about the influences on early school learning that have been derived from longitudinal research in other national contexts. This paper reports data analyses from a nationally representative sample of children participating in Growing Up in Australia: The Longitudinal Study of Australian Children (LSAC). This research involves a longitudinal cross-sequential design. Two cohorts of children (a birth cohort and a kindergarten cohort) were identified from Medicare records and selected based on a stratified random sampling procedure designed to make the sample as representative of the broader Australian population as possible. Biennial data collection commenced in 2004. Three research questions are addressed in the analyses: (1) Are early home learning experiences at age 4 years related to academic outcomes at 8 years? (2) Are differences in academic outcomes at age 8 accounted for by the level of children's language and emergent academic skills at age 4 years? (3) Are differences in academic outcomes explained by children's learning-related behaviours at age 6 years? The regression analyses use data from three data waves of LSAC, when children were age 4, 6 and 8 years. The sample group for the analyses were 3,643 children in the Kindergarten Cohort who were 4 years of age at recruitment into the study. Outcome measures for the analyses when children were 8 years of age are teacher ratings on the Academic Rating Scales (ARS) for language and literacy and mathematical thinking. The measure of classroom behaviour at age 6 and 8 years is a 6-item measure of Approaches to Learning (e.g., attentiveness and task persistence). Children's receptive language competence and emergent literacy skills at age 4 were measured by the Peabody Picture Vocabulary Test (PPVT – short form) and the Who Am I? Early home experiences at 4 years of age include reports of home learning activities from parent interviews. The regression analyses controlled for a number of socio-demographic factors. Results indicated that variables making significant contributions to learning outcomes at age 8 were: being read to daily by an

adult in the home at age 4 years; children's approaches to learning at 6 years of age, and learning competencies at age 4 and 6 years. Children beginning school with early academic skills and with positive approaches to learning indicate a positive learning trajectory that will support ongoing engagement and success through school. While the regression models tested found that early learning experiences and competencies contribute to learning outcomes at age 8 years, over and above socio-demographic factors; nevertheless, the socio-economic position of the family and the child's Indigenous status were influential in the full models tested. Positive learning opportunities prior to school appear to be critical to tackling social inequalities during childhood. In particular, these findings suggest that the early acquisition of learning-related social skills such as attentional skills and self regulatory skills prior to school entry is crucial. Support for socially disadvantaged families can help mediate some of the negative effects on children's early learning, particularly if a comprehensive approach is taken that considers the multiple factors that influence children's early school success.

Motives Whom to Choose as Supportive Persons in Networks

Markus Hirschmann, University of Regensburg, Germany; Hans Gruber, University of Regensburg, Germany

Today's working processes are shaped by innovative and complex problems. In many cases employees are not able to solve these problems successfully on their own. They lack certain knowledge or expertise and thus need support by their colleagues and other employees. This calls for continuous sharing and exchange of individual's knowledge and experiences in teams and networks. Due to that, sharing of expertise in networks is a crucial aspect of modern workplace learning. But at many workplaces knowledge and expertise is shared primarily with close colleagues, but not at all with approved experts. The motives of these decisions with which persons expertise is shared, have not been analysed. The purpose of this study is to get better insight into this process. Therefore, we used a social network analysis (1) to identify individuals who are in a central position within a network, because they share their knowledge and experiences with colleagues, and (2) to elaborate factors that predict the choice of these persons on three different levels – individual, socio-cultural, and organisational. In the domain of software engineering and business consulting, we analysed five project teams each in small and medium-sized enterprises. Data collection is still in progress. We will use multilevel analysis to analyse the data. At the conference we will present the results of this study.

Wasko, M., & Faraj, S. (2005). Why should I share? Examining social capital and knowledge contribution in electronic networks of practice. *MIS Quarterly*, 29, 35-57.

Promoting Psychological Well-Being Globally: Findings from Italian Primary and Secondary Schools

Alessandra Cavallo, University of Padova, Italy

This contribution represent the Italian part of a large international project being conducted in countries around the world, under the leadership of Dr. Bonnie Nastasi of Tulane University, USA. The purpose of this international project is to develop definitions of psychological well-being and psychologically healthy schools, based on perspectives of key stakeholders (teacher, student, school, community) within participating countries. The project represents a first step in understanding psychological health of individuals and schools from a social-cultural perspective and subsequently developing programs to promote well-being of students through individual and ecological change. Preliminary findings suggest that basic education has two main goals: to promote high quality learning outcomes and pupils' personal growth and well-being. The interrelated nature of learning and well-being is here referred by examining the kind of condition that pupils, teachers, parents, school administrators and psychologists find correlated to students' well-being during primary and secondary school.

Theoretical Framework

The following depiction reflects an ecological and developmental framework for conceptualizing psychological well-being (Nastasi, 2004). The goal of this project is to depict the individual and social-cultural factors that influence well-being within specific countries, communities, and/or cultural groups. In order to avoid imposing Western-based student mental health and well-being, collaborators conducted formative research to gather data from key stakeholders, within participating countries, about conceptions of psychological well-being for individuals (children and adolescents) and school and community contexts. More information can be found in the following publication Nastasi, B.K., Moore, R. B., & Varjas, K. M. (2004). *School-Based Mental Health Services: Creating Comprehensive and Culturally Specific Programs*. Washington, DC: American Psychological Association.

Project Objectives

Identify definitions of psychological well-being held by various stakeholder groups.

Identify definitions of psychologically healthy environment held by various stakeholder groups.

Research Questions

What is a psychologically healthy environment (home, school, community, society)?

What factors influence psychological well-being of children and adolescents?

What are the roles of schools, families and communities in promoting psychological well-being?

What are effective ways to promote development psychological well-being of children and adolescents in schools?

Methods

Focus group interviews—students, parents, teachers.

Ecomap activity—students.

Individual interviews—administrators, physical/mental health support staff.

Italian participants

Students—primary and secondary grade levels (8 groups of 6-8 each: 4 primary; 4 secondary). Data collection involved 2 sessions with each small group of 6 to 8 students, who are similar in age level (e.g., ages 6-8, 9-11, 12-14, & 15-17). Groups were gender-specific, with balance of male and female across age levels. The first session concerned a focus group discussion consisting of general questions like what is expected of children/adolescents your age in school? What is expected of friends your age? What are children/adolescents your age expected to contribute to your community, society, country? Describe a good/ not good parent, describe a good/ not good teacher; questions about emotions and questions about the sources of distress. The second session concern a Ecomap activity. The purpose of this activity was talk about the people and events that were important for the students, for example, in their home, school, community and describe a drawing that showed their relationships with these people and events.

Parents of primary and secondary grade level students (4 groups of 6-8 each: 2 primary; 2 secondary). Data collection involved 4 focus groups with small groups of 6 to 8 parents primary school children (ages 6-11) and secondary grades (ages 12-17). The purpose of this activity was identifying ideas about children's well-being, parents expectations for their children, ideas about child rearing, and how parents think schools and families can help to promote children's well-being.

Teachers of primary and secondary grade levels (4 groups of 6-8 each: 2 primary; 2 secondary). This session concerned a focus group discussion on teachers ideas about children's well-being, their expectations for their students, their ideas about disciplining students, and how teacher think schools and families can help to promote children's well-being. School administrators (5 individual) and school or community mental/physical health staff (5 individual). This session concerned a focus group discussion about issues related to promoting the psychological well-being of children and adolescents. The data yielded were analyzed throw the use of Atlas.ti software. This process were supported by a top-down strategy based on the following code categories.

Valued competencies. Any reference to competencies valued in the culture, to optimal functioning, engaging in culturally acceptable behaviour.

Adjustment difficulties. Any reference to adjustment problems, mental illness, dysfunction, maladjustment, lack of competence, or culturally unacceptable behaviour.

Feelings. Any reference to emotions; includes labels or terms for feelings, how feelings are expressed.

Stressor. Any reference to risk factors or stressors present in the social-cultural environments of family, school, peer group, community, and society. Any risk factor/stressor that can potentially impede an individual's development or education or cause psychological distress.

Support. Any reference to resources or sources of social support available in the social-cultural environments that can facilitate coping with stress, address psychological problems, or provide some type of help or support. Includes both informal social supports (e.g., family, peers, teachers; and formal supports or professional services (e.g., from school counselor, psychiatrist).

Reaction to stressor. Any reference to how an individual responds to or copes with stress or problems; can include emotional, cognitive, and behavioural responses.

Reaction to support. Any reference to how an individual responds to support or help from others; can include emotional, cognitive, and behavioural responses.

Role definitions. Any rfence to the defintion of a spific role in society (e.g., teacher, student, parent, fried).

Socialization practices. Reference to how one becomes socialized according to social-cultural norms, or how one facilitates development of education of the child/student. Includes practices related to discipline or education that are used to help children develop competencies or meet adult or situational expectations.

Definition of psychological well-being. Definition of psychological well-being (these are explicitly provided in interviews with administrators/providers) or reference to attitudes toward mental health (e.g., how cultural or societal attitudes and understanding have changed over time).

Results highlight the importance of listening pupil's voices where aspects of well-being are concerned. The perspectives of children and adolescence can provide a salient basis for making recommendations, directing further exploration and constructing ideologies. The research data represent an interest possibility in terms of create the conditions for educational development in school, aimed at promoting more and more plenty well-being of the students. Results showed that a positive relations with teachers in the classroom and between home and school (as a support and presence of positive communication), is acting on the psychosocial adaptation of children and adolescents at school. Such information may in fact result in lines as design active collaboration between school administrators, teachers, students and families in building a school environment which stimulate the freedom of expression and mutual respect. This aspect requires that the people working together from different point of view, respect one another, avoid stereotypes about particular disciplines and consider individuals for their ability to contribute to a collaborative process.

Educational success despite difficult circumstances. Profiles of resilient students

Manfred Prenzel, TUM School of Education, Germany; Katharina Mueller, Technical University Munich, Germany

The OECD coordinated "Programme for International Student Assessment" (PISA) has repeatedly shown a strong dependency of students' academic achievement on their socio-economic background (Ehmke & Baumert, 2007). Internationally, this dependency is particularly high in Germany. While showing that the competencies of 15-year-olds depend strongly on economic, cultural and social background variables, the PISA-findings do not yet answer the question whether all students who are socio-economically deprived are affected by social disparities in the same way. Regarding the group of 'top performers' (OECD 2009) it can be assumed that there are atypical developments of positive adaptation which are favored by differential student- and school-level input and process variables. The presented research project investigates this question by a person-centered approach applying the PISA-2006 database (Prenzel et al., 2007). The aim of the secondary data analysis is (1) to identify disparity-causing variables, (2) to operationalise the phenomenon of academic resilience (Luthar 2006) on the basis of large-scale-assessment data, and (3) to describe profiles of positive adaptation. For this purpose, we are using latent class analyses (Hagenaars & McCutcheon, 2002) to identify subpopulations of students who are characterized by low socio-economic and cultural resources but strong achievement in the scientific PISA tests. These students show resilience in a sense that their actual achievement is over what is predictable with regard to their socio-economic status.

State of the art: Large scale assessments like PISA show that there are great social disparities in the educational success of students. In particular, features of the socio-economic background plays a major role for students' competence development and access to higher educational institutions. The interaction of social disparity causing effects ranging from structural and process features of family life conditions to institutional mediation mechanisms turns out to be extremely complex.

Recent findings from PISA have indicated a decreasing - but still strong - social gradient (described by the relation between social background and the achieved level of competence) for Germany (Ehmke & Baumert, 2007). However, the international comparison shows that good performance is not necessarily dependent on social origin, because the degree of social disparity varies strongly in the other OECD countries. Moreover, international comparison of so-called 'top performers' (i.e. students belonging to the leading group on the competence levels V and VI) indicate that there are a number of students showing high levels of competence in science despite having a low socio-economic status (OECD 2009).

Whereas there are detailed findings for the group of 'top performers' as a whole (OECD 2009), we still need to gain a deeper understanding of the processes and mechanisms that enable some students with below-average economic and cultural resources to perform highly. We use the concept of "academic resilience" to describe these students' atypical process of positive adaptation in the face of adverse circumstances. More precisely, "Resilience refers to a dynamic process encompassing positive adaptation within the context of significant adversity" (Luthar, 2006, p. 543). Resilience is characterized (1) by the fact that it is a dynamic, bi-directional development process between the individual and the environment, (2) that it is variable over time and situations (Wustmann, 2005). (3) Moreover, resilience is a domain-specific concept (Luthar, 2006). Based on the already existing results we assume that the so defined resilient students as well as 'top performers' differ from the total sample by differential interests, motivations and domain-specific activities regarding science subjects and positive attitudes towards learning (OECD, 2009b). Additionally, gender, migration status, home language and the socio-economic context of school supposedly relate to students' performance as well as self-concept (Artelt, Demmrich & Baumert, 2001) and educational processes and settings at home Ehmke, 2008).

Aims and research questions:

The study focuses on top performing students in PISA who have weak socio-economic and cultural resources in their families. Their atypical development of positive adaptation is assumedly due to differential student- and school-level input and process variables. The aim of the secondary data analysis is (1) to identify these variables, (2) to operationalise the phenomenon of academic resilience on the basis of large-scale-assessment data, and (3) to describe profiles of positive adaptation. The findings should help to develop an evidence-based concept of academic resilience.

The research questions are: (1) Which student- and school-level input and process variables characterize 15 year-olds with top performances in scientific literacy, but below-average indices of social background? (2) What qualitatively different profiles of resilience can be identified?

Methodology:

The presented research project investigates these questions by using a person-centered analytic approach and the PISA-2006 database (Prenzel et al., 2007). In a first step subtypes of related cases are extracted that differ from the sample average by both top performances and low socio-economic backgrounds. With regard to individual, institutional and family characteristics (student- and school-level input and process variables) this group is compared with those students showing a competence development as expected. In a second step qualitative profiles of resilience are identified within the group of deprived students using Latent Class Analysis (Hagenaars & McCutcheon, 2002).

Theoretical and educational significance of the research:

These different findings of empirical educational research are used to adapt the concept of resilience within the scope of large scale assessment data and thus gain empirical evidence of traits reducing social disparity. It is investigated whether the interdisciplinary approach of resilience is methodologically connectable and applicable for issues in the context of school particularly in internationally standardized assessment of schools.

Special Needs Education

Factors that influence high school completion regarding students with special needs

Karen Tetreault, Université du Québec à Trois-Rivières, Canada; Sylvie Frechette, Université du Québec à Trois-Rivières, Canada; Nadia Rousseau, Université du Québec à Trois-Rivières, Canada; Helene Fournier, U. du Québec à Trois-Rivières, Canada

Mainstreaming is a priority in the Quebec school system. However, very few studies have documented the situation of students with special needs in this setting. Therefore, this study aims to determine school related factors that influence their high school completion, to document suggestions provided by students to improve school experience, and to compare the nature of the suggestions from students with or without diplomas. Two methodological approaches are used. Statistical analyses are performed on data collected from 10,059 students from one Quebec geographic area. Qualitative analyses are conducted on 35 semi-structure interviews with youths having a high school diploma or not. This study enlightens our comprehension of the obstacles encountered by students with special needs.

Introduction

In the last forty years, the Quebec school system changed considerably. Various committees advised the government over the years. The Ministry of Education implemented various services to help students with special needs. Mainstreaming has become a priority. The services offered to students officially identified as having special needs should improve both retention and certification rates. Currently, few studies have considered the school experience of students with special needs within this context.

Theoretical framework

The Ministry of Education (MELS, 2009) had determined a classification of students. Most students can be at risk at one time or another during their schooling. This group includes students with learning disabilities and behaviour issues. Another group includes students with special needs such as intellectual disabilities, physical disabilities, behaviour problems, dysphasia, and pervasive developmental disorders. These students are particularly vulnerable to leaving school without certification.

The Ministry of Education (MELS 2009) defines dropping-out as abandoning one's schooling without certification before the age of twenty. Dropping-out is a multidimensional phenomenon that results of the combination of many variables. Students that drop out of general education give the following reasons: lack of motivation, academic reasons, personal or family related issues, hope to earn a living or have a job, their training perceived as completed, wanting to continue their schooling elsewhere, and repeated academic failures (Potvin et al., 2004). Three quarters of high school dropouts regret their decision and would like to complete their high school degree (Gauthier et al., 2004).

At risk students have the following characteristics: male gender, unproductive coping strategies, low self-esteem, poor social skills, negative perception of school, academic difficulties, lack of motivation, and behaviour problems (Fortin, Potvin & Royer, 2000). Repeated school failures greatly influence a teenager's decision to drop-out of school. An advisory committee to the Quebec government (CSE, 1996) states that the current school system's homogeneous curriculum negatively affects school success and perseverance of students with special needs.

Objectives:

- 1) Determine the school related factors that influence high school completion.
- 2) Analyse the suggestions provided by students (with or without diplomas) to improve the school experience of future students.
- 3) Compare the nature of the suggestions from students with and without diplomas.

Method

Two methodological approaches are used in the study. A quantitative approach is chosen to fulfill the first objective. Statistical analyses are performed on data collected from 10,059 students from one Quebec geographic area. These students are grouped in three cohorts according to their first year in the school system, known as kindergarten. At the time of our data collection, the 1983 cohort subjects are 25 to 26 years old, the 1988 cohort ones, 21 to 22 years old, and the 1992 cohort ones, 16 to 17 years old. All students are divided in two main categories: regular students and students with special needs.

A qualitative approach is used to attain the second and third objectives. One-hour semi-structured interviews are performed with 35 youths of the above cohorts: 19 are high-school dropout and 16 have a high school diploma. A questionnaire is created to focus on personal characteristics, school experience and work field experience. Also, youths are asked to give suggestions to improve the school experience.

A first step of coding is performed using Atlas-ti. Codes and categories are created by one coder. Then they are all reviewed by a second coder. Two procedures are used to score the interviews: code frequencies and subject frequencies.

Findings and discussion

The data analysis focuses mainly on the school trajectory of students with special needs. The preliminary data shows that approximately one third of the cohorts (1983: 30.5%; 1988: 37.9%; 1992: 28.9%) are officially identified as having special needs. Within the students with special needs groups, boys are more represented than girls. For instance, in the 1988 cohort, 47.1 % of boys are identified as student with special needs compared to 28.0% of girls. Amongst the 29% of students without diplomas in the 1988 cohort, 84.2% are students officially identified as having special needs.

Youths with or without diplomas identify academic, family related and personal factors perceived as affecting school success. They are investigated and outlined in an extensive description. A comparison based on frequencies shows that youths without diplomas make more external attributions to explain success or failure such as teachers' attitudes and pedagogical techniques whereas youths with diplomas assigned success to student engagement and will. More precisely, factors relevant to school and teachers are more frequent than family or personal factors among youths without diplomas. Several suggestions will be made to keep students in school or reconnect them with.

Conclusion and educational significance of the study

The originality of the study is twofold. Firstly, no study in Quebec has ever documented the school trajectories of students from kindergarten to university. Secondly, students were asked to voice their opinion on their school experience. Therefore, this study enlightens our comprehension of the obstacles encountered by students with special needs. The latter will provide useful information in the creation of recommendations to improve their situation.

Grandparents with a typical and a disabled grandchild: their involvement in care and development

Ekaterina Kornilaki, University of Crete , Greece; Maria Kypriotaki, University of Crete , Greece

The prolonged life expectancy and changes in family are responsible for the increased involvement of grandparents in their grandchildren's rearing and development. Research evidence suggests that grandparents have a variety of roles within their intergenerational families and a positive effect on their grandchildren's well-being. However, less is known on grandparents of children with special educational needs. This study aims to investigate and compare the extent and kind of grandparents' involvement in families with a typical developing grandchild and a child with special educational needs. The potential factors associated with their involvement will be explored (geographical distance, health, family status etc), their emotional closeness with the child and the satisfaction they derive from this relationship. Structured questionnaires were administered to paternal and maternal grandparents with a nursery or primary school grandchild. The study is in progress. The findings will be discussed in relation of the need to consider grandparents as part of the family support system and provide them support and encouragement.

There is a growing body of research evidence on the role of grandparents on their grandchildren's upbringing. The reasons of grandparents' increasing involvement on of their grandchildren's lives are several. People now live longer and on average they become grandparents at around the age of 54 (Dench & Ogg, 2002). That means that they will be grandparents for about one third of their life and will probably spend more time being grandparents than parents with underage children (Harpert & Levin, 2005). Family changes are also responsible: working parents, single parents, families in crisis. As a result grandparents will try to fill the parental void (Tan, Buchanan, Flouri, Attar-Schwartz, & Griggs, 2010). Although their involvement can range considerably, research shows that when they are involved they

have a variety of functions. According to Ross (2006) they can be the confidants to whom children tell their secrets, the protectors and supporters, the benefactors as they provide financial support and those who connect the family with their roots as they are the living history of the family. Grandparent involvement has been found to have beneficial outcomes for the children. Closeness and involvement are positively associated with children's well-being measured as psychological adjustment (Griggs, Tan, Buchanan, Attar-Schwartz, & Flouri, 2010).

Less research evidence is available on grandparents' involvement with their grandchildren with special educational needs. Grandparents provide emotional and instrumental support in those families and help parents cope with the stress and the daily errands (Seligman, 1991). It has been found that they also add to the mother's well-being and adjustment (Florian & Findler, 2001).

In Greece the members of intergenerational families are closely knit. Grandparents are actively involved in their grandchildren's lives. However, their involvement has not been recognized by policy makers and studied sufficiently. The aim of this study is to explore and compare grandparents' involvement in families a) with a typical developing grandchild and b) with a grandchild with special educational needs. More specifically, this study aims to assess: i) The extent and ii) the kind of grandparents' involvement. It is hypothesized that grandparents will fill the parental gap during the hours parents are at work, will play with their grandchild, will help with school work, teach skills and participate in extra-curriculum activities. The degree and the kind of their involvement are expected to vary depending on the age and kind of difficulties faced by their grandchild. iii) Potential factors associated with their involvement will be examined including geographic distance between their home and their grandchild's home, age, health, family status, educational level, professional commitments and free time. iv) The emotional closeness between the child and the grandparent, v) the relationship between emotional closeness and the extent and kind of their involvement and vi) the satisfaction they derive from their involvement. vii) The difference in the kind and the degree of involvement between maternal and paternal grandparents.

The participants of this study are a) the grandparents of nursery and school aged typical developing children and b) the grandparents of children with difficulties who attend special schools. Grandparents' demographic information, the extent of their involvement and the kind of activities they share with their grandchild will be accessed by structured questionnaires. Elder & Kings (2000) grandparent involvement scale has been adjusted for this purpose. The factors associated with their involvement, such as distance, health, free time etc will also be examined by a structured questionnaire. The emotional closeness between the grandchild and the grandparent is accessed by Elder, Conger, Parke, & Kings (2000) scale.

The study is in progress. The findings will be discussed in relation of the need to consider grandparents as part of the family support system and provide them support and encouragement.

Parents and children with or without special educational needs: Beliefs, relationships & activities

Maria Kypriotaki, University of Crete , Greece

The purpose of this study was to explore: a) the quality and b) the quantity of the relationships that parents develop with a child with special educational needs or with a child without special educational needs. The sample of the study consisted of 199 parents with children attending a public school in Greece. Parents responded to a questionnaire in order to have their beliefs on the value of children and their relationship with their children explored. A check list assessed the time that parents spend with their child and the activities that parents do with their child on weekdays and on Sundays. The main findings revealed that: a) parents of children with special educational needs have a stronger belief that their child is a source of personal and family trouble than parents of children without special educational needs, b) both parents of children with and without special educational needs display an equivalent degree of the belief that their child offers them personal happiness, c) parents of children without special educational needs have a stronger sense of cooperation with their child than parents of children with special educational needs, d) fathers spend less time with their child on weekdays and on Sundays in comparison with the time that mothers spend with their child; this was found for both parents of children with and parents of children without special educational needs.

The role that a family plays in a child's development is indisputable (e.g. Goldstein, Hamm, & Schumacher, 2007). Parents play a crucial role, because the parent-child relationship gives children the opportunity to develop skills and abilities, useful to future social interactions and affects their social behavior (Korosis, 2003).

Many researchers focused on the family that has a child with special educational needs and concluded that:

- there is a negative impact on the quality of the relationships between the couple (e.g. Eddy & Walker, 1999),

- the family faces an increased degree of difficulty when coping with crisis situations (Minnes, Nachshen, & Woodford, 1999),
- parents have increased physical, financial and emotional needs (Oelofsen & Richardson, 2006),
- parents experience increased levels of stress (e.g. Ainbinder, Blanchard, Singer, Sullivan, Powers, Marquis, & Santelli, 1998),
- parents have limited social interactions, (e.g. Edwards, Higgins, & Zmijewski, 2007).

The involvement of parents in their child's activities strengthens the positive self-image of the child (King et al., 2003). The participation of the child in the family life is of crucial importance for the development of many social skills (King et al., 2003).

Research has also revealed that:

- mothers spend more time with their child (Bundesministerium für Familie, Senioren, Frauen und Jugend, 2006),
- there are some differences between the kind of activities that fathers prefer and the activities that mothers do with their child (Woodworth et al., 1996),
- there is a difference in the time that fathers spend during weekdays according to the gender of the child, when the child is at the pre-school age (Fthenakis & Minsel, 2002).

The literature review reveals that the role that parents play to the future development of their child is multidimensional. A family that has a child with special educational needs deals with a variety of difficult situations. The participation of the child in different activities and the interaction of the child with the members of the family, as well as with other people (outside the family) are of great importance. The time parents spend with their child (each parent separately and both parents together) is very important, because the activities that parents do with their child, help the child to develop several abilities and skills that he/she will use in the future. Many researchers focused their surveys on the difficulties and problems that the members of a family that has a child with special educational needs face. A considerable part of the international research has focused on the everyday participation of a child with special educational needs in family activities (e.g. King et al., 2003; Murphy et al., 2008; Sandler et al., 2004). On the other hand there is little research as far as it is known, on the perceptions that parents have about the value of the child with special educational needs, on the quality of the parent-child interaction, as well as on the amount of time and the activities that parents do with their child (during weekdays and on weekends). The present research responded to this lack of research.

The aim of the present study is to explore: a) the quality and b) the quantity of the relationships developed between parents with a child with special educational needs, and between parents with a child without special educational needs. Participants were 199 parents of children (7-12 years old) with and without special educational needs. Parents responded to a questionnaire with a five-point Likert scale which assessed the quality of relationships between parents and children and parents' beliefs on "the value of the child". A check list also explored the time that parents spent with their child and the activities that parents do with their child on weekdays and Sundays.

The results of the study revealed that: a) parents of children with special educational needs have a stronger belief that their child is a source of personal and family trouble than parents of children without special educational needs, b) both parents of children with and without special educational needs display an equivalent degree of the belief that their child offers them personal happiness, c) parents of children without special educational needs have a stronger sense of cooperation with their child than parents of children with special educational needs, d) fathers spend less time with their child on weekdays and on Sundays in comparison with the time that mothers spend with their child; this was found for both parents of children with and parents of children without special educational needs, e) both parents of children with and parents of children without special educational needs spend more time with their child on Sundays than on weekdays, f) parents of children with special educational needs do less activities with their child on Sundays than parents of children without special educational needs, g) mothers do more activities with their child on weekdays than fathers do.

The findings of the present study are in line with previous research findings (e.g. Ainbinder et al., 1998; Eddy & Walker, 1999; Fthenakis & Minsel, 2002). Moreover, the present study extended exploration into the quality and the quantity of the parent-child relationships in families with children with or without special educational needs and the differences these relationships reveal between mothers and fathers.

The Transition to School for Children with a Developmental Disability: What makes a Difference?

Donna Berthelsen, Queensland University of Technology, Australia; Susan Walker, Queensland University of Technology, Australia; Jan Nicholson, Murdoch Childrens Research Institute, Australia; Suzanne Carrington, Queensland University of Technology, Australia; Stephanie Dunbar, Queensland University of Technology, Australia

The transition from early intervention programs to inclusive school settings presents children with developmental delays and disabilities with a range of social and learning challenges. The Transition to School Project is a longitudinal project which began in 2008. The study is tracking cohorts of children with developmental disabilities from recruitment in the year in which they commence school and across the next two years. This poster presents quantitative and qualitative data from parents and teachers for 150 children participating in the Transition to School Project. Data was collected through parent phone interviews, teacher questionnaires and direct child assessments. Research questions addressed are: How satisfied are parents with their child's inclusive program and the level of support provided for the transition? How easy was it for the child to make the transition? What are the benefits and challenges for the teacher to include the child in regular classroom? Collective responses from parents and teachers are reported as well as two case studies of children contrasting easy and more challenging transition experiences. Findings from this project can inform the development of effective transition-to-school programs and inclusion through the early school years for children with developmental delays and disabilities.

The transition from early intervention programs to inclusive school settings presents children with developmental disabilities with a range of social and academic challenges. While the inclusion of young children with disabilities in regular classrooms has been an important direction in Australian educational policy for the last two decades, research on child outcomes for successful inclusion in mainstream classrooms is limited. The transition to school represents a qualitative change in context for young children, in which they are confronted with a number of social and academic challenges (Rimm-Kaufman & Pianta, 2000). Typically, most children make the transition to school successfully and embark on learning trajectories that are characterized by few or no difficulties. However, children with disabilities have additional support needs and are at high risk for poor outcomes. It remains important to identify potentially modifiable factors that are causally related to transition difficulties for children with additional learning needs. In the Australian state in which this research was conducted, young children with developmental disabilities attend sessional programs at Early Childhood Special Development Programs (ECDPs). In the transition year, when typically developing children begin a preparatory (Prep) full-time school program, many children with developmental disabilities continue to attend an ECDP for 2 to 3 days each week, while beginning attendance in a mainstream Prep program for 2 to 3 days; increasing to full-time attendance across the year if the transition is successful. The research question addressed in this paper is: What factors are predictive of a successful transition to school? The processes that are hypothesised to affect child outcomes are the teacher-child relationship, teacher support, and parent involvement. The child outcomes examined are children's classroom engagement, peer acceptance, and social adjustment. The Transition to School Project is a longitudinal project which began in 2008. The study is tracking cohorts of children from ECDPs through the early years of school from recruitment in the year in which they begin attendance in a Prep program and across the next two years. Data collection in the project involves direct assessment of children in the first year, parent phone interviews across three years, and questionnaires completed by the children's teachers in each year of the study. Quantitative and qualitative data are collected. Data from parents and teachers for 150 children in their first year of participation in the study are analysed for this paper. Mean age of the children is 5.6 years and 74% are boys. The most common diagnostic category as identified by parents is Autism Spectrum Disorder (ASD) including Asperger's Syndrome. From the qualitative data, benefits for the child's attendance in the Prep program noted by the teachers included the availability of positive peer models. Child-related concerns related to the management of children's aggressive and non-compliant behaviours. Major challenges for teachers related to planning to ensure appropriate activities across the curriculum. Results from parent interviews indicated that most parents saw socialisation and learning to play with other children as a major benefit of their child attending an inclusive setting. However, some parents also mentioned preparation for formal schooling and the opportunity to learn skills that would be important for future participation in educational settings as potential benefits for their child. Inclusion in a regular classroom also presented some challenges for parents. A number of parents commented that their child's particular needs (e.g., communication or attentional difficulties) posed problems for the child in a regular setting. Parent satisfaction with the school placement was related to the extent that they felt the school provided support to the child. Quantitative analysis using logistic regression to identify child characteristics, family and school factors that explained teacher and parent-reported ease of transition indicated that teacher-reported ease of transition was related to the children's learning related social skills (e.g., attentiveness and task persistence) and the child's level of competency from parent reported data, as well as the extent to which the teacher believed that the child was appropriately placed in the Prep program. Parent-reported ease of transition was related to the child's level of competency (from parent report) and the extent to which the parent felt their child was receiving adequate support in the school setting. Two case studies of children contrasting easy and more challenging transition experiences are presented to illustrate the diversity of

children's experience. Findings from this project will inform the development of transition-to-school programs to promote adjustment and achievement in the early school years for children with developmental disabilities.

Did Fidgety Philip delay his homework? - On the coincidence of procrastination and ADHD in children

Lars Behrmann, University of Munster, Germany; Fred Rist, University of Muenster, Germany; Elmar Souvignier, University of Muenster, Germany

Research from the last years has shown a connection of ADHD and procrastination in adults. Regarding children, however, this relation was never clarified. The purpose of our study was to examine if child procrastination consists of the same behavioral and emotional characteristics as it does in adults. Furthermore, we wanted to shed some light on the relation between child procrastination and ADHD plus their predictive values for student achievement (school grades). We therefore adapted the Procrastination Questionnaire for Adult Students (PQS; Glöckner-Rist et al., 2009) for the demands of children from grades 5 to 7 and administered it to a sample of $N = 1967$ students (54% boys, 46% girls: M age = 11.3 years, $SD = 1.03$). ADHD ratings were assessed by 77 teachers using the German translation of the SNAP-IV Teacher Rating Scale. Our findings show that procrastination in children is not different from adults concerning delaying behavior, though, in that motivation to alternative activities and estimated aversiveness of delayed tasks cannot yet be discriminated by 5th-7th grade students. Moreover, we found procrastination and ADHD to be non-linearly related, meaning children exhibiting either ADHD or procrastination values above the 85 percentile had a 4.8 times increased risk of developing comorbidities, whereas below this threshold there was no relation at all. Procrastination and ADHD independently predicted grades (18% overall variance explanation). Both constructs should therefore be ascertained separately in educational and research settings to allow for selective analyses and interventions.

Adult procrastination is commonly assumed to consist of three behavioral and emotional characteristics, i.e., delaying behavior, aversiveness of the delayed task and the motivation to start alternative activities. In the last years, research connected these symptoms to the appearance of ADHD in that adults diagnosed with ADHD frequently report higher procrastination rates than non-diagnosed adults (e.g. Ferrari & Sanders, 2006). Regarding children, however, it is still unknown whether procrastination symptoms are exhibited in the same way as in adults. Furthermore, to our knowledge, the relation between child procrastination and ADHD has not yet been examined at all. The purpose of this study was, first, to present a child-oriented adaptation of the Procrastination Questionnaire for Adult Students (PQS; Glöckner-Rist et al., 2009) and an overview of its factorial structure. Second, we wanted to shed some light on the relation between child procrastination and ADHD. For that reason, we correlated students' ADHD and procrastination scores and, in addition, cross-tabbed student data for risk analysis. Furthermore, we examined the predictive values of ADHD and procrastination values for student achievement.

Sample:

The sample consisted of 77 teachers and their classes ($N = 1967$ students) from a moderately sized German city and its suburbs. The classes ranged from grades 5 to 7 and covered all three regular German educational levels. Gender ratio was almost balanced with about 54% of the students being male and 46% being female. The students' age ranged from 9 to 15 years (mean age = 11.3 years, $SD = 1.03$).

Instruments:

The Procrastination Questionnaire for Adult Students (PQS; Glöckner-Rist et al., 2009) consists of 20 self-report items that measure delaying behavior, aversiveness of the delayed task and the motivation to start alternative activities. The PQS was adapted for language and content to fit the demands of students from grades 5 and higher. All item difficulties were in the acceptable range from .30 to .57. (mean item difficulty = .44). In accordance to the adult version of the questionnaire, exploratory factor analysis revealed the items indicating delaying behavior to form a distinct factor. However, the "Aversiveness factor" and the "Alternative Activities factor" merged into one single factor "Distractibility". Internal consistencies were high for "Delaying Behavior" ($\alpha = .80$) and for "Distractibility" ($\alpha = .86$). Due to sufficiently high scale intercorrelations ($r = .70$), an overall procrastination score was computed.

ADHD in students was assessed with the German translation of the SNAP-IV Teacher Rating Scale for ADHD (Steinhausen, 2006). The genuine factor structure could be exactly replicated with very high internal consistencies of the factors "Attention Deficit" (9 items, $\alpha = .96$), "Hyperactivity" (9 items, $\alpha = .96$) and "Oppositional Behavior" (8 items, $\alpha = .95$). High scale intercorrelations ($r = .69$ to $r = .82$) allowed for the computation of an overall ADHD score.

Design:

The study was conducted in the framework of a longitudinal intervention program to lastingly enhance children's reading comprehension. Beside various achievement tests, self reported procrastination was assessed for all participating children. Teacher ratings concerning ADHD in individual students, however, were merely assigned to an alphabetically determined sample of up to 15 students from each class. This procedure was chosen due to time-related feasibility of the assessments in the regular school setting. Therefore, data on ADHD were only available for $n = 936$ students.

Analyses and Findings:

The Pearson correlation coefficient between self-reported procrastination and teacher-rated ADHD was moderate ($r=.24$, $pr=-.01$, $n.s.$) . To determine the relevance of both disorders for student achievement, regression analysis was conducted with ADHD and procrastination scores as predictors and grades in the subject German as criterion. Collectively adding both predictors in the regression model led to an additional 4.7% of variance explanation (from 13.3% respectively 12.3% to 18.0% overall variance explanation).

Theoretical and educational significance:

The factorial structure of the child-oriented version of the PQS (Glöckner-Rist et al., 2009) indicated procrastination symptoms to present itself in a different way as it does in adults: As the "Aversiveness factor" and the "Alternative Activities factor" merged into one single factor, it appears that the ability to discriminate between both constructs is not yet developed in children from grades 5 to 7. From a test- theoretical perspective, the item adaptation can be considered successful in that item difficulties and scale reliabilities were in a very good range.

Moreover, results indicated a non-linear relationship between procrastination and ADHD since both constructs were meaningfully related only in students above the 85 percentiles. In other words, children demonstrating either increased ADHD or procrastination values are at special risk of developing mutual comorbidities. Combining this finding and the fact that both constructs independently explain variance in student achievement, ADHD and procrastination should therefore be ascertained separately in educational and research settings to allow for selective analyses and interventions.

THEMATIC POSTER

Teacher Education

Self-directed professional development of teachers. How they search for information about SEN.

Rune Andreassen, Ostfold University College, Norway

The study addressed how school teachers search for and read information about special educational needs (SEN) to develop their professional knowledge. In particular, we focused on experiences in searching for information from colleague consultations, printed sources and Internet sources. A digital questionnaire was administered to 263 Norwegian elementary school teachers. The digital survey data were analysed using descriptive statistics and correlations. The results supported the notion that teachers use several information sources extensively, Internet included, to develop their competence on SEN. Specifically, domain knowledge seems to be important, not only for teachers' competence per se, but also by promoting their curiosity to search for more information as part of their ongoing self-directed professional development. Teachers' beliefs about their evaluation of Internet sources' trustworthiness were highlighted. Few other studies have explored the role of teachers' self-efficacy beliefs related to information literacy.

Aim

The aim of this study was to investigate how in-service teachers search for and read information about special educational needs (SEN) to develop their professional knowledge. TheoryResearch indicates that teachers' initial professional training is not sufficient to cope with the complex and demanding nature of teaching in inclusive

classrooms of today (Coutsocostas & Alborz, 2010; Flores, 2005; Mehdinezhad, 2008). Osler (2002) argues that there is increasing evidence to indicate that the level of understanding about SEN conditions and what implications they can have for teaching makes a significant difference to the effectiveness of the teaching strategies on these children's learning. In recent years there has been a sense of dissatisfaction with how issues related to SEN are included within initial teacher training courses (Garner, 1996; Mintz, 2010). At the same time there has been an extremely increase in easily accessible information, especially through the Internet. As stated by Demiralay and Karadeniz (2010), information literacy can be one of the important bases for lifelong learning both in private and professional life. When it comes to teachers, research indicates that conversation with colleagues may play the dominant role for professional development (Jensen, 2008). In this study we investigated how elementary school teachers search for information about SEN. We hypothesized that conversation with fellow teachers was the most common way to acquire knowledge about SEN, with Internet and printed sources also frequently used. The use of Internet sources in searching for such information was proposed to be related to gender, age, domain knowledge and participants' beliefs in their capability to evaluate source trustworthiness in the domain of special education.

Method

The sample consisted of 263 in-service teachers from 40 elementary schools who responded to a Web survey. One 30-items digital questionnaire was constructed and used to outline the present circumstances and relationships of teachers' self-directed professional development in the field of special educational needs. A mix of Likert scale and multiple choice questions were asking for participants' gender, age and domain knowledge related to special needs education by reporting on their level of educational specialization and to self-rate their special education competence. Participants experience in searching for information on special education was assessed by asking them about the amount of colleague consultation, use of printed information and use of Internet during the current school year for the purpose of developing their knowledge about SEN. They were also asked to indicate which SEN topics they had most frequently been in search of. To assess participants' beliefs about their capability to evaluate the trustworthiness of Web-based information on special education, we developed the Source Evaluation Self-Efficacy Scale (SESES) by combining questions. Finally, the participants were asked to indicate to what extent they emphasized different source features when judging the trustworthiness of web sites on SEN related topics. The data were analyzed using SPSS, and the survey results were interpreted on the basis of descriptive statistics and correlations.

Results

Firstly, this study confirms that in-service teachers extensively search for SEN related information. The most dominant way to search such information is by consulting teacher colleagues. More than 90 % of the participants had consulted colleagues about SEN topics during the current school year, followed by printed material (57 %) and Internet sources (51 %). Secondly, the more domain knowledge teachers possessed in the field of special educational needs, the more they searched for information in printed material and on the Internet to develop their competence. Thirdly, learning difficulties (problems with reading, writing and/or mathematics) and socio-emotional difficulties were found to be the most searched topics among the participating teachers, regardless of information source. Fourthly, participants' SESES scores, that were generally high, were significantly related to domain knowledge and use of domain-specific Internet sources.

Conclusions

This study contributes to the burgeoning literature on source use and source evaluation within both reading and information literacy related to special educational needs. In-service teachers seem to consider themselves as lifelong professional learners by using several information sources extensively, the Internet included, to develop their competence on SEN. Relevant domain knowledge seems to be important, not only for teachers' competence per se, but also by stimulating their curiosity to search for more information as part of their ongoing self-directed professional development. Few other studies have explored the role of teachers' self-efficacy beliefs for educational use of information technology (Hoy & Davis, 2006).

Teachers' beliefs on making a Professional Development Plan

Sandra Janssen, Open University, Netherlands; Karel Kreijns, Open University, Netherlands; Theo Bastiaens, Open University, Netherlands; Sjef Stijnen, Open University, Netherlands

Professional development plans (PDP) are increasingly used on Dutch schools as an instrument to promote professional development of teachers. By implementing a PDP it is expected from teachers to be more pro-active in their professional development. Moreover it provides teachers an opportunity for dialogue about performance and learning with colleagues and supervisors. However, the use of PDPs in school is rather new and it can be regarded as an innovation process within a school. Teachers might have their own beliefs about making a PDP and this determines how teachers make sense of this 'innovation', and consequently, how they act on it. Our research aims to investigate the beliefs teachers have about making a PDP and how these beliefs interrelate with individual and organizational factors. To answer this question an explorative case study is performed on four schools. Within these schools the teachers and the person who implemented the PDP in the school are interviewed about the implementation and beliefs about making a PDP.

The Dutch government has introduced a law of Professions in Education that obligates teachers to maintain and develop their abilities in their profession and file this in a portfolio. Subsequently, many schools have to implement different kind of instruments to act upon this policy. A Professional Development Plan (PDP) is one of these instruments. The PDP is the section of a teacher's portfolio that is used to structure the professional development in terms of learning goals and plans of action. Often, the PDP is part of a cycle in which teachers get a performance interview, update the PDP, and receive evaluations from their supervisor to determine whether they developed their abilities. However, research from the Dutch National Platform for Professions in Education in schools showed that schools have relative small experience with implementing personnel policy. The introduction of the PDP can therefore be regarded as an innovative process. Implementing an innovation in school policy does not mean that teachers will act in the same way as the management had in mind. Indeed, Kelchtermans, Ballet, Peeters, and Verckens (2009) pointed out that: "teachers are no passive receivers or mechanical and obedient performers of what others have decided. Desirable objectives (e.g. from the government or society) are always analysed, interpreted by the knowledge, beliefs and values of those who are involved" (2009, p. 163). Teachers have their own frame of reference that determines how they make sense and act on the school policy or development in work. This sense-making is an interplay between the individual's prior knowledge, beliefs and experiences, the context in which the policy is implemented the representation of the policy (Spillane, 2002). In our research we investigate the beliefs teachers have on making a PDP and how this relates to individual and organisational factors. With this knowledge schools may implement a PDP more successfully and guidance in making a PDP can be adjusted to the beliefs, knowledge and skills of teachers to be more effective.

Teacher's beliefs

According to the theory of planned behaviour (TPB), do beliefs people have about particular aspects of the behaviour influence the intention to perform or not to perform the behaviour. In general, intention is determined by three variables; attitudes toward the behaviour, subjective norms and perceived behavioural control. These variables in turn are determined by salient beliefs about the behaviour. First, attitudes are based upon beliefs of the consequences of performing behaviour and evaluations of those consequences (outcome beliefs and their evaluations). Second, normative beliefs determine the subjective norms people have; the beliefs about the views of other individuals about the behaviour and strength of the individual's desire to gain approval of these groups (normative beliefs and motivation to comply). Third, beliefs about factors likely to facilitate or inhibit the behaviour determine the perceived

behavioural control (Ajzen, 1991). Identifying these beliefs is the first stage in planning an intervention for those cases where teachers do not have the intention to adopt and use the PDP as an instrument for their professional development. In general, an intervention that is adjusted to the beliefs people have, might change their intention and thereby their behaviour. We hypothesize that the beliefs about making a PDP are influenced by individual and organisational factors. The process of meaning making is influenced by individual factors and the context in which something is implemented (Spillane, 2002; Kelchtermans, et al., 2009). Indeed, research on professional learning distinguish individual and organisation factors (e.g. Geijssels, Sleegers, Stoel, & Krýger, 2009). Individual factors included in our research are knowledge about making PDPs, and experiences with professional development. Organisational factors are support from colleagues and management and supporting conditions. Our study aims to get more insight into the adoption of PDPs by teachers and the variables that influence the beliefs they have about making a PDP. In other words, which organisational and individual variables interrelate with the beliefs of teachers about making a PDP? An explorative case study was chosen to uncover the interaction between factors that are significant for making a PDP (c.f., Merriam, 1994). Four different schools participated to determine the influence of contextual factors. Each school represents a case in which different actors were interviewed. The person who is involved by the implementation of a PDP and the teachers of the school. The data of all teachers were analysed to find out which beliefs teachers have and how they can be influenced by individual factors. Besides that, the cases are compared by similarities and differences in organisational factors that might influence the beliefs of teachers. By the time that the EARLI takes place, the data is analysed as data collection is now happening (October-November 2011). Based on earlier research, it is expected that the way the making of a PDP is supported by management, the culture in the school, and sustained use will influence teachers' beliefs about making a PDP (e.g. Smith, & Tillema, 2001). Besides that, differences are expected between teachers beliefs about the PDP, as teachers differ in how they approach professional development. Moreover, with this research we uncover how different organisational and individual variables interrelate with the beliefs of teachers about making a plan for their professional development.

Differences in the use of learning diaries and conditions for an effective use in teacher education

Tina Hascher, University of Salzburg, Austria; Franz Hofmann, University of Salzburg, Austria

The present study aims at clarifying to what extent and in particular under which circumstances teacher students' use and evaluation of learning diaries during first field experiences support the learning process of reflection on action. Two dimensions are of special interest: (1) differences in the use of diaries depending on teacher students' attitudes towards diaries; (2) differences in the teacher students' attitudes towards diaries depending on personality factors and differences in the use of diaries depending on personality factors.

In winter 2008 46 teacher students collected field experiences in a school setting of 15 lessons which have been framed by preparing sessions and reflective post-discussions with their mentors. For all participants, data from three instruments are available: a questionnaire about personality aspects administered about 6-8 month before the field experiences; a less structured learning diary during field experiences; a questionnaire on diary writing after field experiences. The results support the idea of the relevance of students' attitudes towards learning diaries as well as the role of individual pre-conditions for the use and the efficacy of learning diaries. The results are discussed in terms of learning to become a reflective practitioner.

Theoretical Framework

Instruments of self-regulated learning like learning diary and portfolio are popular and commonly used in teacher education. Primarily, those tools are supposed to support the development of reflective teaching. Based on numerous publications it must be assumed, however, that diaries are often implemented without considering whether they

meet the learners' individual needs and whether they cause valence and acceptance by all learners. Thus, it has to be analysed if learning diaries provide beneficial learning conditions for everyone (for corresponding remarks about undifferentiated use of learning diaries see Badr Gßtz & Ruf, 2007; Bosse & Messner, 2008; Hofmann & Thonhauser, 1998; Kroath & Mayr, 1998).

Objectives

The present study aims at clarifying to what extent and in particular under which circumstances teacher students' use and evaluation of learning diaries during first field experiences support the learning process and the acquisition of the competencies of reflection (for an overview see Gläser-Zikuda & Hascher, 2007). We investigated whether learners' positive attitudes towards the instrument and selected personality variables are important prerequisites (see also Ackerman, 1993). With regard to the concept of „aptitude-treatment-interaction" the interaction between student teachers preconditions and the efficacy of learning diaries is worth to be analysed. Which roles do personality aspects play if the use of this instrument is compulsory for all learners of the training-groups and the instrument is not structured? Furthermore, the present study investigates whether learners do not appreciate unreservedly and indiscriminatingly the production of learning diaries (see the role of acceptance for treatment efficacy mentioned by Dane and Schneider, 1998). If effects of the writing of learning-diaries prove to be unequal a need for change in pedagogical practice has to be discussed.

As an authentic setting for our study we choose the first field experiences in the context of a teacher education course at an Austrian university. One objective of the course was that the participants clarify their professional motives under a pedagogical perspective and to contribute to the acquisition of reflective competencies. Although research on self-regulated learning points out the role of individual preconditions for a successful learning process the relevance of a fit of the used learning material and the individual learner was not yet analysed systematically. We hypothesised that teacher students' use of learning diaries, the quality of their learning process and their evaluation of learning diaries as a tool will be influenced not only by the learning setting but also by cognitive, motivational and social personality aspects.

Methods

In winter 2008 254 students started the teacher education program at the University of Salzburg. Out of this group, a representative sample 46 teacher students participated. All participants collected field experiences in a school setting of 15 lessons which have been framed by preparing sessions and reflective post-discussions with their mentors. For all participants, data from three instruments are available:

- (1) a questionnaire about personality aspects administered about 6-8 weeks before the field experiences (verbal competencies, the Big 5, and motivational variables; NEO-FFI, Borkenau & Ostendorf, 1993);
- (2) a less structured learning diary during field experiences where the teacher students were asked (a) to document an observation, (b) to comment the observation in own words, and (c) to reflect the observation with references to familiar scientific literature;
- (3) a questionnaire on diary writing (e.g., attitudes towards diary writing; individual style of diary use; uncertainty orientation, Dalbert, 1999).

All diaries were analysed in terms of quantitative (e.g., amount of signs, number of days) and qualitative aspects (e.g. design of the diary, mentioned perspectives). Personality aspects were tested as predictors of diary differences.

Results and Discussion

The results indicate that learning diaries with sparse structures and norms lead to a tremendous heterogeneity in productivity and outcomes. The observed episodes were mainly presented in narrative style by the teacher students and only seldom related to theoretical knowledge. It has to be noticed that according to the questionnaire about the diary use, reflexion on action was more often initiated by discourse with peers than by reflective writing. As was shown in other studies on the use of learning diaries in teacher education (Hascher & Wepf, 2007; Hascher, Moser & Cocard, 2005; Nissilä, 1999; Numrich, 1996), the teacher students appreciate the potential of cognitive scaffolding like the support of remembering, growing awareness and deeper understanding of a situation. A positive evaluation of the diary method is closely related to the definition of learning diaries as a learning tool.

The results also show that attitudes towards diaries are independent of language competence but the use is not with regard to teacher students' writing styles. Accordingly, students with low language competence seem to prefer oral exchange with peers in comparison to written reflexion in diaries. The same preference can be found for extraverted teacher students.

As expected, relationship between personality traits and the use of learning diaries can be found. The results count for different functions of different personality aspects. For example, low openness seems to lead to a higher need of

feedback to learning diaries. Interestingly, the use of diaries as a learning tool was related to low tolerance of uncertainty on the one hand and low neuroticism on the other hand. The findings also indicate that moderator variables like conscientiousness as a pre-condition for a careful work with learning diaries should be taken into account. Furthermore, the results give some information about pre-conditions of the field experiences as learning setting. Openness and extraversion seem to be favourable factors for teacher students to cope with the school reality and to reflect about the tasks of a teacher. There are no significant differences in motivational orientations with regard to diary quantity but the findings point toward a trend of the role of outcome orientation and differences in terms of attitudes and quality. Positive attitudes towards learning diaries seem to be supported by low competition orientation; low tasks orientation less supportive for deep level written reflexion. The results will be discussed with regard to the aim of supporting the development of reflective practitioners through the use of diaries (Schßn, 1991).

Pupils' voice in primary school – a valid basis for diagnostics and evaluation?

Gerlinde Lenske, Universität Koblenz-Landau, Germany; Anna-Katharina Praetorius, Universität Koblenz-Landau, Germany; Andreas Helmke, Universität Landau, Germany

Teaching is very complex, therefore it is almost impossible for a teacher to perceive all information needed to reflect and analyse a given lesson. A teacher needs to take another point of view to get a more realistic image of the lesson. Therefore, feedback focussing on teaching skills and lesson quality plays an important role for the advancement of a teacher. One opportunity to get feedback is to ask the pupils. Pupils' voice is considered to be as meaningful as a colleague's feedback. Previous studies generally focussed on judgements made by pupils from the fifth or higher grades. At the moment we know very little about the validity of pupil's voice from younger students. Therefore validating the generalizability over different age groups is an important issue. Our current study focuses on that issue. We tested how valid the judgements of pupils in primary schools are, if they are faced with items of common standardized questionnaires. Therefore, we used standardized interviews combined with vignettes, describing typical classroom situations. Our sample includes 90 students from the third and fourth grade. We analysed the data with Qualitative Content Analysis after Mayring (2000). The results show that young pupils have a lack of understanding the items of common questionnaires in the intended way. The conclusion is that it is necessary to modify the instruments for primary school. Otherwise, by using common instruments, the validity of pupils' voice is highly limited.

Previous studies show that the prognostic validity of pupil's voice (aggregated on class level) is comparatively high, if the increase of school achievement or school interest should be predicted (Clausen, 2000). With evidence-based feedback in form of pupil's voice, teachers can compare their own view of instructional quality to the pupil's perspective. Through that teachers are able to analyse their strengths and weaknesses. In a next step they can derive an intervention to improve their teaching skills. In the context of instructional quality, feedback in the form of pupil's voice is the foundation of diagnostics and evaluation (Helmke, 2009).

But is every feedback of every class valid enough to be the basis of diagnostics? Several studies investigated the judgements of pupils from the 5th grade up to the 13th grade. However, there is a lack of studies dealing with this topic in primary school. Our knowledge on the validity of pupil's voice in primary school is limited. More surprisingly, a lot of standardised questionnaires for primary school dealing with instructional quality are already developed and in use (i.e. in Germany, Switzerland, Austria).

The aim of the current study is to gain a first insight on how valid the pupil's voice of younger children is. We focus on two research questions:

- 1) To what extend are pupils (3rd and 4th grade) able to understand items of common standardised questionnaires dealing with instructional quality?
- 2) Are pupils (3rd and 4th grade) able to rate the quality of a lesson validly by answering those items?

Using the information of Developmental Psychology we can assume that items including complex information won't be interpreted in the right way, because young children (up to 11 years of age) often reduce complex information in an incorrect way. Furthermore we know that children at that age mostly do not realise if they make an absurd interpretation because of their egocentric or subjective view (Piaget, 1979). Additionally it is known, that young children have problems to define abstract terms (Case, 1999). Contradictory, many instruments used for feedback in primary school include items with complex information and some also employ abstract terms.

Considering the results we generated the following hypotheses:

- 1) The children will show inter-individual differences in the comprehension of the items.
- 2) There will be items the pupils will not understand in the intended way (complex items).
- 3) In most cases the pupils won't realize their misunderstanding of the item.

In order to explore these questions and to validate the hypotheses, our first step was the retrieval of available questionnaires to generate an itempool. In addition, we accomplished a delphi-study and had a discussion of experts to select 60 items of the pool for the current study.

In our on-going study we used standardised interviews to explore how far the young children are able to understand those selected items and how far they can answer them validly by rating vignettes (containing typical classroom situations). Our sample includes 90 children from three different schools. For the data analyses we used the Qualitative Content Analysis according to Mayring (2000) and the software Maxqda. To rate the item-comprehension of the pupils we developed a system of five categories. This system was derived deductively from theory and was completed inductively by detailed analyses.

Results

The analyses show that there are inter-individual differences in the comprehension of the items. There are items which some children understand in the intended way, but other children at the same age and class don't. Additionally, the second hypothesis could be verified. We found items from standardized questionnaires developed for primary school, which none of the tested children could understand in the intended way. In this context the third hypothesis could be verified too, because in 74% of the cases, children are not aware of their misinterpretation. Furthermore we identified halo-effects, which made some children rate teacher performance better than they objectively would have done. Our results also show that there are some items, which children can understand, but cannot judge correctly, because these items require didactical knowledge.

Discussion

This study shows that we should focus on the development of age-appropriate standardised instruments for pupil's voice in primary school. Young Children are able to give feedback, but we have to find the right questions or items for this procedure. Not only abstract terms cause problems, but also the complexity of items and item topics requiring didactical knowledge are too difficult for younger children. Our study makes clear that a lot of the common instruments include items, which could not be answered validly from children at that age. Therefore it could be useful to investigate problem-causing items in a systematic way (i.e. IRT-Modelling). Maybe the halo-effects could be reduced with suitable instructions before giving feedback. In order to find out, which instruction works best, experimental studies are planned as one of our next steps. Furthermore the results show that young children often do not realise when they misinterpret information. Researchers should be aware of that fact and should not try to valid instruments by asking children questions like "Are there any questions or items you did not understand?".

Fear and Self-Appointed Superiority: Two Hindrances in Education for a Global Networked Society

Anna Tapola, Linnaeus University, Sweden; Lena Fritzen, Vaxjo university, Sweden

The aim of this paper is to examine the preconditions for education for a global networked society in teacher education, especially with regard to food security and increased health for a growing world population of seven billion people. Research questions were linked to Swedish preservice teachers' (i) willingness to contribute to social justice; (ii) their readiness to promote increased health among others; and (iii) their attitudes towards collaborating with others who have a different cultural background. The data consisted of 18 randomised individual position statements

(N=235) written by preservice teachers, and constitutes a 7,774 word corpus. The position statements were collected after the preservice teachers had carried out a mandatory exercise that included a dilemma discussion. They completed the exercise by writing their individual statements. The data were subject to a critical discourse analysis embracing a discourse-historical approach. The analysis of the position statements shows: (I) a low level of willingness to contribute to social justice; (II) a reluctance to promote increased health among others; and (III) negative attitudes towards collaborating with others who have a different cultural background. The findings show that a significant discursive construction – Discourse of Xenophobia – was particularly prominent. This discourse reveals a fear of what is different; risks, and a lack of safety; unequal relationships with other people; and the idea that someone else needs 'us' more than we need 'them'. Finally, our research outcomes are discussed in terms of preconditions for education for a global networked society.

THE AIM of this paper was to examine the preconditions for education for a global networked society (EGNS) in teacher education (TE), especially with regard to food security and increased health for a growing world population of seven billion people. The study addressed three RESEARCH QUESTIONS, all of which concerned standpoints taken by a group of Swedish preservice teachers. (1) What are the preconditions for contributing to social justice in an international arena? (2) What are the preconditions for promoting increased health among others? (3) What are the attitudes towards collaborating with others who have a different cultural background? THE CONTEXT was Swedish TE, the first term of study, and a mandatory exercise that involved working on a dilemma. The dilemma text consisted of an intricate fictional story about a proposed international collaboration project between two agricultural colleges; one in Sweden and another in a vastly different Asian context. Preservice teachers were required to take a stance on a series of moral-laden issues, for example aspects of food security and health for all, democracy versus dictatorship, and whether the proposed collaboration would comply with the democratic core values that professional teachers are supposed to protect in their teaching practice. The exercise included A FOUR-STEP PROCEDURE:

A. Prior to the exercise, all of the preservice teachers received detailed information about the dilemma and its scientific context, which enabled them to make necessary preparations.

B. Discussions first took place in 18 workgroups (at the university) where the preservice teachers had to find as many valid arguments as possible, which would support different positions with regard to the dilemma text.

C. The initial discussions were immediately followed by discussions in cross-groups, where the preservice teachers presented and exchanged the various arguments they had discussed in their original workgroups.

D. Preservice teachers wrote their position statements (as homework) where each person individually took a stance, and argued in favour of a chosen position. All of the position statements were sent to the teacher educator and stored in a database. A randomised sample of these position statements constituted the data that was analysed. NO PARTICIPANTS were involved in the study. We analysed authentic texts only. THE DATA consisted of 18 individual position statements (N=235). A randomised multi-stage cluster sampling included one position statement from each workgroup; the analysed data corresponded to 7.7 per cent of all of the written position statements. THE DATA COLLECTION METHOD consisted of a database search. THE METHODOLOGY is grounded on critical discourse analysis (for example, Fairclough, 2010) and the discourse-historical approach (DHA) (Reisigl & Wodak, 2009; Wodak, 2001a, 2001b). Three dimensions are of particular interest within DHA: (i) immanent dimensions that focus on functional linguistic characteristics of the constituents; (ii) socio-diagnostic dimensions that focus on properties related to power, democracy, morality, and various rationalities that inform our choices to act in certain ways, etc; and (iii) historical dimensions, i.e. dimensions that focus on variations over time with respect to the phenomena under study. Several ANALYTICAL METHODS were used in order to analyse the three dimensions mentioned above. Systemic functional linguistics (SFL) was used in analysing the immanent dimensions (Halliday & Matthiessen, 2004). SFL focuses on the functions of language use, for example, 'who is doing what to whom, in what way, and why' (transitivity analysis). The socio-diagnostic dimensions were covered by a Habermasian argumentation analysis (Fritzién & Tapola, 2010), theoretically grounded on Habermas's Theory of Communicative Action (Habermas, 1984, 1987), and his discourse ethics (Habermas, 1994). The historical dimensions were covered by a contextual analysis in the sense that the findings of the previous analyses (the present) were contextualised with regard to the past, and also in some respect, to the future. The contextualised analysis was theoretically grounded on DHA (for references see above)

ETHICAL CONSIDERATIONS:

All of the data consisted of authentic texts only. All of our findings were reported in a de-identified form, and it is not possible to trace the original position statement. In summary, FINDINGS from the analyses of position statements written by preservice teachers showed: a low level of willingness to contribute to social justice; a reluctance to promote increased health among others; and negative attitudes towards collaborating with others who have a different cultural background. The study showed that a significant discursive construction – Discourse of Xenophobia – was particularly prominent. This discourse deals with a fear of what is different; risks, and a lack of safety; unequal relationships with other people; and the idea that someone else needs 'us' more than we need 'them'. We CONCLUDE that the preconditions for EGNS in TE were negative. According to the present study, Swedish preservice teachers

were reluctant to collaborate with peers who are culturally different, and live far away. This conclusion shows, on the other hand, that EGNS is much needed in order to counteract prejudices, oppression, and self-appointed superiority.

Between curricular demands and „dangerous moments“: multiperspectivity in history lessons

Katrin Kello, University of Tartu, Estonia

Based on individual interviews with Estonian history teachers, the paper will discuss different choices or even dilemmas a history teacher faces when attending to different educational aims and external expectations – especially, the expectation that history teaching should contribute to constructing and maintaining collective memories, i.e. shared conceptions of the past, and the concurrent need to relativize and deconstruct these collective memories by enhancing the pupil's critical thinking and his or her understanding of the constructed nature of history. Particularly, the paper will discuss how teacher's considerations and practices may be influenced by the pupils' and teacher's belonging to a mnemonic community other than that of the ethnic Estonians, as well as by the country's culture of history generally.

Based on 26 individual interviews, the paper will look at how Estonian history teachers who belonged to different mnemonic communities (teachers teaching mainly ethnic Estonians, and teachers teaching at Estonian schools with Russian as the main language of instruction), described dealing with different interpretations of past in their lessons.

The study is based on the notion that in addition to the history education's aim to transmit some common repertoires of representations about past, also ability to decide on the validity of historical accounts and understanding the diverse ways in which the past functions in the present-day society (Seixas 2000), as well as critical self-reflection, ability for dialogue, and a more „cosmopolitan orientation toward human affairs" (Hansen et al. 2009) need attention in contemporary history teaching (cf. e.g. Council of Europe 2001).

More broadly, the study has been informed by the concept of culture of history by Jörn Rüsen (1994), and the theory of social representations (Wagner and Hayes 2005).

Most of the interviews (two pilot interviews in 2007 and 24 more focused interviews in 2009-2010) commenced by request to describe two to three of the interviewee's main aims as (history) teacher. In the conversation that followed additional questions about the interviewee's vision about the subject and his or her pupils were asked. In the second part of most of the interviews the teacher could comment on 22 anonymous statements chosen from a decade (1999-2008) of the Estonia's teachers'-oriented weekly's „Õpetajate Leht" (Teachers' Newspaper) articles on history teaching. The statements were partly contradictory, partly provocative, and intentionally ambiguous, so that the comments reflected various concerns and discourses that were actual for different interviewees.

The group-level representations of the school subject 'history' that could be constructed based on the interviews approximates the official representation contained in the Estonian national curricula for history: knowledge, understanding and analysis of the facts of the past; skills of deliberation, argumentation and self-expression; critical mind, ability to gain knowledge independently and to account for various perspectives, interest for history or the subject, tolerance and other positive traits.

Delivering knowledge was however the center of the teachers' work, so that their other educational aims were dependent on it. And although the teachers acknowledged the contextual and conventional nature of the body of knowledge taught, as well as the interpretive role on the teacher and pupil, and valued bringing different interpretations and perspectives into the classroom, they were somewhat pessimistic about the pupils' ability to deal with this diversity – to accept the multiplicity of interpretations and to form their own opinions. Many teachers maintained that a multiperspective approach was appropriate only or mostly at the upper secondary school level. Also the teacher's methodical problems and lack of time were mentioned or implied.

Unsurprisingly, if referring to occurrences of different interpretations in their lessons, the teachers mostly referred to topics from the 20th century Estonian and Soviet history. Partly, the metalevel discussions (e.g. explaining why different interpretations of a same event exist) had been provoked by the pupils' voiced opposition to official or textbook history (i.e., the "dangerous moments", as one teacher referred to them). Connected to this, some teachers who worked at Russian-medium schools mentioned political dilemmas connected to their task of teaching – critically, as expected by the National Curriculum – the official interpretations of Estonian and Soviet history, and of raising simultaneously loyal and critical citizens of the Estonian state.

A more general dilemma common to most of the teachers was the simultaneousness of the need to construct and deconstruct (to learn and understand the 'basics' on object-level, and to analyse different interpretations on meta-level) under a time pressure, in face of students with different interests and abilities, in face of national final examinations, etc. Thus, all history teachers have to coordinate various, sometimes contradictory educational aims, partly set to them from above (the national curriculum, national final examinations), and they need support in such efforts: for example, examples about how to recognise a fruitful question on the backdrop of different educational aims, so that there could be more possibilities to coordinate different approaches (i.e., enhancing as well as relativizing of collective memories) in history teaching.

Also, it seems possible to conclude, that although in the media, the existence of a "mnemonic divide" in Estonia seems to be presented as a problem for the school history teaching, pupils who belong to mnemonic communities other than the mainstream can also be viewed as a resource that helps to pay more attention to different interpretations of – and perspectives on – the past. Another important potential resource could be the teachers' more relaxed or even playful attitude towards the historical knowledge, as well as the notion that it is good, right and fun to have a diversity of interpretations and associations.

THEMATIC POSTER

Instructional Strategies

The impact of motivation-related variables on scaffold use

Lai Jiang, Institute Tropical Medicine/Katholieke Universiteit Leuven, Belgium; Jan Elen, Katholieke Universiteit Leuven, Belgium

The use of scaffolds lies at the core of the effectiveness of learning environments. In view of establishing a solid research agenda on the optimization of the use of scaffolds, this study aims at investigating the effects of motivational variables on scaffold use. More specifically, the effect of (a) achievement goal orientation and (b) self-efficacy on students' use of learning goals and postquestions were studied. One hundred and ten students in three conditions

studied a science text in 50 minutes. Participants had to respond to learning goals and/or to postquestions. Their usage of these scaffolds was recorded in log files. The results revealed that quantity of scaffold use was influenced by achievement goal orientation and self-efficacy. Avoidance goal orientation and self-efficacy influenced quality of scaffold use which in turn was found to predict students' posttest score. The results confirm the importance of motivational variables in scaffold use.

Introduction

Scaffolds are often added to/inserted in the learning environment because of anticipated or typical learner difficulties associated with a task. They are beneficial for learning only when they are adequately and optimally used (Elen & Clarebout, 2006). Therefore, the use of scaffolds lies at the core of the effectiveness of learning environments and the study of that use is of paramount importance to instructional research. It has been claimed that to make best use of scaffolds, students must be knowledgeable and motivated enough to (1) recognize scaffolds' functionalities, (2) be able to carry out the cognitive operations these scaffolds suggest (knowledgeable: cognitive / metacognitive ability required), and (3) be willing to pursue the learning path proposed by the scaffolds (motivation required) (e.g., Elen & Clarebout, 2006; Winne, 1983). In order to ensure students are knowledgeable and motivated to adequately and optimally use scaffolds, the factors that contribute to students' knowledgeability and motivation need to be identified. While cognitive and metacognitive (regulative factors), such as prior knowledge and self-regulation skills, have already been widely empirically studied (e.g., prior knowledge: Martens, Valcke, & Portier, 1997; metacognitive skills: Azevedo & Witherspoon, 2009), much less is known about what makes learners motivated to use scaffolds. To date self-efficacy and achievement goal orientation have been claimed to influence quantity of scaffolds use through its impact on task engagement (Aleven, Stahl, Schworm, Fischer, & Wallace, 2003). In addition, self-efficacy and goal orientation were assumed to exert influence on quality of scaffold use through their impact on strategy use. However, the arguments are mainly theoretical rather than empirically supported. Thus, there is a need for research that identifies the variables influencing students' motivation on adequate and optimal use of scaffolds. Of special interest in the current study is the investigation on how students' achievement goal orientation and self-efficacy influence their actual use of two scaffolds (i.e., learning goals and postquestions).

Method

Materials

A program, called OBESITAS (See figure 1), provides a computer-based prose environment in which participants were asked to study a scientific text on the relation between overweight and impulsivity. The text comprises 2,178 words (17 paragraphs). Each paragraph was displayed on a separate screen. Learning goals were provided at beginning of the text and/or postquestions were inserted at the end of the text.

Participants and procedure

One hundred and ten university students were pre-tested one week before the experiment. The results of the pretest were used to equally assign higher/lower prior knowledge students into three conditions. In the experiment, before completing the self-efficacy and goal orientation questionnaires, participants got the opportunity to have a glance at the to-be-learned text and to read a short description of the post-test. This would allow them to have a clear idea about the task demand. Afterwards they were invited to indicate their self-efficacy and goal orientation with respect to the upcoming task. Then, they got the text on their computer screen. Students studied the text in one of three conditions: with learning goals ($n = 37$); with postquestions ($n = 37$), and with both ($n = 35$). During the learning session, all learning behaviours of each participant were recorded in individual logfiles. Finally, a post-test was conducted to measure participants' factual knowledge (i.e., terms and abbreviations) (recorded as knowledge score), understanding of the relations between causal factors for obesity (recorded as insight score) and the ability to solve problems (recorded as application score).

Measure quality of scaffold use

Students in the learning goal condition and combined condition were asked to interpret the assigned learning goals and specify their learning objectives based on the assigned goals. A note space was provided which allowed students to write down notes. These were recorded and used to find out whether students carried out the intended cognitive processes (e.g., searching the text for relevant information and making inference of the text). The following variables were recorded in logfiles and used to assess quality of scaffold use: students' responses to learning goals, answers to the postquestions, notes and study sequence. The quality assessment intended to find out whether students used learning goals/postquestions to monitor their cognitive actions and to adjust their studying processes when necessary.

Results

The relations between quantity and quality of scaffold use and performance

The current results are in line with the argument that scaffold use is a highly relevant factor for students' performance in instructional environments. Time spent on postquestions was found to be positively related to the knowledge score. Quality of scaffold use was found to be highly correlated to knowledge score, insight score and application score.

The relations between learner variables and quantity of scaffold use

A negative correlation between performance-avoidance goal orientation and time spent on the postquestions, $r = -.21$, $p < .05$ (one-tailed) was found. The relation between mastery-avoidance and time spent on learning goals was not linear (see figure 2). Students who were medium mastery-avoidance goal oriented were willing to spend the most time on learning goals. Self-efficacy was negatively related to the sum of the access times of postquestions, $r = -.17$, $p < .05$ (one-tailed).

The relations between learner variables and quality of scaffold use

Avoidance goal orientation (i.e., performance-avoidance goal and mastery-avoidance goal) had negative impacts on quality use of scaffolds. A quadratic relation is found, suggesting that a medium self-efficacy is most beneficial for scaffold use.

Conclusions

This study provides insights into the impact of scaffold use on performance and of motivational variables on scaffold use. Results suggested that goal orientation and learning efficacy are the potential variables influencing quantity of scaffold use. Hence, instructors may create situations in which students' motivation for using scaffolds are promoted. Examples could, for instance, manipulate students' learning efficacy as a means to promote optimal scaffold use. Specifically, in this study, avoidance goal orientation and learning efficacy were found to be important variables for quality of scaffold use. This implies that instructors should pay attention to students' task specific goal orientations in environments as well as their learning efficacy level. Research has shown that altering the general goal structure of learning environments as well as the feedback students receive during their learning can affect students' goal orientation and self-efficacy (e.g., Linnenbrink, 2005).

Incorporating digital resources into Early Childhood classroom: An analysis from teachers' practices

Elena Ramirez, University of Salamanca, Spain; Begona Orgaz, University of Salamanca, Spain; Jorge Martin, University of Salamanca, Spain

This research examines how six early childhood teachers integrate into their practice a digital technological resource consisting of a technological desk designed to be used with children at early ages. It includes an IBM computer with a CD-Rom reader, Internet access and Windows XP operating system. Using a system to analyze classroom interaction that allows us to segment teaching practice into categories differentiated by level of generality, we studied recordings of 18 classroom sessions (three per teacher) in which the resource described above is used. The results show that common patterns exist among the teachers studied as regards the development of these practices. The most important pattern detected is the central nature of tasks in the classroom and the subordination of ICT resources to these curricular elements. It is also important to underscore the appearance of different pedagogical approaches when ICT are incorporated into the early childhood classroom. These findings pose challenges for the development of future research studies regarding the consistency and diversification of the patterns of action found and for teacher education.

Summary

Knowledge of what teachers actually do with digital resources in their classroom practice is essential in order to explain not also what aspects form the basis for the real incorporation of information and communication technologies (ICT) into teaching processes, but also to be able to untangle the mechanisms behind how these resources are employed in direct teaching situations (Loveless, 2003). From our theoretical approach, two key aspects can be emphasized: first, the incorporation of ICT resources into classroom practice will depend on the teacher's pedagogical knowledge of the discipline (Loveless, 2003; Koelher y Mishra, 2009), specifically on the intersection between that knowledge and knowledge of ICT; and second, it will also depend on whether these resources make sense or not within the 'action plans' that the teacher is using to manage his or her activity in direct teaching (Leinhardt, Weidman and Hammond, 1987; Zhao, Frank, Ellefson, 2006). This study examines how six early childhood teachers integrate into their practice a digital technological resource consisting of a technological desk designed to be used with children at early ages. It includes an IBM computer with a CD-Rom reader, Internet access and Windows XP operating system. The purpose of this study is to analyze how teaching is carried out using these media in direct teaching contexts, describing what is done with the classroom activities, the actions carried out and their relation to

the most important elements of the curriculum: contents, objectives, activities, and assessment. By means of this analysis we hope to locate the role of ICT within the teachers' action plans and in relation to their knowledge of the subject.

Method

Participants We video-recorded 18 class sessions in early childhood education taught by six different teachers who were collaborating in our research project, at December, March and May-June of 2009. Our intention was to collect data regarding their classroom practices involving the ICT resource. So we were recorded in video and audio each of the 18 sessions lasting approximately 60-70 minutes each. The moments were selected randomly along the morning journey. All the audio and video recordings were transcribed in order to analyze the data, and thus we had available the texts of all them.

Procedure Using a system to analyze classroom interaction that allows us to segment teaching practice into categories differentiated by level of generality (Sánchez et al. 2008a, 2008b), we studied recordings of 18 classroom sessions in which the resource described above is used. The research was carried out was based on the transcriptions of the 18 classes, using the methodology of class interaction analysis described below: First, the class is divided into Typical Classroom Activities (TCA), which identify all those activities having a defined goal during the class. Some examples of TCA are: explaining contents, doing individual work, class planning, giving homework, preparing to go out for recess, and so on. TCA allow us to work out a general pattern of the class and what takes place in it. Secondly, each TCA is divided into Episodes that specify the teacher's classroom activity in more detail. These allow us to organize the TCA internally, structuring them into smaller activity sequences that serve specific goals. Thirdly and finally, the teachers' instructional actions are identified and classified into five types: Identifying, Planning, Explaining, Recapitulating, and Supervising-Assessing. These five actions in turn are performed on elements of the curriculum: Objectives, Contents, Tasks, ICT Resources, and Non-ICT Resources (Gimeno, 2010), which can figure in the foreground (primary elements) or the background of the action (secondary elements). In the research we present, the study of the instructive actions that the teacher carries out in the classroom, together with the analysis of primary and secondary curricular elements, provides a profile of the action schemes of the teachers analyzed. This profile gives us information as to the central points around which teaching activity is organized in actual practice.

Results and discussion

In particular in this study we have obtained important findings that allow us to identify the schemes of action that the six early childhood teachers carried out in their classrooms with the digital resource and its role in these teaching practices. The table below provides summary information which indicates the differences between our first categories. These initial data show significant differences between the instructional actions teachers performed on each TCA, and also significant differences between primary and secondary curricular elements in each TCA. Table 1: Initial partial results Instructional actions Primary curricular elements Secondary curricular elements Typical Classroom Activities (TCA) $\chi^2=184,83$, $p<.001$; $\chi^2=93,65$, $p<.001$; $\chi^2=52,068$, $p<.001$

The results show that common patterns exist among the teachers studied as regards the development of these practices. The most important pattern detected is the central nature of tasks in the classroom and the subordination of ICT resources to these curricular elements. It is also important to underscore the appearance of different pedagogical approaches when ICT are incorporated into the early childhood classroom.

These findings pose challenges for the development of future research studies regarding the consistency and diversification of the patterns of action and found.

Scaffolding Japanese students' refutation in classroom and its effect.

Mika Nakano, Fukuoka Institute of Technology, Japan

In Japan, the number of the schools which introduce debate into classes is now increasing from elementary to higher levels, as a means of cultivating argumentative skills as well as developing human resources in a globalized world. Despite this trend, however, empirical studies about how to teach debate are scarce and its effect has not been sufficiently tested yet. The problem here is that teachers who have tried debate education experienced difficulties, as opposing others is sometimes too hard for Japanese students mentally and technically. The present study aims at (1) introducing a teaching method of refutation especially for students who learn debating for the first time, and (2) examining the influence of refutation on the quality of argument through the course. The curriculum was consisted of thirty classes (90 minutes) throughout a year from April 2009 to February 2010 for 160 college freshmen in the engineering department in Fukuoka, Japan. The main points of the findings were: (1) most participants improved their organization structure referring to other points of view, and (2) a developmental process of understanding refutation was revealed. For pedagogical implication, to teach debate to Japanese students who are especially unwilling to debate, we need scaffolding to have them realize their improvement with confidence by reducing their mental blocks. By discussing their developmental stages of subordinate skills and argumentative patterns, the future prospects of argumentative education for Japanese students will be further explored.

Recently, argument has been receiving increasing attention from educational researchers to explore human interaction. Previous studies have focused on how social influences affect development of reasoning, regarding argumentation facilitates deep understanding and elaborative learning (Anderson et al., 2001; Barron, 1991; Bell & Linn, 2000). In Japan, the number of the schools which introduce debate into classes is now increasing from elementary to higher levels, as a means of cultivating argumentative skills as well as developing human resources in a globalized world. Despite this trend, however, empirical studies about how to teach debate are scarce and its effect has not been sufficiently tested yet. The problem here is that teachers who have tried debate education experienced difficulties, as opposing others is sometimes too hard for Japanese students mentally and technically. In the past, Japanese education hadn't placed much significance on argument for a long period. This is mainly because the main stream of Japanese education has long been centered on individual memory, not interaction among students and teachers (Maruno, 2001). Education has deprived students of chances to learn how to argue, unless they access to special environment surrounded by people who like to do so. The author found that Japanese students tend to hesitate to argue with friends: low in approach argumentativeness and high in avoidance argumentativeness, compared to other Asian countries (Nakano, 2007). These attitudes make classroom discussion difficult for not only students but also teachers.

On the other hand, among various kinds of discussion, it has been clarified that the format of debate is suitable for inexpedient Japanese college students in the early stage (Nakano, 2006, 2008). There are two reasons for this. The first reason is to experience the basics of argument. As debate is designed to develop arguments by constructing one's own argument, refuting others' and summarizing the whole arguments separately, participants smoothly learn what they should do during their participation in the argument. The second reason is to refute someone without conflict that arises in relationships. It is not always simple to distinguish between people who argue and the content which is argued. In these senses, debate can be utilized to teach argumentation in a way which reduces students' psychological barrier to argue with peers. Debate provides a section assigned to each purpose for argument, which facilitates arguing in the order that suits appropriate goals.

The present study aims at (1) introducing a teaching method of refutation especially for students who learn debating for the first time, and (2) examining the influence of refutation on the quality of argument through the course. The curriculum was consisted of thirty classes (90 minutes) throughout a year from April 2009 to February 2010, and was used for college freshmen in the engineering department in Fukuoka, Japan. The number of students were 160 ($M=157$, $F=3$). The average age was 19.7 ($SD=1.8$). The course as a whole was divided into three stages according to the developmental model of argumentation. The students can learn basic skills and knowledge which are necessary for argumentation and debate. In this program, the lesson for refutation began in the 18th class on November 2009. To test the effects of learning refutation, the pretest ($N=154$) was conducted on the day for the first refutation class, and the posttest ($N=150$) was in the last 30th on February 2010 by questionnaire and interview. In this study, analysis was based on the answers for the question asking "please refute to the written text about smoking". This text has 260

words and was created by one of the freshmen who don't take this class. They were asked to fill in the questionnaire in ten minutes before the classes began. The research questions are as follows:

- (1) Do students explain more about their ideas using various data, examples, and reasoning by learning refutation?
- (2) Are the quality of refutation improved and highly evaluated by others by learning refutation?
- (3) Are the structures of refutation organized by learning refutation?

The part of the results are shown here, according to the above three categories. As for the first question, the number of the refutation texts output was calculated. In the pretest, the average number was 70.0 (SD=57.5). In the posttest, the average number was 115.0 (SD=57.7). From this result, we can find that they wrote 1.6 times as many texts as before ($p<.0001$).

As for the second question, an evaluator as the third party, who is the same generation of the participants and don't take this argumentation lesson, rated the quality of their refutation from 1 to 3: "1" is "unreasonable"; "2" is "reasonable"; "3" is "persuasive". In the pretest, the average score was 1.45 (SD=.61). In the posttest, the average number was 1.96 (SD=.53). The percentage of 1 "unreasonable" decreased: 62% in the pretest to 16% in the posttest. We can conclude that the evaluation by others was improved by the refutation lesson ($t(211)=6.69$, $p<.0001$).

As for the third question, the five coding schema were set: "pointing", "claim", "reason", "data & example", and "conclusion", which are necessary components for refutation. In the pretest, the average number of components covered was 1.65 (SD=.12). In the posttest, the average number was 2.59 (SD=.11). From this result, we can find that their refutation improved and organizational through the lesson ($p<.0001$). The component which changed most between pretest and posttest was "pointing". The percentage of "pointing" increased: 6% in the pretest to 45% in the posttest ($r=.54$, $p<.0001$). In addition, we found correlation between "pointing" & "persuasive" ($r=.36$, $p<.0001$), which shows the refutation which include "pointing" were evaluated higher by the third party.

For pedagogical implication, to teach refutation to Japanese students who are especially unwilling to argue, teachers need to have them realize the importance of refutation reducing their psychological barriers. By reducing the mental block, it is then easier and more effective to teach a higher level of debate skill. By discussing their developmental stages of subordinate skills and argumentative patterns, the future prospects of argumentative education will be further explored.

Effects of conversational function coding in small group discussion

Eiji TOMIDA, Ehime University, Japan

The author has developed a discussion scheme and a paper work sheet called "the track sheet" to help students' learning. The aim of the present study is to examine the effects of introducing the track sheet on discussion processes in actual classes for undergraduate students. Sixty-seven students were participated in the discussion sessions. Each group consisted of from three to five discussants. They were assigned to one of three groups: total-coding, self-coding, and non-coding. In the total-coding groups, they were instructed to code the function of utterance made by all members. The self-coding groups were instructed to code the function of their own utterances. The non-coding groups did not code any utterance. The measurement for dependent variables was performed with single-item questions to be self-rated and conversational categories actually observed in the sessions. As results, the facilitating effects of the track sheet were partially indicated. It is also shown the difficulties in using the track sheet can be easily solved through repeated practice. The findings indicate that the discussion training program using the track sheet would be a potentially effective leaning situation with further improvement.

Introduction

In educational studies, the positive effects of social interaction on learning have been examined and the verified findings are widely acknowledged (Pontecorvo, 1993). Following the theoretical and empirical attentions to the learning benefits of social interaction, teachers across the world have introduced far more group discussion sessions into their classes than before (Kimmel & Volet, 2010; Slavin, 1995). The researchers have revealed that the advantage of social interaction is determined by the quality of discussion (e.g., Wegerif, Mercer, & Dawes, 1999). However, in general, managing group discussions is often difficult for students ranging from elementary school to college levels. This is especially true for those who have not been particularly exposed to low context communication environments.

The present study is related to the endeavor to improve the discussion skills of such learners in a university course that is held in a large classroom with over 50 students. The author has developed a discussion scheme and a paper work sheet called "the track sheet" to help students' learning. The aim of the present study is to examine the effects of introducing the track sheet on discussion processes in an actual class for undergraduate students.

Method

Participants and class contexts

The present study targeted the third to the fourth classes of the course "student guidance" that was offered at a national university in Japan. This course was open to juniors in a teacher-training course. Ninety-seven students who took this course were the participants of this study. Sixty-seven students out of them participated in all the relevant activities and were subject to the subsequent analysis. As the main task, the participating students took part in a small group discussion in each class on a problem related to student guidance. In the third class, they discussed how teachers should have dealt with an injury case which actually happened in a junior high school in the past. In the fourth class, they discussed whether or not they should introduce a richer career education program to students preparing for college entrance at the cost of their course hours.

Discussion Scheme

The discussion scheme used in the program was developed in the author's previous study. It consists of three major categories: "proposal," "reaction," and "management." The proposal category, which pertains to proposing one's own ideas or opinions to other discussants, has three conversational actions: "opinion," "reason," and "example." The reaction, which pertains to the responsive moves to other discussants' previous statements, involves six actions: "reply," "question," "addition," "impression," "doubt," and "refutation." The management, which pertains to contributions to group management in discussion, has five actions: "definition," "goal," "facilitation," "summary," and "approach." These categories were used in the track sheet next to blanks with each speaker's name and their options for conversational action. In employing this sheet, the discussants are made aware of the elements of discussion and supposed to become more sophisticated in their discussion methods.

Research design and hypothesis

The participating students were assigned randomly to one of three groups: total-coding, self-coding, and non-coding. Those who were assigned to the total-coding group were instructed to code the function of every utterance made by all members on the track sheet. The self-coding groups were instructed to code the function of their own utterances. The non-coding groups did not code any utterance. They were simply aware of the scheme for the discussions. In addition to the one between-subject factor, repeated measures for dependent variables were arranged as a within-subject factor.

In the present study, the following predictions were made concerning the effects of functional coding on a track sheet. The coding may promote the participants' thinking and/or discussion development, since they are required to reflect on their own speech before speaking. However, the positive effect will not be manifested before the second discussion session. It is expected that in the first session their thinking will be inhibited by the coding procedure, because they are not familiar with the activities.

Measures

Measures for the effects were twofold. The first measures were single-item questions to be rated on a 5-point Likert-type scale for (a) speaking difficulty, (b) well-organized speech, (c) promoted thinking, (d) well-organized discussion proceeding, (e) inconvenience for speech, (f) inspirational discussion, and (g) confusion by complexity of the scheme. Attitude toward and personal involvement in the discussion themes were also self-rated in the same manner as the previous ratings. The second measures were the frequencies of actual conversation category. The numbers of the categories were counted for each participant.

Result and Discussion

As to the first measures, it was found that the scores of both speaking difficulty and inconvenience in speech significantly improved between the first and second discussions. This result indicates the both scores improved through repetition in all groups in spite of the difference in usage of the track sheet. Those who discussed in the total coding condition marked higher personal involvement score than those in the other conditions with marginal significance. This result partially supports the prediction that the coding may promote the participants' discussion development. However, in contrast to the prediction, the effect of the coding appeared in the first session, not in the second.

In analysis of the second measures, the frequency of doubt in the second session appeared significantly less than in the first. It is implicated that, through repetitive discussions, vague status of thinking such as doubt was transformed into clearer utterances such as question and refutation. On the other hand, the frequencies of refutation, facilitation, and approach declined in the second session. Those facts can be interpreted in terms of the primacy effect of introducing the track sheet.

Even though further analysis is needed, the facilitating effects of the track sheet were partially indicated. In addition, it is shown the difficulties in using the track sheet can be solved through repeated practice. The findings indicate that the discussion training program using the track sheet would be a potentially effective learning situation with further improvement.

Learning-supportive communication structures in tutorial dialogues

Anneliese Elmer, Institute of Education, University of Zurich, Switzerland; Christine Pauli, University of Zurich, Switzerland; Kurt Reusser, University of Zurich, Switzerland

In the school context, silent work phases harbour potential for tutorial teaching-and-learning discourse. On the basis of sociocultural theories, this specific form of learning support from the teacher is attributed with great importance for students' learning. There is consensus that pedagogical skills in a tutorial setting provide effective support for the student's learning process. Moreover, empirical findings point to the importance of the active role of the student in the interaction, as well as of the interaction itself, for effective tutoring.

The question of what characterises tutorial teaching-and-learning dialogues in the context of mathematics instruction when solving mathematical word problems was examined using video analyses of 12 tutorial dialogues, each with one teacher and one student. The content and structure of these dialogues was analysed by coding the type of teacher and student contributions and identifying three patterns of discourse organisation (consensual, constructive, transactive). The results indicate that in all tutorial dialogues, the constructive pattern of discourse (substantial contributions from teacher and student, clearly directed by the teacher) occurred the most frequently, compared to the rather seldom occurring transactive pattern of discourse, in which the teacher's and student's participation in the course of the dialogue is on virtually equal footing.

Theoretical background

Didactic communication takes place in various contexts of instruction. Besides classroom discourse, independent student work makes up approximately half of lesson time in most countries (cf. Hiebert et al., 2003). These silent work phases harbour potential for tutoring, which is seen as an effective form of instruction. Based on sociocultural theories, effective tutorial dialogue in a mutual problem-solving activity should enable socially supported learning in the zone of proximal development (Vygotsky, 1986), by optimally adapting support to the student's level and current needs. Investigations show that the effectiveness of tutoring does not merely depend on the tutor's pedagogical abilities. Chi, Nastasi & Pressley (2001) report that although tutors dominate the teaching-and-learning discourse, students' contributions to constructing shared understanding, and their interaction, influence learning effectiveness in a tutorial setting. Moreover, this study shows that learning based on open, cognitively activating hints of the tutor can be equally as good as when students receive explanations and feedback.

Investigations into tutoring refer predominantly to dialogues between students with differing expertise or dialogues between adults and small children, but rather rarely to dialogues between qualified teachers and students within school instruction.

Embedded in the Pythagoras Study (authors, 2009), the current investigation therefore addressed the question of how teachers, as professional tutors, support students in solving problems typical for school mathematics instruction in 1:1 teacher-student interactions. Of concrete interest was the extent to which teachers successfully stimulate constructive activities of the students and/or enable students an active role in the discourse, making substantial statements. Thus, the tutorial teaching-and-learning discourse was examined regarding the following questions:

- a) What types of teacher and student contributions occur in the discourse?
- b) What discourse patterns regarding students' participation in mutually solving the task are shown in the tutorial dialogues?

Methods

The data base consisted of 12 videotaped tutorial dialogues, in which 6 Swiss and 6 German teachers each solved a mathematical word problem with one student (8th/9th school year). All students solved the same word problem. The analysis is based on a qualitative, two-stage approach which, through two coding systems, describes the teacher-student interaction both regarding content and structurally. The analytical instrument is based on a similar instrument developed by Hogan, Nastasi and Pressley (2000) for analysing group discourse in science instruction. It was developed further for the current purpose. In a first stage, all discourse contributions of the teachers and students were recorded and categorised into various types of statements (e.g. substantial vs. non-substantial contributions, metacognitive contributions etc.) in order to discern who was involved in developing the solution and with which discourse contributions. On this basis, the second stage identified three types of discourse patterns, which differ in

quality regarding the extent and type of student participation: consensual pattern (barely any substantial student contributions), constructive pattern (substantial contributions from teacher and student but no mutual elaboration), transactive discourse pattern (mutual elaboration). This second phase describes the interaction in terms of participation of teacher and student in the problem-solving process and in the discourse. For the description of the quality of the interaction, in each dialogue, the number of statement types and of discourse patterns was ascertained.

Results

The results show that the lengths of the tutorial dialogues vary greatly, lasting between 6.5 and 17 minutes, which is related to the solution process. Comparing the progression of the tutorial dialogues with one another, independently of the total duration of the dialogues, a similar distribution of the three discourse patterns is shown throughout. The constructive discourse pattern occurs the most frequently, the consensual pattern constitutes a smaller proportion, and the transactive discourse pattern occurs very rarely. Thus, it is apparent that no one discourse type is predominant for any of the 12 teachers. Furthermore, based on the analysis of the discourse contributions, the results show in what form teachers and students participate in the problem-solving process in terms of content. While in the consensual discourse pattern, the teacher predominantly poses narrow questions and the student answers briefly and with little content, in the constructive discourse pattern, the student's content-related participation in the problem-solving process is clearly extended. In the transactive discourse pattern, an interaction between teacher and student then becomes apparent, which shows a mutual elaboration of the problem-solving process.

Conclusion and significance

The results of the analysis of communication structures in tutorial dialogues highlight, particularly through the dominance of the constructive discourse pattern, that teachers successfully adapt their questions and prompts to the cognitive achievement level of the students, enabling them to make substantial discourse contributions. The constructive discourse pattern might therefore be considered as an indicator of scaffolding (Wood, Bruner & Ross, 1976). However, the discourse remains clearly driven by the teacher and does not assume traits of an equal discussion, as is apparent from the rare occurrence of the transactive pattern. A transfer of responsibility or a fading of support was very seldom observed.

On the methodological level, it was apparent that the analytical system was successful in illuminating the typical process of supporting learning during problem-solving. Thus, possibilities for optimisation are also apparent, which are important for teacher training, as individual learning support in instruction with heterogeneous learning groups is highly valuable.

The Creative Process and Cycles of Feedback: Models, feeling and the genesis of new ideas

Carol Aldous, Flinders University, Australia

Innovation and enterprise, in a global networked society, depend for their success on the development of new ideas. But from where do new ideas come? How do they arise? Are feeling and intuition involved? Finding answers to questions such as these have been at the heart of creativity research for more than fifty years and hold important implications for education.

The early twentieth century heralded creativity as a definitive process involving a series of stages that take time. Introspective methods and case study research identified the phases of preparation, incubation, illumination and verification. One model, the 'Eureka Process' (Shaw 1989), sought to highlight the role of feeling in the genesis of new ideas and predicted the presence of a series of feedback loops arising between each of the phases. The feedback loops

were named after researchers who theorised their existence. However no large scale data to confirm their existence have been presented.

A study of 405 middle school students solving two novel problems in the Mathematics Challenge for Young Australians found empirical evidence of these feedback loops. A set of scales tapping both cognitive and non-cognitive approaches to reasoning, identified the 'Areti', the 'Vinacke', the 'Lalas', the 'Communication' and 'Rossman' loops. Of note was the finding that the 'Lalas loop' was characterised by gradual illumination for the number oriented problem, but by sudden illumination for the spatially oriented problem. Data were tested by full structural equation modelling with maximum likelihood estimation procedures using AMOS graphics version 4.01

Aims

The research documented in this paper forms the basis of a major study which set out to discern whether there is any substance to the idea that individuals can feel their way to a solution in a novel mathematics problem solving event (Aldous 2009.) This necessitated identifying, describing and measuring this so called feeling in order to test its relationship with solving novel mathematics problems successfully. This was done through the structural equation modelling of a comprehensive model of creative problem solving that encompassed the person, process, product and environmental dimensions of creativity.

An unanticipated outcome of this research is evidence, found within the measurement model of the comprehensive model of creative problem solving, of a series of feedback loops arising at different stages of the creative process. These feedback loops are consistent with those proposed by Shaw (1989).

Theoretical Background:

Building on the classic model of creative problem solving which included the phases of preparation, incubation, illumination and verification have been a plethora of process models of creative problem solving (e.g. Cropley, (2001); Finke, Ward, & Smith, (1992); Shaw (1989) among many others). However, of these process models only two of them (viz: Shaw and Cropley) have highlighted the role of feeling in the creative process. Interestingly, Shaw identified and named five feedback loops arising between each phase of the classic model and speculated the presence of many more. The existence of multiple feedback loops, operating simultaneously and successively, both consciously and non-consciously, over n parallel paths, is consistent with neural network models of the brain.

The first loop, the 'Areti loop', refers to the cycling that occurs between the phases of preparation and incubation and is hypothesised to involve moving between conscious and non-conscious processing. The second loop, the 'Vinacke loop' relates to the cycle of feedback existing between the phases of incubation and illumination. It also draws upon non-conscious and conscious thinking. The third loop, termed the 'Lalas loop' relates to the cycle of feedback occurring between the phases of illumination and verification. Within the 'Lalas loop', explanation and verification lead to further illumination. The 'Communication loop' occurs between the verification phase and the creative outcome or product. Finally the 'Rossman loop' encompasses multiple feedback loops and validation processes from all previous steps in the creative process.

Methodology

The comprehensive model of creative problem solving was developed using a set of constructs hypothesised to have a bearing on successful novel mathematics problem solving. The constructs were derived from Carroll's (1963) model of school learning, and Shaw's (1989) model of creative problem solving. The constructs and their allied dimension of creativity are listed below.

Antecedents;

Personal abilities (including spatial and verbal) (Person dimension);

Perseverance and motivation (Person dimension);

Opportunity to learn (Environment dimension),

Achievement outcome (Product dimension), and

Approaches to reasoning (Process dimension)

Importantly, the latter construct was used to measure both cognitive and non-cognitive approaches to reasoning including those of feeling and intuition. A self-report instrument known as the Systems of Reasoning Questionnaire

(SRQ) comprising a set of five scales was used. Items in these scales measured five approaches to reasoning. These were a Strategic approach, a Free-flowing approach, a Spatial-verbal approach, a Feeling approach and a Systematic approach to reasoning.

Data were collected from 405 middle school students who were participants in a national program known as the Mathematics Challenge for Young Australians. Entrants had three weeks in which to answer six novel problems. Students involved in the study answered the (SRQ) upon completing two of the six novel problems. One of the problems was spatially oriented the other number oriented.

Findings in brief

Fit statistics revealed a good fit to the data for the comprehensive model of creative problem solving (RMSEA of 0.036) for both the spatial and number oriented problems.

Standardised estimates were used to prioritise the order of the three highest items within each process scale for the two measurement models. Patterns of emphases were similar in both data sets but with some notable differences.

Within the strategic approach to reasoning the pattern of emphasis was on preparation leading into incubation indicative of the 'Areti loop'. Within the Free-flowing approach to reasoning the pattern of emphases was on incubation leading into insight or illumination consistent with the 'Vinacke loop'. The Feeling approach to reasoning was characterised by feelings of knowing culminating in sudden illumination in the case of the spatial problem, but a more gradual realisation in the number problem. The cycle of explication and illumination was consistent with the 'Lalas loop'. Finally the systematic approach to reasoning was characterised by the elaboration and organisation of ideas in the case of the spatial problem but verification and checking in the case of the number problem.

Of interest was the finding that the spatial-verbal approach to reasoning indicated simultaneous processing in the case of the spatial problem, but sequential processing in the case of the number problem.

Theoretical Significance

Research into creative problem solving has theorised the existence of a number of oscillatory mechanisms involving the interaction of both conscious and non-conscious reasoning, the role of feeling in listening to the self and the interaction of spatial and verbal reasoning involving a series of feedback loops. However empirical evidence for such mechanisms involving large scale data has been scarce. The findings presented here go some way to redressing this issue.

THEMATIC POSTER

Collaboration

Journal clubs - an intervention to promote collaboration between higher education and working life

Lea-Riitta Mattila, Metropolia University of Applied Sciences, Finland; Eija Salomaa, Hospital of the city of Espoo, Finland; Hannele Hokkanen, Metropolia University of Applied Sciences, Finland; Arja Haggman-Laitila, Metropolia University of Applied Sciences, Finland

The aim of this presentation is to describe journal club intervention which is part of the project Collaborative Intensity launched by Metropolia University of Applied Sciences and the hospital of the city of Espoo. A model for the partnership between higher education and working life is developed in the project. The concept journal club refers to arranged meetings where the staff of acute geriatric wards convene to discuss the use of research knowledge in patient care to promote evidence-based practice and to improve the outcomes of patient care.

In the clubs, the topics discussed dealt with clinical issues and answers were sought from research articles to solve problems specified by each ward/outpatient unit. The clubs met once a month to form a series of presentations dealing with a problem by employing research articles. The students paired up to make an oral presentation of a research article to staff members. After the presentation, they acted as chairpersons in the discussion. The students had a vocational college diploma in nursing and they studied towards a bachelor's degree in nursing. The articles were presented according to the written guidelines based on the phases of research process. The theoretical background and implementation of the journal club intervention will be described in the conference.

The aim of this presentation is to describe journal club intervention which is part of the project Collaborative Intensity launched by Metropolia University of Applied Sciences and the hospital of the city of Espoo. A model for the partnership between higher education and working life is developed in the project. The initial conceptual model for the partnership developed in the project Collaborative Intensity identified attitudes and lack of common understanding as factors impeding partnership. The journal club intervention is aimed to diminish these impeding factors. Three acute care hospital wards are involved in journal clubs. The mission statement of the wards is to support patients' rehabilitation in a patient centered way after the acute phase of illness and to promote patients' independence. A multidisciplinary team of nurses, social workers, physicians, occupational therapist and physiotherapists serve the patients in the wards. Patient safety, discharge planning and continuity of care are emphasized in daily care. The concept journal club refers to arranged meetings where the staff of acute geriatric wards convene to discuss the use of research knowledge in patient care to promote evidence-based practice and to improve the outcomes of patient care. A nursing journal club is a meeting of staff at the workplace to discuss the application of research knowledge to patient care. The club provides an opportunity to enhance critical thinking skills and to find peer support for new ideas on the development of care. The aim is to foster the special expertise of the staff as well as to encourage them to have professional discussions and share knowledge. The staff need guidance on how to apply research knowledge to their work. Key skills include the capability to read research reports critically and to consider research results from the point of view of practical applicability. Discussing scientific studies together may help staff to understand research and its practical implications. The nursing students have a prominent role in the clubs as presenters of the article and in chairing discussion. The students pair up to make an oral presentation of a research article to staff members. After the presentation, they act as chairpersons in the discussion. The students have a vocational college diploma in nursing and they study towards a bachelor's degree in nursing. The articles are presented according to the written guidelines received from the teacher based on the phases of research process. The journal club creates a common learning environment to the staff members and students. The planning phase of the clubs started in April 2010 by a discussion at a project meeting during which the idea was presented. Subsequently, the units that had decided to participate named a common patient care-related subject with development needs. The subject was narrowed down into problems whose solutions were sought in research articles. It is required of the chosen subject and problem whose solutions are sought in scientific studies that they are significant to patient care. It is also characteristic of the problem that they occur repeatedly in clinical practice and that it is possible to find several studies offering potential solutions to them. In the implementation phase the nursing journal club meetings will be held on the premises of the wards. Nursing students present the articles and chair the discussions. The articles are presented according to instructions given to the students. The presentations will focus on the significance of the research results to patient care and their practical applicability. A club meeting lasts 45-60 minutes. The topic discussed since November 2010 to April 2011 will be assessment of patient's confusion or delirium. The clubs meet once a month to form a series of presentations dealing with a problem by employing research articles. In the evaluation phase the learning experiences of the staff and students will be discussed to enhance common understanding and positive attitudes between the professionals and to develop journal clubs further as a multidisciplinary learning environment. The theoretical background and implementation of the journal club intervention will be described in the conference.

Collaboration of teachers investigated within three different learning situations in primary schools

Jannet Doppenberg, Eindhoven University of Technology, Netherlands; Anouke Bakx, Fontys PABO Eindhoven, lectoraat L&I., Netherlands; Perry den Brok, Eindhoven University of Technology, Netherlands

During the last two decades there has been a growing awareness of the potentially strong role of teacher collaboration in relation to teacher learning. However, while theoretical 'ideals' of teacher learning are abundant in the literature, relatively little is known about what teacher learning in collaboration with colleagues actually looks like in everyday work. The aim of this study was to obtain more understanding of teacher learning related to different learning situations in which teachers collaborate with each other. In this study teacher learning was studied within three learning situations, differing in nature, taking into account both the undertaken activities by teachers and learning outcomes. Data was collected through a structured questionnaire completed by 411 teachers representing 49 primary schools. The questionnaire was based on a literature review and results of a prior interview study. Preliminary quantitative analyses showed that, four reliable and independent scales for undertaken activities and three reliable and independent scales for learning outcomes could be identified, which are comparable with categories defined in literature. Variance analyses showed that the undertaken activities and learning outcomes differed between the three learning situations. Moreover, large differences were found between activities and learning outcomes across schools.

Rationale and theoretical framework During the last two decades there has been a growing awareness of the potentially strong role of teacher collaboration in relation to teacher learning (Levine & Marcus, 2010). Collaboration with colleagues is seen as a powerful learning environment, which stimulates the professional development of teachers, the innovative development of schools as well as student learning and also characterises professional learning communities (Vescio, Ross, & Adams, 2008). However, while theoretical 'ideals' of teacher learning are abundant in the literature, relatively little is known about what teacher learning in collaboration with colleagues actually looks like in everyday work (Borko, 2004). In this study teacher learning is defined as a process of conscious and unconscious undertaken activities by teachers in collaboration with colleagues, which lead to change in cognition and/or behaviour at the individual and/or group level (Meirink, 2007). Following the literature, in this study we distinguish the context conditions that influence teacher learning in collaboration with colleagues; the organisation (structure, size of group) and topic and nature of collaboration. In a prior interview study conducted by the authors, teacher learning was studied within different collaborative settings in primary schools. Results of this study indicated that depending on the collaborative setting more or less different activities and learning outcomes were reported by teachers and school leaders. However, no direct link could be established between activities and outcomes. Thus, the first aim of the present study was to check if the reported activities and learning outcomes of that study could be confirmed with a larger sample of teachers and schools. The second aim was to investigate the link between activities and learning outcomes across different learning situations and schools. Accordingly, the following research questions were formulated: 1) What activities and learning outcomes do teachers perceive across different learning situations? 2) To what degree do the reported activities and learning outcomes vary between different learning situations? 3) What associations exist between reported activities and learning outcomes?

Method

To answer the research questions a questionnaire was developed based on a literature review and results of the mentioned prior interview study. The constructed questionnaire consisted of three learning situations referring to a specific topic and nature of collaboration. One situation referred to the implementation of new lesson materials, another to the implementation of a new teaching method and the last to teachers sharing the responsibility for one class. Per situation the same set of questions were asked with respect to the activities undertaken (22 items) and perceived learning outcomes (9 items). Items in the questionnaire scales were constructed as concrete point scales for undertaken activities (never, weakly – yearly) and as a Likert-type five-point scale for learning outcomes (almost not – very much). Data was collected from 411 teachers, representing 49 primary schools in the Netherlands. Thus, across situations the total data set contained 1233 response sets. Gender distribution of the respondents was as follows: 24 % were male and 76 % female. Exploratory factor analyses suggested the existence of four relatively independent scales for activities - labelled exchange and assistance, discussion and joint work, intervision and collegial consultation -, and three scales for learning outcomes - labelled individual outcomes, group outcomes and individual outcomes referring to changes towards colleagues. These scales seemed to align well with categories such as distinguished by literature. Reliability analyses (Chronbach's alpha) showed that these scales were consistent (alphas ranged from .74 to .95). Among the activities and among the learning outcome scales correlations were moderate ($r=.40$) suggesting that they were relatively independent. To answer the research questions we performed descriptive analysis (research question 1), variance analysis (research question 2), and regression analysis and correlations analysis (research question 3).

Results and conclusions

Since the data analyses are still in progress, at this moment only preliminary result can be reported. Variance analysis showed that the undertaken activities and learning outcomes differ between the three learning situations. Especially for the situation referring to the implementation of a new teaching method, teachers reported more learning outcomes than for the other situations. Moreover, large differences were found in activities and learning outcomes between schools. More precise and elaborate results will be discussed and presented in the poster.

Partnership between higher education and working life - Developing a conceptual model

Leena Rekola, Metropolia University of Applied Sciences, Finland

The collaboration and partnership of organizations and higher education has been depicted for decades in international literature. In spite of this, research information covering the subject is still rather sparse and the research is considered challenging. Partnership requires a new paradigm and new cooperative practices. There is no co-ordinated definition for it, nor have any widely tested work models been compiled to ensure its development. Metropolia University of Applied Sciences and the hospital of the City of Espoo involved in a project called Collaborative Intensity, in which a work model for partnership between higher education and working life is being developed. In the first stage, knowledge of the development of the partnership model will be produced through a systematic literature review and the recognition and naming of the terminology for the model. The second stage will create a preliminary model for partnership. In the third stage the development of the partnership model will be presented as well as specified and complemented. In the fourth stage a presentation of the partnership model and its development process will be produced, and complemented by specialist feedback.

The purpose of the ESR-funded Collaborative Intensity project (2008-2011) is to produce a partnership model between higher education and working life. The partnership model is being developed as a multidisciplinary collaboration between the hospital of the City of Espoo and Metropolia University of Applied Sciences. The focus will be on sharing expertise and knowledge, in addition to parallel development. Partnership enhances the sharing of the newest research information and the best practices, and group together the training and activities of social, rehabilitative and health care sectors in particular, along with their evaluation and development. The project aims to produce an innovative collaborative model for different organizations. It is based on functional coactive relations and learning environments which transcend boundaries. The new work model is intended to advance the collective recognition, use and development of know-how between different organizations. At the beginning stages of the project the partnership will operate through a pilot programme, in which work models based on the service idea of the newly planned hospital in Espoo will be developed for geriatric work. The pilot consists of three partially independent subprojects carried out at the Espoo hospital.

The collaboration and partnership of health care organizations and higher education have been depicted for decades in international literature. In spite of this, research information covering the subject is still rather sparse and the research is considered challenging. Partnership aims at offering new solutions for new problems, which no organization can overcome alone. Partnership requires a new paradigm and new cooperative practices. Partnership is used in various instances. There is no co-ordinated definition for it, nor have any widely tested work models been compiled to ensure its development

The aim of this presentation is to describe the conceptual work model as well as the development of the model. The partnership model and its development process will be presented in the action research, in which the principle, structural and processing factors of the model are recognized, evaluated and named. The results and their actualization will be evaluated with the help of experience gained from the project. The research for the project is

divided into four phases (2009 – 2011) and the following research questions will be answered: What kind of partnership models have been developed for working life and higher education? How were they developed? Which factors advance and hinder the partnership? What kind of results have been achieved through development work?

Information retrieval and material analysis are performed through qualitative analysis. In the first stage, knowledge of the development of the partnership model was produced through a systematic literature review and the terminology for the model was recognized and named. Reference literature was searched in the Cinahl, PubMed and Eric databases for 1999-2009. The search yielded 1012 references, of which 205 abstracts were picked according to certain inclusive and exclusive criteria. Altogether 21 full texts were chosen for the final analysis. In the second stage an initial model for the partnership was created. A total of 31 persons from the partner organization took part in the focus group interviews. They were carried out in six groups. The interviews were performed during 2009. The material was analyzed through qualitative content analysis.

In the third stage the development of the partnership model was presented as well as specified and complemented through the experience gained from the project collaborations. A total of 29 persons took part in the focus group interviews carried out in four groups during the autumn 2010. In the fourth stage a presentation of the partnership model and its development process will be produced (autumn 2010 – spring 2011), and the presentation will be complemented by specialist feedback (spring 2011).

Based on the results of the literature review and the first focus group interview, features seen as advancing partnership included the arrangements of the co-operation, an ethical principles and culture of the organizations, work principles directing co-operation, management of change, and publicity. Features hindering co-operation were cultural differences between the organizations, prejudice, and the lack of respect, resources and mutual understanding. Partnership processes in the development and sharing of expertise transpired as unilateral cooperation or shared learning. Shared learning occurred in student guidance, the improvement of treatment work premised on demonstration, the advancement of leadership, and in collective training. For the sharing and developing of expertise, configurations of student guidance had been established. The development of the model and its concepts will be presented at the conference.

The Coach Teacher as an Advocate of the Partnership Between Higher Education and Working Life

Liisa Lukkari, Metropolia University of Applied Sciences, Finland; Minna Marjamäki-Kekki, City of Espoo, Finland

The aim of this lecture is to view the coach teacher as a "tool" in the partnership frontier between higher education and working life. The coach teacher pilot is a part of Collaborative Intensity project (2008-2011) and its goal is to produce a partnership model between higher education and working life, which can be transferred and adapted to any collaboration between different parties. The partnership model is developed as an action research in the Espoo-Metropolia pilot project.

The coach teacher acts as a coordinator, a support for students and a developer of the clinical instructors' guidance skills. The coach teacher seeks and creates opportunities for students to take part in innovative and multidisciplinary learning situations with representatives from working life and higher education. The basic skills demanded of a coach

teacher are the good guidance of students and availability to and support of students during clinical practice. The aims of the coach teacher pilot are the support and guidance of students, the support of the mentors and development of their pedagogical competency, the purpose being to improve the quality of guidance. The aim is also cooperation and coordination between the working life and higher education.

The partnership model is developed as an action research in the Espoo-Metropolia pilot project. Involved in the pilot are the Faculties of Welfare and Functioning and Health Care and Nursing of the Metropolia University of Applied Sciences and the staffs of the hospital of Espoo city and Recruiting unit of Espoo city. The coach teacher acts as a coordinator, a support for students and a developer of the clinical instructors' guidance skills. The coach teacher seeks and creates opportunities for students to take part in innovative and multidisciplinary learning situations with representatives from working life and higher education. The basic skills demanded of a coach teacher are the good guidance of students and availability to and support of students during clinical practice. This clinical practice plays a major role in the development of professionalism, competence, and the skills needed in working life. Clinical practice should enhance work in multiprofessional working groups. Clinical work comprises almost one half of the degree programme.

The aims of a coach teacher:

Aim number one is the support and guidance of students. Students should commit themselves to clinical practice and the practice environment, which creates opportunities for advance recruitment. They receive a welcome letter before clinical practice, the head nurse of the hospital and the coach teacher hold an information session, after which the coach teacher presents the hospital premises and accompanies the students to the wards where the information session continues. According to research, during clinical practice students experience a supportive mentor relationship and regular feedback as important (Warne et al 2010). Within this pilot students and the coach teacher meet for reflection meetings, in which they discuss subjects connected to learning in multiprofessional student groups. The coach teacher makes regular rounds of the wards, at which time she/he meets with students and mentors and provides support and guidance.

Aim number two is to support the mentors and development of pedagogical competency, the purpose being to improve the quality of guidance. According to research, an individualized mentorship as well as the teacher/student relationship is of fundamental importance during clinical practice (Warne et al. 2010). Mentors are informed about the curriculum, the learning context, and they are assisted in integrating theory and practice. According to research, mentors need pedagogical training (Vuorinen 2005). The aim is to enhance mentors' skills with pedagogical education and unify the quality of guidance in the hospital. Regular meetings of the mentor network should bring consistency and better quality to mentorship. Guidance material is developed and updated, and at the end of clinical practice feedback from students is collected (Mikko Saarikoski's Cles-scale).

Aim number three is cooperation and coordination between the working life and higher education. According to research, the appointment of a contact person promotes operations and understanding of methods as well as the exchange of practices found to be useful (Hinkkanen 2002). The coach teacher coordinates collaboration between education and working life.

The aim is mutual expertise and networking as well as making up-to-date information on education available to working life. The coach teacher coordinates teachers' working life periods in which exchange of expertise facilitate the creation of innovative learning environments. Teachers' working life periods promote mutual understanding, exchange of expertise, strengthening of teachers' skills and multidisciplinary learning situations in a clinical environment.

Research and development is practically orientated, and beneficial to both working life and education. Research club activities allow students to present scientific articles based on the needs of the working community and bring research knowledge to the working community in a clear and understandable way. Multidisciplinary patient case study exercises develop both students' and working life representatives' professional skills in multidisciplinary work and the assessment of the patient's condition. The theses written for the project support the hospital and profit unit strategy. Thesis subjects relate to the sub-project themes of the Collaborative Intensity project: patients' safe medication, rehabilitation and discharge.

Virtual Collaboration and Intercultural Learning at Universities

Julia Huenniger, University Augsburg, Germany; Klaus Bredl, Institute of Media and Technological Enhanced Learning, Germany; Jane Fleischer, Institute for Media and Educational Technology, Germany

These days, societies are characterized by their interculturality. International communication is a part of everyday life and cross-cultural contacts go without saying. As a tool to broaden the sphere of interculturality social software can be used. This paper promotes the use of digital media in teaching to encourage intercultural learning in all subject areas. To begin, we will define social media and changes in the internet. Specifically, we will go into detail on the varied possibilities of collaboration online. Subsequently, a short description of the relevance of intercultural learning at universities and the potential of digital media to create intercultural communication possibilities will be demonstrated through several examples. We will conclude with challenges and possibilities for future research.

Virtual CollaborationFirst, we must define the term "web 2.0". According to Kerres (2006), web 2.0 can be defined as changed perception and use of the internet: "Characteristic of web 2.0 is that conventionally computer-run applications are translocated into the the internet" (p. 1). The internet is no longer just used for the gathering of information from experts, because contributions can come from anyone and content is created in a dialogue between many users. Users have an active role, because their contributions are in the center of everything: "Opinions can be shared in various forms, linked with contributions of a similar nature and can eventually become influential opinion pools" (Stanoevska-Slabeva 2008, p. 16). The internet becomes social through the offering of new things: On one hand, through the possibility that everyone can take part. On the other hand, through the growing importance of communication with other users.[1] This so-called "participatory web" phenomenon is not a term we will come to hear less often in the near future (Fisch/Gscheidle 2008)."Participation" is a prerequisite for collaboration, a method that is becoming more and more important, especially in regards to social media. Ideas and experiences are shared online. Users generate content and work together - creating synergies. Collaboration has additional value, because individual work is reviewed, edited and criticized by others to create a final product. The objective in all of this is not, however, necessarily the end result, because collaboration "focuses on processes: transformations that lead to learning" (Neumayr 2007, p. 123).Collaboration requires participation from everyone involved: At universities, this means the participation of everyone involved in the teaching and learning process. Similarly, online all authors need to be engaged.Consequently, integration of the social web to promote collaboration seems appropriate for university teaching. The degree to which intercultural learning and communication through digital media can also be implemented will be presented in the following section.Intercultural LearningThe prefix "inter" is Latin and means "between". It declares that new things can be found or founded between people from different cultures (Leimgruber 2007, p. 19).Intercultural learning begins with the dialogue between people from different cultures. This is where social software can be used to motivate intercultural learning, because online interculturality can be authentically produced and shared (Bolten 2007): The internet offers "forms of publication and communication that can not only be used for individual and collaborative knowledge management, but next to its informative function it also facilitates social connections between users" (Býffel/Pleil/Schmalz 2007). In addition to blogs and wikis, forums and podcasts also help to support intercultural learning at universities (for example, to learn a foreign language, or in specific subject areas such as international management, etc.). Students from different cultures can write about their learn progress in blogs and share their experiences with others. These blog entries can be commented by other users and this, in turn, can lead to some interesting discussions. Another option is wiki projects: Students can write about everyday things from their cultural standpoint, for example, which might also generate a dialogue with others. Participants not only learn about their own and other cultures, but also about how to negotiate. Bolten describes the negotiation process: "Collaboration via internet depends on time differences, languages and the set rules for working together. Because of this, the learning process here is intercultural and, subsequently, also authentic and believable" (Bolten 2007, p. 228). Especially through the use of digital media and media products in teaching - which have been simplified by social media - intercultural learning is conceivable for all subject areas.Virtual Collaboration and Intercultural LearningTo date, intercultural learning has been implemented mostly in social or economic fields of study, in addition to foreign language studies. However, even in these subject areas the social web isn't utilized to its full potential. The establishment of an extended concept of culture and diversity have led to an increase in intercultural themes at universities. With the advancement of globalization, it is important particularly for all social

and arts scholars to have special knowledge of intercultural issues, especially because society today is characterized by interculturality. Economic, political, social and ecological relations at a state level are increasingly being put into a more global context. International exchange is a part of everyday life; cross-cultural contacts go without saying (große Holthaus/Kßler 2004, p. 7f.). In this context Social media can be used to create and promote interculturality via emails, forums, news groups, blogs, e-Tandems, Wikis (Bolten 2007). In this regard Banks (2006, p. 76) points out what is crucial in terms of intercultural web collaboration: "We have learned that intercultural collaboration on e-learning is demanding and time-consuming but is ultimately worthwhile, because new knowledge, creativity, insights and practices can be developed. However, critical shared reflection on beliefs and practices of e-learning is an essential requirement to maintain the process of effective intercultural collaboration." Conclusion Virtual collaboration has become essential in the field of intercultural learning. Bolten (2005) describes the corresponding terms of social media and intercultural learning as "double chance", because they not only deliver important information, but help to build connections, relationships between users. Dervin (2010, p.2) gives advice on the implementation of intercultural learning in Web 2.0. He thinks, that learners "should be led to reflect on how to make intercultural communication more respectful of individuality and how people use identities and cultures to talk about themselves, construct who they're and others, manipulate, etc. Project pedagogy and taskbased learning represent good alternatives for combining Web 2.0 and interculturality." As a result of the above research, it can be concluded that prerequisites for and relevance of virtual intercultural communication should be a topic for future study. At the University of Augsburg's Institute of Media and Educational-Technology a concept for a seminar will be developed, implemented and evaluated in the winter semester of 2010/2011, in which the above mentioned will be tested.[2]-----[1]To account for this development and omission of the from the advertising industry originating (O'Reilly 2005) controversial term "web 2.0": Changed and new offers online will be identified with the term "social media". The new internet will be described accordingly as the social web.[2]The results will be available when the finished paper is handed in.

Building a school-family-community partnership based on a structuring device: success plans

Dany Boulanger, Université de Sherbrooke, Canada; Francois Larose, Université de Sherbrooke, Canada

Aims

In this paper, we will present the results of a second-order data analysis from a study focused on school-family-community partnerships. We assess how the evolution of a particular device, that is to say schools' success plans, promotes building partnerships. This study used two central constructs: the ecosystemic approach (Smith & Thelen, 2003; Bronfenbrenner, 2004) and the activity theory (Engeström, 1987, 2001).

Methodology

The failed partnership practices attributed to a lack in the systematization of the activities identified and in their articulation lead us to study success plans as a requirement when building a partnership and when requesting the participation of all the stakeholders, parents in particular. Data analysis will be accomplished by using the activity theory (Engeström, 1987, 2001). We have conducted a textual data analysis (Lebart, Salem, & Berry, 1998) on all of the success plans produced over a period of seven years. We applied a similar process to stakeholders' responses to semi-structured interview questions carried out among all of the stakeholders (N=357) participating in the program.

Findings

We are witnessing all the stakeholders coming together around shared zones and a change in the status of parents in which their skills are being recognized.

Theoretical and educational significance of the research

This study shows the efficiency and relevance of using activity theory when analyzing the dynamics of jointly building a school-family-community partnership, and underlines the importance of all the stakeholders participating, the parents in particular.

Aims

In this paper, we will present some results of a second-order data analysis from a study sponsored by the Fonds québécois de recherche sur la société et la culture (2006-2009). We studied how the evolution of a particular device, that is to say schools' success plans, reflects how a partnership between school and community stakeholders and parents from disadvantaged backgrounds is built. This study used two central constructs: the ecosystemic approach (Smith & Thelen, 2003; Bronfenbrenner, 2004) and the activity theory (Engeström, 1987, 2001).

Problem and research objectives

On an international level, we are witnessing the implementation of practices that seek to build a partnership between school, family, and community based on an ecosystemic logic. In partnership-based programs, school personnel and community workers define and implement activities that seek to promote school participation among parents from socio-economically disadvantaged communities. The inefficiency of these practices is often associated with the fact that they are centered strictly on the school, so that the leadership is mainly taken on by the teachers and school board, who treat parents as mediocre support workers (Vincent & Martin, 2002; Gutierrez, Field, Simmons, & Basile, 2007). They are based on a phenomenon of cultural discontinuity and imply a weak link between systems, known as cultural realms (Cairney, 1997, 2001). Moreover, these practices do not generally have devices facilitating this articulation and making it possible to define and assess activities identified in an operational way and build them over a long period of time.

Theoretical framework

This talk is based on a second-order data analysis of data gathered within the framework of a study on the impact of a program developed in the Province of Quebec, seeking to support educational achievement among primary school pupils in socio-economically disadvantaged communities. The program *Famille, école, communauté, réussir ensemble* (FECRE) is based on a structuring device, which is to say schools' success plans. Defined within an ecosystemic perspective, success plans target systems as a whole, perceiving them as resources.

Data analysis will be accomplished by using the activity theory (Engeström, 1987, 2001). Activities carried out among children, by each of the stakeholders, from their reference system, are defined as objects to whom stakeholders attribute meaning and who reflect their socio-cultural realm. They are based on patterns of recurring practices. Cultural tools are used to mediate the relationship between these activities and the objects that are associated with them. They may be material tools (documents, texts) or semantic tools such as attitudes or beliefs. These tools, which facilitate the articulation between objects from distinct cultures, are a components of practices developed where systems meet and determine the conditions of the stakeholders' participation.

Our research objectives are to identify: 1) how implementing a device that will organize curricular and extra-curricular activities, that is to say the success plan, when it is jointly built by stakeholders coming from different networks, will create an effective school-family-community partnership; and 2) in what way a longitudinal interaction perspective will make this joint venture possible.

Methodology/research design

This talk is based on a second-order data analysis of data gathered within the framework of the FECRE's assessment. This program, over a period of seven years and involving 22 primary schools (between 2002 and 2009), was assessed during the three last years of the implementation. We have conducted a textual data analysis (Lebart, Salem, & Berry, 1998) on all of the success plans produced over a period of seven years. In this approach, which uses correspondence analysis on a body of discourses, a certain number of forms (words) or segments (concepts) characterize certain activities. These discursive elements, as they pertain to operators reflect the more or less off-centered position of specific activities in relation to the centre of the factorial plan. In turn, these off-centered positions reflect the part of the variance that is not explained by successively taking factors into consideration. We applied a similar process to stakeholders' responses to semi-structured interview questions carried out among all of the stakeholders participating in the program (N=357). By conducting this analysis, we obtain a measure of effect for the success plans on the implementation of partnership practices based on their ecosystemic roots. In this way, we were able to compare how the success plans evolved according to what the stakeholders' discourses. Thus, we compared these discourses to how the parents' participation evolved, such as it can be extrapolated from the success plans.

Results

The results show a progressive evolution of the success plans' means, displaying a complex articulation between school, family, and community. In the beginning, the means were centered on the school. Progressively, the ties between stakeholders developed and became a component of the implementation of several means that tend to decompartmentalize. We are witnessing all the stakeholders coming together around shared zones and a change in the status of parents in which their skills are being recognized. Notably due to their ecosystemic foundation, the success plan is considered a first rate tool for implementing an effective school-family-community partnership and instigating parental participation.

Theoretical and educational significance of the research

This study shows the efficiency and relevance of using activity theory when analyzing the dynamics of jointly building a school-family-community partnership, more specifically when this partnership is based on a non-instrumental conception of parental participation as stakeholders in their children's schooling. It underlines the importance of the

participation process of all school stakeholders, parents included, when building, implementing, and assessing the efficiency of operationalization devices with respect to the school-family relationship in a perspective of real empowerment, notably in disadvantaged communities.

THEMATIC POSTER

Self-regulation and self-efficacy

Teacher Self-Efficacy as a Predictor for Instructional Behaviour? A Longitudinal Analysis.

Doris Foerster, University of Frankfurt, Germany; Mareike Kunter, Goethe-University, Institute of Psychology, Germany; Anja Philipp, University of Frankfurt, Germany

This paper investigates teachers' self-efficacy beliefs as possible influences on their instructional behaviours under a longitudinal perspective. In a sample of 155 secondary teachers, teachers' self-efficacy beliefs and teaching practices (e.g. cognitive activation, classroom management, individual learning support) were assessed at the end of grade nine and the end of grade ten. While teachers reported their self-efficacy beliefs, their instructional behaviours were evaluated by the teachers as well as their students. Cross-sectional correlations between self-efficacy beliefs and characteristics of instruction could be substantiated; however, cross-lagged analyses confirmed a longitudinal effect of self-efficacy only on individual learning support. By contrast, instructional features such as cognitively activating behaviour were determining the level of teachers' self-efficacy one year later. This was true even when students rated the instruction. These results indicate that the influencing effects of self-efficacy are as yet unclear and that classroom contexts can determine motivational orientations of teachers, which had the capacity to change even in highly experienced teachers.

Aims and theoretical framework

Motivational characteristics of teachers - as part of their professional competence (e.g. Alexander, 2008) - have been increasingly investigated over the last few years. Constructs like self-efficacy, enthusiasm, autonomous or controlled motivation - originally used to describe students' motivation - have been applied to teachers in order to explain differences in teachers' behaviours. One of the most widely researched motivational construct is teachers' self-efficacy. While some researchers link teachers' self-efficacy beliefs to student outcomes such as student achievement (e.g. Caprara et al., 2006) or student motivation (e.g. Midgley et al., 1989), others consider their consequences for teachers' well-being (e.g. Schwerdtfeger et al., 2008) and teachers' instructional behaviours (e.g. Tschannen-Moran et al., 1998). Despite these attempts to corroborate the relevance of teacher self-efficacy for educational purposes, previous studies leave at least two questions open. First, few studies have yet examined teachers' self-efficacy beliefs from a longitudinal perspective. Consequently, the assumption of a positive causal influence of self-efficacy on outcome variables such as instructional behaviours is often based on cross-sectional data. Secondly, data from previous research may be biased due to confounding of data sources: In many cases, teachers not only assess their level of self-efficacy, but also rate their instruction at the same time. This paper therefore deals with teachers' self-efficacy beliefs and their impact on instruction over time. In line with previous research findings, it is expected that teachers' self-efficacy at an earlier date will influence their later instructional behaviours, i.e., their classroom management activities, cognitive activation and individual learning support they provide to their students. At the same time, however, we investigate to what degree earlier teaching behaviours impact on teachers' self-efficacy beliefs. Moreover, analyses will address the question whether the expected relationships can be established not only for teachers' self-reported items but also for a more objective measure such as students' evaluation of teacher instruction.

Method

Sample: Analyses were based on a sample of German secondary mathematics teachers. A representative sample of 9th-grade mathematics classes and their teachers were recruited within the COACTIV study - a study embedded in the German PISA study of 2003. For undertaking the intended longitudinal analyses, it was, however, critical that classes and teachers did not fluctuate over the two measurement points. Thus, the resulting subsample included 155 teachers (53% male, mean age 48 years, average professional experience of 22 years) and their corresponding students (N=4413, mean age 15 years), facilitating the linking of the different data sources. **Design:** Data were collected at two measurement points; at the end of grade nine and at the end of grade ten. All scales were administered at both time points. **Instruments:** Scales from the teacher questionnaire tapped teachers' self-efficacy ($\alpha = .67$ at Time 1/.68 at Time 2) and teachers' instruction in mathematics covering cognitive activation (e.g. cognitively challenging instruction), classroom management (e.g. disciplinary problems) and individual learning support (e.g. personal confidence). The student questionnaire also gauged the three dimensions of teachers' instruction (e.g. cognitive autonomy, effective use of time, adaptive explanations, respectively). Cronbach's α 's for the teacher rating scales

above .7 and intra-class correlations above .82 indicated good reliability of the aggregated student responses. Statistical procedure: After ensuring reliability of student ratings as well as sufficient agreement on the students' assessments (ADm

Results

Analyses supported the well established cross-sectional correlations between self-efficacy beliefs and characteristics of mathematics instruction (e.g. cognitively challenging tasks $r=.17$, cognitive autonomy $r=.18$, individual support $r=.38$, all p 's

Theoretical and Educational Implications

This paper investigated the role of teachers' self-efficacy beliefs to support high quality teaching behaviours. Using a longitudinal design, the – often implicitly assumed – effect of self-efficacy on instruction was challenged. Instead, it could be demonstrated that earlier teaching "successes" – i.e., teaching in a way that students find cognitively stimulating – had a positive impact on later teachers' self-efficacy beliefs. In addition, our findings show that self-efficacy beliefs change and develop, even for highly experienced teachers. This finding underlines the reciprocity and high interdependency of classroom activities (Caprara et al., 2006). In-class conditions seem to influence motivational orientations of teachers. Future research attempts will need to further clarify whether there are contextual circumstances under which motivational orientations may be reflected in teachers' instructional behaviours.

Social utility and social desirability of self-presentation strategies. An exploratory study.

Maria Cristina Matteucci, University of Bologna, Italy

The main purpose of this study was to identify the use of self-presentation strategies on undergraduate students and to explore the underlying dimensions of self-presentation tactics in terms of social utility (or competence) vs. social desirability (or sociability). These two main dimensions have been recognized by the literature on social judgment as fundamental for the production of assessments. Recently several studies have shown the predominant role of morality as a distinct dimension used by individuals to achieve positive evaluations. In order to investigate relations between morality, competence and sociability norms, fifty undergraduate students were asked to complete a questionnaire with different self-presentation strategies, namely, to appear as likable versus as likely to succeed to their teachers. They were asked to indicate to what extent they considered important each trait included in the questionnaire in order to achieve the desired outcome. The same questionnaire was completed three times: the first with standard instructions, the second with social utility instructions, the third with social desirability instructions. Factorial analyses suggest the presence of two main dimensions that underlie self-presentation tactics. Findings confirm that students are able to make desired impression on others with appropriate responses based on the particular purpose suggested by the instructions. Theoretical and educational significance of the research are discussed.

Aims.

In educational settings the use of self-presentation strategies in order to influence opinions and judgments of others, especially teachers, has been widely demonstrated (Matteucci, 2004). In order to use the right strategy to influence the judgments of others and obtain a positive evaluation, people have to know what features are relevant to the audience (Baumeister & Jones, 1978). The literature on social judgments has been working for two decades on the dimensions that organize the production of assessments by individuals (for a review: Judd, James-Hawkins, Yzerbyt, Kashima, 2005). In summary, what emerges from the literature is that not all features have the same kind of value and

two main dimensions have been recognized: the social utility and social desirability (Beauvois, 2003; Dubois, Beauvois, 2005). The social desirability refers to what makes people pleasant or unpleasant, socially attractive, and includes features such as pleasant, friendly, sociable and helpful. The social utility refers to the individual's ability to meet the requirements of a particular social context or organization, then the chance of success within that group or organization. Some authors have defined the social utility as "competence" (Wojciszke, 2005), and usually it includes traits such as "competent", "intelligent", "smart" and features such as internality (Beauvois, 2003). Recently, several research lines have shown the predominant role of morality as a distinct dimension and characteristic that people use to evaluate their ingroup positively (Leach, Barreto, Ellemers, 2007) and in forming global impression of others (Wojciszke, 2005). Given the centrality of these dimensions in social judgment and, consequently, in educational context, it seemed important to begin to understand the relation among the three dimensions.

This paper describes an explorative study realized within a research programme aimed at identifying the use of self-presentation strategies in educational settings. The main purpose is to investigate whether students are able to enhance their self-descriptions by using different traits for different purpose and to explore the underlying dimensions of their self-presentation tactics.

Method

Participants, procedure and materials. Fifty undergraduate students (F: 80%, mean age: 25.1, SD: 7.1) attending an Italian University volunteered for this experiment. The self-presentation paradigm (Darnon, et al. 2009) was used. They were asked to respond to the same questionnaire three times using three different instructions. The first asking them to assess the subjective importance ("standard" condition) of 30 traits, on a 7-point Likert scale (1 "not at all important" to 7 "very important"), then they were asked to evaluate the 'importance of these traits to be judged by their teachers as students who are successful ("social utility" condition) and, finally, students were asked to rate the importance of the same traits to be judged by their teachers as someone appreciated by others ("social desirability" condition).

Findings

First, a factor analysis on the traits items was conducted. Principal components factoring with oblique rotation (Oblimin) was used. The analysis revealed two factors accounting for 45.17% of the variance. The first factor accounted for 27.1% of the variance and contained desirability traits such as: good, honest, benevolent, sincere. The second factor included the utility items: skilled, valuable ambitious, and competent. It accounted for 18% of the variance. The correlation between the two factors was not significant.

A Friedman's non-parametric test was conducted to determine whether participants had a differential rank ordered preference for the items according to the three instructions (independent variable). Results confirm a statistically significant difference in mean ranks across instruction conditions with $p < .05$. In this case, the multiple comparisons indicate (at the 0.05 significance level) that several traits obtain higher values than at least one of the other instructions (see Figure 1).

Theoretical and educational significance of the research

This explorative study led to encouraging results confirming that students are able to use different self-presentation strategies for different purposes. Results suggest also the bi-dimensional structure of the social judgment. The present findings might well apply to the educational contexts, where self-presentational motives can be translated into behavioural tactics. Thus, the ability to adjust one's self-presentational tactic when interacting with different audiences and with different purposes is a social skill pertaining to the self-monitoring capacity. In order to achieve specified social goals (e.g. get included in a peer study group) or to influence evaluative judgments, the results of the present study emphasize the powerful importance of the underlying dimensions of traits. Social utility and social desirability seem to include also morality traits. Further studies are planned in order to deeper investigate the issue.

Self-Efficacy, Prior Knowledge, and Confidence in Prior Knowledge on Conceptual Change Learning

Jacqueline Cordova, University of Nevada, Las Vegas, United States; Gale Sinatra, University of Nevada, Las Vegas, United States

This study explored how combinations of self-efficacy, prior knowledge and confidence in knowledge interacted with time during conceptual change learning. One hundred and sixteen college students rated their self-efficacy and confidence in their knowledge about seasonal change prior to reading a refutational text. Students also completed a test of their knowledge of seasonal change at pre, post, and delayed posttest. Students were divided into three profiles based on similar self-efficacy, prior knowledge, and confidence in prior knowledge at pretest using k-means cluster analysis. The profiles included 1) moderate self-efficacy, low knowledge, low confidence, 2) high self-efficacy, moderate knowledge, moderate confidence, and 3) high self-efficacy, high knowledge, high confidence. The combination of high self-efficacy, moderate knowledge, and moderate confidence was most productive for conceptual change. This group exhibited the greatest reduction in misconception as well as a significant increase in conceptual understanding from pre to post and these gains were maintained at posttest. The combination of high self-efficacy, high knowledge, and high confidence was least productive for conceptual change. Those high on self-efficacy, knowledge, and confidence demonstrated the lowest reduction in misconceptions and no increase in science ideas over time. Results indicate that learner characteristics most productive for conceptual change learning may differ from those most productive in traditional learning situations.

Pintrich, Marx and Boyle (1993) hypothesized that self-efficacy beliefs may facilitate conceptual change through fostering confidence in one's ability to gain understanding and change one's ideas. Conversely, self-efficacy beliefs may hinder conceptual change through fostering confidence in one's own conceptions to the point of reluctance to accept alternative ideas. Limited research has been conducted investigating the combined role self-efficacy, prior knowledge, and confidence in prior knowledge may play in conceptual change. Therefore, the purpose of this study was to explore how varying combinations of self-efficacy, prior knowledge and confidence in prior knowledge would influence conceptual change science learning through refutational text.

Two research questions guided this study including: 1) What basic profiles of students exist based on their topic specific self-efficacy, prior knowledge, and confidence in prior knowledge? and 2) Do these emergent profiles explain differences in conceptual change?

Methods

Participants

One hundred and sixteen students from a large southwestern U.S. university participated in the study. Participants ranged from 18 to 52 years of age ($M = 25.39$, $SD = 7.93$); most were female (72.4%), white (69.8%), and juniors (50.9%).

Procedures and Materials

Participants first completed a demographics survey, followed by a series of researcher-developed questionnaires measuring their 1) self-efficacy for learning about seasonal change, 2) current knowledge about seasonal change, and 3) confidence in that knowledge.

Participants then read a five paragraph refutational text presenting the scientific conception of why the seasons change which had been shown to promote conceptual change in college student participants in prior research (Broughton, Sinatra, & Reynolds, 2010). Afterwards and at a two week follow-up session, students were asked to again complete the Seasons Concept Inventory, which was scored for both misconceptions and scientific understanding.

Results

In regards to our first research question, students were divided into groups based on similar learner characteristics using k-means cluster analysis. Three theoretically sound profiles were revealed using self-efficacy, prior knowledge, and confidence in prior knowledge at pretest. The three group profiles were 1) moderate self-efficacy, low knowledge, low confidence (moderate/low/low) ($n=38$), 2) high self-efficacy, moderate knowledge, moderate confidence (high/moderate/moderate) ($n=44$), and 3) high self-efficacy, high knowledge, and high confidence (high/high/high) ($n=34$).

In regards to the second question, two mixed model 3 x 3 factorial ANOVAs with group profile serving as the between-subjects factor and time (pre, post, delayed post) serving as the within-subjects factor were conducted on two aspects of students' conceptual change (number of scientific ideas and number of misconceptions).

The results of the first ANOVA indicated that the interaction between profile and time on the number of scientific ideas was statistically significant, $F(4, 226) = 8.88$, $p = .136$. Follow-up ANOVAs indicated that the high/moderate/moderate group exhibited a significant increase in conceptual understanding from pre to post with no significant reduction in science ideas at follow-up, $F(2, 86) = 40.66$, $p = .486$. The moderate/low/low group also demonstrated a significant increase in conceptual knowledge at both post and delayed posttest; though there was a significant reduction in the number of science ideas from post to delayed posttest, $F(2, 74) = 41.69$, $p = .530$. The high/high/high group, however, showed no significant increase in science ideas over time, $F(2, 66) = 1.53$, $p > .05$, $\eta^2 = .044$. Means and standard deviations are presented in Table 1.

The results of the second ANOVA indicated that the interaction between profile and time on the number of misconceptions was not statistically significant, $F(4, 226) = 1.65$, $p > .05$, $\eta^2 = .028$. Therefore, main effects were examined.

There was a statistically significant difference by time, $F(1, 113) = 14.52$, $p = .114$. Although all three groups did demonstrate a significant reduction in misconceptions from pretest to posttest as well as from pretest to delayed posttest indicating that they did experience enduring conceptual change, all three groups showed a significant return of misconceptions from posttest to delayed posttest. There was also a statistically significant difference by group, $F(1, 113) = 35.49$, $p = .386$. The moderate/low/low group and the high/moderate/moderate group showed the greatest reduction in misconceptions with no significant difference between them. The high/high/high group showed the lowest reduction in misconceptions. Means and standard deviations are reported in Table 1.

Discussion

The combination of high self-efficacy, moderate knowledge, and moderate confidence was most productive for conceptual change. The high self-efficacy, high knowledge, and high confidence combination was least productive for conceptual change. It is important to note that whereas this group started out high in prior knowledge, they were not at ceiling. This group's mean for scientific ideas was 9.26 out of 34. Though research generally indicates that moderate to high self-efficacy, high prior knowledge and high confidence in that knowledge may typically be positive for learning, it appears that this may not be the case with conceptual change learning. Our results indicate that learner characteristics most productive for conceptual change learning may differ from those traditionally viewed as most productive in learning situations. In conceptual change, learners who are too confident in their prior knowledge may be reluctant to change that knowledge. These results show that there is still much to learn about the optimal combination of individual difference characteristics for promoting conceptual change (see Sinatra & Mason, 2008). These differences between traditional learning and conceptual change based learning may further demonstrate the need for conceptual change based instructional practices in content areas where misconceptions abound over more traditional instructional practices.

A Qualitative View On Students' Acceptance & Subjective Perceived Learning Success

Petra Herzmann, Universität zu Köln, Germany; Michael Stralla, University of Cologne, Germany

The efficient use of learning strategies is crucial for learning success. However, there is little analysis as to whether these competencies can be taught effectively in the classroom. The aim of the reported pilot study was to clarify, whether specific trained teachers indirectly stimulate the build of coherent mental representations of their 5th grade secondary school students. Therefore we compared four geography classes. The project consists of two stages: the enhancement of teachers' knowledge about techniques of coherence formation in school (stage 1) and the enhancement and support of students' strategies for learning with texts, with pictures, with text-picture-combinations and for metacognitive regulation of these strategies in regular school lessons (stage 2).

The scientific monitoring of our project based on a self-developed classroom test as well as items for strategies for text comprehension, picture comprehension, mapping between text and pictures and metacognition before and after the training. Additionally, we emphasize the context the strategy training was implemented by using qualitative measures. Therefore we investigate the students' experiences with the project to reconstruct their perspective on the implemented strategy training. Through a Qualitative Content Analysis of classroom discussions, five substantial categories could be developed inductively, describing aspects of context encouraging and supporting students' interest and persistence in the strategy training.

Referring to the results of the previous project we conduct a following project at present. To extend the results described above the poster will show first results of the qualitative measures, particularly with regard to the classroom discussions.

The efficient use of learning strategies is crucial for learning success. However, there is little analysis as to whether these competencies can be taught effectively in the classroom. The aim of the reported pilot study was to clarify, whether specific trained teachers indirectly stimulate the build of coherent mental representations of their 5th grade secondary school students. Therefore we compared four geography classes. The scientific monitoring was an integral part of this project which consists of two stages: the enhancement of teachers' knowledge about techniques of coherence formation in school (stage 1) and the enhancement and support of students' strategies for learning with texts, with pictures, with text-picture-combinations and for metacognitive regulation of these strategies in regular school lessons (stage 2). These strategies and skills can be called strategies for coherence formation because they enable learners to construct one coherent mental representation based on multiple external representations (Seufert, 2003). Following the three-layered model of self-regulated-learning by Boekaerts (1999) the taught cognitive strategies and metacognitive skills were didactically supported by a motivational framing. The motivational framing was based on the program 'Text Detectives' (see Gold, Mokhesgerami, Rýhl, Schreblowski & Souvignier, 2004).

In line with a direct strategy training approach the participating teachers taught the strategies mentioned above explicitly. Lessons of two training classes and two control classes were parallel concerning the topics, materials (despite the training) and the test. After the direct instruction the students received cards where the four strategies were described stepwise. These cards were implemented in lessons and homework whenever students had to deal with learning material that includes texts, pictures, tables or formula. Overall, the training program lasted six weeks.

Researchers on the topic of learning strategies and self-regulated learning typically ask quantitative research questions (such as "how much?" or "how often?") and tended to measure strategy knowledge and use with self-report surveys. The scientific monitoring of our project was also based on questionnaires the students had to fill in. For example a self-developed classroom test to analyse the learning performance before and after the training. The ANCOVA with verbal abilities as a covariate revealed significantly higher learning outcomes for the training group. A repeated measure analysis showed improvement of the training group concerning the text, picture and mapping strategies.

Additionally, we emphasized the context the strategy training was implemented by using qualitative measures. Therefore we investigated the students' experiences with the project. What changes did the students perceive? What were their experiences during the training? Did they accept the program? How did the strategies affect their learning process? To answer these research questions we conducted classroom discussions to reconstruct the students' perspective on the implemented strategy training. The written transcripts of classroom discussions were analysed by using techniques of Qualitative Content Analysis (Mayring, 2008).

Through analysis five substantial categories could be developed inductively, describing aspects of context encouraging and supporting students' interest and persistence in the training. The first category may be designated 'level of preparatory training in using learning strategies'. The prior knowledge and usage of learning strategies for encoding texts, pictures, graphics and formulas has a strong influence on the acceptance of training components. If the level is high, the willingness to deal with new strategies and to discard one's own strategy inventory to finally rebuild it considering the new strategies is low.

A second essential category is associated with the first. For learners it is essential to derive benefit from the usage of new learning strategies. For example to execute the reading strategy – altogether five steps – requires additional time and mental effort. The students are willing to invest, but have to see added value of their endeavours. Furthermore the interviewed students underlined the need for challenging tasks to practise the new learning strategies. The students raise a topic, which seems to be particularly important. The students reported back that challenging tasks enhance their willingness to deal with the new learning strategies. Another essential aspect to increase students'

persistence is the amount of incentives to use learning strategies. The students have articulated that in order to be more motivated, setting is very important. In their opinion, the variety of methods function as incentive. Working in groups, one of the new learning methods, enrich and enliven ordinary instruction which students find an especially positive aspect of the new training. The last substantial category concerns the (metacognitive) understanding of strategies. In the learners' opinion strategy training in lessons seems to be more effective, if the teacher ensures a broad (metacognitive) understanding of the taught strategies.

Referring to the results of the previous project we conduct a following project at present. The aim of the following project is to qualify teachers how to diagnose and to foster the use of learning strategies of their students. From each of the 40 participating schools in three regions of Germany between 6 and 10 teachers will be part of the program. We include teachers who teach Math, German and natural science Classes to ensure the transfer of the taught strategies and skills.

The expected increase of competences will be measured by using quantitative measures concerning the outcomes of the learning process (school grades, self-developed tests) as well as by using qualitative measures. The qualitative measures focus on the implementation of training-contents in lessons and the process of school development. Therefore, interviews with the participating teachers and the students will be conducted. At the school level we will carry out expert interviews with the headmasters and coordinators from 4 schools as well as in-depth interviews with 20 participating teachers to investigate their experiences with the project, particularly their attitude about the collaboration of the staff and their realization of training components in lessons. To deepen the analyses at classroom level additional observations will be conducted by videotaping selected classrooms in phases of direct training. To extend the results described above the poster will show first results of the qualitative measures, particularly with regard to the classroom discussions.

Development and evaluation of an observation instrument to assess 4th grade students' self-regulated

Manuela Leidinger, Saarland University, Germany; Franziska Perels, Saarland University, Germany

The aim of the study was to develop and evaluate an observation instrument to assess 4th students' self-regulated learning in regular classes. Within the theoretical background of the study self-regulated learning is defined as a cyclical process that "...refers to self-generated thoughts, feelings, and actions, that are planned and systematically adapted as needed to affect one's learning and motivation" (Schunk & Ertmer, 2000, p. 631). It is an important factor for effective (school-based) learning and academic achievement because learners are active, constructive participants in the learning process (e.g. Pintrich, 2000; Zimmerman & Bandura, 1994). To assess learner's self-regulation often self-report measures are used. The difficulty, which comes with using self-report data, is that there are only few correlations between self-regulation and other types of assessment (e.g. Winne & Perry, 2000). Observational research has the advantage to provide information on learner's self-regulatory competencies from a more objective perspective. In this context Perry et al. (2002) point out that one advantage of observation measures over self-report measures is that they reflect what people actually do versus what they say to do. In the present study an observation instrument was developed and evaluated to assess students' self-regulated learning. Altogether, the learning behaviour of 124 students was coded regarding the use of strategies of self-regulated learning. The instrument served to produce reliable and valid scores.

The aim of the study was to develop and evaluate an observation instrument to assess 4th grade students' self-regulated learning in regular classes. Within the theoretical background of the study self-regulated learning is defined as a cyclical process that "...refers to self-generated thoughts, feelings, and actions, that are planned and systematically adapted as needed to affect one's learning and motivation" (Schunk & Ertmer, 2000, p. 631). It is an important factor for effective (school-based) learning and academic achievement because learners are active, constructive agents in the learning process (e.g. Pintrich, 2000; Zimmerman & Bandura, 1994). In our study we refer to

the self-regulation model of Zimmerman (2000) that describes self-regulation as a cyclical process with three learning phases: the forethought or planning phase, the performance or volitional control phase and the self-reflection phase. Between the self-reflection phase and planning there are feedback loops. So feedback from prior performance influences current performances. The forethought phase focuses on self-motivation beliefs and task analysis, which includes goal setting and strategic planning. These components lead to emotional and motivational conditions, which affect the planning of the given task. During the performance phase the self-regulation strategies include the use of self-control and self-observation (self-monitoring) strategies. In sense of self-regulated learning dealing with a task people monitor their own behavior. Therefore, self-monitoring is described as the systematic observation and documentation of thoughts, feelings and actions regarding goal attainment. It is a basis of self-regulated learning (Bandura, 1986; Zimmerman, 2000). After having completed the task, the self-reflection phase begins, which is characterized by self-judgment and self-reaction, including the comparison of one's behaviour with goals (Bandura, 1986). The learners evaluates the results and attribute their behavior regarding their effort and draws conclusions for further learning behaviour.

To assess learner's self-regulation often self-report measures are used (Spßrer & Brunstein, 2006). The difficulty, which comes with using self-report data, is that there are only few correlations between self-regulation and other types of assessment (Winne & Perry, 2000). Observational methods have the advantage to provide information on learner's self-regulatory competencies from a more objective perspective. In this context Perry et al. (2002) point out that one advantage of observation measures over self-report measures is that they reflect what people actually do versus what they say to do.

In the present study an observation instrument was developed and validated to assess students' self-regulation in regular classes at primary school. In 21 math classes four or six students were videotaped and subsequently coded regarding the use of strategies of self-regulated learning. 18 of these 21 math classrooms took place in grade 4, six of them in grade 3. As the focus was on the learning behaviour of each singular student, the videotaped classroom lessons had to be analysed four or six times according to the number of students, which were videotaped. As mentioned before, the coding system is based on the model of self-regulation by Zimmerman (2000), which groups self-regulation strategies into three areas according to the cyclical phases of self-regulation. Some of these strategies weren't observable, so they became excluded. For example it wasn't possible to observe, if students set realistic and ambitious goals. So for the forethought phase planning (e.g. "The student organises his/her desk space") and self-motivation strategies (e.g. "The student encourage him-/herself") were assessed, for the performance phase volitional (e.g. "The student works constantly") as well as self-monitoring strategies (e.g. "While learning the student controls his/her approach with regard to the given task") and for the self-reflection phase strategies of self-evaluation (e.g. "The student controls his/her results"). The final version of the rating scale contains 22 items altogether. The coding captures whether a certain strategy takes place or not.

Before the analysis of the collected observation data, two observers went through an observer training by using the videotaped classroom lessons, which were not included in the analysis of this study. In the beginning of the training, observers were trained in differentiating between the categories of the observation instrument, based on the theoretical model of self-regulation, as mentioned above. After two collaboratively coded video-tapes (six observed students), observers started coding separately. The results were discussed together afterwards. The observer training took place until interrater agreement reached 80% or more.

Most of the participating schools were located in a rural landscape in south-western Germany. The participation was voluntary. Altogether, 21 classroom lessons took part in the observation study, whereupon three lessons were used for observer training. Finally the learning behaviour of 124 students (Mean age = 10 years, SD = 0.621; 47.1 % male, 52.9 % female) was coded by capturing which strategies per minute were available. Each time sample took one minute, producing 45 segments for one lesson. But because the observations could have been different in length, a standardized average frequency related to the total length of each lesson was generated (rates per minute).

To validate the instrument the reliabilities of the ratings for the coding system were appraised by computing Cohen's (1960) Kappa coefficient. This measurement method is for nominal data and is most frequently used to assess the reliability of the data of observation studies. Students' self-regulation strategy use during each one minute segment was coded. Interrater reliability based on the coding of 124 videotaped students ranged between 0.43 ("The student gets distracted from learning for a short time (In order to estimate content validity, the observation instrument was shown to experts of self-regulated learning (teachers, researchers, educational psychologists...). The experts estimated the representativeness and relevance of the generated items and categories in real-life classrooms. The results of the evaluation will be discussed at the conference.

Regulation of Learning in the Context of Collaborative Challenges

Lindsay McCardle, University of Victoria, Canada; Stephanie Helm, University of Victoria, Canada; Allyson Hadwin, University of Victoria, Canada; Kara Shaw, University of Victoria, Canada; Peter Wild, University of Victoria, Canada

The purpose of this study was to (a) explore strategies individuals identify for themselves (I strategies) and for their team (WE strategies) to address challenges encountered in 3 collaborative tasks, and (b) examine regulatory shifts in the challenges students encountered across tasks. Data included: (a) self-reported challenges, (b) I strategies, and (c) WE strategies proposed for addressing these challenges in future. The most prominent collaborative challenges reported included teamwork and collaboration. The predominant strategies students proposed to address both types of challenges were related to improving communication. Students evidenced changes over time in the challenges they reported suggesting they successfully regulated learning. We posit that if students are successfully regulating themselves (SRL) and their team (SSRL), by choosing and applying specific strategies to address challenges, those challenges should change over consecutive collaborative tasks.

Success in collaboration depends on: (a) strategies and self-regulatory skills individuals contribute to the group, (b) support members provide to one another that facilitates individuals' self-regulatory competence (co-regulation), and (c) shared or collective regulation of learning involving metacommunicative awareness and successful coordination of strategies (Barron, 2003). Winne and Hadwin's (1998) model describes SRL as comprising four weakly sequenced recursive phases including: (a) task definition, (b) goal setting and planning, (c) strategy enactment, and (d) evaluation/adaptation. Similarly, successful collaboration among group members is assumed to occur when individuals collectively regulate their learning across these four phases (Hadwin, Jarvela, & Miller, in press). From this perspective, strategies are repertoires of tactics applied selectively for specific tasks and task conditions (McKeachie, 1988). Students are strategic when they: (a) deliberate about the appropriateness of alternative study methods for this task and task purpose, (b) base judgments on sound strategy knowledge about how tactics work, why they work, and when they are useful, (c) draw on self-knowledge about past task and strategy experiences, and, (d) make conscious choices between alternative study methods (Hadwin & Winne, 1996).

Episodes of challenge or difficulty provide salient contexts for studying regulation in action. Challenges create need for engaging regulatory processes including monitoring and evaluating challenge sources, and deliberating about strategies to address that challenge. When learners confront challenge they are required to change strategies or beliefs (Hadwin et al., in press). Complex tasks that present challenges are a rich context for empirically investigating regulatory processes and strategies (Hadwin et al., in press). However strategies become more complex in collaborative tasks. Strategies might focus specifically on what "I" can do to address the challenge my team encountered (SRL strategies), or they may focus on what "we" can do to address that same challenge (shared regulation strategies; Jarvenoja & Jarvela, 2009).

Research Purpose

The purpose of this study was to (a) explore strategies individuals identify for themselves (I strategies) and for their team (WE strategies) to address challenges encountered in 3 collaborative tasks, and (b) examine regulatory shifts in the challenges students encountered across tasks. We posit successfully regulating individually (SRL) and collectively (SSRL) by choosing and applying specific strategies to address challenges should reduce the likelihood of experiencing the same challenge on a subsequent task.

Methods

Forty-two upper year students participated in research. Students were enrolled in an Environmental Science (N = 24), or a Mechanical Engineering (N = 18; unspecified, N = 6) course at the University of Victoria. Students worked in interdisciplinary collaborative teams to complete two assignments during class time and one major assignment outside class time. After each assignment, students individually completed a structured reflection on their collaborative process.

Data included: (a) individuals' perception of the main challenge their team encountered (Jarvenoja & Jarvela, 2009); (b) individuals' self-generated list of two things they would like to do to address this collaborative challenge in future tasks (I strategies); and (c) individuals' self-generated list of two things they would like their team to do to address this collaborative challenge in future tasks (WE-strategies). Challenges grouped into four broad categories: (a) personal priorities, (b) work-communication, (c) teamwork, and (d) collaboration. Answers to open-ended questions were coded using an inductive coding scheme guided by Winne and Hadwin's (1998) model of SRL. Students' strategies for addressing challenges fell into one of seven categories: (a) communication, (b) regulation, (c) group processes, (d) task processes, (e) motivation, (f) no change, and (g) other. Multiple codes were applied if more than one idea was present in a student's statement.

Results and Discussion

Conditional probability matrices were used to examine patterns of I strategies and WE strategies proposed for each type of challenge. Findings regarding I strategies indicated that for personal priority, students most often suggested they needed to adapt communication (43%). For work-communication challenges, students most often suggested they needed to adapt communication (56%). For teamwork challenges, students suggested using communication (33%), group process (27%) and regulation (26%) adaptations. For collaboration challenges, students also suggested using communication (37%), group process (22%) and regulation (22%) adaptations.

In terms of how their team could adapt (WE strategies) to address personal priority challenges, predominant suggestions were communication (41%), group process (24%) and regulation adaptations (20%). For work-communication challenges, students predominantly suggested communication adaptations (40%) and group process adaptations (26%). Teamwork challenges elicited suggestions to adapt communication (37%), regulation (23%) and group processes (20%). Finally, for collaboration challenges, students suggested communication (34%) and regulation (31%) adaptations.

One indicator of regulating learning would be if students differentiated strategy recommendations according to specific challenges they experienced. Preliminary findings suggest that this occurred to a limited extent. Students did propose different kinds of strategies for each type of challenge. For example, students suggested regulation adaptations as a WE strategy more often for dealing with collaboration challenges than other types of challenges. However, students most often suggested improved communication as both an I strategy and a WE strategy, regardless of the type of challenge encountered. This could indicate lack of regulation or emphasize the role of communication in collaborative tasks. A conditional probability matrix was also used to examine patterns in challenges faced across time. From the first to second in-class assignment, students the majority of students identified new challenges (65%). From the first in-class assignment to the major collaborative assignment, the majority of students again identified new challenges (81%). While further research is warranted this may suggest that the I strategies and WE strategies students chose helped them to successfully regulate those challenges in a subsequent task.

Findings inform theory on collaboration by investigating both SRL and SSRL strategies for adapting in response to collaborative challenges. They also offer potential guidance in scaffolding and supporting collaboration in interdisciplinary tasks.

ROUND TABLE

Constraints of institutional and social trust among students

Hermann J. Abs, University of Giessen, Germany; Bryony Hoskins, University of London, United Kingdom; Germ Janmaat, University of London, United Kingdom

Background: Current social research shows the importance of trust for the functionality of societies (Bryk et al. 2002; Putnam 2000). Moreover research hints to the transient character of trust, which is likely to decrease during adolescence and constrained by many social factors (e.g. Rahn et al. 1998; Welch et al. 2005; Flanagan et al. 2010). In this paper we distinguish between institutional and social trust. The social dimension relates to fellow human beings while the institutional dimension relates to subsystems of the society. **Purpose:** The research question for the study is in how far the social constellation within the class, individual group memberships and students' interpretations of equality within school and society constrain attitudes towards trust. **Sample:** Data has been collected in schools in Denmark, England, France and Germany during the first half of 2010. More than 2000 students of the age of 14 (grade 8), 17 (grade 11) constitute the sample used. Sampling acknowledged the fact of diverse school systems within countries, so that comparison between different academic profiles is possible. **Design and Method:** The analysis proceeds as comparative analysis for the four countries using descriptive statistics and structural equation modelling with an adjustment for the nestedness of the data. **Results:** Research will compare between country and within country (school or school type related) differences with respect to levels of trust. Starting from this, different models for the prediction of trust are tested. Hypotheses on the predictive value of the proportion of students with a unfold and a multifold sense of belonging to various groups within class are analysed in different school systems and socioeconomic school contexts.

Background:

Current social research shows the importance of trust for the functionality of societies (Bryk et al. 2002; Putnam 2000). Trust is seen as one component of social cohesion (Green et al. 2009). Moreover research hints to the transient character of trust, which is likely to decrease during adolescence and constrained by many social factors (e.g. Rahn et al. 1998; Welch et al. 2005; Flanagan et al. 2007 & 2010). In this paper we distinguish between institutional and social trust. The social dimension relates to fellow human beings of the same or other groups while the institutional dimension relates to subsystems of the society like parliament, police, banks and schools.

Purpose:

The research question for the study is in how far the social constellation within school systems and the classes, (multiple) individual group-memberships and the interpretation of inequality within school and society constrain attitudes towards trust. A special interest consists in the analysis of conditions which allow for the development of belief in a just world as a coping mechanism for perceived inequalities (Furnham 2003), so that people can develop trust even under conditions of unequal distributions of goods and even unequal acknowledgement for performance.

Sample:

Data has been collected in schools in Denmark, England, France and Germany during the first half of 2010. More than 2000 students of the age of 14 (grade 8), 17 (grade 11) constitute the sample used. Sampling acknowledged the fact of diverse school systems within countries, so that comparison between different academic profiles is possible.

Design and Method:

The analysis proceeds as comparative analysis for the four countries using a range of methods from descriptive statistics up to structural equation modelling with an adjustment for the nestedness of the data. **Results:** Research will compare between country and within country (school or school type related) differences with respect to levels of trust. Starting from this, different models for the prediction of trust are tested. Hypotheses on the predictive value of the proportion of students with a unfold and a multifold sense of belonging to various groups within class are analysed in different school systems and socioeconomic school contexts. Moreover students' perception of inequalities in school (assignment of grades) and society (distribution of goods) and the interpretation of these perceptions in terms of being fair or unfair are taken into account. The study is going to test the whole path from Perceptions (equal-unequal) over interpretations (just-unjust) towards attitudes (trust-no trust) and wants to show in how far belief in a just world can be looked on as a coping resource that allows people to develop trust even in contexts of high inequality.

Psychological Correlates of Individuals' Perception of Society and Right-Wing Authoritarianism

Lori Olafson, University of Nevada Las Vegas, United States; Gregory Schraw, University of Nevada, United States; Catherine Ortner, Thompson Rivers University, Canada; Raelynn Lee, University of Nevada, Las Vegas, United States; Jennifer Palma, Thompson Rivers University, Canada

In order to explore the psychological correlates of perceptions of society and right-wing authoritarianism, we conducted a mixed methods study involving 104 undergraduates (50 Canadian undergraduates and 54 American undergraduates). Quantitative data sources included the Belief in a Dangerous World scale, the Right-Wing Authoritarianism scale, the Epistemic Beliefs Inventory, the Mindful Attention Awareness Scale, and the Need for Cognition scale. Additionally, participants read a news article about Iran's nuclear capability and responded to an essay prompt. The purpose of the essay was to determine if undergraduates' beliefs and attitudes as measured by the quantitative instruments were also reflected in their writing about a real-world issue. Our preliminary findings are in accordance with the proposition that individuals' authoritarian views are related to their beliefs in a dangerous world and cognitive styles. Individuals high in right-wing authoritarianism tended to show a perception of the world as threatening and were more fearful than those low in right-wing authoritarianism. These beliefs were reflected in the essays. Undergraduates who endorsed more extreme right-wing views were apt to view Iran as a threat to national security. In addition, American students scored higher than Canadian students on Beliefs in a Dangerous World and Right-Wing Authoritarianism; however these results were not statistically significant owing to the small sample size. From this preliminary analysis, it appears that a conservative ideology is a function of both personal beliefs and nationality. In our round table session we will explore the educational implications of these findings.

Purpose

Today's world has been described as a "current global crisis of terrorist violence," (Pyszczynski, Rothschild, & Abdollahi, 2008, p. 318) where media reports of negative world events contribute to increasing fears of world danger, death, and the appeal of extreme political conservatism (Jost et al., 2003). In addition, our information age—characterized by the abundance in publication, consumption, and manipulation of information, provides plenty of opportunities for the constant bombardment of negative reports. Such information is a critical determinant for effortful cognitive elaboration and processing in the political world (Rudolph & Popp, 2007) because it has the ability to motivate, rationalize and legitimize people's construction and preservation of ideological belief systems (Jost et al., 2003). Within this context, van Leeuwen and Park (2009) proposed that people adopt a conservative ideology "to fulfill psychological needs related to managing uncertainty and threat" (p. 170). The purpose of the current study was to explore the relationship between people's perception of how dangerous society is and authoritarianism, while examining if the amount of attention/awareness to the present time and their preference for complex cognition plays a role in these relationships. We examined the relationship among beliefs, especially negative beliefs about danger versus positive beliefs about cognition and agency. We also examined the relationship between country of residence and beliefs. The study was guided by the following research questions: 1) To what extent do participants express an extreme conservative ideology? 2) Do more sophisticated epistemological beliefs and need for cognition mediate beliefs about social dangers and support of extreme authoritarian ideologies? 3) How is political ideology invoked when participants are asked to consider a real-life dilemma?

Methodology

Participants Sample 1. The first sample of Canadian undergraduates (9 males, 41 females; average age 20.76 years) was gathered in October 2009 at a small university in the southwest region of Canada. Sample 2. The second sample of American undergraduates (9 males, 45 females; average age 24.05 years) was collected in February 2010 at a large university in the southwestern United States.

Measures In addition to collecting basic demographic information, data was collected from the following sources: Belief in a Dangerous World Scale (BDW; Altemeyer, 1988) - a 12 item scale that assesses individual differences in perceptions of a dangerous world. Right-Wing Authoritarianism Scale (RWA; Altemeyer, 2006) - a 20 item scale that measures attitudes about authoritarian submission, authoritarian aggression, and conventionalism. Epistemic Beliefs Inventory (EBI) - a 28 item scale that examines adults' beliefs about the nature and acquisition of knowledge (Schraw, Bendixen, & Dunkle, 2002). Mindful Attention Awareness Scale (MAAS) - a 15 item scale that measures the presence or absence of attention to and awareness of what is occurring in the present (Brown & Ryan, 2003). Need for Cognition Scale (Cacioppo, Petty, Feinstein, & Jarvis, 1996) - an 18 item scale measuring a person's preference for complex cognition. Structured Essay Task developed for this study. Participants read a newspaper article about Iran's nuclear capability, and then responded to an essay prompt. Participants in both samples received identical research packets and completed the measures in small groups with one of the researchers present.

Results

Quantitative Analysis As predicted, Beliefs in a Dangerous World and Right-Wing Authoritarianism were highly correlated ($r = .49$) and Need for Cognition and Right-Wing Authoritarianism were negatively correlated ($r = -.40$). American students scored higher than Canadian students on the BDW and RWA; however these results were not statistically significant owing to the small sample size. From this preliminary analysis, it appears that a conservative ideology is more a function of personal beliefs than nationality. In the next phase of analysis, we will divide our sample into three groups based on RWA scores (low RWA, medium RWA, and high RWA) and conduct additional analyses to determine how these groups differ on other measures. From this, we hope to gain an understanding of the kinds of thinking and beliefs that drive extreme views.

Qualitative Analysis The essays were entered into a program for qualitative analysis (ATLAS.ti) and will be scored in two phases. In phase 1, we coded the essays based on responses to two questions that were asked. When asked "Is Iran developing their nuclear program for peaceful purposes or nuclear weapons?" 55.6% of the American sample and 47.1 % of the Canadian sample indicated that they believed the nuclear program was for weapons capability. Participants also responded to the question "How should the United Nations respond?" For both groups, continued monitoring was the most frequent response (42.6% for the American sample; 39.2% for the Canadian sample). However, more American respondents (35.2%) than Canadian respondents (19.6%) indicated that increased sanctions or closing the plant should be considered by the UN. These qualitative results provide support for the view that American students are more apt to endorse the belief that the world is inherently dangerous and that perceived threats must be dealt with in a punitive way. In phase 2 of the essay analysis, we will engage in a more inductive form of analysis, following procedures for grounded theory analysis (open coding, axial coding, selective coding).

Theoretical Issues to be Discussed at the Round Table

During our round table discussion, we will revisit the research questions and provide results of the fully completed quantitative and qualitative analyses. Topics for discussion will include the following: 1) What are the psychological correlates of conservatism as a belief system (i.e. what are the cognitive and motivational needs that are met with conservatism)? 2) Why might individuals in different countries respond to world threats differently? 3) Given that resistance to change and endorsing inequality are two key aspects of conservative thought (Jost, Glaser, Kruglanski, & Sulloway, 2003), what are the classroom implications for undergraduates with extreme views? For example, RWA is positively correlated with endorsement of military aggression and suspension of civil liberties (Crowson, 2009) – how can these issues be addressed in a democratic classroom?

Students' knowledge of the national past: a shared frame of reference?

Marc Kropman, University of Amsterdam, Netherlands; Carla Van Boxtel, University of Amsterdam, Netherlands; Jannet van Drie, University of Amsterdam, Netherlands

There is an ongoing discussion in the field of history education on the topic of teaching the national past. In the Netherlands there are complaints about the presumed lack of knowledge on Dutch history, which is considered important in the context of citizenship education and social cohesion. Yet there is no clear understanding of what students do know about Dutch history, nor about the narrative structures they use, or the connections they draw to their own lives or the community they live in. Studies from other countries indicated that students of different ethnic background give a different appraisal of the significance of facts, events, developments, and persons in their respective national histories. The main question of this study is: What knowledge of the national past do students acquire during secondary education and to what extent is this knowledge shared? We have collected data from

interviews with students age 15 -16 in intermediate general secondary education. Furthermore, we have collected 177 essays from freshmen in history teacher training. Analysis focuses on events, persons, and developments that students mention, the narrative structure used, and sources of knowledge. Although we have identified what students considered important in Dutch history, we will discuss in this contribution the problematic aspects of relating these to the background of the students.

There is an ongoing discussion in the field of history education on the topic of teaching the national past. In the Netherlands there are complaints about the presumed lack of knowledge on Dutch history, which is considered important in the context of citizenship education and social cohesion. Yet there is no clear understanding of what students do know about Dutch history, nor about the narrative structures they use, or the connections they draw to their own lives or the community they live in. Studies from other countries indicated that students of different ethnic background give a different appraisal of the significance of facts, events, developments, and persons in their respective national histories (e.g., Barton & McCully, 2005; Epstein & Shiller, 2005; Levstik, 2008; Peck, 2010). In addition, Barton & Levstik (2004) showed that students from the US use the same narrative structure – a 'story of progress and emancipation'- to describe their national history. Cercadillo (2001) classifies significance into five types: contemporary, causal, pattern, symbolic and present/future. Peck (2010), building on findings of Cercadillo (2001), argues that ethnic identity structures historical significance addressed to event, persons, and developments, which leads to specific narrative templates. The main question of this study is: What knowledge of the national past do students acquire during secondary education and to what extent is this knowledge shared? Data collection included task-based interviews with 12 students age 14-15 (intermediate general secondary education) following the interview format developed by Levstik (2008). The interviews were conducted in groups of three students, and one group of six students. The students were asked to make a selection of 5 out of 25 pictures on Dutch history (1500 – 2000). Furthermore, we have collected 177 essays of freshmen in history teacher training at the University of Applied Sciences, who were asked to describe what they thought were the main themes in Dutch history since 1500 and give arguments for their choices. Analysis focuses on events, persons, and developments that students mention and how they relate these to their personal life stories, the narrative structure used, and sources of knowledge. From the analyses of the essays two main themes in Dutch history emerged: the Dutch Revolt (1566 - 1648) and the Occupation (1940-1945). Also from the task-based interview it becomes clear what persons and events are considered important, such as the murder of William of Orange, the voyages of the East Indian Company, and the deportation of the Dutch Jewish community during WO II. In analysing the essays and interviews we'll use the types of significance developed by Cercadillo (2001) and Peck (2010). A preliminary look at the interviews show that in the process of choosing pictures the students refer to their ethnic background. However, in the essays no such references are explicitly made. It is well possible that the task based interview elicit more explicit referring to their respective ethnic background than the writing task. Complementary interviews seem to be necessary to clarify the absence of explicit references to ethnic background. Although we have identified what students considered important in Dutch history, we are still in search of adequate methods that shed light on the underlying narrative structures underlying these main lines. In this contribution, we will discuss the problematic aspects of relating these findings to the background of the students.

Hong Kong tertiary students' conceptions of assessment: Reading their drawings

Zhenlin Wang, Hong Kong Institute of Education, Hong Kong; Gavin Brown, Hong Kong Institute of Education, Hong Kong

Assessment in Hong Kong is a meritocratic basis for upward social mobility and for selecting talent and has very high-stakes. Chinese learners attribute success to effort and quality teaching. However, Chinese society also attributes individual merit, worth, and value through academic performance. In a highly competitive environment in which individual worth depends on performance, it is likely that students are aware of both positive and negative aspects of the educational assessment system. Since the uses of assessment in Hong Kong are similar to western contexts and since there are aspects which differ, we expect that current models of how students conceive of assessment may be inadequate in Chinese contexts. The study aims to identify patterns in Hong Kong students' beliefs about assessment from six focus groups drawn from multiple faculties and departments in seven Hong Kong higher education institutions. Students drew a picture of assessment and discussed their drawings. Content analysis showed that students are aware of assessment's potential to improve their learning and performance, through feedback. Additionally, the student drawings showed much greater awareness of the evaluative, controlling role that assessment plays or has played in their lives. Consistent with the evaluative role, the dominant emotional response was negative. The paper will discuss aspects of students' beliefs that are unique to the Hong Kong context and culture and those that have also been reported in western contexts. This will contribute to a greater understanding of the unique and universal aspects of assessment's role on student learning and life.

Background

Students appear to be aware that assessment serves multiple purposes. For instance, they might recognize that assessment can lead to improvement, or that it might be irrelevant; they might be aware as well of some of its social and emotional effects, and see that assessment is a function of external factors. In previous studies, often students appeared to endorse most of those purposes that lead to greater academic performance. For example, they showed endorsement of the improvement purpose predicted increased student performance among New Zealand secondary students and, among university students, increased effort (Wise & Cotten, 2009) and learning strategy selection (Hirschfeld & van Brachel, 2008). These results are consistent with the notion that the "improvement purpose" of assessment involves students' regulating their response to assessment and teachers using assessment to improve teaching. Furthermore, students showed both positive (e.g., enjoyment, pride, and hope) and negative (i.e., boredom, anger, anxiety, helplessness, and shame) emotional responses to achievement experiences (Pekrun, Elliot, & Maier, 2006). Hence, we can expect that students will have multiple conceptions of assessment as a consequence of its multiple purposes and effects.

Assessment in Hong Kong plays a powerful selective role (e.g., there are spaces in tertiary education in Hong Kong for only 20% of students). At the same time, high academic performance on high-stakes examinations is seen as a meritocratic basis for upward social mobility and for selecting talent, regardless of social background (Cheung, 2008). Furthermore, Chinese learners are known to attribute success to effort and quality teaching, consistent with self-regulation theory (Li, 2002). However, Chinese society has historically attributed individual merit, worth, and value through academic performance (China Civilisation Centre, 2007), and this habit persists in Hong Kong (Pong & Chow, 2002). In a highly competitive environment in which individual worth depends on performance, it is likely that students are aware of both positive and negative aspects of the educational assessment system. Since the uses of assessment in Hong Kong are similar to western contexts and since there are aspects which differ, we expect that current models of how students conceive of assessment may be inadequate for use with students from Chinese contexts.

Aim of the study

The study aims to identify patterns in Hong Kong students' beliefs about assessment from samples of students who have successfully overcome the selective processes used to admit students into higher education.

Method

Six focus groups drawn from multiple faculties and departments in seven Hong Kong higher education institutions were asked to draw individual pictures of assessment and discuss their drawings within the group. Previous picture drawing studies have revealed student understanding of both the improvement and evaluative roles of assessment, as well as students' emotional responses to assessment.

Analysis and results

Content analysis of the discussions, drawings, and captions focused on students' understanding of the purposes and structures of assessment and their personal and emotional responses to assessment.

Preliminary results indicated that students are aware of assessment's potential to improve their learning and performance, through feedback. Although, this awareness appeared to be more prevalent among students from the

more prestigious institutions, suggesting the ability to perceive assessment as more than evaluative may be conditional upon awareness of relative status. However, the student drawings showed much more awareness of the evaluative, controlling role that assessment plays or has played in their lives. Such pictures include images of athletic contests (e.g., races and even a bull-fight), surveillance by assessors, and entrapment or oppression by the high-stakes consequences of the system. Consistent with the evaluative role, the dominant emotional response was negative.

Foreseen discussion

The pattern of results appears to be ecologically rational (Rieskamp & Reimer, 2007); that is, students perceived assessment as predominantly highly selective and highly controlling, which is classically how the public examination system for entry to university is implemented in Hong Kong. Furthermore, evidence was seen for the evaluation of an individual's worth as a consequence of assessment, a characteristic associated with even contemporary Chinese societies. With further detailed categorical analysis, the paper will be able to identify aspects of students' beliefs that are unique to the Hong Kong context and culture and those that have also been reported in western contexts. This will contribute to a greater understanding of the unique and universal aspects of assessment's role on student learning and life.

Perceptions of Wildlife Conservation among Zoo Visitors in Multicultural Societies

Chagit Tishler, Ben Gurion University of the Negev, Israel; Michael Fried, Ben Gurion University of the Negev, Israel; Orit Ben Zvi -Assaraf, Ben Gurion University of the Negev, Israel, Israel

The nature of education in zoos is that of a free choice learning environment. The present paper looks exclusively at experiences and prior knowledge and at the cultural and socio-cultural aspects of visitor learning in the specific setting of the Tisch Family Zoological Gardens in Jerusalem (TFZ). Among its main goals TFZ aims to: promote the values of nature conservation and wildlife protection among its visitors; enhance public awareness of environmental issues and encourage the love of animals. The questions of the study address the breadth and level of understanding of wildlife conservation issues and concepts, and the aspects of the zoo, as a free-choice learning environment, that most influence the different visitor populations in this regard. The TFZ provides an excellent opportunity to study possible cultural influences on how zoo's conservation messages are perceived, by Jewish, religious and nonreligious visitors and Muslim, and Christian Arab visitors. Preliminary findings show that Arab and Jewish visitors: perceive nature conservation differently; have differences in preference to animals; Different degrees of religiosity also seem to affect the ways in which the zoo messages are perceived. These results raise questions as to the factors that influence the impression an animal makes on the zoo visitor, how these are affected by the background of the visitors and what are the possible implications of these on the means to convey environmental messages in the zoo.

There are about 10,000 zoos worldwide visited by an estimated 600-700 million visitors annually. About 1000 of these zoos are federated into national, regional, or international zoo federations. They are formally obligated to promote conservation of endangered wildlife and aim to assist in inculcating positive attitudes towards wildlife, highlight the importance of maintaining biodiversity, and foster sustainable development. Because of this commitment, federated zoos are of obvious interest in examining zoos' potential for educating the public vis-à-vis conservation and

environmental issues. From the educational point of view, zoos are for the most part free-choice learning environments. To gain insight into how learning occurs in such environments, and in zoos specifically, it is necessary to take into account visitors' prior knowledge and experiences, the physical aspects of the zoo as well as cultural and socio-cultural influences. The connection between their knowledge and experience, and the ways both relate to the zoos' own educational intentions are essential for understanding ultimately whether and how zoos fulfill the educational potential described above. In the present paper, we shall present findings on visitors' experiences and prior knowledge manifest at one particular zoo, the TFZ. The research to be reported, however, is part of a broader investigation taking into account other aspects of zoo visits. Our research questions were designed to probe the state of visitors' prior knowledge, the connection between that knowledge and their zoo experience, and the ways both relate to the zoos' educational objectives. A special focus is given to the different visitor populations, as will be outlined below. With that in mind, the questions are: What conservation themes are prevalent among different populations of zoo visitors? What are the principal features of these themes?2. What messages do visitors think the zoo is trying to convey to them? How do these relate to the actual mission statements of the zoo?The study takes place at the Tisch Family Zoological Gardens in Jerusalem (TFZ), which is a member in EAZA (European Association of zoos and Aquaria). Among the explicit goals of the TFZ are the following: to develop and conduct educational activities and outreach programs for promoting values of nature conservation and wildlife protection in the general public. The zoo also encourages community participation, and conducts educational and cultural activities geared towards Jerusalem's unique and diverse population. To this end, one of its main challenges is to respond to heterogeneous visitor populations, including ultra-orthodox, orthodox and secular Jews, Christians, and Muslim Arabs. The significance of the research derives first of all from its focus on zoos as an educational conduit for conservation messages. The examination of this particular zoo, the TFZ, provides an excellent opportunity to study possible cultural influences on how a zoo's conservation messages are perceived because of its diverse visitor population (Jewish, religious and nonreligious and Arab Muslims, and Arab Christians). To the extent that the zoo is a free-choice learning environment, the study should provide, moreover, insights into the character, difficulties and potentialities of such environments. This paper is the summation only of the first stage of that more general investigation, the stage addressing the two research questions given above. For this stage, an open questionnaire was developed, "Zoo Messages Open Questionnaire." Respondents were first asked to choose three kinds of species they saw in the zoo. Afterwards, they were asked to elaborate on the message they believed the zoo wanted them to remember about the animals of their choice. Finally, they were asked to define 'nature conservation'. The results were analyzed with respect to the general population and according to the following cultural groups: Religious, semi-religious, and nonreligious Jews; Arab Muslims; and Arab Christians

Preliminary finding show:a) Zoo visitors used various expressions showing some exposure to environmental issues. They had no special preference to species conservation but were familiar with the term. The different cultural groups seem to have had the same general knowledge about nature conservation. We assumed that in light of their zoo experience these visitors would connect their general knowledge to what they found in the zoo. Our results, however, did not support this assumption ($\chi^2(1, N=276)=13.077, p<0.01$).b) How visitors received messages conveyed by the zoo seems to be dependent on the degree of their religiousness. Specifically, different degrees of religiosity in the Jewish population seem to affect how visitors receive messages conveyed by the zoo. A significant difference was observed between the messages of conservation associated from the animals exhibited in the zoo noted by the religious/semi-religious visitors and those of the secular visitors. Secular visitors included animal conservation in their messages 17% more often than did the religious/semi-religious visitors ($\chi^2(2, N=359)=11.737, p<0.01$). c) An observation was made relating the degree to which that the animals were chosen as a representative of the zoo, and whether or not the visitors associated the animal with conservation. Findings suggest differences in which exhibits and animals were most popular among the Arab and Jewish populations. For example, large predators, monkeys and elephants, which were the three most popular groups of animals among the Jewish visitors while the Arab visitors chose the large predators and did not tend to chose monkeys. Although these animals were the most popular they did not associate them with a conservation message. For example, only 5.4% of the visitors who chose monkeys associated them with conservation. Questions arising from the results are: Is the conservation message reproduced differently by Jewish and Arab visitors? What role does religious faith have in the ways of perceiving conservation concepts and ideas in zoos? Is the difference due only to a different set of formulations of the same concepts and ideas? A more general question arises as to the factors influencing the impression an animal makes on the zoo visitor and how these are affected by the background of the visitors. The kind of differences according to cultural and religiosity that we have described calls to mind the claim that zoos must speak to the community or communities in the 'language of their values'. Our study strengthens these claims and reinforces the need to investigate further the different aspects of the zoo that were intended to mediate these messages. Ultimately, our results may add to zoos' ability to develop improved means for conveying general environmental and more specific conservation messages.

Identifying and overcoming methodological challenges associated with interviewing in academia

Tine Wirenfeldt Jensen, Aarhus University, Denmark

I would like to discuss some of the challenges specific to interviewing in academia and to propose an adapted version of the concept of the elite interview (Leech, 2002, and Aberback & Rockman, 2002) as one way of articulating the challenges the interview poses for the "novice researcher" (Gunasekara, 2007) in the field. I suggest the vignette technique (Barter & Renold, 1999) as one especially useful strategy for overcoming some of these challenges in semi-structured interviews with focus on the themes provocation, power and establishing alternative frameworks for discourse. I draw on experiences with interviewing 20 Master's thesis supervisors at a Danish university about their conceptualization of the Master's thesis as a form of assessment and its meaning and role in HE.

On the basis of the interviews performed for my PhD project and prior academic interview experiences (Andersen & Jensen, 2007), I draw on the concepts of the elite interview (Leech, 2002, and Aberback & Rockman, 2002) and the active interview (Holstein & Gubrium, 1995) as well as others' experiences (Gunasekara, 2007) in order to identify some of the specific factors that should be taken into consideration when interviewing teachers and supervisors in HE. An elite interview is an interview with "people in decision-making or leadership roles" (Leech, 2002), which has implications for interviewing, as "a good many well-informed or influential people are unwilling to accept the assumptions with which the investigator starts: they insist on explaining to him how they see the situation, what the real problems are as they view the matter" (Dexter, 1969, in Leech, 2002). In this sense, Master's thesis supervisors certainly qualify as elite interview candidates. However, the academic interview situation is complicated by the position of the interviewer within the very hierarchy to which the supervisors belong.

As Gunasekara's (2007) work reveals, hierarchy and accompanying power structures are a central part of academic life: "Hierarchical structures in academia are often linked to seniority and perceived experience, at least in terms of certain norms that subsist in academe." This means that the PhD student or young researcher interviewing a supervisor assumes the position of the "novice researcher" (Gunasekara, 2007). In this context, the roles of subject/interviewer have many similarities to the supervisor/student relationship, and as a consequence, the roles of 'supervisor/student' might interfere with the roles of 'supervisors as subject'/'PhD student as interviewer'. For the novice researcher, the academic interview is therefore an elite interview in more than one respect, and the consequences of the potential overlap between the roles of participants should be considered when planning and carrying out interviews in this setting. Possible subject reactions which should be anticipated include unwillingness to be "put in the straightjacket of closed-ended questions" (Aberback & Rockman, 2002), wanting to know everything about the research project and the research questions 'behind' the interview questions, wanting to know about the hypothesis shaping the research, what the final dissertation or report will conclude (see also Gunasekara, 2007) and questions about who the supervisor of the project is.

Because interviews with supervisors are elite interviews in this double sense, the interviews need to be framed as active interviews (Holstein & Gubrium, 1995) and the active, contributing and meaning-making role of the subject needs to be emphasized. This means that semi-structured interviews shaped in a conversational manner can be a good strategy, as they give the subject a sense of freedom from "the straightjacket of closed-ended questions" referred to above.

The use of vignette technique in semi-structured interviews: provocation, power and alternative frameworks for discourse. Interviewing as a method in HE research must be conducted with an awareness of the aspect of hierarchy in academic culture. But on a very basic level, it is also important to be aware of the fact that when interviewing in HE we are by definition doing research in our own cultural backyard; more likely than not, the interviewer shares a lot of tacit knowledge with the subject. We therefore need strategies and methods to help us avoid interviews dominated by vague references and implicit understanding.

To avoid this trap, I have explored several strategies. Employing the vignette technique (Barter & Renold, 1999) in semi-structured interviews with supervisors about the Master's thesis as a form of assessment has proved most successful.

During the interviews, I offered the supervisors six alternatives to the current Master's thesis form (for example a shorter Master's thesis, acceptance of website/films/performances with no requirement to submit other written work or discontinuation of the Master's thesis altogether). Some of these were deliberately designed to provoke the supervisor and as a result to provoke critique. The norms, criteria and values revealed by such critique are of interest, as they reveal how the subject understands the Master's thesis as a form of assessment. Instead of a conventional approach to the interview based on accounts of the role and justification of the existing Master's thesis, I offered the

subjects an alternative framework which allowed them to articulate their understandings in terms of negation and critical reflection rather than simple affirmation or declaration.

The vignette technique placed the supervisors in a position of power and invited them accept and reject the alternatives I proposed and to offer their reasons for doing so. I chose this approach for several reasons: it highlights the supervisors' active role in the interview, it accommodates the elite subjects' understanding of themselves as decision-makers, it offers an alternative framework for discussing the topic that makes simple reproduction of the dominant discourse on the topic impossible, and as a result it forces the supervisors to actively reflect on and articulate the values and criteria they base their decisions on.

I would like to discuss the challenges specific to interviewing in academia and the relevance of my adaptation of the concept of elite interviews to an academic setting for preparing and conducting interviews in HE. I would also like to discuss the potential pitfalls of using this version of the vignette technique with regard to the quality of the interviews and the process of analyzing them.

Research as a Patchwork Quilt: International Collaborative Research.

Jacqueline van Swet, Fontys, Netherlands

The scope of policies within universities is becoming increasingly global and more and more networks of professionals and researchers are starting to work collaboratively. They often experience problems caused by cultural differences, power issues, differences in contexts, differences in perspectives towards research. In this round table I will tell about an international masters programme where we have tried to prepare students for such collaborative (research) projects. I will present data about alumni's experiences, based on reflective logs, informal meetings, a survey asking the alumni (105; with a response rate > 50%) and on an ongoing collaborative research project. We have found that collaborative research is a process, which takes time. It requires careful and precise communication in order that participants can create their own, new shared culture with rules that are acceptable to all. The metaphor of research as a patchwork quilt is used as a model for collaborative research and examples of that strategy will be given. In such a model it is possible to work towards both bonding, tying people with people who are more like them within in their cultural context, and bridging, tying people who are unlike them and are from another cultural context (Putnam, 2007).

In this round table I would like to explore the issue of conducting collaborative research on an international perspective, the problems that may be encountered and I will present a model for collaborative research that might be a helpful strategy. I will draw from my experiences in the Erasmus Mundus programme of which I have been a programme convener for five years (2005-2010) and the research we have done in this context. One of the aims of this programme is to build a global network of professionals working in the field of SEN and inclusive practice. Such a network has the potential to become a very powerful network where teachers, researchers and educators can collaborate and exchange their ideas (Diniz-Pereira, 2002). The expectation is that after the programme former students and staff will keep in touch and will be engaged in collaborative research and projects. However, many authors have written about the complexity and often problematic outcomes of such collaboration. Many factors are playing a role such as cultural differences, power differences between participants and parties involved, the influence of the context, intercultural and communicative competences of participants, group dynamics and the establishment of trust between partners and parties involved. Awareness and openness of those factors without any judgment is often described as helpful (Hoffman 2002). Hoffmans's theory of intercultural communication assumes that communication and behaviour cannot be explained by someone's cultural background only, but by many other factors as well, such as social class, religion, age and gender. Hoffman's so called TOPOI-model offers a reflective tool to

discuss and analyse the communication between participants systematically. Establishment of trust between participants is generally seen as conditional (Gannon, 2004). This issue of trust has been extensively discussed in literature on 'social capital', for example by Robert Putnam (2007) who is developing his theory about social networks, ethnic diversity and social trust. These theories use concepts like 'bonding' and 'bridging', which might be important concepts in the area of international collaborative research. In bonding there are ties between people who are like each other in some important way and in bridging there are ties between people who are unlike each other. Research has found that people find it easier to trust one another and to cooperate when there is less social distance between them (Putnam, 2007). Many authors stress the possible impact of cultural differences and of often implicit behaviour and values on collaboration (see f.e. Hall & Hall, 1990; Hofstede & Hofstede, 2005; Matsumoto, 2000) and it thus seems important in international collaborative research to be aware of this phenomenon. One of the often emphasized factors influencing international collaboration is the issue of power and especially the problematic effects of the inequality and dependency relationship between countries from the North and from the South (Armstrong, Armstrong, and Spandagou 2010). Stephens (2007) for example warns for the often made mistake of what he calls 'Glocalisation', which means that global solutions are being applied too easily to local problems. People involved in collaborative projects will differ in many aspects, and thus also in their intercultural competences. For example Bennett (1993) has described a developmental model of intercultural sensitivity and describes six stages where individuals move and go through different stages. Group dynamics will play a role and have to be dealt with (Judith Torney-Purta, 2006, Kant and Sprenger, 2004). It is a challenge to achieve equal roles (Avgitidou, 2009) and clarity about the level of participation of all stakeholders (Arnstein, 1969) and this takes time and demands a systematic procedure. Participants need time to get to know each other, to discuss their expectations towards the collaboration, to engage gradually in the project and feel more and more confident. During and after the Erasmus Mundus programme the staff has conducted several studies on the collaboration between students and students and staff (Van Swet e.a. 2009a, Van Swet e.a. 2009b). Reflection reports have been analysed qualitatively, action research on critical friendship has been done and a questionnaire has been sent to 105 EM alumni (response rate > 50%) in order to find out more about the opinions on and experiences with research after their study MA/Mgr SEN. The concept of trust was prominent in the reflections of the alumni, in the research on critical friends and in the questionnaire. Overall the research has indicated that communication about the differences in contexts is important and at the same time problematic, especially in the first phases of the collaboration. Tools like the TOPOI-model, where for example the T stands for Tongue (=Language) can be helpful in analyzing the important elements, such as the practical issue of differences in accents or in competence in speaking English and the English terms used in the projects. Another item that was mentioned frequently in relation to collaboration was the power issue. In this round table I would like to discuss the metaphor of international collaborative research as a patchwork quilt and how we prepared our students for this collaborative research. Like patchwork quilting collaborative research demands good preparation, taking enough time and no rushing. Both work best if one adapts to the characteristics of the rags available and allows oneself get inspired by these rags, their shapes and colours. It is important to invest in the relationships, to make the expectations of all participants explicitly and to take the time for the last phases of finishing and sharing the results. This patchwork quilt model combines bonding and bridging (Putnam, 2007) and recognizes the existence of both.

Global teaching and learning for sustainable development

Birgitta Norden, Malmö University, Sweden; Elsie Anderberg, Jönköping University, Sweden

Though, repeatedly since 1972 (Agenda 21, chapter 36) proclaims for initiating the process of global teaching and learning about sustainability issues in global-local settings, reviews of literature show a dominance of rhetoric (Anderberg, Norden & Hansson, 2009). Few implementation attempts have led to continuity in the didactic steps to developing global teaching. By capturing some of the experiences of the many stakeholders in a recent research project on the process of initiating implementation teaching and learning in global settings, Lund Calling (Norden & Anderberg, 2010), a framework for the further development of the implementation processes was recognised. To be of practical use, the process of developing global teaching for sustainable development has to be understood more carefully. This paper describes an empirical follow-up research of the implementation process, concerning how 13 teachers at an upper secondary school develop their common planning and conduct teaching for sustainable development with a global focus transdisciplinarily, during the years 2010–2011. A phenomenographic approach and semi-structured interview questions are used for analysing and describing the teacher thinking in relation to the process. The result of the participating teachers' concrete practice will be presented. The findings show among other things the importance of awareness raising dialogues among teachers, who from their various subject matter expertises were heading for a common development of education in teaching of sustainable development with a global focus. This research clearly points to a link between transdisciplinary and global teaching within the field of global learning for sustainable development (GLSD).

Towards sustainability the implementation of Global Learning for Sustainable Development (GLSD) is crucial in education (Scheunpflug and Asbrant, 2006). A better understanding of how to – from a global didactic angle – establish globally genuine dialogues (Biesta, 1994; Roth, 2006) forming nuanced conceptions of sustainable development (SD) is necessary (Scott and Gough, 2004; Tatoo, 2007; Jickling and Wals, 2008). Global teaching as well as global learning has to identify the challenges in various contexts for transdisciplinary knowledge formation (Wals, 2010). Aiming to reach established and new target groups; higher education and secondary school as well as informal learning situations demands a holistic understanding (Pierce, 1934; Bateson, 1972; Hansson, 2000). The challenges take their main point of departure in the particular global perspective (Anderberg, Norden & Hansson, 2009), and concerns ways to see the whole and the parts, on the one hand, while on the other learning how to relate the parts to one another, and to the whole (Svensson, 1986), respectively. Students in a globalized setting could also achieve intercultural qualities of learning outcomes, in terms of competencies and capabilities (Bowden, 2004; Anderberg, Haggstrom & Nordquist, 2007) needed for constructive intercultural encounters and interaction. According to Svensson and Wihlborg (2010), intercultural learning could lead to a development of 'global consciousness' and support global citizenship, capabilities and competencies. On a global level, an 'emergent holistic consciousness', through the connection of cultures to a complex collective whole, would form a collective consciousness. Because of the complex demands underlying the discourse of GLSD and related topics, a curriculum dimension is also needed, for learning and teaching SD in a globalized context. Emphasizing that 'globalization and the need for curricula change will become the great challenge in higher education world-wide in the decades to come', Svensson and Wihlborg (2010, p. 15) recommend this. Though, the global perspective (Svensson & Wihlborg, 2010) has to be integrated in curriculum to achieve a competence-driven global curriculum. Thereby, capabilities through constructive interaction for various qualities of global learning and knowledge formation for sustainable development will be a central part of the outcome. According to Rickinson (2001), until recently, most studies have devoted less attention to learning processes and the students' learning experiences and preferences, than to learning outcomes and 'factual' knowledge about sustainability. This has serious implications, since: "Quintessentially, global learning is not about conveying factual knowledge, but is a critical approach to concerns, interests and experiences. Global learning per se cannot serve to create a better world, but encourages self-determination in a global context" (Rauch and Steiner, 2006, p. 121) More specifically, global learning presupposes competencies, which individuals need to acquire if they want to actively shape the development of world society. The aim of the study is not to research social policy, and how or what tends to promote and reinforce a more global perspective in education (Stevenson, 2007). Nor is focus placed on globalization in terms of changes, at economic, technological, political, and cultural levels of society. The purpose is instead to highlight some crucial elements of the global dimension in teaching and learning towards sustainability in the context of professional teacher development and i.e. their development of teaching management strategies (Reid, 2009; Cole, 2006). Within this framework, global learning for sustainable development (GLSD) has been recognized as a productive concept (Anderberg, Norden & Hansson, 2009). Our approach addresses the challenge of teaching about the complex field of sustainable development (SD) in a number of contexts, including higher education (HE), secondary school education, informal or life-long learning situations, as well as in outreach from university or enterprises, aiming to reach new target groups. The understanding of learning, which underpins most of our research studies of the context for learning, is that which has emerged from phenomenographic studies, now known as variation theory (Marton and Booth, 1997). Learning is characterised above all as coming to see things in qualitatively new ways. This involves the learner (i.e. the "learning" teacher) becoming able to discern new qualities in some focal phenomenon or aspects of that phenomenon, which demands opening dimensions of variation in awareness, becoming able to see that that which has been taken for granted could be otherwise (Åkerlind, 2007; Runesson, 2006). With a phenomenographic approach, semi-structured interview questions are used for analysing and describing the process of teacher experiencing, teacher thinking and teacher reflection concerning global teaching and learning of SD. Upper secondary school teachers (n=13), who have competence in different subject matters and are working together in teams educating SD transdisciplinarily in a global context, are interviewed three times (before, in the middle of, and after a specific course moment of SD with a global focus) in a longitudinal study during 2010-2011. According to the theoretical foundation of the research questions, we will through the phenomenographic approach (Marton & Booth, 1997) focus on (1) the content that is the transdisciplinary subject matter of SD within a global focus; (2) the individual learning within awareness raising dialogues with a global focus, and (3) the knowledge formation and the development of capability, competence and skills (Booth & Anderberg, 2005; Bowden, 2004). The result, presented at the EARLI 2011 conference, will be related to teacher thinking. The findings show that in any educational context – and in this teaching practice, particularly, how – the concept of GLSD continuously needs to be renegotiated by participating teachers in every concrete learning situation (Dahlin, 1999). While Rauch and Steiner (2006) see SD mainly as a narrowing idea, providing a heuristic format for reflection, the complexities of SD also provide a bearing for processes of global research and learning. Due to the complexity of SD issues, it is necessary to bring in an open-minded elucidation of the globalization factors actually present, already in the foundation of the SD concept. The findings clearly point to a link between transdisciplinary and global teaching within the field of global

learning for sustainable development (Nordéén and Anderberg, 2010). With this study, we wish to shed light on the concept of SD from a global didactic angle.

Understanding Teachers' Personal Epistemologies

Gregory Schraw, University of Nevada, United States; Jo Brownlee, QUT, Australia; Donna Berthelsen, Queensland University of Technology, Australia

This roundtable summarizes the rationale, results, and educational implications of a recently completed volume on teachers' personal epistemologies by Brownlee, Schraw and Berthelsen (2011). Each of the three editors will participate. Personal epistemology involves an individual's cognition about knowing and knowledge. This research field has explored the nature of teachers' personal epistemologies and how these cognitions inform teachers' practices in classrooms to promote effective learning and teaching in a range of education contexts. The rationale for the volume was to focus on the current status of research knowledge in this field that aimed to improve teachers' personal epistemologies as a catalyst for better educational practices in classrooms. This volume augments other recent volumes that have addressed students' personal epistemology and measurement issues. Joanne Brownlee will discuss the theoretical rationale for the importance of addressing personal epistemologies in teacher education and professional development programs. We summarize five main themes of the research from the edited volume (Gregory Schraw) and discuss implications for educational practice and future research (Donna Berthelsen). The roundtable will inform a critical discussion about the current and future directions for research in development and change in the personal epistemologies of teachers.

The goal of the round table interactive discussion is to summarize the rationale, contents, main themes, and educational implications of an edited volume on teachers' personal epistemologies (Brownlee, Schraw & Berthelsen, 2011). The three co-editors will each participate. The editors will bring their personal experiences with the test's chapters to the roundtable, including their interpretations of each chapter and the overall contribution of the edited volume. This roundtable will enable participants' interests in epistemology to be updated on cutting edge research by 16 authors representing eight different countries. A personal epistemology involves an individual's cognition about knowing and knowledge, but especially the origins and development of knowledge. This research field has explored the nature of teachers' personal epistemologies and how these cognitions inform teachers' practices in classrooms to promote effective learning and teaching in a range of education contexts. The rationale for the volume was to focus on the current status of research knowledge in this field that aimed to improve teachers' personal epistemologies as a catalyst for better educational practices in classrooms. This volume augments other recent volumes that have addressed students' personal epistemology and measurement issues through its focus on teachers' personal epistemologies and learning; teachers' personal epistemologies and teaching; and changing personal epistemologies in teacher education programs. Joanne Brownlee will describe the rationale for the edited volume and situate its unique contributions within the context of recent research and edited volumes that focused on students' personal epistemologies and theoretical/measurement issues related to personal epistemologies. Brownlee will provide definitions of teachers' personal epistemologies and discuss the intended contribution of the volume. Personal epistemologies will be linked to previous work by Perry (197), Kuhn (1991), King and Kitchener (1994), Schommer-Aikins (2004) and Hofer (2004). Gregory Schraw will provide a summary of 16 chapters, focusing on five overarching research questions which include: How do we conceptualize teachers' personal epistemology? Are personal epistemologies domain-specific or domain general? How are teachers' personal epistemologies related to teaching? How are teachers' personal epistemologies related to student learning? How do personal epistemologies change? Schraw will discuss data and theoretical conjectures from each of the authors who addressed these questions, focusing on whether authors reached consensus and how to characterize their consensus. Donna Berthelsen will discuss the contributions of the volume compared to other recent volumes that addressed related topics and the implications for educational practice. This discussion will center on the propositions that active cognitive engagement with the subject matter promotes conceptual change; that awareness of typical preconceptions of teachers and teacher education students can provide the means to inform efforts for change; whether a focus on explicit, concrete principles and strategies promotes conceptual change more than does a focus on abstract generalizations; how information and events that create disequilibrium promote change; and the importance of frequent and critical self-reflection. The argument will be made that each of these factors promotes epistemological development in a manner that improves explicit awareness of one's personal epistemology, classroom teaching practices, and student development. The three authors will present a prioritized list of implications that focus on two key concerns. The first is to develop a better understanding of the intellectual mechanisms which mediate teachers' personal epistemologies, teacher's classroom practices, and student learning. The second is to develop strategies to promote change in personal epistemologies in order to improve teaching practices and student learning. Each author will be given 6 to 8 minutes to present a summary and orient participants to summary tables and visual displays prepared for the round

table. Participants will be encouraged to ask clarifying questions. The remainder of the session will focus on interactive discussion of points raised by the editors, but personal epistemologies improving teacher practice in the classroom, changing personal epistemologies, and identifying questions for future research.

Two different classroom activities with the same interaction classroom context

Javier Rosales Pardo, Universidad de Salamanca, Spain; Irene Alvarez, University of Salamanca, Spain; David Munez, University of Salamanca, Spain; Santiago Vicente, University of Salamanca, Spain; Jose Chamoso, Facultad de Educacion, Spain

Classroom context can facilitate or frustrate the supporting autonomy process. Normally, teaching patterns are based on teachers' individual routines and knowledge structures which can vary over the course of different lessons (Seidel & Prenzel, 2006). In this study, we are interested in how the task (word problem solving or text comprehension), might determine the interaction classroom context. The participants were 2 Primary Education teachers with more than 10 years' experience. All of the participants were audio-taped in their ordinary classrooms and during the time normally devoted to text comprehension and word problem solving. An analysis of the interaction was required at different levels: 1) The interaction was broken down into episodes; 2) The episodes were broken down into interaction cycles and 3) The interaction cycles was categorized as: Monologue, IRE, IRF or Symmetric. No significant differences were found when comparing the participation structures between two different classroom activities (word problem solving and text comprehension). Furthermore, in both classroom activities the percentage of cycles categorized as IRE was significantly superior to the percentage of cycles categorized as IRF and Monologue.

Introduction

One of the main goals for educators is to create and foster classrooms that support students in becoming truly autonomous or self-determined as learners. Scaffolding involves students as co-participants in teaching and learning by constantly balancing challenge and skill. In scaffolding, the teacher provides guidance for accomplishing the learning goal only as necessary and to move from a position of shared responsibility to one in which the student takes control of learning goals and processes (Turner, Meyer, Cox, Logan, DiCintio & Thomas, 1998). Obviously, classroom context can facilitate or frustrate this scaffolding process. In this sense, Stefanou, Perencevich, DiCintio & Turner (2004) propose that autonomy support can be manifested in the classroom in at least 3 distinct ways: organizational autonomy support (e.g., allowing students some decision-making role in terms of classroom management issues), procedural autonomy support (e.g., offering students choices about the use of different media to present ideas), and cognitive autonomy support (e.g., affording opportunities for students to evaluate work from a self-referent standard). In the present study, we are interested in studying cognitive autonomy support and, specifically, we want to analyse how the task (word problem solving and text comprehension) might determine the interaction classroom context. Normally, teaching patterns are based on teachers' individual routines and knowledge structures which vary over the course of different lessons. For example, Seidel & Prenzel (2006) suggest that teaching patterns vary due to the domain of instruction, the topic taught in class, as well as the individual instructional practices of the teachers. However, as stated by the same authors, in order to change and stimulate teacher improvement, further research is required with respect to the variances that are caused by domain specificity, topic specificity and individual teacher routines.

Method

The participants were 2 primary education teachers with more than 10 years' experience. Each teacher was audio-taped when teaching two fourth-grade lessons (Science and Mathematics), which were composed by different sessions. Two typical classroom activities, word problem solving and text comprehension, were isolated from each session. In sum, our aimed involved two different classroom activities that were carried out by the same teacher. All of the participants were audio-taped in their ordinary classrooms and during the time normally devoted to this type of work. Analysis of the interaction required 3 different levels: 1) the interaction was broken down into episodes. An episode was defined as a set of activities that presents: a) a recognizable objective or goal, b) a regular structure of participation, and c) a recognizable sequence of routines. In the present work we distinguish four types of episodes; 2) the episodes were broken down into interaction cycles. Basically, an interaction cycle starts with an initial question/order and it finishes when that question/order is completed; 3) the interaction cycles were categorized as participation structures: Monologue (students do not participate); IRE (the cycle involves a closed question and a simple feedback); IRF (the cycle involves an open question and a complex feedback which allows the students 'participation'); Symmetric (students begin the interaction cycle). Measures In the present study the percentages of participation structures during word problem solving and text comprehension were considered.

Results

Overall, no significant differences were found when comparing the interaction classroom context between problem solving and text comprehension $\chi^2(3, N= 200) = 2.77, p > .42$. However, in both classroom activities, significant differences were found between the percentages of the different participation structures: Science, $\chi^2(4, N= 100) = 165.60, p$

Discussion

The absence of significant differences between the participation structures points out that the task does not influence on how the interaction classroom context is organized when solving word problems and comprehending texts. Similarly, in both groups significant differences were found between IREs and the rest of participation structures which indicates that the teachers take control of the learning process. Despite the results found by Seidel & Prenzel (2006), which suggests that teaching patterns can vary due to the domain of instruction and the topic taught in class, our results show that if we take into account the interaction patterns then the instructional classroom context does not vary. Educational implications Knowing what teachers usually do in their classrooms is important because it will allow us to propose changes that are not very remote from what is already being done. In this sense, the present study reinforces the idea that teaching patterns remains the same under different tasks. Hence, this fact should be taken into account in order to improve teaching practices.

An Examination of the Assessment Accuracy of Teacher Tutors and Student Tutors

Stephanie Herppich, Georg-August-University Goettingen, Germany; Joerg Wittwer, University of Goettingen, Germany; Matthias Nuckles, University of Freiburg, Germany; Alexander Renkl, University of Freiburg, Germany

Tutors often have difficulty with accurately assessing a tutee's understanding. However, little is known about how the professional expertise of tutors influences their assessment accuracy. Therefore, we conducted a study with $N = 46$ tutor-tutee dyads and compared the accuracy with which teacher tutors and student tutors assessed a tutee's understanding of the human circulatory system. The results showed that whether teacher tutors were more accurate in assessing than student tutors depended on the type of a tutee's understanding being assessed. When assessing a tutee's understanding at the level of concepts, teacher tutors outperformed student tutors. However, this was only true for the assessment of a tutee's correct understanding of concepts. When assessing a tutee's understanding at the level of mental models, teacher tutors and student tutors faced similar difficulties. However, in contrast to student tutors, teacher tutors were more aware of their ability to accurately assess a tutee's understanding. Overall, the results suggest that teacher tutors assess a tutee's understanding at the level of concepts more systematically than student tutors. In contrast, when assessing a tutee's understanding at the level of mental models, teacher tutors like student tutors tend to be overwhelmed by processing all information that make up a tutee's mental model. Hence, regardless of their professional expertise, tutors need to be supported in assessing a tutee's understanding.

Aim

To be effective, instruction should be adapted to the individual learner. Human one-to-one tutoring is a method that offers many opportunities to adapt instruction to a tutee's understanding. However, an important prerequisite of adaptive instruction is the accurate assessment of the tutee's understanding. Research has shown that tutors have difficulty with accurately assessing a tutee's understanding. Nevertheless, no previous study has directly compared the extent to which tutors with different levels of professional expertise can accurately assess a tutee's understanding. It can be assumed that – due to their professional expertise – teachers who serve as a tutor process information about a tutee more systematically than students who serve as a tutor. As a result, teacher tutors are more likely to assess a tutee's understanding accurately than student tutors.

Methodology

In this study, we investigated how the professional expertise of tutors influenced the accuracy with which they assess a tutee's understanding. We examined the accuracy with which 21 teacher tutors and 25 university student tutors assessed a tutee's understanding. In the tutoring session, the dyads of tutors and tutees discussed a text passage about the human circulatory system. After tutoring, the tutees completed a concepts test measuring their correct and incorrect understanding of concepts related to the human circulatory system. The tutors were asked to indicate how the tutee would answer each of the items in the concept test (= level of concepts). Moreover, the tutees were asked to draw and explain the blood path of the human circulatory system. The tutors were asked to draw and explain the blood path as they assumed their tutee to draw and explain it (= level of mental models).

To analyze the tutors' assessment accuracy, we compared the tutees' actual performance with the tutors' estimates of the tutees' performance. We measured the assessment accuracy for the concepts test by comparing the tutors' estimates of how many items the tutees would answer correctly or incorrectly against the number of items that were

actually answered correctly or incorrectly by the tutees. To measure assessment accuracy for the drawing task, we compared the number of tutors that assumed their tutee to have a correct or incorrect mental model against the number of tutees that actually had a correct or incorrect mental model. The correctness of a mental model was coded by assigning a tutee's mental model to one of twelve categories with higher categories indicating a more complete understanding. In addition, we asked the tutors to self-assess their assessment accuracy in the drawing task on a 4-point rating scale.

Results

Results showed that tutors overestimated the tutees' correct understanding and even more strongly underestimated the tutees' incorrect understanding. This was true for the level of concepts (correct: MTutor = 14.59, SDTutor = 3.21, MTutee = 13.35, SDTutee = 3.18; $t(45) = -2.05$, $p = .05$, $\eta^2 = .09$; incorrect: MTutor = 6.83, SDTutor = 1.91, MTutee = 9.70, SDTutee = 3.23; $t(45) = 5.98$, $p = .01$, $\eta^2 = .44$) and for the level of mental models (correct: nTutor = 36, nTutee = 19; incorrect: nTutor = 10, nTutee = 27; goodness of fit test: $\chi^2(1, N = 46) = 14.70$, p

The comparison between the teacher tutors and the student tutors revealed that the teacher tutors (MTutor = 14.19, SDTutor = 3.04; MTutee = 14.10, SDTutee = 3.13) assessed a tutee's correct understanding at the level of concepts significantly more accurately than the student tutors (MTutor = 14.92, SDTutor = 3.37; MTutee = 12.72, SDTutee = 3.16): $t(44) = 1.77$, $p = .04$ (one-tailed), $\eta^2 = .07$. However, there was no significant difference between the teacher tutors (MTutor = 7.29, SDTutor = 2.22; MTutee = 9.57, SDTutee = 2.96) and the student tutors (MTutor = 6.44, SDTutor = 1.56; MTutee = 9.80, SDTutee = 3.50) with regard to the assessment of a tutee's incorrect understanding: $t(44) = -1.12$, $p = .27$ (one-tailed), $\eta^2 = .03$. At the level of mental models, the assessment accuracy of the teacher tutors (correct: nTutor = 16, nTutee = 9; incorrect: nTutor = 5, nTutee = 12) was also not significantly different from the assessment accuracy of the student tutors (correct: nTutor = 20, nTutee = 10; incorrect: nTutor = 5, nTutee = 15): $\chi^2(1) = 0.00$, $p = .49$ (one-tailed; log-linear analysis). However, the correlation between the teacher tutors' self-assessments ($M = 2.85$, $SD = 0.49$) and their assessment accuracy, reflected by the difference between the category number assigned to the tutor's assumed mental model and the category number assigned to the tutee's actual mental model (MTutor = 10.00, SDTutor = 0.84; MTutee = 8.05, SDTutee = 2.67), indicated that the teacher tutors were fairly accurate in self-assessing their assessment accuracy ($r = -.56$, $p = .01$). The student tutors' self-assessments ($M = 3.00$, $SD = 0.58$), however, did not reflect their true assessment performance (category number: MTutor = 10.12, SDTutor = 0.93; MTutee = 7.84, SDTutee = 2.75; $r = .00$, $p = .99$). Thus, in contrast to the student tutors, the teacher tutors were quite aware of whether or not they were able to accurately assess a tutee's mental model of the human circulatory system.

Theoretical and educational implications The results replicate previous findings and suggest that the tutors' assessment accuracy is influenced by a bias that leads them to impute their own understanding to the tutee. Consequently, tutors overestimate a tutee's correct understanding and underestimate a tutee's incorrect understanding. Teacher tutors, however, seem to be less influenced by such a bias because they assess a tutee's correct understanding at the level of concepts more accurately than student tutors. Nonetheless, teacher tutors and student tutors face similar difficulties in assessing a tutee's understanding at the level of mental models. Despite these similarities, teacher tutors seem to be more aware of the difficulties with assessing a tutee's mental model than student tutors. Overall, the results suggest that tutors need support in assessing a tutee's understanding to help them providing adaptive instruction in tutoring.

Is there an integration process of pictures and words in working memory?

Jana Arndt, Knowledge Media Research Center, Germany; Anne Schueler, Knowledge Media Research Center, Germany; Katharina Scheiter, Knowledge Media Research Center, Germany

According to the Cognitive Theory of Multimedia Learning (Mayer, 2009) one crucial step for learning with words and pictures is the integration of the verbal and pictorial representations with each other. However, so far, there have been no studies explicitly investigating this assumed integration process. Thus, the first aim of the current study is to investigate the integration of words and pictures by using a paradigm introduced by Gentner and Loftus (1979): Learners are instructed to memorize 40 pairs of pictures and sentences that result from cross-varying type of picture (specific vs. general) with type of sentence (specific vs. general). Integration is assumed to occur whenever the two sources of information differ in their specificity (i.e., when a general sentence is paired with a specific picture and vice versa). As a consequence, learners should be less able to trace back the learned information to a specific representation. Hence, they should have higher false alarms when for instance being asked to verify whether they have seen a specific picture when this specific information had actually been given in a sentence paired with a general picture compare to a situation where both representations have the same level of specificity. The second aim of the

present study is to investigate whether the assumed integration process takes place in the episodic buffer of working memory (Baddeley, 2000). The results of the study as well as the appropriateness of the used methods will be discussed at the conference.

ROUND TABLE

A typology of informal learning in the workplace

Anoush Margaryan, Glasgow Caledonian University, United Kingdom; Colin Milligan, Glasgow Caledonian University, United Kingdom; Allison Littlejohn, Glasgow Caledonian University, United Kingdom

The aim of this study is to contribute to understanding of the ways in which professionals learn and develop their expertise in the context of work. A key research question is: What is learned in the workplace? To address this question, the study was designed to elicit categories of knowledge, skills and dispositions that professionals acquired through engagement in work. The study was conducted in a multinational company in the energy sector. Data was collected using semi-structured interviews. Participants were 29 professionals (engineers, scientists, learning specialists and others) working in 12 different countries. Respondents were asked to think about their most significant learning experience in the past year - the project or task from which they had learned the most. Through a series of semi-structured questions they were prompted to articulate what they learned. Synthesis of the responses generated a typology of knowledge and skills acquired through work. These were grouped under 5 categories: understanding and awareness; know-how; locative knowledge; personal development and enculturation. The findings contribute empirical evidence on the breadth and variety of types of knowledge and skills that can be acquired through work, helping refine our understanding of the learning potential of the workplace. The findings could contribute to practice by enabling organisations to provide more effective learning opportunities for their employees and ensuring recognition of knowledge and skills that employees acquire through every day.

The workplace is often viewed as site of experience and performance rather than learning. This is partly explained by organisational imperatives, whereby learning is considered a by-product of work rather than a goal in itself, and partly by the complex politics of naming oneself as learner in the workplace (Boud et al, 2003). However, this separation between learning and work also reflects a certain bias that traditionally existed towards informal workplace learning as being devoid of structure, situationally non-transferrable, lacking certifiability and a sound basis in codified knowledge (Billett, 2001). The workplace thus tended to be viewed as a place of application, extension and augmentation of learning, while learning itself has been viewed to occur mainly through participation in formal education and training (Colley et al, 2002). In reality the workplace is an environment where powerful, deep and effective learning takes place (Eraut et al, 2000). The aim of this study is to develop an understanding of the ways in which professionals learn in the context of their work. Of special interest is the question of how professionals interact with the collective knowledge (knowledge residing in people, epistemic practices, resources and machines) in the process of their learning. The study was conducted in a multinational company in the energy sector. The study was guided by three research questions:

- 1) What is learned in the workplace?
- 2) How is it learned?
- 3) Who is it learned with?

In this session, we report initial findings related to the first research question only, presenting a typology of what is learned in the workplace.

Methodology:

The data was collected through semi-structured interviews with 29 professionals (engineers, scientists, learning specialists, among others). Participants were distributed in 12 countries and the interviews (lasting on average 1 hour) were conducted by telephone. At the start of the interview, the respondents were asked to think about their most significant learning experience in the past year - the project or task from which they had learned the most. The interview questions were designed to elicit data about the ways in which professionals set and attain their learning and development goals to complete the project/tasks. The interview script is available at: <http://www.scribd.com/doc/15426750/Interview-Script> Data was coded using both pre-defined codes related to the key research questions, as well as codes emerging from the data. Coding for a sample of data was cross-checked by two researchers to ensure inter-rater reliability and consistency.

Findings:

Synthesis of responses generated a set of 21 categories that cover a wide collection of types of knowledge and skills. These range from conceptual knowledge (know what) and procedural knowledge (know how) to locative knowledge (know where) and dispositional knowledge (personal values and behaviours). The typology is outlined in Table 1.

Conclusions, contributions and issues for discussion:

The traditional view is that the acquisition of certain types of knowledge (eg conceptual knowledge) can only occur in formal learning settings (such as a university programme or a training course in a corporate learning centre). However, as our findings show, this view is limited. This initial typology demonstrates the breadth and variety of knowledge and skills that individuals acquire through work. These findings contribute empirical evidence on the variety of types of expertise that can be acquired through work itself, helping refine our understanding of the learning potential of the workplace. Improved understanding of what can be learned through work can also contribute to practice, enabling organisations to provide more effective learning opportunities for their employees and ensuring that the knowledge and skills that employees acquire through every day work are recognised.

The study highlighted some theoretical, methodological and pragmatic issues. We propose to discuss the following three issues:

1. To what extent 'what is learned' can be linked to 'who with/from' and 'by what mechanism'? Do any patterns emerge? This could be an interesting area for further research.
2. What are the appropriate methodologies to help us study how people learn in the context of work? Given the informal and often tacit nature of workplace learning, much of it tends not to be recognised as learning, meaning that people often lack awareness of what they are learning in the context of work. Quantitative surveys are generally considered inappropriate for studying the sorts of research questions that we posed here. Interviews are the most common method, but are they may not allow a sufficiently in-depth exploration. Ethnographic studies (including observations) could give more in-depth insights, but they are costly and it is difficult to get organisational commitment or funding for these.
3. How can this typology be used in research and practice? How could organisations/individuals apply it to improve learning?

How to cultivate experts to their new tasks?

Tuire Palonen, University of Turku, Finland; Erno Lehtinen, University of Turku, Finland

The changes taking place in the societies and their technological systems, and future's demands in general, create pressures for the experts' work in different types of organizations (Tynjälä & Heikkinen 2010; Hakkarainen et al. 2004). There is evidence that experience alone does not cultivate workers so that they could learn without being aware of it (Boshuizen, 2004). Not either the traditional professional programs organized by the centers of extensional studies have fulfilled the expectations related to the future's competences. Therefore, new type of education model for academic experts was implemented in Finland. The aim was to integrate higher education and workplace learning. The purpose of the study was to investigate how the new type of education can train experts to their future tasks. The reply to the online questionnaire was sent back by 108 respondents, studying altogether in 6 expert programs.

The opinions toward the new educational model were varying. The prior knowledge of the participants were not always taken into consideration, expectations toward the programs were high and not always met. Obviously, there is a need to re-think how to create new educational models that combine the strengths of the university training and workplace learning. The comments toward the apprenticeship type features of the model were critical, especially given by the respondents coming from rather tiny organizations or working at the field in which they did not have any close colleague that would have shared their tasks.

Introduction

The changes taking place in the societies and their technological systems, threats brought along globalization, limits of the environmental capacity and future's demands in general, create pressures for the experts' work in different types of organizations (Tynjälä & Heikkinen 2010; Hakkarainen, Palonen, Paavola & Lehtinen, 2004). There is evidence that experience alone does not cultivate workers so that they would easily learn without being aware of it and even if the environment is changing and new knowledge would be at hand (Eraut, 2007; Boshuizen, 2004). Not either the traditional professional programs organized by the centers of extensional studies of the universities have fulfilled the expectations focused on future's competencies. Obviously, there is a need to re-think how to create new educational models that combine the strengths of the university training and workplace learning. Therefore, new type of education model for academic experts was implemented in Finland. The aim was to integrate higher education and workplace expert knowledge together by supervising, learning by doing and getting newest pieces of knowledge to students along various channels provided by universities. The ten first programs called as "apprenticeship type education" started at 2009, following by 35 next programs at 2010. These first 45 pilot programs are focusing on very different domains such as environmental and technological expert tasks, work on the field of social and health care and business administration. They were tailored to train experts to tasks such as game addiction therapy, energy counseling, multicultural counseling and leaders for rapidly growing industry and so on. The first pilot courses are soon finishing their first year and the evaluation round was conducted in order to study the first impressions of the new model.

Research problems

The aim was to investigate 1) how the new type of education that is tightly tied to workplace learning can train experts for their future tasks. 2) How mentoring, apprenticeship type workplace counseling and face-to-face sessions at university can be integrated together? 3) Is prior learning taken into consideration by supervisors and planners of the courses?

Participants

Altogether 108 experts responded to the online questionnaire from 6 different pilot programs. Their experiences and evaluation about the new model were asked in the formula. Instruments An online questionnaire was created in order to evaluate the prior knowledge base and overall evaluation of the supervising practices and the ways how the learning was sequenced during the studying period. In addition, in three open-ended questions they were asked about the profits and obstacles of the new education model in general. The data gathered by questionnaires will later be complemented by interviews.

Results

The opinions toward the new educational model were varying. The prior knowledge of the participants did not always fit to their work tasks or learning episodes. The expectations toward the programs were high and not always met. There were many obstacles in organizing the supervision, mentoring or guidance at workplaces. The face to face sessions were not always integrated to the problems found at workplaces. Especially, the time was too short for learning tasks and there were too much of them. The most positive comments were given for work-circulating practices and training the students toward the new skills somewhere else than in one's own workplace. Further, expert lectures organized by universities, were often experienced to be fruitful. In sum, the comments toward the apprenticeship type features of the model were critical, especially given by the experts coming from rather tiny organizations or working at the field in which they did not have any colleagues that would have shared their field.

Discussion

Even if positive comments about the new model were given, it seems obvious that the first pilot programs have not been able to renew the earlier practices very much. More innovative tools, methods and styles are needed to get real change that is needed to educate the future experts.

Reorganization of collaboration and learning in organizational change in emergency unit

Kaija Collin, University of Jyväskylä, Finland; Sanna Herranen, University of Jyväskylä, Finland; Ulla Maija Valleala, University of Jyväskylä, Finland

In this paper we aim to describe various organizational changes caused by increasing volume of patient care in regional emergency polyclinic at the Central Finland Central Hospital. In particular, we focus on how changes unfold in division of labor and recomposing the nursing teams and how the change challenges personnel's learning. The paper is part of a larger research and developmental project which aims to uncover the different teamwork processes and inter-professional collaboration and learning that take place in medical emergency work. Despite the voluminous amount of research in the area of organization and management studies and nursing there has been little focus on inter-professional collaboration in organizational change situation.

Ethnography was applied as a methodological approach in conducting the research. With this approach we aim to describe and understand the organizational culture, everyday work practice and inter-professional collaboration in the clinical context of emergency work. Empirical data will be collected with the help of observations and interviews. Suitable qualitative methods will be utilized in the data analysis. As preliminary findings we describe the process of how head and charge nurses as well as charge physicians are prepared to changes, that is, to increased volume of patients from the beginning of 2011.

The findings will be utilized in building a model of inter-professional shared expertise which will be applied more broadly in hospital organizations, particular in promoting physicians' and nurses' inter-professional education and continuing education among health care professionals.

In this paper we aim to describe various organizational changes caused by increasing volume of patient care in regional emergency polyclinic at the Central Finland Central Hospital. In particular, we focus on how changes unfold in division of labor and recomposing the nursing teams and how the change challenges learning. The paper is part of a larger research and developmental project which aims to uncover the different teamwork processes and inter-professional collaboration and learning that take place in medical emergency work. The project is divided into three phases and the findings presented in the paper are based on the second phase in which inter-professional team work processes are developed. In the project we aim to identify what practices of inter-professional team work most effectively enhance employee wellbeing and patient safety. In addition, we aim to identify what inter-professional practices need to be further developed in the project.

Hospitals are environments in which inter-professional teamwork and collaboration are essential to ensure patient safety and effective practice (e.g. McCallin 2001; Nembhard & Edmondson 2006). However, it has been revealed in many studies that inter-professional collaborative work in hospital organizations faces many challenges and constraints (see Kvanström 2008; Lingard, Espin, Evans & Hawryluck 2004; Phelan, Barlow & Iversen 2006; Pisano, Bohmer & Edmondson 2001). In order to enhance the effectiveness of patient-centered practices, such as ensuring patient safety, the Central Finland Hospital has started a regional, the first of its kind in Finland, emergency polyclinic. Since a massive structural and functional change of this kind has not been properly investigated and assessed before, research which could assist in the further development of collaborative innovations is needed. From the beginning of 2011 an additional increase of volume of patients in regional emergency polyclinic will occur. Due to this change reorganization of collaboration is needed. Besides the reorganization also other conditions can be taken care of. These are, for instance, ensuring patient safety, ensuring wide expertise of nursing personnel in emergency unit (including expertise of primary health care and special health care) and competence development, wellbeing and orientation of new personnel.

Despite the voluminous amount of research in the area of organization and management studies (Nembhard & Edmondson 2006; Ramanujam & Rousseau 2006) and nursing (Baker, Day & Salas 2006; D'Amour, Ferrada-Videla, Rodriguez & Beaulieu 2005; Kvanström 2008) there has been little focus on inter-professional collaboration in organizational change situation. As a change situation in this paper we refer to increased volume of patients in regional emergency polyclinic. Since emergency work occurs in circumstances of continuous change in the composition of team members, especially nursing practices are challenged. Consequently, in this paper we ask how various planned organizational changes are manifested in reorganization of nursing and division of labor in emergency

work. In particular, we focus on changes that can be seen in the division and reorganization between different care groups and team composition.

Ethnography was applied as a methodological approach in conducting the research. With this approach we aim to describe and understand the organizational culture, everyday work practice and inter-professional collaboration in the clinical context of emergency work. Empirical data will be collected with the help of observations, audio taping and individual and focus group interviews. Suitable qualitative methods, such as ethnographic, discourse and thematic analysis, will be utilized in the data analysis.

As preliminary findings we describe the process of how head and charge nurses as well as charge physicians are prepared to changes, that is, to increased volume of patients from the beginning of 2011. We also describe how the planned changes actually will be shown after the date of which the changes come into effect. We also describe how the recomposition of care groups and inter-professional teamwork will succeed from the point of view of how the changes were explained and argued. In addition, what kinds of new challenges and possibilities for learning will emerge in the situation will be discussed. The findings will be utilized in building a model of inter-professional shared expertise which will be applied more broadly in hospital organizations, particular in promoting physicians' and nurses' inter-professional education and continuing education among health care professionals.

Can we improve student satisfaction by team learning in a first year undergraduate accounting course

Evelien Opdecam, Ghent University, Belgium; Patricia Everaert, Ghent University, Belgium

This paper discusses student satisfaction and experiences of a large cohort of first year undergraduate students. Team learning was implemented in a financial accounting course. The learning experiences and the satisfaction, as perceived by students in the team learning condition, were compared to those in a traditional lecture-based control condition. A post-experimental questionnaire, with open and closed-ended questions, was administered. Students reported higher levels of satisfaction in the team learning condition and a better learning experience compared to students in the lecture-based condition. The amount of pre-class preparation and in-class participation was higher for the team learning students in comparison to the lecture-based students. This paper elaborates on the elements in effective team learning design in accounting education and contributes by illustrating a basic model to implement team learning in a large undergraduate accounting course.

Introduction

Implementing team learning in the current circumstances in higher education is not easy. The pivotal change in higher education of the last decade has been the massification of student population (Tynjala, Valimaa, & Sarja, 2003). As a

result, many accounting courses are taught in large classes (Cunningham, 2008). The large size makes it challenging in terms of effort and resources for the university to offer small class tutorials or to check up on homework assignments. Students attend accounting class with about 500 students and attend the tutorials in classes of around 100 to 150. Many students would wait until the end of the semester to practise accounting topics and, as a result, fail the course. This sense of freedom is in sharp contrast to high school, where students are forced to study on a continuous basis. The reason to place more pressure on studying the material during the semester by increasing pre-class preparation for tutorials was one of the motivations for implementing team learning.

Previous research has investigated the effects of cooperative learning on student performance in accounting (Hite, 1996; Hwang, Lui, & Yew Jen Wu Tong, 2008; Ravenscroft, Buckless, McCombs, & Zucherman, 1997). To date, few research has focused on the influence on student satisfaction and learning experience in an accounting context. It may be interesting to consider information concerning student satisfaction and learning experiences, as educators construct the learning environment (Strand Norman, Rose, & Lehmann, 2004). Therefore, the first objective of this study was to investigate the influence of team learning on satisfaction and learning experiences. Furthermore, the second objective was to explore the advantages of team learning in an accounting setting.

Research Design

In this research setting, team learning was introduced to a first year undergraduate class in financial accounting. For the tutorials students were able to choose between lecture-based and team learning. Lecture-based was a traditional method of teaching using lectures to discuss the curriculum materials. There is almost no interaction between teacher and student; students mainly absorb the information. As such, there are few opportunities for students to ask questions, receive feedback on their pre-class preparation, or to find an answer on a problem they might have with the course content. Furthermore, in this lecture-based setting, students decide themselves whether they prepare the exercises beforehand or not. For the second learning path, team learning, students were required to be active learners. To make a proper implementation of team learning in an accounting setting, the five basic elements of cooperative learning (Johnson & Johnson, 1999) were taken into account. Students were divided into student-selected (Hilton & Phillips, 2010) groups of five. The teacher assigned these groups exercises to prepare (identical to those of the lecture-based path) and students were required to discuss their solutions with team members during the sessions. During these sessions, the instructor was available for questions. The core issue in team learning is that students do not learn solely from their own experiences, rather they learn from the experiences of the other team members as well. Because team members interact, they can possess and transfer information through feedback, explanation, or advice (Ellis et al., 2003). Furthermore, in the team learning condition, students were given the opportunity to accept responsibility for their own learning process (Michaelsen & Black, 1994). As a result, students in the team learning condition were expected to attend classes fully prepared.

Measurement Instrument

In order to evaluate the success of team learning, a post-experimental questionnaire was developed. Data were collected during the Spring 2010 semester. Satisfaction was measured via six items adapted from Janvrin (2008). In these items students were asked to report whether they liked the learning experience and whether the chosen path fulfilled their expectations. To measure learning experiences, the latest version of the 'Course Experience Questionnaire' (CEQ) was used. The CEQ has been successfully deployed in an accounting context in the past (Byrne & Flood, 2003). Specifically, Byrne and Flood highlighted the potential of the CEQ to offer reliable and useful feedback on teaching effectiveness. A 19-item CEQ with a 5-point Likert scale, consisted of four scales: Good Teaching; Clear Goals; Appropriate Workload; and Generic Skills. The specific items in each scale, factor loadings, and Cronbach's alpha are detailed in Table 1. Almost all items loaded as expected and the alpha values were satisfactory and demonstrate moderate to high levels of internal consistency.

Although the analyses of this quasi-experiment are still in progress, it is possible to report some preliminary results. Students who opted for team learning reported a significantly higher satisfaction than did students who opted for lecture-based learning ($F = 53.81$; $p = .000$). More team-learning students, in comparison to lecture-based students, declared that they made the right choice concerning the learning paths. Second, students in the team learning path reported a significantly higher mean score for good teaching ($F = 55.72$, $p = .000$) and generic skills ($F = 40.19$, $p = .000$), while there was no significant difference in the mean score for clear goals ($F = .00$, $p = .955$) and workload ($F = 1.72$, $p = .191$). Third, the time spent studying and preparing for the class during the semester was significantly higher for the team-learning students compared to the lecture-based students ($F = 59.82$; $p = .000$). The radar diagram illustrates these differences (see Figure 1). Fourth, the qualitative analyses of the open-ended questions provided further insight into the reasons for higher satisfaction and better learning experience. Important advantages of the team learning path were a factor in forcing students to study the theories and prepare the exercises prior to the class. Furthermore, the discussions on the material within the team were helpful for understanding the difficult topics within the course.

The aversion of accounting, for some students, changed into a slight appreciation of accounting. Finally, the team learning path was considered fun. The ability to provide a stimulating learning atmosphere is the main reason why we have implemented this innovative approach.

Inclusion in Secondary School: a training for teachers

Bortolotti Elena, Università di Trieste, Italy; Emanuela Cren, PhD at the Università degli Studi di Trieste, Italy., Italy;
Francesca Zanon, Faculty of Formation at the Università degli Studi di Trieste, Dipartimento della Formazione e dei Processi culturali, Italy, Italy

The Convention on the Rights of Persons with Disabilities (2006) is a recent international human rights instrument of the United Nations, that intend to protect the rights and dignity of persons with disabilities. In the field of Education, the Convention states that persons with disabilities should be guaranteed the right to inclusive education at all levels. The inclusion in a regular classroom is a important step for people with disabilities, but it requires a new perspective of teachers training.

This research investigates the ways in which the learning in blended modality is functional to the specialized knowledge development and how it promotes the effective practices sharing, on the theme of inclusion. The sample is given by a class of 54 teachers and one e-tutor attending a postgraduate course. This training iter requires that probationer teachers discuss about practices and question them inside the fields of disability and teaching students with special needs. Students are required to reflect on issues debated online. The strengths are the online collaborative discussion, presentations among participants and the interactions between online participants and tutor.

The role of educational research is to develop models that can explain how educational processes take place, evaluate their effectiveness and efficiency, propose and analyze intervention strategies (Klieme et al., 2008). An important topic that today involves the world of education, concerns the issues of inclusion of people with disabilities. The inclusion in a regular classroom is an important step for people with disabilities, it provides age-appropriate role-models and interactions with peers. Naturally, additional support services might be needed to ensure that all students' needs are met (Ashman, 2005). Despite the trend towards more inclusive practice, research has indicated that regular classroom teachers are not convinced of the effectiveness of this approach (Cook, 2001). One explanation for this attitude can be found in the absence of strategies for inclusion. At school it's very important planning support actions: teachers are required to modify the curriculum to include the needs of students, to develop positive attitudes to disability, to examine the role of school integration policies and to assume major responsibility for educating children with special needs (Elkins, 2005). In this way the teachers education becomes very strategic to guarantee the right of inclusions for students.

The Convention on the Rights of Persons with Disabilities (2006) is a recent international human rights instrument of the United Nations, that intend to protect the rights and dignity of persons with disabilities. Particullary, in the field of Education, the Convention states that persons with disabilities should be guaranteed the right to inclusive education at all levels, regardless of age, without discrimination and on the basis of equal opportunity.

The Convention notes that disability is an evolving concept and results from the interaction between a person's impairment and obstacles such as physical barriers and prevailing attitudes that prevent their participation in society. This concept is present in another important document, the International Classification of Functioning, Disability and Health, known more commonly as ICF, a classification of health and health-related domains.

In the future, all countries that have signed the Convention, should organize inclusive practices, and the school is an important starting point. For this reason, there is the need to establish models of learning to frame the inclusive experience. It should be considered, for example, the importance of models already coded, the opportunities for reflection, proposals, etc.

The aim of this work is to examine the effectiveness of online learning in courses of high professional training, for teachers who are specializing in supportive teaching (in Italy people with disabilities are used to attend common schools, and they have a support by a specialized teacher).

This training iter requires that probationer teachers discuss about inclusive practices at school. Questions involving the fields of disability and teaching students with special needs. Students-teachers are required to reflect on issues debated online.

Methods

Subjects

The 54 teachers involved in the research are specializing in working with students with special needs. They work in secondary school in regular classes yet. The specializing course they have been attending aims at preparing them to be special education teachers, what implies working for the inclusion of students with special needs in a regular class.

Instruments

The instruments given to the course participants included the use of LMS (Learning Management System) and Virtual classroom. These set up the structure through which the group can naturally switch from a guided learning configuration to a Practice and Learning Community. The online discussion is an interesting topic to develop. It lends itself to a constructive and cooperative approach, thanks to the access to online discussion forums and to the web contacts with the e-tutor educator and with other students.

In order to facilitate the passage from Virtual Classroom to Practice Community, an e-tutor has faced the themes connected to the know how (f.i. "Special education teacher", "Didactic strategies"). Debates and experience narration were the interaction modalities present in the forum.

Results

The paper will present some data obtained from surveys.

The development in the themes confirms the usefulness of a learning activity mediated by the share of knowledge and practices. They regard for instance: the number of themes developed (f.i. disabilities and school facilities; complicated relations ...), the practice exchange (f.i. for instance, how to control outbursts; physical restraint ...), material exchange (f.i. detection grids, didactic materials ...), listening and informal counselling activities targeted on the unique need (emphatic sustainment, listening and comparison to get the teacher to define a possible action to take when needed ...).

Honors education in the Netherlands

Nelleke de Jong, Utrecht University, Netherlands; Marca V.C. Wolfensberger, Hanzehogeschool Groningen, Netherlands

The topic of this paper is the development of honors education in the Netherlands. In the last 15 years the number of honors programs on offer in higher education institutions is increased. We have made a list of excellence programs offered in higher education institutions in 2010. Educational institutions are more and more interested in attracting highly motivated and talented students. The various honors programs currently on offer are indicative of this phenomenon. In this paper the differences in content as well as in objectives of programs will be discussed. The development of honors programs in higher education will be explained on different levels. The longitudinal character of this study illustrates the impact of interventions coordinated by the government. The study further opens up possibilities for developing various plans for new excellence programs in higher education in the Netherlands. Insight in the relationship between societal developments and the development of excellence education, as well as knowledge of the various ways in which excellence education can be shaped, can provide directions for further development of excellence education in higher education institutions across Europe.

Introduction

The topic of this paper is the development of honors education in the Netherlands. In the past 15 years the number of honors programs on offer in higher education has increased. Honors programs are specially designed programs for talented and motivated students, also called excellence education. More and more energy seems to go into providing academic challenges for talented students. Excellence education, although initially only provided by a small number of research universities, is increasingly offered by other higher education institutions such as universities of applied

sciences. This increase in the number of excellence programs in higher education is among other things caused by a greater interest in the promotion of excellence in Dutch society. The Dutch government for example, has developed and funded two initiatives in order to promote excellence in higher education. In this paper, the relationship between developments in society concerning excellence and the development of excellence programs in higher education will be explored.

The bachelor/master system was implemented in the EU in order to, among other things, make the European higher education more transparent. It also makes it easier for students to study abroad. As a consequence students have more choice in selecting programs in the Netherlands and abroad. This has resulted in greater competition between different educational institutions. Institutions can attract highly motivated and talented students by offering excellence programs and this is one of the reasons why institutions are offering honors programs. There are also other ambitions, such as the promotion of an innovative knowledge economy that are related to the growth of the number of honors programs. For students it can be an advantage having successfully completed an honors program when applying to competitive master programs. Excellence education in this way contributes to the internationalization of student communities. This paper offers an overview of the Dutch situation by analyzing the objectives and content of excellence programs during a period of 10 years.

Methods

We have compiled a list of the characteristic features of all excellence programs offered by Dutch higher education institutions in 2010. All higher education institutions, both research universities and universities of applied sciences were included (N=55). A combination of sources was used to create this empirical data set, in a similar way as Long (2002) did. Institutional reports were analyzed and digital information was combined with conducted interviews and some in-depth interviews. This review builds upon previous studies (Eijl et al., 2003; Eijl et al., 2005; Groothengel & Van Eijl, 2008), thereby allowing for a longitudinal analysis of the development of honors education in the Netherlands. For the case study of Utrecht University we analyzed assessments, student material and conducted several interviews.

Included in the list of characteristics were organizational features, content-related features and characteristics of students. Content-related features include the objective of the program, its content and the employed methods of teaching. Organizational features include the scale and duration of the program and the way in which the program is organized within the institution as a whole. Furthermore information about the criteria for selecting prospective students was requested.

Results

Nearly all research universities are currently offering one or more honors program(s) at the undergraduate level and an increasing number of the universities of applied sciences are developing honors programs. The increasing number of programs on offer as well as the efforts used in developing new programs are indicative of a greater interest in the promotion of excellence. Educational institutions are more and more interested in highly talented and motivated students which can be seen from the abundance of programs currently on offer. Whilst in some programs an emphasis is placed on research and academic qualities, others stress the importance of personal development, the promotion of excellence or interdisciplinarity. In this paper the development of honors programs in higher education will be explained on different levels. The effects of initiatives by the national government to promote excellence in higher education will be discussed. Differences between programs of different institutions concerning content as well as objectives will be discussed. Utrecht University designed the first honors programs and the first residential honors college. The development of excellence education at Utrecht University will be used as an example of the laboratory impact of initiatives on higher levels.

Significance of the research

Honors education is emerging as an innovative, challenging academic agenda in Europe and especially in the Netherlands. In this research the development of excellence programs in the Netherlands has been outlined. The longitudinal character of this study illustrates the impact of interventions coordinated by the government. Also the relations between societal developments and the changes within higher education are outlined. The study opens up possibilities for developing various plans for new excellence programs in higher education and it shows different ways within education to evoke excellence. Insight in the relationship between societal developments and the development of excellence education, as well as knowledge of the various ways in which excellence education can be shaped, can provide directions for further development of excellence education in higher education institutions across Europe.

Re-Conceptualising the Core Competences for Adult Learners in the Knowledge-Based Society

Rosario Sergio Maniscalco, University of Turku, Finland

This paper investigates the intertwinement between the scientific terminology used in the academic research on adult skills in the fields of education and cognitive neuroscience, and the use of concepts such as 'soft skills' and 'key competences' in the organizational and educational policy debate. The prevailing definitions of skills and competences, in fact, do not seem to be adequate to feed the educational policy statements, which seem to give emphasis mainly to the basic skills for adult learners, and a remarkable mismatch with the theoretical frameworks developed in the fields of the education and cognitive science, business and organizational studies has appeared rather evident. The methodology used in this paper is the interpretative concept analysis, which combines the features of knowledge, skills and competences together with recurrent expressions such as 'hard' and 'soft skills', 'key competences' and other labels nowadays widely used in the human resources and political debate. The concept definition is significant, in this scenario, not only for theoretical use, but is intended to be a useful tool for scholars and practitioners. For this purpose, a theoretical proposal seeks to strike a functional balance of the concepts first conceptualized.

Introduction

This article investigates the intertwinement between the scientific terminology used in the academic research on adult skills in the fields of education and cognitive neuroscience, and the use of concepts such as 'soft skills' and 'key competences' in the organizational and educational policy debate. The prevailing definitions of skills and competences, in fact, do not seem to be adequate to feed the educational policy statements, which seem to give emphasis mainly to the basic skills for adult learners, and a remarkable mismatch with the theoretical frameworks developed in the fields of the education and cognitive science, business and organizational studies has appeared rather evident.

BackgroundThe terminological disambiguation is not straightforward. Interesting conceptual research has been carried out by CEDEFOP (an agency of the European Union): Descy & Tessaring (2000), for example, is indeed a first meaningful attempt to conceptualize buzz-word 'soft skills' in the framework of the recent policy statements on skills, but still containing ambiguities and cross-definitions (skills defined as knowledge or experience, competence as capacity to use "know-how, skills, qualifications or knowledge" etc.) and again borrowing a big deal from the business and HR sector. A deeper link with the cognitive science developments on skills, competences and knowledge has been established in a tender also by CEDEFOP to the Groupe ESC Toulouse of the Centre for European Research on Employment and Human Resources (Winterton et al., 2005) containing a very comprehensive scientific review on the issue, where also a new theoretical 'prototype' is introduced in order to solve the incoherence and fragmentation of the former literature reviewed, called "Unified typology of Knowledge, Skills and Competence". Indeed keeping an eye on the mandate of bridging the academic research and the HR literature with the last EU policy documents on competence, skills, qualifications and recognition/validation of previous learning, it reflects well the main trends in the scientific studies on KSA which are more and more often using holistic approaches to the definition of competence (Gonczi, 1994; Tovey, 1993; Engle et al, 2001; Hager, 1994), aiming at "combining knowledge, skills and attitudes" (Winterton et al, 2005: 40).

MethodologyThe methodology used in the paper is the interpretative concept analysis, which combines the features of knowledge, skills and competences together with recurrent expressions such as 'hard' and 'soft skills', 'key competences' and other labels nowadays widely used in the human resources and political debate. The concept definition is significant, in this scenario, not only for theoretical use, but is intended to be a useful tool for scholars and practitioners. For this purpose, a theoretical proposal seeks to strike a functional balance of the concepts first conceptualized.

Theoretical proposal

In the light of the literature review presented in the paper, the only explicit classification of the soft skills is 'by contrast' with the hard skills in terms of wider range of measurability and broader applicability. The measurement of

the outcomes of the skills deployed in a certain situation is strictly correlated to the possibility to analytically approach them for the assessment. According to the most recent research on the functioning of the human brain, and in particular the theory of the brain functions lateralization (Tucker, Shearer & Murray, 1977; Tucker, 1981) and in particular the right-hemisphere hypothesis (Borod, Koff & Caron, 1983; Heilman & Bowers, 1990; Ross, 1985), knowledge can be defined as a conceptual base ('propositional knowledge'), while skill holds the place of the procedural access to the knowledge base and its analytical domain-related use ('hard skills'), while the competence is the operational access to the knowledge base and its global non-domain-related use ('soft competence'). Discussion Especially in view of the mismatch existing nowadays between the learning curricula and the qualifications obtained and the core competences required by the knowledge societies. And as the world has new rules, democracies involve their people in other ways than a few decades ago, and the media have become an incredibly powerful tool to spread knowledge but also a dangerous instrument of mass persuasion. Knowledge is nowadays broadly accessible but, considering the quantity of data available, without scanning and synthesizing skills and without critical thinking it has become almost impossible to organize these data into a coherent and usable framework. In other words, learning how to google does not involve being able to deal with the impressive amount of information this tool can provide, and the political approach of the basic skills-centered curricula for adult learners will soon reveal its limits in the perspective of proactive citizenship in a global and integrated- knowledge and competence-based society.

Searching for a reliable method to listen to the voice of the young child in school.

Anja Tertoolen, Interactum, Netherlands; Bert van Oers, VU University of Amsterdam, Netherlands; Jeannette Geldens, Kempelresearchcentre Helmond, Netherlands; Herman Popeijus, Kempelresearchcentre Helmond, Netherlands

In educational settings teachers always have to deal with children, who have their own images and judgments about the purposes of school, about what is going on there, what you have to or can do, and what is or isn't allowed. Children have the right to be listened to. What do they experience in school? What is the meaning of school? What is their motivation? And if we could answer the formulated questions, what might be the impact of those answers on education for instance? Opinions children have about all kinds of objects are partly determined by social, cultural, historical and biographical influences, as well as elements of context-related interactions (e.g. Bourdieu). The question is then which settings under which circumstances are appropriate to listen to young children taking in account also the notion that the perspective of young children and the way in which they express their views is multiple and changeable. To what extent are the ideas of young children their own? We started our own research project by testing settings, collecting data and building a coding system, using the grounded theory approach. Until now we have carried out a pilot study and two case studies. We'll present and discuss the outcomes of our data analysis, and the measures we took to increase the reliability and construct validity of our research method.

Research aims

In the 'Convention on the Rights of the Child' (1989) it is stated that every child, who is capable of forming his own views, has the right to express his opinions freely in all matters affecting the child (article 12 and 13). In recent years it is assumed that young children have a voice of their own. In the light of this context we raise the question: Is it possible to identify the young child's own voice? From the perspective of educational contexts emphasizing authenticity and autonomy of the child this is a crucial question. This paper reports about a project that aims at the construction of a valid and reliable method for identifying the young child's own voice.

Theoretical and conceptual framework

The theoretical framework of the project is based on the cultural-historical activity theory. From this point of view we start out from the assumption that children should not only be seen as persons who 'become', but especially as persons who 'are' with their ideas, notions, choices and relations (Clark, 2007; Prout, 2003). Children's notions originate from a specific situation, in a specific context in which, besides children, others are involved. In interpreting the children's expressions that specific context needs to be taken in account (Pramling Samuelsson, 2003). Not only the context and the own life history are crucial for the individual's actions, but also the culture in which the individual participates and meets other people. In that sense acting is a form of cultural acting in cooperation with others (e.g. Bourdieu, 1991). Individuals act with the aid of others, who contribute to the activity by being a model, by intervening and/or supporting the agent. In such a context the individual then can connect his actions with emotions, affects and his own motives. In this way the individual can accomplish cultural actions with the help of others and at the same time attach personal sense to his actions. We see here that the autonomy for social participation is developed in cooperation with others (van Oers, 2009). Autonomy can thus be seen as a polyphonic concept, built on different voices, more or less supported by others. A kind of autonomy which is also very diverse, (i.e. different per situation and per person), depending on the life history and culture of the individual, dictated by several others met

by the individual. The voices of those others are not only different; they may also be contradictory (van Oers, 2009). In our research project we focus on voice (expression) and attribution of meaning by young children in situations and events at school, as can be seen and heard in the speaking and acting of these children in interactions with other children and adults. We define attribution of meaning in this research project as the way in which the young child expresses his notions, verbally and non-verbally, on three aspects he encounters in the context of the daily practice of his educational setting: the activities, the organization in the school context and the roles of his teacher or teachers.

Methodology

As yet very little is known about how children's voices should be listened to and reliably interpreted. Due to this situation, it is almost impossible to design experimental research projects for scrutinizing the functional details of children's voices. As we want to study phenomena in real life situations in general, and to answer questions about how we can search for the child's voice more specifically, the most appropriate way in our research project (Yin, 2009) is to use the design of the multiple case study. It enables us to look into meaningful characteristics of young children's school lives by direct observations of young children in the school context and to get a more profound insight in the social process of young children's behavior in context and in the way they experience this context (Wester & Peters, 2004; Yin, 2009). In short, we designed a so called multiple case study (Yin, 2009) with a qualitative-interpretative approach in a flexible design (Robson, 2002). Until now we have carried out a pilot study and two case studies. In each case study a boy and a girl, aged 5 – 6, are involved in interaction with their teacher(s) and peers, while participating and being observed in several activities in school during a week: Observations during daily school activities, playing school in the play area, taking photos and talking about them, answering questions and taking part in an interview. An interview with their teacher(s) and their parents is part of the research design as well. Following the grounded theory approach (Glaser & Strauss, 1967) we analyzed the data first by observing the child in his or her social reality of school life with a researcher participating in the observed educational setting. We have described the way in which we aim to build a method for researching attribution of meaning by children aged 5 to 6 in school, and we have set the first steps in developing a coding system for analyzing elements of the voice of the young child (Tertoolen, van Oers, Geldens & Popeijus, 2010).

Main findings and discussion

One of our main concerns in this research project is the question if it is possible to develop a reliable method to listen to the young child. We follow for instance Yin (2009) in his three principles of collecting evidence in case study research: using multiple sources of evidence, creating a case study database and maintaining a chain of evidence. To increase the reliability of the information we found in our case studies, we have also invited external observers screening the data. They use independently the same coding framework as the internal observer did before. This process is still going on. At the conference we'll present and discuss the outcomes of these processes of triangulation, related to the issues of reliability and construct validity.

Feedback clickers in plenary lectures

Rune Krumsvik, University of Bergen, Norway

This paper focuses on if, and eventually how, feedback clickers (TurningPoint™) can be used to overcome some of the challenges lecturers have in large plenary lectures. The Bologna-process, new standards for national curricula, increasing diversity among university students, the Network society and the digital revolution have changed some of the underlying premises for teaching and learning in today's universities. New policy documents, research and experiences from the university field suggest that there is a potential to develop plenary lectures in light of new technology and more updated teaching methods. A new concept, digital didactics, is underpinning this time of upheaval and this case study focus on how psychology students in large plenary lectures experience the use of feedback clickers from their points of view. This case study consist of surveys, 'live surveys', observations and document studies and shows that the students feel quite positively towards several of the areas focused on in the study. In particular, the feedback clickers have the potential to enhance interactivity, attention and reflection, as well providing feedback, which seem to be of great value for the students in the study. One of the implications of this article is that good planning, the use of feedback clickers and multimodality in plenary lectures seem to overcome some of the well-known challenges in plenary lectures and strengthen the possibility for formative assessment.

This paper focuses on if, and eventually how, feedback clickers (TurningPoint™) can be used to overcome some of the challenges lecturers have in large plenary lectures (100-500 students) at universities. This has become more pressing as a result of the Bologna process (1998, 2005, 2007) with the new degree system (Bachelor/Master's degrees and Diploma Supplement), the European Credit Transfer System (ECTS, Bologna process 2007), The Quality Reform (Ministry of Knowledge, (MOK), 2001), the establishment of the Norwegian Agency for Quality Assurance in Education

(NOKUT 2005), The White Paper 16 (MOD 2006) focusing on lifelong learning, Tuning Educational Structures in Europe (Tuning, 2009) and the new Frame Work for Qualifications (MOK, 2010). All of these demand that student curricula in Norway must be more specifically formulated around learning outcomes as well as the use of (Information and Communication Technology (ICT) as a tool in teaching and student learning processes. This also implies a higher awareness towards the increasing diversity among university students which needs innovative ways of engaging students who might have previously experienced educational alienation. Every university lecturer has experienced the same problem: how to reach the students in plenary lectures when there are several hundred students. Lecturers have tried different remedies throughout history, such as prompting questions and raising hands, for example, but in large classes, like plenary lectures, there are several disadvantages with these kinds of traditional strategies: Many students feel uncomfortable raising their hands in large plenary lectures because they are afraid of giving wrong answers (Caldwell 2007). Another aspect of the same issue is that the students "will vote with the majority" and not give their honest votes or answers in plenary lectures (Caldwell 2007). The minority of students who want to speak up can very often be associated as representatives for the majority of students (Caldwell, 2007). Increased diversity among university student makes it necessary to engage students in more creative ways in large plenary lectures. The average human attention span is no longer than 20 minutes (Burns 1985) and there is a mismatch between this fact and traditional "chalk and talk" lectures in universities. Several of these frame factors have always been there as hindrance to interactions in plenary lectures and it is large challenge for lecturers to give meaningful lectures. Even if we still have many of the same problems and challenges with plenary lectures today, the digital revolution and the Network society (Castells 2001) over the last ten years has altered some of the underlying conditions for teaching and learning. Lifelong learning and an increasing diversity among university students has given both new challenges and possibilities for university teachers which have pedagogical implications. These new educational streams and policy regulations create a situation which calls for a revitalisation of pedagogy in general and the more specific term didactic[1](Hopmann, S. & Riquarts, K. (2000), where one has to elaborate how new concepts, digital didactics (Krumsvik and Almås, 2009) and ICT (more specifically feedback clickers), can function (or not) as remedies to fulfil some of these new policies and also how well they can overcome some of the well-known pitfalls in plenary lectures. The aim of this case study (Yin 2009) was to examine the perceptions of psychology students on the use of feedback clickers in plenary lectures in relation to their own learning processes. The question considered by this article was: What perceptions do psychology students have of feedback clickers in plenary lectures in relation to their own learning aims and learning outcomes? The sample consists of 200 psychology students and was based on purposeful selection (Maxwell 2005). The methods used in the study was semi-structured interview (Kvale & Brinkmann 2008), quasi statistics (Maxwell 2005), observations (Merriam 2009), document analysis (Merriam 2009). Triangulation and respondent validation were used to enhance the validity in the study. Data analysis was carried out by content analysis (Kvale & Brinkmann 2008) and NVivo (Qualitative Analysis Software). Preliminary results show that the feedback clickers have the potential to enhance interactivity, attention and reflection, as well providing feedback (Hattie & Timperley (2007) for the students.

Processes Mediating Expertise in a Visual Task: Eye Movements, Verbal Reports, and Spatial Abilities

Halszka Maria Jarodzka, Open University of the Netherlands, Netherlands; Ludo van Meeuwen, Open Universiteit Nederland, Netherlands; Saskia Brand-Gruwel, Open University, Netherlands; Jeroen Van Merriënboer, Maastricht University, Netherlands; Jeano de Bock, Air Traffic Control The Netherlands, Schiphol-Oost, Netherlands; Paul A. Kirschner, Open Universiteit, Netherlands

Operators of air traffic control (ATC) stations deal with complex visualizations involving many airplanes that must be navigated towards one airport. Making decisions based on those visualizations requires not only domain knowledge but also perceptual skills, like efficient visual search of critical airplane compositions, their quick and correct interpretations, and the appropriate decisions. This study compared 21 participants of three different expertise levels in interpreting ATC stimuli to investigate the role of perceptual skills in this task. ATC performance, eye movements, verbal reports, and spatial abilities were recorded for three task difficulties. Results show that novices performed this task slower than intermediates ($p=.01$) and experts ($pp=.06$) and experts ($p=.05$). Eye tracking data revealed that participants did not differ in total viewing time on the airplanes, but in total viewing time at the airport position. In that, novices looked significantly longer at this area than intermediates (pp

To understand expertise, it is important to investigate its mediating processes and individual characteristics (Ericsson & Lehman, 1996). This has already been done in detail for cognitive processes (e.g., Boshuizen & Schmidt, 1992). For tasks that involve interpreting visualizations, however, not only the cognitive, but in particular the perceptual processes play a crucial role. In these cases expert performance comprises perceptual skills, i.e., the ability to perceive relevant information in complex visualizations and to draw inferences based upon the perceived information. However, not much is known in this topic, yet (for an exception see Jarodzka, Scheiter, Gerjets, & Van Gog, 2010).

Furthermore, literature about the relation of spatial abilities to expert performance is contradictory (e.g., in chess: Frydman & Lynn, 1992; in ATC: Kirchberger, Heintz, & Laaser, 2010).

In sum, in domains that involve complex visual stimuli not much is known about how experts allocate their attention during task performance, how this differs from novices and intermediates, and how this is related to individual characteristics, like spatial abilities. Hence, the present study examined the interplay between perceptual processes (measured by means of eye tracking) and cognitive processes (measured by means of verbal reports) as a function of expertise and its relation to spatial abilities in the domain of ATC.

Method

Participants in the study were 21 individuals with three different levels of expertise (mean age 28.33 years; 5 females). In that, ten participants were experts (full licensed air traffic controllers with at least two years of work experience), five intermediates (final phase of the ATC training), and six novices (initial phase of the ATC training). The experiment was run in individual sessions of approximately 60 minutes. Participants received nine static visualizations of an ATC radar situation composed of a number of inbound airplanes towards an airport and were asked to determine the optimal order of arrival for all planes. The nine trials were composed of three different difficulty levels and were presented in a counter balanced manner. During task performance, eye-movements of participants were recorded with a Tobii 1750 eye tracker (50 Hz). After each trial, participants reviewed the recordings of their own eye movements superimposed on the stimulus and verbalized the thoughts they had while performing the task (cued retrospective reporting; Van Gog, Paas, Van Merriënboer, & Witte, 2005). Finally, participants filled in the mental rotation test (Vandenberg & Kuse, 1978).

Results

Time on task differed for all nine radar screens significantly between conditions ($p=.01$) and than experts ($p=.12$). Similar results were found for the three task difficulty levels. No differences were found for overall mental effort ratings ($p=.18$). Univariate analyses of the three task difficulty levels separately showed that experts experienced significantly less mental effort than novices ($p=.05$) and marginally less than intermediates ($p=.06$). There was no difference between groups for medium ($p=.29$) and for difficult tasks ($Fp=.67$), neither for easy ($p=.09$), medium ($FFpppF$)

Discussion

These results indicate that a higher expertise in the domain of ATC is not related to higher spatial abilities. This, however, does not mean that spatial abilities are not important for ATC. As novices in this study were already preselected to be trained as air traffic controllers, it is possible that they already have high spatial abilities in comparison to non-ATC people. Moreover, experts were faster in performing the easy ATC tasks while investing less mental effort compared to novices and intermediates. This indicates the superiority of experts in this task. Further analyses of the performance data will indicate, whether they are also more efficient. Interestingly, participants did not differ in terms of looking time at the to-be-navigated airplanes. Instead, experts looked less at the airport region. These results indicate that experts have a well established mental model of the airport surroundings such that they do not need to look at the airport to navigate the airplanes towards it. The findings of this study will inform professional education not only in ATC, but also in other domains comprising comparable complex visualizations (e.g., medical specialists, pilots, train traffic controllers).

Personal epistemological and metacognitive awareness (PEMA) in first year university students.

Erika Spray, University of Newcastle, Australia; Jill Scevak, University of Newcastle, Australia; Robert Cantwell, University of Newcastle, Australia

This paper reports a study of preservice teacher education students' developing personal epistemological and metacognitive awareness (PEMA). The study has significance in two areas: in developing the theoretical relationship between personal epistemology and metacognition, and their relationship to self-regulation in learning; and in the practical implications of this for developing the capacity of first year university students to manage the intellectual demands of university study. Text analysis of students' reflective journals produced as part of a first year degree course was undertaken for evidence of PEMA and self-regulation of learning and their relationship to academic success. Relationships were found between PEMA, self-regulatory behaviours and academic performance. The results have implications for first year pedagogical practice to better equip students for successful tertiary study through encouraging higher awareness.

Study of knowledge, or epistemology, has long challenged philosophers; Plato, Socrates and Descartes grappled with the ambiguity of human sense and sensibility. To this day, such issues remain unresolved, yet we depend on knowledge to inform decision-making at every level. The framework within which individuals interpret, accept or reject information is termed personal epistemology (PE) (Hofer & Pintrich, 1997). PE provides an oft subliminal matrix to frame the metacognition by which we interpret our environment, generating meaning and understanding. This process underpins self-regulation, including self-regulation of learning (SRL): the activation and maintenance of cognitions and behaviours oriented toward attainment of learning goals (Zimmerman, 1986).

Clear definitions are often lacking in educational research (Schunk, 2008) and the obvious conceptual overlap which occurs between constructs can easily lead to confusion or misinterpretation of findings, as well as contributing to weaknesses of discriminant validity (Mussel, 2010). Increased effort is required to achieve conceptual clarity of constructs in order to facilitate effective collaboration and to 'focus the conceptual lens' (Dinsmore et al., 2008). This research focused on personal epistemological and metacognitive awareness (PEMA): individuals' conscious recognition and consideration of their own epistemology and metacognition. Such conscious deliberation necessarily forms part of wider metacognition, or 'thinking about thinking', hence a degree of conceptual overlap exists despite the two terms being in no way interchangeable. Similarly, while metacognition is intimately connected to self-regulation by monitoring and controlling cognition, self-regulation and SRL span both cognitive and behavioural domains. (see Dinsmore et al., 2008). Despite its significance for metacognition and thus learning, personal epistemology often operates implicitly: 'assumed' rather than consciously constructed convictions.

The aim of this study was to analyse first year university students' reflective learning journals for evidence of explicit personal epistemological and metacognitive awareness (PEMA) and self-regulated learning to explore the relationship between these constructs and academic performance.

The reflective learning journals of 18 pre-service teacher education students were analysed using content analysis. Students were required to keep a reflective learning journal that was not directly assessed but which would inform an essay that was part of their assessment. The journal and the essay was part of their undergraduate Educational Psychology course conducted in Semester 1 in their first year of university. The journals were selected for analysis on the basis on participants' academic performance in the course, with 1/3 representing the highest achievers, 1/3 the lowest and 1/3 who achieved medial results. The first six weeks of journal entries were analysed, which represented most students' first tertiary experience, so it was anticipated that this challenge may have stimulated PEMA. The journals were produced quite freely, without probing from interviewers or direction from questionnaire items that might impose a framework upon subsequent results. It was therefore expected that only students' explicitly held beliefs were represented, providing direct insight into PEMA and enabling candidness and depth of reflection not always achieved through interviews or questionnaires (Hoover, 1994). This methodology was therefore appropriate and valid for investigating PEMA.

At the end of Semester 1 and after students' final grades were awarded, first year students were invited to participate in the study by giving consent for their journals to be used in the study and consent for their grades in the course to be accessed. Therefore students were not aware of the focus of this research before producing their journals, and this

latency of purpose reinforced the intention that only consciously explicit PEMA was reported, without distraction or bias from external encouragement. As all evidence was self-generated, it was the participants themselves who identified what they considered sufficiently significant to record. This resulted in far greater authenticity than might otherwise have been achieved.

The results of the analysis showed a relationship between PEMA, self-regulated learning and academic performance. Students with higher academic grades produced clearer evidence of PEMA and self-regulatory behaviours. There was a positive relationship between students who reported PEMA, self regulated learning and academic performance. Conversely, students who produced less evidence of PEMA and self-regulated learning were not as successful in their academic performance.

This study contributes to the literature by using text analysis to focus on epistemological awareness as opposed to beliefs or assumptions. It is very difficult to access individuals' actual personal epistemology without risking distortion of data through 'led' methodology such as questionnaires, or influencing responses through the pressure of an interview situation. Awareness, on the other hand, can be observed without such imposition of a research framework. The insights provided by this study are thus drawn from authentic data interpreted through strong theoretical foundations, thereby directly informing pedagogical design to aid students' development of adaptive beliefs to facilitate wider achievement.

Many students enter university showing great naivety (Brownlee et al, 2009), and various techniques have been proposed to support first year students practically and to illustrate academic conventions such as referencing. However, given the results from this study, it may also be helpful to illuminate the process of learning itself, showing students how to develop themselves as effective learners. These findings support previous claims that students' personal epistemology can be influenced by their educational experiences (e.g. Lehrer, Schauble & Lucas, 2008), and indicate that developing stronger PEMA supports achievement of successful academic outcomes. This adds weight to the argument that epistemological considerations should form part of any effective pedagogy. Better understanding of PEMA will enable tertiary educators to provide more effective teaching and learning, particularly for the inclusion of students who may otherwise struggle to successfully engage with tertiary education.

ROUND TABLE

Teaching self-evaluation: a research with Padova University teachers

Raffaella Semeraro, University of Padova, Italy; Debora Aquario, University of Padova, Italy

The University of Padova (Italy) has launched an initiative to promote self-evaluation of teaching by teachers on the basis of the current guidelines of the literature concerning self-evaluation based on self-reflection about the teaching practices (Clegg, 2000; Kane et al., 2004; Kinsella, 2007; McAlpine et al., 2004; Seldin, 1999). In this perspective, the Governing Council of the University promoted a project about teaching self-evaluation and a working group (Commission) including representatives from each of the thirteen Faculties of the University was instituted.

In a first step, the Commission has considered several models and instruments of teaching self-evaluation adopted internationally (the model developed by Seldin, 1999 and some instruments of self-evaluation used by teachers in different universities -Flinders University of Adelaide, Harvard, Berkeley-) in order to develop an initial version of a questionnaire composed by 55 items divided into four sections: 1) organisation of the course; 2) classroom practice; 3) assessment criteria of students' learning; 4) students' outcomes (5-points Likert scale). The questionnaire was emailed to 2000 teachers of Padova University and 1158 of them answered.

After an initial descriptive analysis of the answers, factor analysis has allowed the emergence of four factors (high levels of Cronbach's Alpha). Anova test has revealed significant differences based on the different Faculties.

The findings will be used in order to promote the implementation of self-evaluation procedures in the University and to foster self-reflection in a context of change and improvement of instructional practice.

The University of Padova (Italy) has launched an initiative to promote self-evaluation of teaching by teachers on the basis of the current guidelines of the scientific literature concerning not only the external evaluation of the performance of teachers, but also the self-evaluation based on self-reflection about the teaching practices (Clegg, 2000; Kane et al., 2004; Kinsella, 2007; McAlpine et al., 2004; Moon, 1999; Seldin, 1999). The initiative is part of a three-year plan of development of evaluation models and tools aimed to the improvement of the educational offer of the University. It is the first initiative focused on self-evaluation in this University, where teachers have always been assessed only by students.

In this perspective, the Governing Council of the University promoted a project about teaching self-evaluation aimed at focusing teachers' attention on the importance of self-reflection about their own teaching practice. Under the direction of R. Semeraro, a working group (Commission) including representatives from each of the thirteen Faculties of the University of Padova was instituted in order to conduct a research with the aim of developing teaching self-evaluation procedures.

The recent literature suggests different models for teaching evaluation, all of them sharing the same principle, that is the active involvement of teachers in the evaluation process. Among the most relevant of these models: the participatory evaluation (Cousins, 2003; Scriven, 2003), the empowerment evaluation (Fetterman, 2003), the deliberative democratic evaluation (House and Howe, 2003), the collaborative evaluation (Lincoln, 2003). All these models are based on the assumption of the importance of bottom-up processes, where evaluation is to be considered as a complex process not only directed to the collection of quantitative data, but strongly linked to the assumption of responsibility by all actors involved (Semeraro, 2006). It seems fundamental to adopt a model of participatory, collaborative and democratic evaluation, where teachers are not only assessed from someone else, but become active players in this process.

Basing on these premises, the specific objectives of the research here presented are the following: a) to explore a wide range of models and instruments of teaching self-evaluation; b) to develop a map of aspects of the teaching practice considered important for self-evaluation; c) to develop a teaching self-evaluation instrument to be used by teachers with the aim of reflecting on and evaluating their own teaching practice.

In a first step, the Commission has considered several models and instruments of teaching self-evaluation adopted internationally. Among others, the model developed by Seldin (1999) and some instruments of self-evaluation used by teachers in different universities (Self-Evaluation Inventory of Flinders University - Adelaide, Harvard and Berkeley University) were taken into account. In a second phase, the discussion within the Commission about these models and instruments led to the identification of a set of aspects regarding the instructional practice and to the development of an initial version of a questionnaire. After multiple revisions of the items (through the administration to groups of teachers), the questionnaire results to be composed by 55 items divided into four sections: 1) organisation of the course; 2) classroom practice; 3) assessment criteria of students' learning; 4) students' outcomes (Dublin Descriptors). In addition, there was an empty space in which respondents could indicate other aspects not considered in the questionnaire. Respondents have expressed their points of view about the relevance of the aspects considered in the instrument through a 5-points Likert scale (from "really important" to "not important") plus "not applicable". Respondents were asked to indicate the degree of relevance of each aspect for self-evaluation. The questionnaire was emailed to 2000 teachers of Padova University and 1158 of them answered.

After an initial descriptive analysis of the answers (frequencies, means and percentages), factor analysis has allowed the emergence of four factors (high levels of Cronbach's Alpha): Design and planning of the course, Revision of teaching practice on the basis of students' reactions; Promotion of critical thinking and skills; Use of multiple teaching methodologies. Anova test has revealed significant differences based on the different Faculties.

The findings, that will be presented and discussed in detail, will promote the use of self-evaluation procedures in the University in a context of change and improvement of instructional practice. The next step is constituted by the involvement of each Faculty Dean in the discussion of the results with teachers and in the utilisation of the questionnaire as a proposal for reflection and a guide for the elaboration of a teaching self-evaluation instrument.

Implications for future research and practice concerning undertaking a process within the University to support teachers in the implementation of self-evaluation procedures will be presented and discussed.

Model Competence in Biology Education – Evaluation of a Theoretical Structure using Hands-On Tasks

Juliane Haensch, Humboldt-Universität zu Berlin, Germany; Annette Upmeyer zu Belzen, Humboldt-Universität, Germany

Working with models is an effective way for students to attain basic aims of Science Education (Hodson, 1993; Henze et al., 2007). In this way, not only declarative subject matter knowledge, but also procedural knowledge and manual skills are obtained. The latter are difficult to measure with paper-pencil tests whereas hands-on tasks are an adequate method for such purposes (Hamilton et al., 1997). Modelling skills and applied individual concepts about models are each described in two dimensions of the theoretical structure of model competence (Upmeyer zu Belzen & Krueger, 2010). In this study, problem-oriented hands-on tasks were developed based on this structure. The tasks aim for measuring students' model competence to empirically evaluate the theoretical structure. The tested students (grade 7 to grade 10, Gymnasium) are videotaped. Knowledge about models is covered by two instruments: thinking aloud protocols and a semi-structured interview. The data are analyzed using qualitative content analysis (Mayring, 2003). Students' activities and students' answers are assigned to the theoretical structure using coding manuals. The results of the pilot study indicate that the theoretical model fits to empirical data. Results of the main study in spring 2011 will provide a broader data basis for these findings that will be presented at the Earli 2011.

Relevance

Science can neither be taught nor learned without models (Harrison & Treagust, 2000). Models are not only seen as means to teach scientific knowledge, but also defined as scientific thinking and working tools to generate new knowledge (Stachowiak, 1973; Mahr, 2009; Upmeyer zu Belzen & Krueger, 2010). That is why model competence is also considered as a "door opener" to an elaborated understanding of the nature of science (Leisner, 2005) and as a part of Scientific Literacy (Gilbert & Boulter, 2000).

However, many studies have shown that both students (Meisert, 2008; Trier & Upmeyer zu Belzen, 2009) as well teachers (Justi & Gilbert, 2002; Crawford & Cullin, 2005) have a limited view on the role of models as a scientific inquiry tool. In school everyday life, models are mainly used for visualization and hardly considered as research tools (Treagust et al., 2002).

Theoretical Background

Model competence includes skills to gain useful findings with models and the willingness to apply these skills to solve problems (Upmeyer zu Belzen & Krueger, 2010). In the theoretical structure of model competence, skills needed in scientific inquiry with models are described in the dimension 'modelling' with the aspects 'purpose of models', 'testing models' and 'changing models' (Upmeyer zu Belzen & Krueger, 2010). The dimension 'knowledge about models' with the aspects 'nature of models' and 'multiple models' describes individual concepts that are applied when dealing with models (Upmeyer zu Belzen & Krueger, 2010). Each aspect of model competence is differentiated in three levels of reflection about models (Upmeyer zu Belzen & Krueger, 2010).

Handling models leads to practical skills on the one hand and an understanding of epistemological beliefs on the other (Mayer, 2007). If students experience themselves in problem-solving by using models, they comprehend models as scientific inquiry tools more easily (Grosslight et al., 1991). This project provides two approaches of fostering model competence: The evaluated hands-on tasks can be used as teaching modules for scientific inquiry with models. The coding manual can help teachers to evaluate their students' model competence.

Aims

Until now, cooperating projects (Grýnkorn & Krueger, 2010; Terzer & Upmeyer zu Belzen, 2010; Krell & Krueger, in press) developed open-ended, multiple-choice and forced-choice tasks with the objective of empirical evaluation of the theoretical structure of model competence. The use of different instruments allows the investigation of various facets of model competence (White & Gunstone, 1999). However, this should not be limited to paper-pencil tests, because they hardly measure procedural knowledge and manual skills (Hamilton et al., 1997). That is why this study aims for the empirical evaluation of the theoretical structure (Upmeyer zu Belzen & Krueger, 2010) using problem-oriented hands-on tasks. With this objective, this study will respond to the following questions:

. To what extent is model competence empirically observed applying hands-on tasks?

Hypothesis 1: The students' activities as their statements can be assigned to the theoretical structure.

. In which way are the results of the paper-pencil tests of model competence related to those of the hands-on tasks?

Hypothesis 2:

2 a) Hands-on tasks interrelate to open-ended, multiple-choice and forced-choice tasks, as the development of all task formats is based on the same theoretical structure.

2 b) Hands-on and open-ended tasks lead to similar results in the dimension 'knowledge about models' and the aspect 'purpose of models' since both go back to abstract student concepts about models. 2 c) The results of hands-on and multiple-choice tasks are more closely connected to the aspects 'testing models' and 'changing models' since both include concrete experimental conditions. 2 d) Compared to the open-ended and multiple-choice tasks, hands-on and forced-choice tasks are less closely related to each other, since forced-choice tasks measure model competence in the most abstract way. In contrast, hands-on tasks deal with application-based knowledge and actions of students. Hypothesis 3: Dealing with hands-on tasks, students achieve higher levels than dealing with paper-pencil formats, as students activate more concepts when solving a concrete problem actionally.

. Which aspects of model competence do the activities of students reveal which are poorly covered by paper-pencil items?

H4: In addition to cognitive aspects, hands-on tasks also include procedural aspects of model competence (Ruiz-Primo & Shavelson, 1996).

Methodology

Hands-on tasks are a form of performance assessment and measure especially manual skills and domain-specific knowledge (Baxter & Shavelson, 1994). To cover also the practical facet of model competence (Schecker & Parchmann, 2006), six problem-oriented hands-on tasks were developed on the basis of the theoretical structure. They are characterized by posing a problem and offering students (grade 7 to grade 10, Gymnasium) concrete material for problem-solving in biology (Hamilton & Nussbaum, 1997). In this process, a hypothetical, deductive procedure is required to register students' scientific comprehension via models (Shavelson & Ruiz-Primo, 1999). The tasks were designed using contexts familiar to students in order to support an ambitious problem-solving (Brown, Collins & Duguid, 1989).

The optimal method to cover the behavior and actions at hands-on tasks is the observation (Ruiz-Primo & Shavelson, 1996). To detect students cognitive processes, the students are requested to think aloud when building their own models (Glaser et al., 1992). At the same time, a semi-structured interview points out the knowledge about models (Grosslight et al., 1991). The processing of the hands-on tasks is audio- and videotaped. The audiodata are analyzed by qualitative content analysis (Mayring, 2003). Students' activities and students' answers are assigned to the theoretical structure using coding manuals.

Findings

A first pilot study with 3 students shows that the hands-on tasks can be solved by the students and that the results are compatible to the theoretical structure. As part of ongoing preliminary investigation, 3 students per grade (7-10) solve each 3 hands-on tasks (N=12 students). Coding manuals for the video and the audio data are created on this database. Both are used in the main study with a larger sample (N = 24) for an empirical evaluation of the theoretical structure using hands-on tasks. These results will be available in spring 2011 and will be presented at the Earli 2011th.

Design of a University-Level Instrument for Direct Writing Assessment (DWA)

Jorge Manzi, Pontificia Universidad Catolica de Chile, Chile; David Preiss, Pontificia Universidad Catolica de Chile, Chile; Paulina Flotts, Pontificia Universidad Catolica de Chile, Chile

We present an initiative of direct writing assessment (DWA) implemented in Chile. DWA involves relevant assessment challenges, which include those related to the generation of writing prompts and the rating process. We describe the 2008 round of application of the assessment and how we addressed these challenges. 3612 students took the test in 2008. The assessment used involved 50-minute argumentative tasks. The examinees obtained better scores in content related aspects of the writing (such as structure, text cohesion and thesis), while the worst scores corresponded to two dimensions related to the formal aspects of discourse (orthography and vocabulary). Counter-arguing also showed a low average. If we compare these results across time, we can notice that there has been a steady increase of the scores in all of them excepting orthography. The 76.8 percent of the assessed students obtained scores equal or over to the grade established to pass the exam (3 points). Average differences among academic programs are relevant: the difference between the program with best and worst average represented one and a half standard deviations. The results show that DWA is a good predictor of academic achievement and suggest that the ability to

produce a text and the verbal skills required in multiple choice tests are differentiated. Of particular relevance for Chile, DWA has a minor correlation with socioeconomic measures than other university entry conventional tests.

Aims

The purpose of this paper is to present an initiative of writing assessment implemented in Chile. Large-scale writing assessment has a broad appeal because it has some attributes that make it distinguishable from other assessment tools (Powers, Fowles, & Willard, 1994). Writing tests are commonly labeled as direct writing assessment (hereafter, DWA) since the skills that are the target of measurement are assessed directly. In contrast to multiple-choice tests, which measure latent constructs, writing tests do not measure a latent ability. Provided that measurement standards are established precisely, writing abilities can be assessed in a straightforward way.

Renewed interest for writing in higher education have been instigated by the evidence suggesting that, after twelve years of schooling, only a small group of students are able to produce high quality text (Johnstone, Ashbaugh, & Warfield, 2002; The National Commission on Writing in America's schools and colleges, 2003). Notwithstanding the relevance of written communication skills (hereafter, WCS), it was only recently that educational institutions started to seriously taking systematic assessment of these skills into account (Hamp-Lyons, 2005; Jeffery, 2009; Norris, Oppler, Kuang, Day, & Adams, 2004). In Chile, awareness of the students' deficits in WCS has prompted many institutions to implement writing assessment initiatives either as a graduation requirement or for diagnostic purposes. Specifically, at the Pontificia Universidad Catolica de Chile, since 2003 we have been working in developing a test whose approval is required for graduation.

Writing Assessment involves relevant assessment challenges present across the whole testing process. These challenges include those related to the generation of writing prompts, the definition of the construct and the rating process. Next, we proceed to describe the 2008 round of application of the test and how we address these challenges. Although the results of this round were very similar to previous ones, we present the average profile of students in the dimensions assessed for 2004, 2006 and 2008.

Methodology

Participants. 3612 students took the test in 2008.

Procedure. The assessment used involved 50-minute argumentative tasks. The students were presented with three topics and asked to produce a 2-page essay on a theme of their preference, among three possible alternatives. We excluded themes that were related to specific disciplines to avoid possible biases.

An analytic rubric was used for grading. The rubric distinguishes five performance levels in the different dimensions that are object of assessment: orthography, vocabulary, global structure, textual cohesion, use of sentences, argument quality, thesis, consideration of counter arguments, global assessment.

All the essays were assessed using two raters. 95 percent of discrepancies were less than 1 point, which was established as the critical point. In the few cases where discrepancies between raters exceeded 1 point, a third rater (a supervisor of the assessment process) assigned the final score. In all other cases, the final score was the mean of the two scores produced by the raters.

Final score. The final score for each essay was computed as the mean for each one of the nine dimensions assessed in the rubric. This value was reported with one decimal. The final score shows an adequate level of consistence (Cronbach's $\alpha=0,72$), which supports the use of this global score as a synthesis of the different assessed aspects.

Findings

The students did not perform in a similar way across the different dimensions of the rubric. The examinees obtained better scores in content related aspects of the writing (such as structure, text cohesion and thesis), while the worst scores corresponded to two dimensions related to the formal aspects of discourse (orthography and vocabulary). Counter-arguing also showed a low average. As shown in Figure 1, If we compare these results across time, we can notice that there has been a steady increase of the scores in all of them excepting orthography. On the other hand, in the 2008 assessment we noticed an increase in text cohesion whereas the global assessment has a similar average across the years, excepting 2006.

The 76.8 percent of the assessed students obtained scores equal or over to the grade established to pass the exam (3 points). Average differences among academic programs are relevant: the difference between the program with best and worst average represented one and a half standard deviations.

The scores in the essay were correlated with the scores of students in the national admissions tests (PSU) and high-school grades. Correlations are higher with the verbal ability test ($r=.25$) than with the mathematics ability test ($r=.09$), confirming that the essay is more related to the verbal domain. Correlations with average high school grades fell in between ($r=.17$). We calculated –separately for each academic program- the correlation between the essay score and the students GPA. As shown in Table 1, results indicate that WCT performance is positively correlated to academic achievement in most undergraduate programs, with an average correlation of .12.

We assessed how much the scores in the essay were correlated with socioeconomic antecedents, as measured by parent's education. The results, shown in Table 2, indicate that the essay score is less correlated with socioeconomic background than the tests used in university admissions.

Theoretical and educational significance of the research

The results show that DWA is a good predictor of academic achievement. Consequently, DWA may be used either as an entrance test or as a graduation requirement. Since correlations with the verbal tests are only moderate, these results indicate that the ability to produce a text and the verbal skills required in multiple choice tests are clearly differentiated. Of particular relevance for Chile, DWA has a minor correlation with socioeconomic measures than other university entry conventional tests. This finding must be interpreted cautiously, since it may be a consequence of the lack of attention given to writing in the school system.

Although this test measures a generic argumentative genre, its results are predictive of academic performance in a wide range of academic disciplines. The question remains whether this test will predict good quality writing across a different number of professional genres once their specific writing styles settle in.

Using artifacts in videotaped interviews about the earth with four to six years old children

Asa Larsson, department of education, Sweden; Ola Hallden, Stockholm University, Sweden

Preschool children were interviewed once a year during three years from the year they were four with the aim to describe their developing conceptions of the earth. We describe their development of models and how these were scaffolded by different conceptions introduced during the course of development. The interviews were videotaped by a stationary camera and then transcribed including gestures and bodily movements. During the interviews the children were presented different artifacts. The artefacts used in the interviews—for example, the terrestrial globe and the drawings—together with the interlocutors constituted a relationship that made negotiations of meaning possible. The results show that the children described models similar to earlier findings with regard to older children. For the children the incentive for changing ideas about the earth was their problem solving activities. Conceptual change involves a simultaneous processing of information and complex conceptions, on the one hand, and revisions and changes at a model level on the other. This directs the focus of conceptual change from specific conceptions to structural changes.

Using artifacts in videotaped interviews about the earth with four to six years old children Aim Preschool children were interviewed once a year during three years from the year they were four with the aim to describe their developing conceptions of the earth. We describe their development of models and how these were scaffolded by different conceptions introduced during the course of development.

Methodology

During a three year period 29 preschool children were interviewed about their conceptions of the earth. In the first interview they were about four years old and in the last about six years old. The interviews were videotaped by a stationary camera and then transcribed including gestures and bodily movements. During the interviews the children were presented different artifacts. Data analysis In the analysis the problems the children encountered were identified and how they solved these problems was described (Halldén, 1988). In short, this means reading through the transcriptions of the interviews several times as well as looking at the videotapes for bodily movements and gestures important for the interpretation. Trying to find out what the children talked about also means deciding upon which topic their utterances are relevant to. This also included deciding on the contexts for their explanations. In interviews we cannot take for granted that interviewees use words and expressions like we do as interviewers or in the way they are used in specific speech genres like for example in physics (Halldén, Haglund, & Strömdahl, 2007). In particular, this is pronounced when interviewing very young children, sometimes turning into a situation quite similar to radical interpretation (Davidson, 2001). For example, children use prepositions in quite unpredictable ways. Proposing that people live in the earth does not unequivocally mean that they live inside the earth. The children participating in this study often used gestures and bodily movements in their communication. For example, they pointed upwards to

explain the location of the earth, and they pointed out things on their drawings when explaining them, and showed different things on the representations of the earth. In deciding on the interpretation of meaning of words these instances often were of decisive importance. The process of interpretation already began during the interviews. The interviewer tried to understand the child by ascribing coherence to the child, and it is out of this understanding that the interviews proceeded. This can be regarded as a negotiating process (Fontana & Frey, 2005). At times, this took the explicit form of a triangulation process (Davidson, 2001). A prerequisite for understanding in a dialogue, according to Davidson (2001), is the possibility of referring to a common outside world. By pointing at something in a shared world, we can ask the speaker to assent to or disagree with the specific use of words. The artefacts used in the interviews—for example, the terrestrial globe and the drawings—together with the interlocutors constituted a relationship that made triangulation possible. In the subsequent analysis of the transcriptions and videotapes, these negotiations were often of decisive importance for deciding what problem the child was struggling with (cf. Ehrléên, 2008; 2009; Lindar, Almqvist, & Östman, 2010). The interpretation was done in a holistic fashion by looking for coherence in three respects; first, within the individual interview, second, related to other children, and third, according to development at an individual as well as group level.

Results

The children described models similar to earlier findings with regard to older children (Nussbaum, 1979; Vosniadou & Brewer, 1992). Contrary to Hannust and Kikas (2010) it was here possible to identify models of the earth already when the children were four years old. For the children the incentive for changing ideas about the earth was their problem solving activities. This process was affected by incoherencies revealed in a relation between at least three entities, that is, two or more different facts or conceptions that conflict and this when related to one specific context. Conceptual change involves a simultaneous processing of information and complex conceptions, on the one hand, and revisions and changes at a model level on the other. This directs the focus of conceptual change from specific conceptions to structural changes.

Discussion

Conceptual change is often described as a causal process in which changes in an embraced system of beliefs result in a new system of beliefs. Here, it is argued that conceptual change is better understood as an intentional activity with regard to the learner, that is, what the learner is doing when trying to understand something.

Global Education for Social Justice

Charalambos Vrasidas, CARDET - University of Nicosia, Cyprus; Katerina Theodoridou, Centre for the Advancement of Research & Development in Educational Technology, Cyprus; Michalinos Zembylas, CARDET - Open CY, Cyprus; Christiana Aravi, CARDET, Cyprus; Sotiris Themistokleous, CARDET, Cyprus; Odysseas Christou, CARDET - UNIC, Cyprus

The purpose of this paper is to discuss a European project that focuses on developing curricula for universities to raise awareness on development education (global education). Partners from 4 EU countries collaborated to develop modules that can be used to raise awareness about the Millennium Development Goals (MDGs) and poverty

eradication. Concrete activities will be presented which can be integrated in various education context to raise awareness on poverty eradication and social justice education.

The purpose of this paper is to discuss a European project that focuses on developing curricula for universities to raise awareness on development education (global education). Partners from 4 EU countries collaborated to develop modules that can be used to raise awareness about the Millennium Development Goals (MDGs) and poverty eradication. There is still an ongoing debate on the most appropriate terminology concerning 'development education'. Alternative terms are 'global education', 'global/cosmopolitan citizenship', 'global learning' or even 'MDGs education'. These terms are by no means value-neutral but carry particular cultural and political assumptions. To delineate those assumptions one has to begin from the use of the term 'development' itself—which is clearly not unproblematic.

There are two dominant 'development paradigms' linked to our work. According to the first paradigm, the modernization development paradigm, 'development' means closing the economic gap among nations; at its core is a Western concept of 'modernization' that perceives some means (e.g. technology, industrialization) as important in spreading development from the West to the rest of the world. These means are viewed as crucial in the development agenda because it is argued that they can be used to assist in poverty reduction and the expansion of opportunities for economic development. In this view, 'development' becomes a part of economic discourse while other renditions of its meaning—for instance, cultural development, personal development, spiritual development—are too easily drowned out or marginalized (Selby, 2006). Development is primarily linked, then, to economic output, so the argument is that the 'means' will result in economic growth.

On the other hand, the second paradigm, the social justice development paradigm, questions the meaning and type of 'development' governments or agencies aspire to. In this view, 'development' aims at problematising the capitalist model of expansion that harms people and the environment. By 'development', writes Rigby, "we mean simply moving forward in time, rather than that the majority world has to convert to the western obsessions with competition and increasing materialism" (cited in Selby, 2006, p. 356). The 'means' of development—that have center stage in the first paradigm—may in fact increase existing inequalities. Development can no longer be understood merely in economic terms but has to say something about how unequal social structures and power relations are questioned. Consequently, the question "Who really benefits from this?" has to be constantly addressed in discourses and practices that deal with development issues. Our project, then, places notions of social justice and equity at its core and engages in curriculum development that provides opportunities to raise this and other important questions.

Recognizing the current popularity of indicators, given that they measure, simplify and communicate important information, any references with our project curricula will avoid purely economic indicators that reflect the modernization paradigm, such as "standard of living" and privilege indicators that challenge the economic model such as "quality of life". The term 'social justice' is hotly contested throughout the field of education (North, 2006), but in our theoretical framework we define socially just education as the efforts to develop curricula, policies and pedagogies that improve the learning and life opportunities of typically underserved students (Cochran-Smith, 2004; Ladson-Billings, 1994).

For the purposes of this project, curricula are developed to provide opportunities to students in their mastery of content in order to acquire the equitable level of education each citizen needs to function as a successful member of society. Curricula with this focus lead students to problem-pose the ordinary, taken-for-granted events of life that are, in fact, hegemonic expressions of oppression (Freire, 1970; Giroux, 1988; Kincheloe, 2005; McLaren, 2003). Students need to be exposed to particulars of societal injustice that can pierce apathy and provoke the empathy and outrage needed to prompt them to act for the betterment of society. In the development of our modules we should make sure that there are openings for students and teachers to delve into the particulars of societal injustice.

Each module within our project will aim to broaden the understanding of the learner (i.e. those targeted by our modules) of the various kinds of power and our sense of possibilities for social justice. For each module we will be looking into developing the (political) skills to act on the power relations. Furthermore, the modules currently being developed place notions of gender equality at their core and consider gender equality to be a prerequisite to human development. Concrete activities will be presented which can be integrated in various education context to raise awareness on poverty eradication and social justice education.

Complex systems and learning about racism: A 21st century pedagogy for 'color-blind' racism?

Thomas Philip, UCLA, United States

Through a synthesis of Omi and Winant's (1994) seminal work on racial formation and scholarship in the learning sciences on students' understandings of complex systems, I analyzed in-depth interviews with teachers to argue that reasoning about race and racism requires complex systems reasoning. I further argue that part of the difficulty teachers face in reasoning about these issues is their reliance on mechanistic reasoning. This study contributes to the literature on teacher preparation and development and also contributes more generally to how students reason about complex systems and processes that pertain to issues of equity and justice.

Aims

Through a synthesis of Omi and Winant's (1994) seminal work on racial formation and scholarship in the learning sciences on students' understandings of complex systems (Chi, 2005; Jacobson, 2001; Jacobson & Wilensky, 2006; Rappoport & Ashkenazi, 2008; Wilensky & Resnick, 1999), I analyzed in-depth interviews with teachers to argue that reasoning about race and racism requires complex systems reasoning. I further argue that part of the difficulty teachers face in reasoning about these issues is their reliance on mechanistic reasoning.

Educational Significance

The equity implications for how teachers understand the nature and purpose of their work, particularly when there are stark differences between teachers' and students' racial, ethnic, class and immigration backgrounds has been well documented (Hollins & Guzman, 2005; Sleeter 2008). This study contributes to the literature on teacher preparation and development, particularly for teachers from dominant backgrounds who teach historically marginalized students. It also contributes more generally to how students reason about complex systems and processes that pertain to issues of equity and justice.

Theoretical Framework and Significance

Omi and Winant's (1994) theory of racial formation is perhaps one of the single most influential contemporary theories of race. I argue that due to the different disciplinary traditions in which theories of race and complex systems have developed, prominent theories of race conceptualize society and racial processes as a complex system, albeit without the explicit language of emergent properties. While complex systems are implicitly central to these theories of race, the pedagogical approaches used to teach these theories are still largely mechanistic, creating a highly problematic disjuncture between theory and pedagogical practice.

Omi and Winant disrupt the idea of race as an essence or an illusion, arguing that "race is a concept which signifies and symbolizes social conflicts and interests by referring to different types of human bodies" (p. 55). A defining characteristic of Omi and Winant's concept of race is that they approach it as "an unstable and 'decentered' complex of social meanings constantly being transformed by political struggle" (p. 55). Strikingly parallel to the language and central tenets of complex systems, Omi and Winant argue that is useful to think of racial order in Western

democracies as an "unstable equilibrium," stressing that such order is in the "continuous process of formation" (p. 85). The racial order is equilibrated by the state as it is encoded in law, organized through policy-making, and enforced by a repressive apparatus. The apparent "order" is dynamic and the equilibrium is constantly in flux.

Findings from scholarship on complex systems reasoning closely parallels many of the difficulties that are observed when teachers reason mechanistically about racialized inequity, which is characterized by thinking about the parts of a system in isolation without considering their interdependent relationships (Chi, 2005; Jacobson, 2001; Rappoport & Ashkenazi, 2008; Wilensky & Resnick, 1999). For instance, Chi (2005) proposes that difficulties arise in conceptualizing emergent properties because agents have a non-direct effect on the observed pattern, some of the actions of agents might not correspond to the observed pattern, and agents do not interact with the purpose of producing a global goal. People often make sense of complex dynamics by "expecting the components to act as small copies of the observable system, or to intentionally move in the direction that fulfils the goal of the system" (Rappoport & Ashkenazi, 2008, p. 1589). Similarly, teachers often assume that people's intentions must correspond to systemic patterns, which makes it difficult for them to reason through the nuances of contemporary forms of "color-blind" racism, where racialized outcomes can emerge from seemingly unracialized actions (Bonilla-Silva, 2003). (Additional parallels that offer insights into teachers' racialized reasoning will be explored more extensively in the presentation.)

Methods and Data Sources

The data sources consisted of fourteen in-depth, open-ended interviews with pre-service teachers in which they were asked to explain the reasons of differential achievement among racialized groups of students. The interviews were coded for evidence of mechanistic and complex systems reasoning based on characteristics proposed by Jacobson (2001).

Results

While the participants reasoned across a spectrum of mechanistic and complex systems reasoning when explaining differential achievement among racialized groups of students, of the 14 participants, 12 mostly relied on mechanistic reasoning and 2 mostly relied on complex systems reasoning. The patterns and nuances of shifts between mechanistic and complex systems reasoning in the data will be discussed through the interpretative lens of the theoretical framework described above.

Carbon cycle narratives in diagram form: their variety and some content and design issues

Simon Gates, University of Exeter, United Kingdom

The visual literacy of narratives for the carbon cycle topic in secondary school science in England, as displayed in diagrams, was investigated in an interpretive study. A selection of diagrams was used by informants at interview. Educators' published output was also evaluated. In all, the creations of over 200 educators were inspected. The study showed that rectangular and circular shapes are common. Many diagrams have visual literacy faults as well as content

errors. Little has been reported in the literature about the visual literacy, narrative version, diagram form, or accuracy of these diagrams. It seems to be assumed, wrongly, that published diagrams will have accurate content and be visually literate; that teachers and pupils will use them without difficulty. Although they can be made so they translate precisely into speech and written English, informants did not find their narratives easy to access. This poster presentation provides a reference diagram for the visual narrative; illustrates shapes, and forms; presents visual literacy faults and content errors; displays the range of different narrative versions found in publications for school science; examines the problems informants reported in teaching the part microbes play in the cycle.

The aim of this qualitative research has been to explore, with educators, issues of visual literacy, design, content and use of diagrams available to teach the carbon cycle topic to secondary science pupils aged 14-16 in England, as part of our National Curriculum. Research questions were general: How do educators see and use carbon cycle diagrams? What do they notice, like and dislike about them? The methodology for this empirical, interpretive-constructivist study, (Schwandt, 1994), was modelled on a naturalistic approach, and contained elements of multiple case studies (Bassey, 1999). Two instruments were used. First, semi-structured interviews with an opportunistic selection of educators, focused on tasks set with carbon cycle diagrams selected from textbooks and exam papers. This was followed by an archival survey of the content, structure, and accuracy of published carbon cycle diagrams. Its focus was informed by the first instrument. The informants, and the outputs of other diagram makers, together provided evidence about carbon cycle narratives produced by over 200 education professionals, most in the UK; others in Europe and the USA. Informants were asked to evaluate carbon cycle diagrams, carry out tasks with them and say how they might use them in their own teaching. Informants talking at interview; the transcripts; diagrams they made, were coded for categories, and then transformed to present the findings. A number of criteria were used to provide reliability, and generalizability (Taylor and Wallace, 2007). Importantly, each of the two instruments did provide evidence which reinforced and complimented the findings of the other.

Findings.

Informants preferred diagrams which contained naturalistic depictions. They commented on surface features, not those to do with narrative version, accuracy of content, the visual conventions used, or form and its implications for using these visual narratives with pupils. Most flaws in design or content went unremarked. When presented with unfamiliar diagrams they found their narratives difficult to access and evaluate. The first poster shows how a text version of the carbon cycle narrative is translated into a reference diagram. The places in the narrative where faults occurred are marked. Informants agreed a preferred version of the diagram. This diagram is presented and their reasoning is summarised. The second poster illustrates content faults, which include the following: Entity confused with process; Process confused with entity; Wrong process linking two entities; Placing a process the wrong side of an entity; Another entity substituted for microbes; Confused use of process and entity symbols. It is the processes that usually prove difficult to use accurately. The third poster introduces the shapes and forms found in textbooks and exam papers. Informants preferred circular shapes, but rectangular ones are common in exam papers. Forms are created when the maker puts the entities in place on the page. They have a strong influence on the usefulness of a carbon cycle diagram. Some forms are easier to 'read' than others, as shown by adding reading pathways. The fourth poster presents different versions of the narrative found in textbooks and exam papers. Informants disliked contracted versions, finding it difficult to access their narratives or to accept their designs. The fifth poster examines a common problem for informants: telling the narrative accurately with respect to the microbes. Surprisingly, omitting the microbes is common in textbook versions. In the late 90s, they were omitted from exam board syllabus versions of this topic. They have since been restored. Reasons why the cycle cannot be taught effectively without them are demonstrated visually. Informants reported that their pupils found this sector of the narrative difficult. However, reports of research on the topic carried out elsewhere do not confirm this. Possible causes and proposed solutions are presented.

Educational significance.

No direct reference is made to these diagram features in the literature, except that the features presented here are to be found in them. Teaching the topic is discussed by Winterbottom, 1990. Exposing the problems informs a useful training specification that would provide for accuracy and fluency in the visual literacy required for more effective instruction with carbon cycle diagrams, a topic which should be of interest to all of us now that we are confronted with the change in atmospheric carbon dioxide and its consequences (Fýssel, 2009). More generally, Avgerinou gives a current perspective on the universal importance of visual literacy. Pauwels, too, describes what we need for practical, everyday, 21st century 'visuality'. Without it, we cannot teach, learn, or function adequately in or out of school, in our contemporary, global, visual culture. Visual literacy is a fundamental requirement for unambiguous communication using any and every medium.

Pedagogical Reasoning in Special Education in Authentic Contexts

Julien Mercier, University of Quebec in Montreal, Canada; Line Laplante, University of Quebec in Montreal, Canada; Marie-France Cote, University of Quebec in Montreal, Canada; Andree-Anne Cyr, University of Quebec in Montreal, Canada

The processes by which theoretical knowledge gets integrated into teaching practice are relatively under-researched from a cognitive perspective. Current cognitive theories led to the construction of a model of pedagogical reasoning, as a prototype of situations of theory-practice articulation. The aim of this study is to test such a model in authentic teaching contexts and to examine novice-expert differences using a sample of special education student teachers and teachers. Eighteen participants planned remedial reading instruction in the context of their regular teaching during three weeks. Through think-aloud protocols, pedagogical-reasoning processes were identified. Results show the prevalence of the processes and their typical chronology. Novice-expert comparisons reveal essentially no difference in prevalence but differences in the sequencing of the processes. This model suggests the configuration of learning activities in teachers' preservice training.

Aims The stance adopted in this study is that the translation of theory into practice in the context of preservice teacher education is a pedagogical problem that can be solved by the design of appropriate instructional tasks on the basis of the study of teacher cognition (see Cochran-Smith & Fries, 2006). The aim of this study is to test a model of the cognitive processes involved in pedagogical reasoning in the context of authentic teacher planning and to examine how these cognitive processes get enacted across different expertise levels.

Theoretical framework

Cognitive research suggests a pedagogical-reasoning model constituted of three modules: (1) the comprehension of the case, (2) the diagnostic of student's difficulties, and (3) the elaboration of pedagogical interventions (Mercier, Girard, Laplante & Brodeur, 2010). These modules are associated with theories of discourse comprehension and production, reasoning, and problem solving, respectively. The first module, comprehension of the case, is based on the activation of one or more schemas on the basis of information provided and on teacher's prior knowledge. Second, the diagnostic implies the elaboration of one or more hypotheses and their testing, including their hierarchical organization when more than one hypothesis is formulated. Finally, the module handling the elaboration of pedagogical interventions comprises the identification of goals, their hierarchy, followed by the identification of actions, accompanied by pertinent justifications such as the diagnostic, expected effects, application constraints and available means. These three modules are articulated by a problem-solving process that controls the performance of the global task. The results presented are limited to the control process and component actions due to space constraints.

Methodology

The sample was constituted of 12 student teachers (six in second, six in fourth year) and 6 teachers in special education (2 had between 5 and 10 years of experience and 4 were remedial education teachers who had graduate training in reading instruction). Participants were asked to plan lessons for remedial reading instruction as they would do normally during practicum or everyday teaching during a period of three weeks. They were instructed to think-aloud and to use a portable computer especially configured to record automatically the computer screen, ambient sound, and any documents. To ensure completeness of the protocols, the computer was configured to display a reminder to talk out loud whenever no voice was recorded for five seconds. The protocols were coded; frequencies and conditional probabilities are used to aggregate sample data as related to levels of expertise.

Results and Conclusions

Tables 1 and 2 present time-budget information regarding how often participants engaged in particular pedagogical-reasoning activities. Globally, participants spent the bulk of their time (around two thirds) performing pedagogical-reasoning actions. There is no difference in the prevalence of categories attributable to expertise. At the level of actions, there is a strong tendency to put more time on diagnosis and less time on the elaboration of the intervention as the level of expertise increases, with experts spending twice as much time as beginners on diagnosis.

The following section presents general results regarding the modulations in the sequential structure of pedagogical reasoning that are attributable to expertise levels. Conditional probabilities in the following four figures represent the probability of a particular process of being followed by another given process. Probabilities below 0.15 were not included for clarity. Please see the attached figures. Globally, differences attributable to expertise lie in the sequence of pedagogical reasoning processes, and not in their prevalence (with the exception of making a diagnostic). By showing differences in pedagogical reasoning related to the level of expertise, the results suggest that more emphasis should be put on the diagnostic of student's difficulties in initial training, especially if this diagnostic is seen as a foundation for differentiated instruction. Domain knowledge seems to have an impact on how pedagogical reasoning unfolds. More analyses considering the modeling of the domain knowledge evoked during pedagogical reasoning and associated to each process are needed to explain these differences.

Theoretical and educational significance

This study is part of a series of studies investigating the relations between teacher knowledge and teacher decision-making and extends our prior results from laboratory data. The proposed cognitive model, as a way to characterize proactive decision-making, complements models of interactive decision-making (Peterson and Clark, 1978) ; Shavelson and Stern, 1981). This complementarity represents potential for future studies examining discrepancies between teacher planning and classroom processes in terms of how they arise and how they are resolved. This discrepancy is linked to important findings of earlier studies (Morine-Dersheimer, 1978-79) and has implications for the transfer of theory into practice since teachers' interactive decision-making and information-processing is highly influenced by it (Morine-Dersheimer, 1979). Initial investigations are leading to descriptive models of teachers' pedagogical reasoning. These models may develop into more prescriptive models that could orient teacher education programs. Empirically validated models of pedagogical-reasoning skills determine, on the one hand, the nature of teacher pedagogical reasoning skills that should be taught. On the other hand, they serve as a basis for studies investigating the design of methods for teaching and assessing these skills.

The Noble Image of Bildung

Herner Saeverot, University of Bergen, Norway; Glenn-Egil Torgersen, Norwegian Defence University College , Norway

This paper will show selected results from the ongoing research project "The Noble Image of Bildung." The paper will raise several questions that in their own way centre on pedagogic challenges, but the main question is: Do art students remember images better than others? The study will reveal if the art students (n=100) have a greater capacity to remember pictorial information than others with different backgrounds (eg. officers (n=94) and teachers (n=194)), but not in a stigmatising way. Twenty assertions relating to an image was used to measure the respondent's memory of this particular image. A digital-based short-term memory test measured the general capacity/memory span, and a non-verbal intelligence test (Raven) was used to identify the form combinatorial ability. These cognitive processes can affect iconophobic development, and may also be an underlying cause of art skills. The empirical data are discussed in light of cognitive theory and classical theory of Bildung. Art educational, and general pedagogic implications, are discussed on the basis of the empirical outcomes and the theoretical approach.

This paper will show selected results from the ongoing research project "The Noble Image of Bildung," with the overall problem: Do art students remember images better than others? The purpose is to examine how well art students (n=100) remember from a particular image, compared with other groups (including teachers (n=194) and officers (n=94)). The study will reveal if the art students have a greater capacity to remember pictorial information than others with different backgrounds, but not in a stigmatising way. A non-verbal intelligence test (Raven) is also used to identify the form combinatorial ability. These cognitive processes can affect iconophobic development, and may also be an underlying cause of art skills.

The study relates to the German word Bildung, which activates a broad association register. Firstly, the word relates to the formation or transformation of something. Second, Bildung is strongly associated with the image, so that the word is given a pictorial and figurative sense. The notion of Bildung is fairly unique in the sense that it combines the idea of

creation and transformation with the use of evocative images. Bildung is in many ways to transform oneself as a human being in the light of a by-frame or an ideal. The study's concern is that the individual creates or draws itself by way of images, which also means that one obtains insight.

In Norway and other Nordic countries, none has investigated these issues with both empirical and theoretical approach. This research is therefore important with regard to art educational challenges. These include facilitation of teaching with images, image analysis, image mediation of knowledge, development of artistic skills in visual arts, educational use of ICT, as well as basic educational-psychological understanding of image reception and learning, etc. The empirical data will be discussed in light of cognitive theory and classical theory of Bildung. The discussion will be directed towards iconophobic features and other aspects of perception of images that can affect the use of images with regard to learning. Art educational and general pedagogic implications will be discussed on the basis of the empirical outcomes and the theoretical approach.

The respondents are art students, all categories. The survey is carried out in the sense that all respondents are gathered in a plenary/ classroom. There will be displayed a PowerPoint series of pictures and Raven matrices. Questions and time for answering are integrated in the presentation. The collection lasts for 20 minutes. Surveys are then collected. Data is transmitted in Statistical Package for the Social Sciences (SPSS). The material will be statistically processed (ANOVA/MANOVA-analysis). The project is registered in the Norwegian Social Science Data Services (NSD).

The project The Noble Image of Bildung (NIB) is using a developed digital-based short-term memory test measuring capacity and capability functions (Raven). This test was developed at the Norwegian Defence University College for use in the military. The test can be carried out for large groups in natural learning environments. NIB has already spent 120 hours to prepare and facilitate empirical implementation at a national academy of the arts in Norway. There will be a need to collect 100 respondents. The test should be carried out during the fall 2010 and spring 2011. A psychologist specialist with lots of experience in psychometric analysis from the military will be connected to the project.

Frequency and intensity ratings of school-related participation experiences.

Gregor Maxwell, Hogskolan for larande och kommunikation, Sweden; Lilly Augustine, Statens folkhalsainstitut , Sweden

This to compares the self-reported experience of pupils with an additional support need (including children with disabilities) of being involved with what they were thinking or doing. Data about what children were thinking or doing during an activity were gathered from self-reporting questionnaires from 22 children with and 22 without additional needs. This will be analysed for relation between thinking and doing and also interpretation of focus with a view to getting an accurate measure of the intensity of the participation in the activity. All items have been coded with ICF-CY values using the Cieza et al. (2005) coding rules and will be analysed using factor analysis and multi-variant methods to identify if a measure of the intensity of participation can be made.

Theoretical background

With children the nature of child functioning and environmental settings of life situations vary greatly in comparison with adults (WHO, 2007) and for this reason the Child and Youth version of the International Classification of Functioning, Disability and Health (ICF-CY) has been produced in 2007 (WHO, 2007). Building on the existing and previous research results within the Children Health Intervention Learning and Development research group (CHILD,

see <http://www.hlk.hj.se/doc/5531>) this paper investigates participation from an involvement perspective of children in need of additional support (including children with disabilities) at school.

Participation can be regarded as a multi-dimensional phenomenon and can be defined as “involvement in a life situation” (Bjorck-Akesson, Granlund, & Simeonsson, 2005; WHO, 2007). However, the need to provide clarity on the participation construct is currently well debated in the literature with a number of studies discussing how to measure participation (Badley, 2008; Coster & Khetani, 2008; McConachie, Colver, Forsyth, Jarvis, & Parkinson, 2006). While definitions of participation may vary, higher degrees of participation will lead to increased independence, academic achievement and social inclusion for students with disabilities. Participation can be conceived as a complex and multi-dimensional phenomenon (Simeonsson, Carlson, Huntington, McMillen, & Brent, 2001). From previous studies it has been shown that differences in participation are context-specific (Eriksson, Welander, & Granlund, 2007) for both children with and children without disabilities. Participation patterns and students’ concepts of participation are not strongly dependent on type or degree of disability (Almqvist & Granlund, 2005; Eriksson & Granlund, 2004a, 2004b; Granlund, Eriksson, & Ylven, 2004) with students’ conceptions of participation being more age-dependent (Eriksson & Granlund, 2004a). Similarly, environmental factors are also seen as influential in these studies.

Aims

To compare the self-reported experience of pupils with an additional support need (including children with disabilities) of being involved with what they were thinking or doing with a view to creating a measure of intensity by using these research questions:

When thinking and doing descriptions are positively correlated is a child involved in an activity? Does this correlate with whether the child thinks he or she was focused on the activity?

How does the frequency and intensity of participation of school-aged children with additional needs in an educational setting manifest itself within the ICF-CY framework?

Methods

Data were gathered from an existing study of participation in school environments of students with disabilities in Sweden carried out by the second author. The data-set consists of data collected from schools which contain both frequency and intensity data. The frequency data are in the form of questionnaires and the intensity data came from self-reports. The data come from self-reporting questionnaires gathered at random points during the course of a normal school week by prompting 22 children with additional needs and 22 controls with questionnaires. Data about what each child was thinking about and doing will be analysed along with data on the child’s rating of being focused. Additional data which could also be analysed was gathered relating to the child’s mood, their interpretation of the importance and complexity of the situation, and with whom they were doing the activity. All items have been coded with ICF-CY values using the Cieza et al. (2005) coding rules and will be analysed using factor analysis and multi-variant methods to identify if a measure of the intensity of participation can be made. Both non-parametric and parametric multi-variant analysis will be used to report on the findings.

ROUND TABLE

Developing The Skills of Critical Thinking by Probability Teaching

Einav Aizikovitsh-Udi, Harvard, Israel

The purpose of this initial study was to explore whether teaching our specially designed learning unit would enhance the students' critical thinking skills. The unit "Probability in Daily Life" was taught to a group of tenth-grade students, with the purpose of encouraging critical thinking dispositions and abilities such as open-mindedness, truth-seeking, self-confidence and maturity. The teacher encouraged class discussion and planned investigative lessons. The students completed a pre and post CCTDI and Cornell test. The presentation will argue that it need not take significant extra teacher time or effort to prepare the unit and that no special training is needed to accomplish the goal of developing students' CT skills. What is essential is the teacher's understanding of CT skills and the importance of developing critical thinking abilities in their students.

In a challenging world that changes continuously, students need to develop their advanced thinking skills, such as critical thinking (Ennis, 1987; Facione, 1994), decision-making and problem solving and to be able to translate these skills and knowledge into responsible action in society (Ben-Haim & Zoller, 2000).

The goal of the new mathematics curriculum in Israel is a conceptual understanding of mathematics through investigation, problem solving, high-order skills and mathematical discourse. The students are supposed to actively construct their knowledge and understanding, while the teachers function as 'mediators' by asking questions, posing challenges and assigning investigation tasks, and helping the students to think in deeper ways about various concepts, ideas and mathematical contexts. To study and teach mathematics in such a way is a very difficult task, because the ways of teaching and learning are very demanding, requiring deep knowledge and understanding of mathematics on the teacher's part, coping with the unknown on the student's part, and much intellectual effort by both. Earlier research findings point to the importance of learning experiences that develop critical thinking by means of various specially designed curricula. The purpose of this initial study was to explore whether teaching our specially designed learning unit would enhance the students' critical thinking skills. The research reported in this presentation is likely to contribute to the development of new study programs and methods based on the connections between critical thinking and the study of mathematics, which this study has revealed. This research offers new possibilities for the integration of critical thinking development programs into the formal high-school mathematics curriculum.

Methods

To investigate whether teaching conducted with the purpose of promoting higher-order thinking skills through probability instruction would improve the students' critical thinking abilities, forty-three children between the ages of fifteen and sixteen participated in an extra curricular program aimed at enhancing thinking skills of students from different cultural backgrounds and socio-economic levels. The study was conducted over one academic year (eight months) and involved fifteen lessons, each lasting ninety minutes. The teacher was one of the researchers. A teaching experiment was conducted in which probability lessons were combined with CT skill development.

Results

This study shows that through the instruction of the probability learning unit students developed three types of CT skills: variable isolation, attention to references and reliability. Results will be reported to show that most (there are three iteration) of the students were able to retain these skills and use them in later mathematical topics. Most importantly, this study has shown that it is possible to incorporate particular CT skill activities into the regular activities of the mathematics classroom in a way that will develop the students' critical thinking abilities. The subject matter was part of the existing high-school curriculum, and the teaching experiment has, therefore, demonstrated that the teaching of CT skills need not take time away from the class syllabus. The presentation will argue that it need not take significant extra teacher time or effort to prepare the unit and that no special training is needed to

accomplish the goal of developing students' CT skills. What is essential is the teacher's understanding of CT skills and the importance of developing critical thinking abilities in their students.

Claims of games: a decade of research on motivational and learning effects reviewed

Jantina Huizenga, Universiteit van Amsterdam, Netherlands; Wilfried Admiraal, University of Amsterdam, Netherlands; Geert Ten Dam, University of Amsterdam, Netherlands

The widespread interest in digital game-based learning can be explained by the popularity of games together with ongoing research on the power of digital game-based learning (DGBL), on the one hand, and increased disengagement of the so-called net generation or digital natives from traditional instruction, on the other hand (Van Eck, 2006). This holds for not only students and researchers, but also teachers and parents (Kirriemuir & McFarlane, 2004). Many claims have been made about DGBL in terms of learning and engagement, including, for example, a claim that it motivates the learners because it's fun (Prensky, 2007, p. 3). With this review we want to answer the following questions: Are the claims on the motivational and learning effects of DGBL substantiated? What are the motivational effects of DGBL? What are the learning effects of DGBL? Are there different effects for different subgroups? We have performed a systematic review to provide answers to these questions. Of the hundreds of articles we started with, only 46 articles have been included in the final selection that has been used for our conclusions. The general outcome of this review is that game-based learning seems to work for both motivation and learning, though not always better than other educational methods. Finally, information that is still lacking includes which game elements might be important to trigger effects on motivation and learning, and how student background moderates the effects.

Introduction

The widespread interest in digital game-based learning can be explained by the popularity of games together with ongoing research on the power of digital game-based learning (DGBL), on the one hand, and increased disengagement of the so-called net generation or digital natives from traditional instruction, on the other hand (Van Eck, 2006). This holds for not only students and researchers, but also teachers and parents (Kirriemuir & McFarlane, 2004). Many claims have been made about DGBL in terms of learning and engagement, including, for example, a claim that it motivates the learners because it's fun (Prensky, 2007, p. 3). Mishra and Foster (2007) found over 250 claims relating to psychological or physiological effects. They commented, however, "most of these claims have not been validated empirically" (Mishra & Foster, 2007, p.3). As we want to use game-based learning in education, a stronger empirical basis for the effectiveness of games for learning and engagement is required. Our research questions in this review are: Are the claims on the motivational and learning effects of DGBL substantiated? What are the motivational effects of DGBL? What are the learning effects of DGBL? Are there different effects for different subgroups?

In addition, we include information on the interventions and what authors consider to be important in future research. We will review the literature of the last decade with respect to claims that games trigger learning, motivation for the content and engagement in playing. We want to provide a review avoiding some of the limitations of previous reviews. In contrast to these reviews, we will: Exclude articles that are not based on empirical research; Exclude articles with a low quality in research methods; Include articles based on qualitative, quantitative or mix-method research, and Be explicit about the research methods used in our review.

Method

This paper provides the results of a review study on digital game-based learning of 4-18 years old children in a formal educational (in- or out-school) context. Only studies of digital games are included, no simulations or card- or board games. We define games as a set of activities involving one or more players with goals, constraints, payoffs and consequences and rule-oriented and artificial in some respects. Finally a game involves some aspects of competition, even if that is competition with oneself (based on Dempsey et al. 1996, p. 2). We also add Prensky's (2007) notions of

game as organised play that gives enjoyment and pleasure, feedback, challenge and representation (meaning that there are some narrative, story or fantasy elements in the game).

To select relevant articles the most-used databases (e.g., ERIC and Digiplay), four journals on technology and education, and proceedings of three conferences are searched for relevant articles and papers published between 1999 en 2009. Generally, we search with the terms Gam*, in combination with Learn* or Educ* with * used as a joker. Analysis of the abstracts of more than 600 articles, resulted in 92 relevant articles.

The analyses of these articles are performed in six steps. In the first step, the quality of the research methods of the articles is measured resulting in 75 articles that meet our basic criteria. In the second step, possible claims are examined on the basis of research questions resulting in 57 articles that meet our criteria. In the third step, relevant conclusions have been examined resulting in 46 articles that meet our criteria. In the fourth step, the 46 articles were analysed on effects on motivation and learning. Motivation is a multifaceted term and we distinguish between engagement in the game and motivation for the content. For learning, we are interested in cognitive learning, not learning of sensory or motor skills. Therefore, we distinguish between factual knowledge, cognitive skills and meta-cognitive skills. In the fifth step, we check whether the conclusions with respect to these five terms are grounded or not. In the final, sixth step, the results of the 46 articles are summarized with respect of the claims that are made, the intervention (both games and teaching) and moderating effects for student background. In addition, we summarize the authors' suggestions – if any- for future research in game-based learning.

Results and conclusions

The conclusions on engagement and motivation are mostly positive and grounded, but conclusions based on comparison with other ways of teaching are not always significant. With respect to learning, all (positive) conclusions on factual knowledge are grounded, with 78% for cognitive skills. Only two effects on meta-cognitive skills are found. The games used in the interventions are mostly educational games. So, the general outcome of this review is that game-based learning seems to work for both motivation and learning, though not always better than other educational methods. Finally, information that is still lacking includes which game elements might be important to trigger effects on motivation and learning, and how student background moderates the effects.

Mathematics teachers' acceptance of computer supported-open learning environments

Enrica Borromeo, Faculty of Psychology and Educational Sciences, Italy; Jan Elen, Katholieke Universiteit Leuven, Belgium; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

The efficiency of instructional methods is not universal but depends on the desired outcomes and the instructional conditions. It is claimed that open learning environments can be an appropriate instructional approach for some goals and challenges in (mathematics) education. This survey study examines mathematics teachers' acceptance of the notion of computer supported-open learning environment (CS-OLE) in relation to teachers' beliefs on the nature of mathematics, mathematics teaching, and technology as a mathematics teaching tool. Data about teachers' beliefs and their acceptance of CS-OLE were collected through a beliefs-questionnaire which reached about 250 Italian mathematics teachers in 36 first degree secondary schools. Four fifth of the answering teachers accept CS-OLEs as a method for teaching/learning problem solving, but half of them do not use them due to lack of technology in schools or lack of competence. As expected, teachers accepting CS-OLEs are significantly more at ease with technology as a mathematics teaching tool and have a stronger problem-solving view than the teachers who do not accept CS-OLEs. Furthermore, they have a different view to some of the four subthemes of mathematics teaching. An unexpected result is that teachers who accept CS-OLEs more strongly hold both instrumentalist and Platonist views of the nature of mathematics.

A deep reflection on the analysis of the data can further increase our understanding of teachers' views on mathematics and on innovative concepts in mathematics education such as CS-OLEs, and may contribute to solve some actual difficulties with respect to mathematics education in Italian schools.

The efficiency of instructional methods is not universal but depends on the desired outcomes and the instructional conditions (Reigeluth, 1999). Teachers may use therefore functionally different teaching strategies (Beane & Brodhagen, 2001). Furthermore, the methods to support student learning used by instructors have great impact on how much students learn (NCTM, 1998). Hannafin's statement that "instruction is neither the only, nor in many cases the best, method to support learning" (1996, revelation 5) opens the door for alternative teaching/learning methods. Open learning environments (OLEs) can contribute to meet the goals and challenges of (mathematics) education. This is one of the reasons to survey how mathematics teachers tackle some specific instructional choices, such as the use of OLEs to support problem solving processes in mathematics. The present survey study examines mathematics teachers' acceptance (in the sense of approving its utility in teaching/learning mathematics and teachers' willingness to implement it) of the notion of computer supported-OLE (CS-OLE) and its relationships with teachers' beliefs on the nature of mathematics (NM), mathematics teaching (MT), and technology as a mathematics teaching tool (TMTT). In this research, we adopt the framework on teachers' beliefs proposed by Philipp (2007) and Thompson (1992). The critical role of teachers' beliefs about education on mathematics classroom practices was demonstrated in several studies (Cross, 2009; Da Ponte, 2009; Fennema & Franke, 1992; Handal, 2003; Hermans, Tondeur, van Braak, & Valcke, 2008; Niederhauser & Stoddart, 2001; Pajares, 1992; Thompson, 1984, 1992; Woolley, Benjamin, & Woolley, 2004). The present study focuses on teachers' beliefs about NM and MT, because they have been argued to specifically affect teachers' approaches to mathematics teaching (Cross, 2009; Ernest 1988, 1989, 2004; Thompson, 1992). Furthermore, since computers have a significant function in CS-OLEs, we also focus on teachers' beliefs about TMTT. This research is based on: -Ernest's theory of the three views of NM (1989, 1991): instrumentalist, Platonist, and problem solving; -the study of Kaiser (Kaiser, 2002; Kaiser, Hino, & Knipping, 2006) on central orientations of teaching in mathematics education, classifying beliefs about MT into two categories with contrasting peculiarities: scientific versus pragmatic understanding of mathematics theory; -the technology acceptance model (Davis, 1989), also applied in educational studies about other curricular domains (Stols, 2007; Teo, 2009). -the model of OLE developed by Clarebout (2005), which integrates the main features of the OLEs given by influential researchers (Hannafin, Hall, Land, & Hill, 1994; Jonassen, 1999).

Aim of the study

This study surveys the answer to the following question: Do teachers' beliefs about nature of mathematics, mathematics teaching and technology as a mathematics teaching tool affect their acceptance of the concept of CS-OLE as an appropriate method for helping students to learn mathematical problem solving? It is part of a wider research project aimed to gain a better understanding of mathematics teachers' views and actual use of innovative concepts in mathematics education, specifically CS-OLEs.

Methodology

The data about the teachers' beliefs and acceptance of CS-OLEs were collected through a beliefs-questionnaire. The survey reached about 250 mathematics teachers in 36 first degree secondary schools in central Italy. In Italy, the situation of mathematical education (particularly concerning students' handling of mathematical problem solving) is in peril (see the results of the last PISA and TIMSS surveys), in spite of the guidelines given by the European Union. The questionnaire is divided into three parts. The first part asks for some basic background information about each respondent. Part two is made up of 31 items. Each item is a statement to be commented through means of a Likert-type scale (Andrews & Hatch, 1999; Philipp, 2007). The following items were included: -two sets respectively of 6 and 13 items to survey NM and MT (measured on 5 points Likert-type scale) proposed by Yu (2008a, 2008b, 2009). His study refers to Ernest's classification of NM and to beliefs on MT based on the conception of mathematics education by Kaiser et al., (2006). The items that survey MT are divided in four sub-themes of MT: introduction of new concepts and methods, position and function of proofs, role of precise language, role of real-world examples; -a set of 12 items to survey TMTT (measured on a 7 points Likert-type scale) proposed by Davis (1989). It is divided in two variables, perceived usefulness (PUT) and perceived ease of use of (a specific) technology (PEUT). The third part of the questionnaire surveys teachers' acceptance of the notion of CS-OLE.

Results

The main results were: Four fifth of the answering teachers accept CS-OLEs as method for teaching/learning mathematical problem solving, but half of them stated that they do not use CS-OLEs for lack of competence or technology in schools. According to the Italian Guidelines for the curriculum (MIUR, 2007), most of the Italian teachers have a strong problem-solving view of mathematics and, on the contrary, a weak instrumentalist or Platonist one. Unexpectedly, these two views of the NM are hold significantly stronger by teachers who accept CS-OLEs than by

those who don't. Furthermore, these two variables came out to be highly correlated. As expected, teachers accepting CS-OLEs have a different approach to the subthemes of mathematics teaching. In particular, the beliefs on position and function of proofs tend to be stronger in teachers accepting CS-OLEs. As expected, beliefs on PUT and PEUT are held significantly stronger by teachers who accept CS-OLEs than by those who don't. With a view to better understand some of the above findings, we are now doing a deeper analysis focusing on the individual characteristics of the sample of respondents and on the psychometric features of the different survey instruments (reliability, factor structure...). An interesting discussion on the emerging data could improve our theoretical understanding of teachers' views on mathematics and on how to teach it effectively by making use of innovative concepts such as CS-OLEs. It may contribute to solve some serious actual difficulties with respect to mathematics education in Italy, mainly concerning students' handling of mathematical problem solving (e.g. through improving pre-service and in-service teacher education).

Methodological issues about time in e-learning research

Elena Barbera, UOC, Spain; Marc Clara, University of Barcelona, Spain; Armando Cortes, University of Barcelona, Spain

Consideration of time is crucial for understanding educational phenomena. In this connection, several conceptualizations have been drawn during the 20th century about this relation: e.g., the work related to the Carroll's model, the operant conditioning approach, and the genetic approach. In the last decades there has been a rising of digital technologies as mediators in educational processes, which have transformed the traditional limits of time regarding these processes. This fact demands to better understand, by means of course of empirical research, how the relationship between time and educational processes is transformed by digital technologies. Addressing this problem from empirical research on on-line learning presents several methodological challenges. The purpose of this paper is to review how empirical literature on on-line learning addresses these methodological challenges. For doing so we qualitatively review 24 systematically selected empirical papers on on-line learning. We examine the following five issues: the conception of time, its inclusion in an explicative model, its inclusion in the research process, the analytical units and the data used in the study of time. According to our analysis, we propose three issues for the further development of e-learning research: the need for a broader consideration of time, the need for a consistent theoretical consideration of time, and the need for theoretical elaboration of the conceptualisation of learning in relation with time.

Introduction

Several influent approaches to learning have consistently argued that educational phenomena can not be properly understood unless time is seriously considered as part of the phenomena. Some of these approaches are for example the Carroll's (1963, 1984) school learning model and the developments based on it (e.g., Bennett, 1978; Bloom, 1976; Burt, 2006; Cooley & Leinhardt, 1975), the Skinner's (1968) operant conditioning and the broad number of approaches influenced by it (see Leiser, 1996; Rodrigo, 1996; Shulman, 1986), or the genetic approach mainly represented by the proposals of Vygotsky (1978, 1997) and Piaget (1980), and the more recent developments based on them (e.g., Coll, Onrubia and Mauri, 2008; Engeström, 2001; Karmilov-Smith, 1994; Mercer, 2008; Pozo, 2001). During the last decades there has been an important increase of the use of digital technologies as mediators of educational processes. This, because of the nature of these technologies, implies the transformation of the time conditions and limits that traditionally had been associated to educational processes. On-line learning research, therefore, faces the challenge of understanding how the digital technologies modify the relation between time and educational processes. Obviously, this understanding can only be reached by grounding it on empirical research. However, empirical research on the relation between time and on-line learning presents several methodological challenges. In this paper we qualitatively review how the empirical literature on on-line learning addresses these challenges.

Method

By means of explicit criteria, we iteratively selected empirical on-line learning papers which included time in analysis. We began from an ERIC selection of on-line papers published during 2006-2009, we get 8511 papers. From these we iteratively refined the search by introducing progressively more demanding time criteria, and in the end of the process we get 24 papers that considered time in the methodological scheme and in the analysis of results. These 24 papers were then qualitatively analysed, by means of a grounded theory procedure (Strauss, 1987). This analytic procedure consists of generating categories directly from data (not from a specific theoretical frame). We analyzed data departing from five generative questions: 1. How is time conceptualised in relation to teaching and learning phenomena? 2. How is time introduced in a theoretical explicative model about on-line teaching and learning? 3. How is time operationalised and introduced in a research process? 4. Which kinds of units are used for this operationalisation of time? 5. Which kinds of data are useful for studying time?

Results

ABLE 1[1] QuestionAnswers found in the review# of papers (n=24)% of papersConceptualisation of timeTime as the while during which a phenomenon is taking place1041.7%Time as the moment in which a phenomenon takes place312.5%Time as the temporal distance between two phenomena833.3%Time as the evolution of a phenomenon729.2%Introduction of time into an explicative modelVariable-based model2083.3%Model of a process416.7%Introduction of time into the research processIntroduction into the phase of defining dimensions and variables 2395.8%Introduction into the analytic phase312.5%Units used for analysing and measuring timeUnits based on formal time1562.5%Units based on internal components of the setting1041.7%Theoretical-based units312.5%Data used for studying timeElectronic log files1250%Questionnaires, surveys and interviews625%Learning process students' products14.2%Institutional documents14.2%Setting design1041.7%

Table 1. Answers found in the review for the five guiding questions. The results of the review are summarized in table 1. Regarding the first questions we found four conceptions of time. Papers which considers "time as the while during which a phenomenon is taking place" typically considers the amount of study time or the amount of time spent on training. Papers which considers "time as the moment in which a phenomenon takes place", are interested in the when an action is carried out. The third conception is "time as the temporal distance between two phenomena", which typically considers, for example, the time a tutor lasts before responding a question of a student. Regarding the second question, we identified two different kinds of explicative models: variable based models, and models of a process. In variable based models, time is considered an isolated variable in specific relation to other variables. Instead, in models of a process, time is not an isolated variable, but it is considered as interwoven with context, as something intrinsic and inseparable of the studied phenomena. Regarding the third question, in the reviewed papers time is incorporated in the research process in two moments. Time is sometimes incorporated in the phase of definition of dimensions or variables: one dimension is time, or time is part of another dimension. But time is also sometimes incorporated in the phase of analysis, by considering in different moments the values of a no time dimension. Regarding the fourth question, we identified three types of units of time: units based on standardized time –minutes, hours, days, etc- units based on intrinsic features of the setting –course, thematic modules, etc.- and theoretically defined units- theoretical phases of a process. Finally, regarding the fifth question, we identified five kinds of data used by the different papers: log files – electronic registration of the participants' activity- questionnaires, surveys and interviews, products of the learning process itself –e.g., a written reflection which is required in the course- institutional documents –e.g., the list of inscriptions of a course- and the setting design itself –which permits manipulate some time variables.

Implications for further research

From the results of the review, we can point out three lines for further development of the consideration of time in e-learning research. First, time should be more broadly included in e-learning research. Second, e-learning research should be based on any explicit and well articulated theoretical conceptualisation of learning in relation with time. Thirdly, e-learning research should take the opportunity and the possibilities of theoretically developing and re-conceptualising the understanding of the temporal nature of learning.[1] The categories in each Question are not exclusive (indeed they are only exclusive in the second question); i.e., one and the same approach can include, for example, two different ideas of time, can introduce time into both phases, can simultaneously use units of different nature, and can combine different kinds of data. For this reason, in each question, the frequencies of each of the categories do not total 24, and the percentages do not total 100.

Languaging in online higher educational environments. Unimodal multilingual behaviors?

Giulia Messina Dahlberg, Dalarna University, Sweden; Sangeeta Bagga-Gupta, University of Orebro, Sweden

This presentation focuses upon a pilot study which is trying to understand the nature of human communication and learning in online synchronous communities within higher education in Sweden. The preliminary findings from the pilot study draws upon empirical material that consist of 12 sessions of approximately 30 minutes each, that are part of an "Italian for beginners" language online course. These sessions take place once a week over a period of one semester. Our study focuses upon interaction in the virtual classroom as a community of practice where students participate without teacher intervention. Our interests here relate to accounting for what communicative strategies are employed by students who are dealing with a common task without teacher supervision, and how these activities are negotiated within the constraints and opportunities accorded in the multimodal multilingual virtual setting. Taking sociocultural theoretical points of departure, we are currently analyzing how students create meaning in language learning using tools that allow them to interact when they have access to multimodal resources. Preliminary findings suggest that the students interact in the online videoconferencing environment using communication strategies in a rather flexible manner. Examples of the use of different modes – i.e. instant messaging, whiteboard and audio – and different codes will be presented. These highlight the complexity of communication in online communities of practice. The fluidity of the written and oral communication in face-to-face interaction appears to be dis-preferred and instead

members in these settings tend to communicate unimodally. Our analysis offers ways to understand this multilingual, unimodal communicative behavior.

This presentation focuses upon a pilot study which is trying to understand the nature of human communication and learning in online synchronous communities within higher education in Sweden. The aim of the study is to investigate the communication strategies employed by participants in a virtual classroom, a setting where the visual access to bodies, gaze and gestures is mediated through the computer screen. The preliminary findings from the pilot study that are presented in this paper draw upon empirical material that consist of 12 recorded sessions of approximately 30 minutes each, that are part of an "Italian for beginners" language online course offered by a Swedish university. The empirical data makes available to us as analysts access to the entire sessions, including sound as well as everything that has occurred on screen during the online lessons. The online synchronous meetings occurred once a week, over a period of one semester, in the videoconferencing program Adobe Connect, an environment that permits oral communication, but that also allows the students to share each other's web cam images, an Instant Messages device and a shared whiteboard, all in one application and one window in the computer desk. In this type of context, different participants are expected to deal with a task and simultaneously adjust their activities according to the options that are offered by the environment where interaction is taking place. The multimodal connotation of this setting, but also the different languages that are available to the participants, are aspects that need to be taken into consideration when analyzing interactional meaning in online synchronous environments since oral communication in different codes is only one of the several modes that can be used in this community of practice. Our interests here relate to accounting for what communicative strategies are employed by students who are dealing with a common task without teacher supervision, and how these activities are negotiated within the constraints and opportunities accorded in the virtual setting. Tudini (2005) argues that in this kind of virtual space, where students are trying to communicate in a language in which they have limited experiences, it is possible to define the notion of collaborative negotiation which defines students' interaction and their activity of languaging in online synchronous environments. Taking sociocultural theoretical points of departure, we are currently analyzing how students create meaning in language learning using tools that allows them to interact using multimodal resources. Preliminary findings suggest that the students are able to interact in the online videoconferencing environment using communication strategies in a rather flexible manner. Examples of the use of different modes – i.e. instant messaging, whiteboard and audio – and different codes will be presented. These will highlight the complexity of communication in these communities of practice. The organization of the meetings without teacher supervision gives rise to an overall pattern where each session can be understood in terms of three phases: an introduction, the core phase and a concluding phase. Some of the characteristics of students' interaction have been mapped and these include utterances like request for confirmation and phatics that can be understood as the equivalents of a smile or a nod where neither mouth nor head is actually visible, thus playing a predominant role as far as the social presence in the virtual classroom is concerned. Moreover, participants in these practices express concern over whether they are doing things right. If a student has problems with the audio modality and he/she has to use the chat-window inside the Adobe Connect environment, the communication tends to get less dynamic. Such delay in eliciting a response implies that there may be uncertainty about which medium they anticipate will be used by participants. The fluidity of the written and oral communication in face-to-face interaction is dis-preferred and instead members in these settings tend to communicate unimodally. Our analysis offers ways to understand this multilingual, unimodal communicative behavior.

Interdisciplinary design research: developing educational technology

Emma Mercier, Durham University, United Kingdom; Steven Higgins, University of Durham, United Kingdom; Liz Burd, Durham University, United Kingdom

As educators facing a global networked society, we recognize the need to develop high quality learning tools, that take advantage of advances in technology and our understanding of how people learn. However, we also recognize the documented difficulties encountered by interdisciplinary research teams, and how this has the potential to harm the development of these new tools. In this paper, we present three themes that may emerged from our own work designing technology-integrated classrooms. These themes, collaboration not cooperation, design research methods and decision making based on multiple disciplines and collaborative design, have the potential to support the interdisciplinary collaborative design of learning technologies.

Aims

Designing, studying and creating educational technology is, by its very nature, an interdisciplinary task, best achieved through an iterative design-research agenda (Goldman, DiGiano & Chorost, 2009). However, studies of interdisciplinary teams tell us that, while publications that result from collaborations can have an usually high impact (Panzarasa & Opsahl, 2008), research that spans multiple disciplines is at risk for not having any publications at all (Cummings & Kiesler, 2007). In this paper, we outline the research approach taken by the SynergyNet team, a research group focused on understanding and developing multi-touch technology for classrooms. This group spans computer science, education and psychology, reflecting the core disciplines necessary to develop and evaluate educational technology. In line with the conference theme, we will explore how the design research approach can be used to foster development of technology to support education for a global networked society.

Methodology

In this paper, we reflect on three themes which emerge through our research process, highlighting how each of these influences design decision, research directions and findings. Drawing on research about the science of team science (e.g. Stokols, Misra, Moser, Hall, & Taylor, 2008), and the design of educational technology (e.g. DiGiano, Goldman & Chorost, 2009), and participant observation of our own process, we will provide examples for each of the themes, and highlight how they can be used to support successful collaborative design of educational technology.

Findings

Collaboration, not cooperation

While interdisciplinary research is on the rise (Whitfield, 2008), the tendency can be for interdisciplinary research groups to function as separate teams, interacting within a 'trading zone' of shared meaning (Galison, 1997), before returning to their separate home disciplines. While this form of interaction facilitates understanding within the sphere of the project, and is identified as providing a useful space for an interdisciplinary team to function, there is little evidence to suggest it promotes transdisciplinary science, the form of interdisciplinary research associated with finding answers to novel questions (Rosenfield, 1992). Research into how students learn to design educational technology suggests that when they identify themselves as part of a cohesive team, they learn more and produce better learning activities, (Mercier, Goldman, & Booker, 2009) indicating the value of true collaborative engagement in the process, rather than the type of cooperative behaviour represented by Galison (1997). We draw on Bratman, (1992) to identify three features of interdisciplinary research collaborations that are necessary for the emergence of transdisciplinary science; namely mutual responsiveness, commitment to a joint goal and commitment to mutual support. Operationalizing these features when conducting design research in the field of educational technology results in the need to develop an attitude of attentiveness to each member of the team's actions, and response to the needs of the different disciplines, the identification of a common goal, and commitment to providing support to each other so that the goal can be achieved.

Design research methods

Design research, identified as a key method to bridge the scientific and practical demands of educational research (e.g. Brown, 1992), provides a structure within which findings from ongoing design and testing of these designs can be fed back into the design and research process, resulting in an iterative form of research, suitable for development of learning technology for formal education use. However, we also recognize the value of integrating traditional research methods, and answering smaller research questions through the process. This results in a process that holds the large research design structure as the driving force behind phases of the study, but integration of smaller, interesting questions, that have relevance to either the interdisciplinary questions, or the single disciplines represented in the team.

Decision making based on multiple disciplines and collaborative design

Our work also points towards the importance of collaborative design (Goldman, Mercier, & Booker, 2009), bringing multiple views to the design process, throughout the process, to inform the work. This results in continued consultation with teachers, researchers, designers, and learners at numerous stages of the design process. In this way, tensions between needs of the learners and teachers, limitations of the technology and research constraints, can be raised and incorporated into the process. In addition to direct collaboration with the various designers, researchers and users of this technology, we also recognize the importance of integrating existing research from multiple disciplines into our development process. From an education standpoint, the field of human-computer interaction provides a vast amount of research on how people interact with technology, creating an unparalleled starting point for those of us adapting or developing new technologies. By drawing on this literature, paying attention to how the findings relate to educational situations, we strengthen the tools that are being created, providing better ways of interacting with the technology, and thus, better opportunities for learning to occur (See Burd et al, under review, for an example of this process).

Significance

Education in a global networked society will require a new approach to the use of technology to support learning, and a new understanding of how interdisciplinary collaboration should function to develop these tools. In this paper, we present three themes that emerge from our interdisciplinary endeavor to create a multi-touch technology integrated classroom. The first theme, collaboration not cooperation, promotes the type of collaboration that should lead to transdisciplinary research, thus leading to a better understanding of how new technologies can be used for learning. The use of design research methodology, while also attending to more discrete research questions, allows for teams to continue to add to particular research domains, while being engaged in a longer-term project. Additionally, this feature eliminates the concern for low levels of publication from inter-disciplinary projects, and early career researcher's documented fear of engaging in such work due to fears that it will harm them within their primary field (Rhoten & Parker, 2004). Finally, by drawing on multiple fields and consulting teachers, students and researchers from different disciplines, the technology that is created for the global networked society can reflect best practices within all spheres, resulting in tools that are more valuable.

Exploring the impact of watching videotaped lectures on student academic performance in exams

Wanda Costen, University of Tennessee-Knoxville, United States

College students have a high degree of comfort with technology, and expect technology to play a large part in their learning environment. Research suggests that incorporating asynchronous web-based learning with face-to-face instruction can enhance student learning. This study was designed to measure the impact of using videotaped lectures posted to the course Virtual Learning Environment (VLE) of a traditional lecture course on student preparation for an exam in a hospitality human resources management course.

Introduction

Today's college students have grown up in the digital age with cell phones, personal digital assistants (PDAs), and computers. This means that today's college students have a high degree of comfort with technology, and expect technology to play a large part in their learning environment (Lowry and Flohr, 2004). As a result of this shift in students' technological capabilities, expectations, and the growing need for employees with digital skills, colleges and universities are pushing the use of technology. Vaidhyathan (2008) cautions however, that only a handful of first year college students understand "how the Internet fundamentally differs from the other major media platforms" (p. B7). Just because today's college students are comfortable texting messages and using Instant Messenger, and spend some of their leisure time playing video games, does not mean that they are truly technologically savvy or even comprehend how to use the available technology to help them learn. One of the ways to begin to leverage the value of technology on college and university campuses is to incorporate asynchronous web-based learning with face-to-face instruction (Garrison and Kanuka, 2004). Some research suggests that this approach can enhance student learning. One study (Tuckman, 2002), found that using a hybrid instructional model (ADAPT), which combined web-based and classroom components, significantly enhanced undergraduate student academic performance.

This study explores to what degree students use videotaped mini-lectures posted to the course Virtual Learning Environment (VLE) of a traditional lecture course to prepare for an exam. Additionally, this study is designed to uncover how using streaming video might help faculty provide additional resources that can deepen student learning. Specifically, this study was designed to address the following research questions:

1. Will students use videotaped mini-lectures posted to a course VLE to help them prepare for an exam?
2. Do videotaped mini-lectures posted to a course VLE help students prepare for an in-class exam?
3. How do videotaped lectures posted to a course VLE help students prepare for an in-class exam?

Methodology

This study was conducted in a required undergraduate human resources management course at a land grant university in the southeastern U.S. This is a traditional lecture course, and the students were primarily second and third year undergraduate students in the Retail, Hospitality & Tourism Management department.

During winter break 2007, the researcher video-recorded thirteen mini-lectures. Ten of the videos were under 6 minutes, and the longest video was almost 14 minutes. Each of the videos was uploaded to the course VLE, which contained separate links to each of the lectures.

After the exam was administered, the researcher conducted face-to-face, semi-structured interviews with each of the students who watched the videos. The interviews, which lasted 10-15 minutes, were conducted in the researcher's

office. The interviews were tape recorded and transcribed by a professional transcriber. The interviews were then coded using QDA Miner qualitative data analysis software.

Findings

The first research question addressed whether or not students would be interested in viewing online videotaped lectures to help them prepare for an exam. Based on the student response, this answer appears to be no. Only 20 of the 65 students (30.7%) in the course actually accessed the videotaped mini-lectures. Twelve of the eighteen participants mentioned that they spent more time studying for the exam than they would have without the online review sessions. One participant commented, "...I would not have hardly read my notes as much as I rewatched those videos". Another participant even remarked that the videotaped lectures actually encouraged her to study more, "Sometimes it kinda made me want to study more since I wasn't like had to read the book, because you get burnt out on reading the book". Yet another added, "It sorta forced me to go ahead and [start preparing for the exam], and that was very helpful in a very stressful week".

One of the most interesting findings was that the participants developed multiple study methods as a result of having the videotaped lectures available to them. Many students created their own study guides or took notes during the online lectures: "...just to be able to listen, and type, and just make me a study guide by what you were saying". Another commented, "I could go to my book or go to my class notes", while yet another mentioned, "I would listen to what you had to say and look in the book and re-read that information".

Finally, providing the video lectures online seemed to prompt the students to take an active role in preparing for the exam. Student participants indicated that they liked having control over which topics they were covering, and when they could study the online material. The findings also suggest that the student participants were engaged in meaningful learning. They were able to take the explanations and examples presented in the videotaped lectures and combine them with the knowledge they had already gained from in-class lectures and reading their text book, to prepare themselves to apply this knowledge to the situations presented on the exam.

Conclusion

The results of this study indicate that using videotaped lectures posted to a VLE website allowed student participants to take control over their learning process, and determine which resources were most valuable to them in preparing for an exam. The videotaped lectures also seemed to encourage these participants begin the exam preparation process earlier than they might have. Finally, the videotaped lectures seemed to help the student deepen their knowledge of the concepts. It is therefore in the faculty's best interest to discover ways of incorporating technology into their teaching methods.

How Do Online Distance Learners Work During Collaborative Writing Tasks?

Virginie Demeure, Universitat Autònoma de Barcelona, France; Margarida Romero, Esade, Spain; Niki Lambropoulos, LSBU, United Kingdom

Online distance learners are in majority adults with work and family constraints. They generally choose to engage in a virtual campus for the time flexibility that is offered through them but are often confronted with collaborative learning activities which, by increasing organizational efforts, reduce their individual time flexibility in proportion. Given this information, this paper argues that time is a major variable in Computer Supported Collaborative Learning (hereinafter CSCL) activities and proposes an assessment of students time use in these situations. The aim being to help instructional designers to propose an adequate temporal scripting to plan these kinds of more and more strewed educational activities. The case study presents an exploratory analysis of temporal patterns of 15 groups of students (n=66) involved in a collaborative writing task. Results reveal that (i) e-learners' time-on-task increased from the beginning of the activity, (ii) they work more during week days than during the weekend, and (iii) they tend to work during "conventional" hours of the day instead of working during early or late hours. The identification of these patterns is the first step toward the development of new methodologies and computer-supported tools able to enhance the temporal organisation and social aspects of CSCL.

Despite the large interest for Computer Supported Collaborative Learning (CSCL), in literature (Dillenbourg, Järvelä & Fisher, 2009; Stahl, Koschmann & Suthers, 2006), very few studies have examined the efforts required in regards to coordination when considering time as a focus variable (Gros, Barbera & Kirshner). This paper supports the idea that time is a major variable in CSCL activities, and that understanding the time factor in e-learning is important to help students succeed.

Indeed, several studies have shown the importance of time flexibility in a student's decision to enrol in an online course, but this individual flexibility is no longer a guarantee in collaborative learning contexts because of the increase in organizational effort. At the collective level, the realization of a task requires not only academic work from students but also organizational efforts to be able to coordinate their work on the task. Students must also find a shared time to discuss their work and decide who will do each part of the task. The more time students spend on coordination, the less remains for the learning task itself. Students' time use is thus valuable data for people trying to support collaborative e-learning activities. However, few studies focus on the time factor assessment in this kind of activities. We think that assessment of temporal patterns of e-learners' activities can provide us with essential information about how and when giving supports in CSCL and e-learning in general.

Temporal patterns have been largely used in working groups to describe their dynamics, but very few studies focused on the learning context in general and the CSCL contexts in particular. We argue that knowing how e-learners manage their time can enable researchers to better understand the learning process in CSCL, while enabling instructional designers and teachers to better adapt the temporal characteristics of learning activities (duration, milestones, synchronicity, etc.). The literature about temporal patterns is highly heterogeneous regarding the duration of the investigated patterns (from some seconds to decades). In our context, we choose to follow the recommendation of Cress (2008), and to study students' temporal patterns according to a multilevel model including task level, weekly level, and daily level. The task level includes the total duration of the academic task and is the least studied in literature. The second level explores the way students organize their time schedule for the week, with a particular interest in the differences between week days and weekends. Finally, the third level compares students' time-on-task during the daytime hours.

Data have been recollected during an authentic CSCL task conducted in an international context. During the collaborative tasks, groups of five students ($n=15$) were asked to write an article on the theme of CSCL on a Knol (wiki technology). Recollected Knols logs describe the type of contribution made by each group member, with its date and hour of publication. For our exploratory analysis, we considered the date of the contribution in relation to the beginning of the task, (day after the start of the activity), the day of the week when the contribution was made, and at what hour.

Results were analysed using within subject ANOVA, including groups of students as a between subject factor. As no group effects have been found in each of the three levels of analysis, the following results include all the students.

Firstly, at the task level, results reveal a main effect of longitudinal activity, [$F(2,46) = 13.09$, $p = .001$], and post-hoc test shows that students' time-on-task increased constantly until the deadline. The mean of participation on the Knol goes from 4.43 ($SD = .80$), at the beginning of the task, (days 0 to 10), to 10.93 ($SD = 1.65$), at the mid-point of the task, (days 11 to 21), $p = .001$, at the end of the activity, (days 22 to 32), $p = .004$.

Secondly, at the weekly level, results conducted on the basis of the participation mean of each participant during week days, (Monday to Friday), as well as weekend days, revealed one main effect on the days of the week, [$F(6,42) = 2.44$, $p = .04$, $\eta^2 = .005$]. Post-hoc tests show that e-learners tend to work more during week days, (mean = 5.36, $SD = 6.57$), than during weekend days, (mean = 3.07, $SD = 4.72$) [$F(1,47) = 7.15$, $p = .01$, $\eta^2 = .04$].

Finally, at the daily level, results reveal a main effect on the time period, [$F(5,43) = 7.61$, $p = .001$], and a post-hoc test showed that students tend to work more in the late morning, (10 a.m. to 1 p.m.), mean = 8.65, $SD = 1.52$, afternoon, (2 p.m. to 5 p.m.), mean = 9.41, $SD = 1.65$, and early evening, (6 p.m. to 9 p.m.), mean = 8.18, $SD = 1.48$, than in the early morning, (6 a.m. to 9 a.m.), mean = 4.15, $SD = 0.89$, (respectively $p = .001$, $p = .002$ and $p = .011$), the late evening (10 p.m. to 1 a.m.), mean = 1.31, $SD = 0.52$ (all $p < .05$ a.m.), mean = 0.27, $SD = 0.24$ (all $p < .05$).

These results tend to substantiate the fact that students spend the first part of the task on organizational concerns and start progressively to work on the academic task itself. They also show that e-learners, maybe due to their work and family constraints, avoid to work during weekends and non-conventional hours of work (i.e. early morning, night and late evening).

On this basis, we can recommend the use of tools facilitating the organizational phase in order to free up time for the academic task earlier in the fixed time of the activity. This measure could help students to succeed by increasing their time-on-task. Moreover, considering that e-learners used residual time for their academic tasks, better knowledge of their temporal patterns can also be useful to help them to free up time of better quality.

Learning and digital technologies: A reframing of the relationship

Judy M. Parr, University of Auckland, Faculty of Education, New Zealand; Lorrae Ward, CYPERUS, New Zealand

Integration of technology into education as a catalyst for change seemingly remains problematic. Computers have been largely a solution looking for a problem. In this paper we illustrate how technology can be a means by which schools can instantiate their educational philosophy and achieve particular goals or meet specific needs for student learning. We examine how the integration of technology into classrooms was given impetus by the provision of personal laptops for teachers. As part of a longitudinal evaluative study of the impact of teacher laptops, we identified from our larger sample, three case study schools, where technology had been embedded into practice. In each, we observed teaching and learning in a sample of classrooms, interviewing both students and teachers. The identified learning goals and needs were different in each school. However, digital technologies were an integral part of the solution in each: to enact invitational learning, the overarching philosophy in the first school; to enrich the learning experiences of students, the foremost aim in the second school and to promote language development, the goal of the third school. Across the schools, the teacher laptops had become a hub for technology-supported learning; a fundamental tool of the trade in classroom practice.

Aims

This paper is drawn from a longitudinal evaluative research project investigating the impact of the provision of portable computers to teachers in primary schools (5 - 13 year old students). Here we specifically consider pedagogical practice in three case-study schools; situating the role of digital technologies within the daily activities of classrooms.

Methods

The study employed a case study design; the bounded phenomenon was that of the teacher laptop in teaching and learning, particularly in the classroom. As a conceptual framework for viewing the thematic data gathered we utilised a simplified version of problem-based methodology (Robinson, 1993). Within this methodology, practice is viewed as a solution to a problem (goal or purpose) within a given context and set of constraints.

Participants

Three schools were selected from our wider sample of participant schools as we had discerned from earlier evaluation activities (surveys, visits, interviews) that the laptops and other technology were likely to be embedded in the school. Three classrooms within each school were purposively selected to represent the age range of children in the primary sector. These had been recommended by senior leaders as classrooms where technology was consistently used by teachers and students to support learning.

Data collection and analysis

Each case study school was visited for two or three days. In a sample of classrooms (n=9), we observed lessons and talked with students about the use of digital technologies. Where possible we asked students to show us samples of their work and tell us about the process of creation. We interviewed teachers about the classroom events we had observed and also about their learning and experiences with respect to technology. We obtained samples of student work, details of blog sites, of assignments and took copies of page dumps from the laptops to examine how teachers utilised their laptops and as an indicator of the range and extent of use. We held a semi-structured interview to discuss technology in the school and the teacher laptop program with both the technology leader and the principal. We also compiled an inventory of available technology and obtained copies of any policies pertaining to technology use.

A constant comparative analysis process (Glaser, 1965) was used to determine the central ideas and themes arising from the data. As an initial step, at the end of each day of observation, we reviewed our field notes, discussed emergent themes and ideas and cross-checked our inferences. A systematic, summative analysis of the data was then undertaken, looking for similarities and differences.

Findings

There were some strong commonalities across all three schools despite the contextual differences such as school demographics and infrastructure. First, each of the schools had a clearly articulated vision for learning. In one of the schools there was a focus on invitational learning; in another on promoting diverse and authentic learning opportunities and, in the third, specific emphasis on supporting and enriching the development of oral and written language in the third.

Second, in each school, the place and purpose of digital technologies was natural and unforced. They were part of a wide range of pedagogies and associated media employed, where appropriate, to meet student needs and to enrich their learning experiences. They were also ubiquitous in terms of planning and professional work.

Third, the teacher laptops were the hub for digital technologies; a central and indispensable tool for teaching and learning. They provided access to resources; links to the outside world and connection to a broad range of other tools and infrastructure. They were resource and student work repositories, communication tools and devices for teacher planning and preparation.

The findings from this study showed that when digital technologies are seen as part of the pedagogical solution to achieving a desired learning outcome they are readily embedded into practice. The use of digital technologies was not an end in and of itself in these schools; it was a means to a clearly articulated and shared vision for learning.

Educational significance

The vision of digital technologies as embedded classroom tools has long remained elusive. Despite, increased access to technology for students there appears to have been little change to the teaching and learning practices in many classrooms (Cox et al 2003; Hayes, 2007). Integration, the vision where technology is a seamless part of the educational environment, providing support for the type of learning experiences that engage students; experiences that are meaningful, relevant and intellectually stimulating (Bransford, Brown, & Cocking, 2003), has reportedly not happened except in isolated instances.

The significance of this study lies in its illustration of the importance of considering the use of digital technologies through a learning lens; both in terms of teacher practice and the study of that practice. The methodology employed specifically focused on classroom practice and on student learning rather than the use of technology. Likewise the teachers studied focused on student learning and pedagogy; the integration of technology flowed from this central concern. Critically, we uncovered more diverse types of use than had been anticipated from the data from the wider evaluation pertaining to these schools. The questions that should be asked both by researchers and practitioners are: what are the desired outcomes for students and what pedagogical tools, knowledge and resources will best achieve these outcomes? Digital technologies are likely to feature in both the answers and the solutions.

Creating Personal Learning Environments with Open Educational Resources

Stefanie Panke, Ulm University, Germany; Tina Seufert, Ulm University, Germany

In the past ten years, the idea of educational material, freely and openly accessible on the Web, has attracted growing attention. Current research on Open Educational Resources (OER) usually focuses on benefits on the institutional and organizational level as well as models for the sustainable production and provision. To fully understand the concept's role in informal as well as institutional learning, we need to shift our attention towards the learners' use of OER. Information is everywhere; but how do learners actively make sense of their everyday information ecology? To adequately inform instructional design practice, we need empirical studies, training programs and theoretical frameworks that address effective self-organized learning strategies for open environments. The goal of the proposed round table is to discuss a research agenda that focuses on the individual learner in a tripartite, exploratory strategy: 1. What is the current level of OER-usage among formal and informal learners? 2. How do informal and formal learners create resp. enrich their personal learning environments with open educational resources? 3. What competencies students need to interact with open educational resources? With regards to methodology, the research design follows a mixed methods approach based on content analysis, qualitative interviews, observations and questionnaires. Initial data will be presented and discussed at the roundtable session.

Introduction

The term OER was coined in 2002 on a forum held by the UNESCO as „the open provision of educational resources, enabled by information and communication technologies, for consultation, use and adaptation by a community of users for non-commercial purposes". Since then, the concept has gained an undeniable momentum. In 2010, the Horizon report, which identifies emerging technologies likely to have a large impact on teaching and learning, described "Open Content" as a key trend, expected to reach mainstream within the next twelve months. In the fall 2010, the UNESCO initiated an international online discussion on OER-related topics. The "European Consultative group on Open Educational Practices" currently develops a roadmap towards quality management in OER.

Despite the substantial attention, a general consensus on the scope and classification of the term OER is yet to be found. Goertz and Johanning (2007) conclude from the analysis of selected OER-portals that their design is extremely heterogeneous. Also, numerous projects are in accordance with the goals of the OER movement, without explicitly referring to the label.

Aims

The aim of this research is to understand the use of open educational resources from the individual learner's point of view, adding a new perspective to the institutional or group focus of recent surveys (e.g. OPAL, 2010). What theoretical considerations account for the assumption that learners profit from OER in the first place? The theoretical framework can build on concepts such as learner autonomy (Bouchard, 2009), self-efficacy (Bandura, 1997), open-ended learning environments (Land & Hannafin, 1996) and cognitive flexibility theory (Spiro et al., 1992). OER provide the building-blocks to construct personal learning environments - and pose challenges to self-organized learners: Given that "the level of adoption of OERs into common teaching practices remains quite low" (De Liddo, 2010), many university students are unaware of open learning opportunities or struggle to negotiate and integrate open educational resources with the formal, institutionalized parts of their education. Informal learners, on the other hand, express difficulties with the lack of formal recognition and assessment components (Godwin and McAndrew, 2008). For both groups, the quantity of OER poses problems in itself - filtering what is useful and applies to the individual learner's needs can be a large task (Richards et al., 2010). Making effective use of OER in instructional contexts requires strategies to support coherence formation to integrate multiple representations from multiple sources (Seufert, 2003).

The research aims at (1) depicting the state of the art of OER usage in formal and informal learning, (2) categorizing learning strategies, (3) identifying the competencies necessary for effective use of OER.

Methods

The research design is exploratory and seeks to gather preliminary information to illuminate the phenomenon. For the roundtable, initial data from the following sources will be presented: User Models & User data of OER suppliers: The secondary analysis of qualitative data (OPAL, 2010; Helsdingen, Janssen & Schuwer, in press) as well as the systematic review of research literature, grey literature, and mailing lists, depicts current OER user models and user data. Learning Strategies of Informal Learners: The participatory observation of open educational practices serves to identify interview partners for gathering primary data on informal learning strategies. Learning Strategies of Formal Learners: Individual students' learning diaries (before and after receiving OER-trainings) serve as a starting point to systematize open educational practices within higher education settings. Competencies for Filtering and Coherence Formation: Thinking aloud protocols, screen recordings and questionnaires are used to observe the interaction of students with selected OER portals.

Outlook

Despite the considerable momentum of the OER movement, its impact is still limited. The mere availability of learning material does not mean that learning occurs. Shifting the focus from the resources to the learners' practices can help to stimulate and support students' integration of open educational resources into their learning environment.

Mobile Phones and Learning: Disruptive or Constructive?

Jocelyn Wishart, University of Bristol, United Kingdom

Whilst research shows mobile phones offer opportunities to support constructive learning in and across a range of context including classrooms, schools are more likely to ban them as potentially disruptive devices. As phones such as the Samsung Beam with inbuilt pico-projectors enabling them to project images on nearby walls or screens become more widely available we have ever more challenging learning opportunities to look forward to. Yet we are in danger of losing such opportunities through collective fear of cyberbullying and irresponsible use by pupils of a technology whose potential their teachers haven't been given time to fully explore. The proposed round table will bring researchers together to debate and share evidence to assess whether this is a sad reflection on the state of current education systems in the 'knowledge age' or a challenge that can be easily addressed through education for 'knowledge age' skills and to consider how this can be achieved. The discussion will address previous and current research into learning and instructional technology that can underpin the proposed focus on supporting young people to develop ethical and responsible practices for the use of personal, mobile devices including phones so that they can be deployed to their full potential in educational situations.

In a number of countries, especially those where information and communications technology (ICT) provision in schools is inconsistent or poor, teachers are turning to the use of mobile devices such as the students' mobile (cell) phones to support teaching and learning. For example, Vanska (2010) describes a project supported by Nokia where over 4,000 South African secondary school students are engaged in learning maths via tutorials and practice sessions that run on their mobile phones. The students' learning and engagement are supported via a Moodle mobile interface and a social networking via Mxlt, a very cheap 'chat' tool. Ekanayake & Wishart (2010) describe a much smaller project where teachers in four secondary schools in Sri Lanka designed science lessons centred on the pupils' use of mobile phones to support their learning. In particular mobile phones appear to offer students the ability to construct their learning by building on information captured (and often shared) across a range of contexts (Wishart, 2007). Whilst the above two projects differ massively in scale, they share a common finding in that the teachers are delighted with their students' response to the initiative. Yet, in secondary schools in the UK, use of mobile phones by students is more likely to be banned than celebrated. In December 2007 England's Children's Minister, Kevin Brennan, backed by the general secretary of a teaching union, urged parents not to allow their children to take their Christmas toys, such as mobile phones, to school (BBC News, 2007). Whilst there are some 'pockets of potential' particularly associated with science teaching such as the Personal Inquiry (PI) project being run by the Open and Nottingham Universities (Anastopoulou et al, 2009) and the Participate project at the University of Bath (Woodgate et al, 2007), these involve handheld data capture tools and netbooks rather than ordinary phones. Even the successful, district wide Learning2Go project run in 18 Wolverhampton schools relies on personal digital assistants (PDAs) customised for teaching and learning. The assumption, prevalent in UK schools, that mobile phones are disruptive devices led teacher trainees to feel reluctant to explore the potential of handheld PDAs loaned to them by their University to support their teaching and learning (Wishart et al, 2007). Their pupils were assuming the PDAs were phones. Similar issues occurred in the ALPS project with nurse trainees who were reprimanded by clinical staff, including their assessors, whilst legitimately using mobile devices for data entry in clinical settings. Patients too, apparently reported their nurses for 'texting' whilst on duty (Sandars and Dearnley, 2009). However, Hartnell Young and Heym (2008) found three secondary schools in England prepared to explore how mobile phones could help learning despite having policies banning their use in class. This led to the identification of 15 key activities where mobile phones could be used

successful to support learning. The use of the phone's camera was particularly helpful to capture one off events and experiments for later revision and review. Hartnell Young and Heym (2008) conclude that schools need to revisit their policies and consider shifting the focus of policy away from the devices themselves to consider the frequently-reported reasons for which mobile phones are banned: fear of distraction in class, cheating, inappropriate recording of students and teachers and publication on sites like YouTube.

As phones such as the Samsung Beam with inbuilt pico-projectors enabling them to project images on nearby walls or screens become more widely available, as does reliable and affordable connectivity, we have ever more exciting and engaging learning opportunities to look forward to. Yet we are in danger of losing such opportunities through collective fear of cyberbullying and irresponsible use by pupils of a technology whose potential their teachers haven't been given time to fully explore. Already state boards like those in New York and Toronto and even countries such as India, Brunei and Sri Lanka are banning mobile phones outright in schools, blaming irresponsible use by students. The proposed round table will bring researchers together to debate and share evidence to assess whether this is a sad reflection on the state of current education systems in the 'knowledge age' or a challenge that can be easily addressed through education for 'knowledge age' skills and consider how this can be achieved. The discussion will address previous and current research into learning and instructional technology that can underpin the proposed focus on supporting young people to develop ethical and responsible practices for the use of personal, mobile devices including phones so that they can be deployed to their full potential in educational situations.

ROUND TABLES

Merging and Crossing Knowledge Domains in Collaborative Design for Networked Learning

Yael Kali, University of Haifa, Israel; Lina Markauskaite, University of Sydney, Australia; Peter Goodyear, University of Sydney, Australia; Mary-Helen Ward, University of Sydney, Australia

Designing networked learning materials requires merging of technological, pedagogical, and content knowledge domains. Multiple-expertise collaborations are often regarded as a solution, however, such collaborations may involve challenges resulting from different ways of thinking between technology and pedagogy experts. The current research examined the collaborative design process of three teams who were part of an initiative to develop high-level networked learning materials within a university setting. Using an ethnographic case-study approach, we found that in all three teams: (1) participants suggested design solutions only after extensive group exploration of the pedagogical-content aspects of the problem, and the technological considerations it entails, (2) design decisions were made in a balanced process in which both academic team members and eLearning designers were equally involved, (3) participants appreciated each other's expertise and used the team-meetings to learn from their colleagues about

aspects of the design challenge they were not aware of, and (4) participants crossed their domain of expertise, and carefully provided ideas that were not in their own domain. The success of the three teams in designing solutions that were based on their shared knowledge is explained in light of the process of the university initiative.

Introduction

Designing networked learning materials requires merging of knowledge from several different domains. Mishra and Koehler (2006), who studied how teachers cope with this challenge, claim that three major knowledge domains are involved: technology, pedagogy content. They describe a unique type of knowledge merging the three, which they name Technological Pedagogical Content Knowledge (or TPCK).

Naturally, when major design endeavours are at hand, and when the knowledge domains involved require high-level expertise, people prefer to work in collaborative teams. There are many advantages in such collaborative design efforts, however, some major challenges have been documented. diSessa, Azevedo, & Parnafes (2004), for instance, note that in teams of educators and technologists, there might be cultural gaps that hinder the collaboration, and that educators tend to have a smaller contribution to the collaborative design effort.

The current research examined the collaborative design work of three teams who were part of an initiative to develop high-level networked learning materials within a university setting (Ward, Atkinson, & Peat, 2010). Each team came from a different knowledge domain (Nursing, Social-work and Health-science), and consisted of a few academic staff-members (domain experts) and one or two non-academic staff-members (eLearning design experts). The goal of the research was to decipher what makes a collaborative design process a productive one.

Method

We observed about 90% of the teams' meetings over a course of four months, in which a major part of the design work was conducted. Our data includes audio-taped team-meetings, observation-notes, team e-mails, and some interviews.

We followed an ethnographic case-study approach to: (a)choose the episodes to analyze, (b)develop and refine a coding scheme, (c)code the data and (d)develop our claims. Our coding scheme combined two frameworks. The first is Mishra & Koehler's TPCK, which enabled us to characterize participants' contributions in terms of the type of knowledge they brought to the collaboration. The second framework – shared epistemic agency - enabled us to distinguish between different types of collaborative knowledge-building activities in the group such as seeking information, sharing ideas, structuring ideas and producing ideas (Damsa et al., 2010).

Findings

Our analysis revealed four unique characteristics of the collaborative design process in each of the three teams:

1.Participants did not attempt to provide solutions before they had a good understanding of the pedagogical-content and technological challenge they were faced with, as is exemplified in Figure-1. (The figure represents the collaborative design process that took place in one of the team meetings. The horizontal axis shows a timeline of about one hour, each tick showing one saying of a team-member. The vertical axis represents accumulation of T, PC and TPC knowledge within the team. Each contribution of a piece of knowledge is counted as one arbitrary unit, and knowledge is viewed as accumulating within the team). The gradual rise of the three lines in Figure-1 indicates that the progression of design ideas was associated with extensive T and PC knowledge sharing.

2.Design decisions were made in a balanced process in which both academic team members and eLearning designers were equally involved. This is exemplified in Figure-2 by the interchange of red and blue light-bulb icons, representing design ideas suggested by academics and eLearning designers.

3.Participants appreciated each other's expertise and used the team-meetings to learn from their colleagues about aspects of the design challenge they were not aware of. This was evident in many instances in which participants seek knowledge either in their own domain of expertise or in the others' domain. See for example the question-marks in figure-2 representing seeking of knowledge by both academics and eLearning designers.

4.In some instances, participants crossed their domain of expertise, and carefully provided ideas that were not in their own domain. This was usually followed by feedback from a domain expert, and was a productive way to move the discussion forward. See for example the red exclamation mark (representing an academic team-member sharing knowledge) on the blue line (representing technology knowledge), and blue exclamation mark on the red line.

Discussion

Despite the challenges described in the literature regarding collaborative design, the three teams that we observed were highly successful in designing solutions that were based on a growing body of knowledge within the team, which was pretty equally contributed by the academics and the eLearning designers. The question is why? What was there in the specific settings of these three teams that enabled them to succeed so well where others have failed? We believe that the answer is in the thought-out process of the university initiative which these teams were part of (Ward et al., 2010).

We see at least two aspects of this process, which might have contributed to the mutual appreciation that academics and eLearning designers had to each other's expertise. First, the eLearning designers are carefully chosen with a significant pedagogical background. Second, the projects are chosen via an extended application and planning period, in which expert committees help to articulate and prioritise projects. We think that in this way only academic teams that have a good sense of what they can expect from the technology are chosen. These two aspects of the process probably helped minimize 'cultural gaps' and enabled the mutual respect that we found in our analysis.

Concluding remarks

Combining the TPCK and the shared epistemic agency frameworks help to shed light on the complex process of collaborative design for networked learning. The full paper will elaborate on our findings and practical implications, discuss the limitations of this study and directions for future research.

Introducing planning in socio-constructionist activities in Environmental Education, Maths, Physics

Nikoleta Yiannoutsou, Educational Technology Lab, University of Athens, Greece; Maria Daskolia, University of Athens, Environmental Education Lab, Greece; Foteini Moustaki, University of Athens, Educational Technology Lab, Greece; Chronis Kynigos, University of Athens, Educational Technology Lab, Greece; Zacharoula Smyrniou, National Kapodistrian University of Athens, Greece

We describe here a research that focuses on the study of planning in constructionist learning environments that involve concepts related to environmental education, mathematics, and physics. We focus on constructionist activities because we consider them a different case for planning from those presented in the literature. Constructionist activities integrate self regulation and what we call emergent planning. We conducted a study with eleven secondary teachers to observe them as learners that plan their constructions and discuss the role of planning with them as reflective practitioners. Our findings show that planning took place during the enactment of the activity and not before and had a mainly reflective and not an "organizing" role for the task.

Planning has been addressed as an element, among others, of self-regulated learning (SRL) or as one of the three phases of cognitive regulation (along with monitoring and evaluation) and it has been described as a general domain metacognitive skill (Schraw 2007). In many studies planning is part of a broader research on self regulated learning and no special emphasis has been placed on it. We identify five main trends in research in self regulated learning a) on factors that influence self regulated learning such as personal epistemologies, motivation, characteristics of the task, discipline (VanderStoep 1996), b) on research and evaluation of self regulated learning and c) on tools that can support self regulated learning with special emphasis on technology based support (for a review see Schraw *ibid*) and d) on the role of self regulated learning in domain specific learning such as maths, (Labuhn et al 2010) reading comprehension etc, and in computer based learning which is the focus of our study also. The emphasis in computer based learning is documented upon the argument that the personal learning styles and the independence in learning require more than ever self-regulatory skills (see for example Strömsö & Bråten 2009 with emphasis on internet based learning) Most of the studies that focus in SRL in computer based environments involve cscl environments, internet based learning, hypertext or hypermedia environments but we found no reference to constructionist environments (i.e. microworlds). Constructionism, which could be considered as a branch of constructivism (Ackermann 2001) as it shares the view of building knowledge structures through progressive internalization of action adds that learning can take place more felicitously if learners are engaged in constructing a public entity (be it a computer model or a sand castle) with

personal meaning (Papert 1991). What makes constructionist activities an important aspect of study is the role of planning during this construction. As Papert claims (1993) learning in computer based constructionist environments (microworld) does not require a detailed planning but the learners can start with a vague idea of what they are going to do. In this case planning is an emergent process which evolves along with the construction informed by the task related feedback offered from the microworld. This seems to be a quite different learning situation from those described with the tools mentioned before. Taking into account that planning in this case is emergent and sometimes it is difficult to be made beforehand because the process of construction is dynamic, it is changing and evolves through the interaction with the microworld we formulated a Research Question that focused on how planning could be used in constructionist activities and apart from the emergent step by step plans that seem to formulate during construction is there place for a more general plan that includes them all?.

Method and research process

To make planning a specific task for the participants of our study we introduced a planning vocabulary consisting of twenty two concepts such as hypothesis forming and testing, discussion, observation, experimentation etc and by 2 types of concept relationships: dependent relationships, alternate relationships. The participants were informed that they could create their own concepts or relationships if those available were not sufficient for their planning. We report here on a study with 11 secondary teachers specialized in mathematics (4), physics (2) and environmental education (5). We used teachers in this phase of our study because we wanted not only to observe learners during the planning process but also to record their point of view about planning as experts. Participants formed 4 groups of two and one group of 3. Two groups worked with a microworld in 3d mathematics, one group worked with a microworld in 3d physics and two groups worked with a microworld in environmental education (focusing on issues of sustainability). All participants were familiar with constructionist environments and constructionist learning. In each group there was at least one person who was familiar with the task at hand and had the role to explain it to the other member(s) of the group. The data collected include: observational notes of group discussions and assembly discussions, the concept maps of the planning process created by the participants and the responses to the questionnaires distributed.

Findings- Final Remarks:

All plans contained task free information. Two out of the six plans were linear, the rest contained alternatives and loop relationships. The most concepts that were more frequently used were "discussion" "experimentation" "observation" and "Reflection". Planning took place during the enactment of the activity and not before. The planning vocabulary was used as a reflection tool and not as a driving force on how to organize the work on the task. Teachers in one group said that the planning vocabulary helped them to think more deeply on the teaching process because it allowed them to focus on the details of the task and on the functionalities of the microworld. These findings suggest that the role of planning in the self regulation process of learning can take a different form according to the characteristics of the learning environment.

A study of the relationship between meta-cognitive knowledge on essay writing and essay score

Aims of this research is to examine

1)the structure of meta-cognitive knowledge on Japanese college students' essay writing based on questionnaire survey

2)the relationship between the importance of each dimension on meta-cognitive knowledge and essay score.

Participant was 119 undergraduate students(98 freshmen, 5 sophomore, 10 junior, 6 senior; mean age=19.4) and they conducted the following two tasks; writing assignment about their participation in part-time job outside universities(in about 600 characters in Japanese) and questionnaire about the meta-cognitive knowledge on essay writing. Results showed that three factors emerged on meta-cognitive knowledge and that the dimension about readability of one's text produced was significantly correlated with "organization" of the text.

Introduction

Essay writing is one of the very complex and tough task even for college students in Japan. Promoting their essay writing skill is one of the most important things. In considering this, differences between expert(good) and novice(basic,or poor) writers on their writing activities is the central issue. Several studies have examined this theme. Bereiter and Scardamalia(1987), for example, found that experts could transform ideas from long term memory into what they wanted to say correctly and fluently("knowledge transforming"), while novice could not. Another study also showed the difference between them. Flower, Schriver, Carey, Haas, and Hayes(1993) pointed out that experts could select ideas and expressions considering readers and contexts in which the text was read. Considering the result of their findings, it would be assumed that writers have some kinds of meta-cognitive activities based on their meta-cognitive knowledge about essay writing, as Flower & Hayes(1980) pointed out.

However, little is known about how the content and structure of meta-cognitive knowledge they have is like, how it relates with essay scoring. In this study the followings were examined.

Aims

Aims of this research is to examine

1)the structure of meta-cognitive knowledge on Japanese college students' essay writing based on questionnaire survey

2)the relationship between the importance of each dimension on meta-cognitive knowledge and essay score

Method

Participant was 119 undergraduate students(98 freshmen, 5 sophomore, 10 junior, 6 senior;mean age=19.4). First, writing assignment was conducted. They were asked to write an essay about their participation in part-time job outside universities in about 600 characters in Japanese (about 250 words in English). Then, one week after the writing assignment, questionnaire about the meta-cognitive knowledge on essay writing was administered, which is consisted of 46 items related to what one does on during essay writing (e.g."I will pay attention to the context of my text produced"). Items were collected from several high-school "kokugo" (Japanese) textbooks (Kiri-hara-shoten,2007;Meijishoin,2007; Sanseido,2007;Sukenshuppan,2007a,2007b;Taishukan,2007a,2007b and Tokyo-shoseki, 2007). They were asked to mark the circle in each item about how they think it is important in writing activities in 7 point scale(1=strongly disagree, 7=strongly agree).

Results

The following data analyses were administered; factor analysis, essay scoring, and the relationship between scores of the importance on meta-cognitive knowledge in each factorial dimension and essay score.

1)Factor analysis

Exploratory factor analysis on meta-cognitive knowledge was examined and three factorial dimensions emerged; "Clarity of one's own ideas"(a=0.92),"Readability of the text produced "(a=0.92), and "Rules of the text production"(a=0.78).

2)Essay scoring

Their Essay produced was scored by JESS(Automated Japanese Essay Scoring System, like e-rater in the U.S.) from three dimensions;"rhetoric","organi-zation",and "content" in 6 point scale(from 0 to 5;0 is the lowest and 5 is the highest).

3)Correlation between factorial score and essay score

Scores of the importance on meta-cognitive knowledge in each factorial dimension was calculated by adding up all of the score participant marked. Then, correlation coefficient between score on the importance of meta-cognitive knowledge and essay score, which resulted in the significant correlation between "Readability of the text produced to other readers" and "organization" ($r=.29$)

Conclusion

In this study, significant correlation between "Readability of the text produced to other readers" and "organization" emerged, which implies some relationship between them. In "Readability of the text produced to other readers" dimension, items related to the better organization of the text (e.g. "I will pay attention to the context of my text produced") were included, which was assumed to lead such results. Considering this, it would be possible to predict "organization" skill from the questionnaire score. However, no significance emerged between other two dimensions on meta-cognitive knowledge and the rest of essay score ("content" and "rhetorical"), so item collection related to content and rhetorical dimensions and elaboration of the factorial dimension related to essay scoring would be required in my future research.

Writing in Bidialectal Settings and the Challenges Posed to Immigrant Pupils

Filio Constantinou, University of Cambridge, United Kingdom

The language of schooling poses a challenge to children, especially second language learners and non-standard speakers (Gibbons, 2006; Schleppegrell, 2004). This challenge becomes even more daunting for immigrant bidialectal pupils (i.e. second language learners concurrently exposed to a non-standard variety), who have to familiarise themselves with the conventions of the school register while developing competence in the second dialect of a second language. This study (work in progress) will explore, in particular, the writing challenges which these pupils are confronted with and is expected to provide policy-makers and practitioners with important guidelines with respect to the language education of a growing but still under-researched group of non-mainstream pupils. The project will adopt a mixed-methods approach to the investigation of pupils' written performance and will be conducted in Cyprus which, due to its bidialectal and increasingly multilingual character, constitutes an ideal setting for this research. The round-table discussion will focus on issues pertaining to the analysis and interpretation of the data.

The language of schooling, that is, the register which pupils are expected to employ when completing school-based tasks, differs from the conversational language typically used for social purposes outside the classroom (Gibbons, 2006; Schleppegrell, 2004). Consequently, its mastery poses a challenge for children who are normally not accustomed to constructing meaning using the linguistic structures favoured by the school register. This challenge becomes more daunting for non-mainstream pupils, such as second language learners and non-standard speakers, who have to familiarise themselves with the conventions of the new register while developing competence in a second language and a second dialect respectively.

The students, however, likely to face greater difficulties operating in the language of schooling, are the second language learners concurrently exposed to a non-standard variety. These pupils, namely immigrants attending schools in bidialectal communities (i.e. communities the members of which communicate through the means of two genetically related but functionally compartmentalised linguistic varieties, a standard and a non-standard one, see Ferguson, 1959/2003), need to develop competence not only in the school register but also in the educational variety, a variety which in reality is the second dialect of their second language. Despite their unique linguistic circumstances, these pupils – henceforth 'immigrant bidialectals' – are nevertheless still been considered under the general heading of 'immigrants' or 'second language learners' which inevitably results in their distinctive school-based linguistic needs remaining unacknowledged and thus unaddressed. In light of this, the current study will attempt to explore and expose the linguistic challenges which these pupils are confronted with at school. It will focus in particular on their written performance, as writing is itself a demanding skill – it is formally learnt rather than naturally acquired – and a domain exclusively occupied by the standard variety, pupils' second dialect. What legitimises and necessitates this inquiry into immigrant bidialectals' school-based written production is the fact that the ability to manipulate the language of schooling is a component of 'academic language proficiency', the inadequate development of which has been associated with the school underachievement which immigrant children often exhibit (Cummins, 2000).

The study will be conducted in Cyprus and will sample twelve-year-old pupils who are in their final year of primary schooling. Cyprus has been chosen as the context of the research for two main reasons. Firstly, its increasingly diverse linguistic landscape is in line with the sampling requirements of the project. In particular, it is bidialectal as Cypriots use two domain-specific genetically related varieties to communicate, Standard Modern Greek (i.e. the educational and written variety) and the Greek Cypriot Dialect (i.e. Cypriots' mother tongue) (Karyolemou & Pavlou, 2001; Pavlou & Papapavlou, 2004; Sciriha, 1996), while at the same time it hosts large numbers of immigrants who do not have

Greek as their first language (Hadjioannou, 2006; Panayiotopoulos & Nicolaidou, 2007; Papapavlou, 2003). Secondly, it provides a very interesting setting for studies focusing on the education of nonstandard-speaking populations, as its educational system tends to treat Cypriots – and consequently the immigrant pupils who attend Cypriot schools – as being monodialectal (Yiakoumetti, 2006). This linguistic and educational status quo necessitates the conduct of the current study, the findings of which are expected to have important implications for educational policy and practice. The issues under investigation will be examined by means of a two-phase mixed-methods design, the implementation of which is scheduled to commence in November 2010. The qualitative phase is expected to facilitate the in-depth exploration of immigrant bidialectals' school-based written language, while the quantitative phase will enable the emergence of its salient characteristics. The design involves mainly writing tasks which will cast light on pupils' actual written production as well as editing tasks aimed at yielding an insight into the participants thinking processes and perceptions about the workings of the school-based written language.

The round-table discussion will focus on the analysis and interpretation of the data. The potential sources of non-standard occurrences, the degree to which dialect interference can be held responsible for such non-standard instances and selecting the most appropriate methods of measuring aspects of pupils' written language, are some of the issues which will be brought forward for discussion.

Teachers' professional learning. Examining "communities of practice" as conceptual and methodologica

Leif Christian Lahn, University Of Oslo, Norway; Kirsti Klette, University Of Oslo, Norway

In recent years "community of practice" (CoP) and similar concepts has become increasingly popular when understanding professional learning among teachers or designing programs for personal development in schools. The purpose of the present paper is to question theoretical assumptions underlying this framework through a secondary analysis of a Norwegian study and a selective review of relevant literature. In our summary we conclude that teachers receive very little feedback on their classroom performance – either from colleagues or school leaders. Thus a community of mutual support reinforced norms of presentism and weakly developed routines for critical inquiries that could make a difference to class-room practices. Compared with our selected literature these findings have to be nuanced as the role of school management, recent educational policies of accountability, and the strength of subject affiliation between teachers at different school levels are intervening factors. In favouring interpretative schemes that highlight interactive patters that stabilize the social setting (the "community") CoP researchers tend to leave out external contingencies (institutions, knowledge domains, "global ideas") and internal contingencies (individual/collective agency, conversational routines etc.) that could be sustaining trajectories of participation. The paper argues in favour of a multi-level and longitudinal approach to studies of teachers' professional learning.

Objectives

In recent years "community of practice" (CoP) and similar concepts has become increasingly popular when understanding professional learning among teachers (Little,2002; Talbert&McLaughlin, 2002; Shulman & Sherin,2004, Orland-Barak,2006) or designing programs for personal development in schools (Borko, 2004; Kazemi& Franke,2004). The purpose of the present paper is to question theoretical assumptions underlying this framework – or a more loosely structured conceptual terrain that we refer to as CoP. We accept the legacy of a communitarian understanding of teaching, but through a secondary analysis of a Norwegian study and a selective review of relevant literature we have identified three elements that need to be addressed when studying teachers' professional learning in their work-place setting; the institutional context, teachers' content knowledge and mediating artefacts, and finally discursive practices within teaching communities. In this paper we argue that these tend to be absent in analyses inspired by CoP.

Theoretical framework

The concept of "community of practice" has served as a rallying point for a large variety of attacks on rationalistic approaches to human development. The prevalent cognitive perspective on expertise was replaced with a metaphor of legitimate participation in a practice and learning as changes of identities as novices moved along trajectories into full membership in their community (Lave,1988;Lave&Wenger, 1991). Very different professional systems and cultures were referred to as "community of practice". CoP has paved its way into the research on schools and teachers work (Little, 2002), taking it as more or less for granted that educational institutions innovate by facilitating the sharing of knowledge between teachers (Stoll & Louis, 2007). Thus creating a "professional learning community" that is seen as a remedial answer to the fragmented character of school as work places. However fine-grained studies of educational institutions challenge this description (Meyer & Rowan, 2006; Bryk et al., 2009). The situatedness of teachers' professional learning is further amplified in the CoP-literature as variants of conversation and interaction analysis become a favorite methodological tool, privileging mundane talk and general linguistic maneuvers for the stabilization of human communication (Emmanuelsson & Sahlström, 2008). Scholars in this tradition refrain from making conjectures about underlying mechanisms (of stabilization). However in understanding social and individual change, learning and destabilization of social orders, we need be concerned with causal chains – although in a non-deterministic version (Maxwell, 2004). To be short and somewhat programmatic, prevailing CoP-methodology does not sensitize the researchers towards external contingencies (institutions, knowledge domains, "global ideas") and internal contingencies (individual/collective agency, conversational routines etc.). It favors mechanisms that stabilize the social setting to those that transcend and change practices.

Methods

Above we have presented elements of a theoretical critique of the CoP literature that will be subjected to an exploratory validation based on two types of evidence. First a secondary analysis of a larger project on professional learning among Norwegian accountants, engineers, nurses and teachers (ProLearn). We will be using a subset of data that has a focus on novice teachers' collaborative learning and was collected in structured and focus group interviews, and "learning logs". Secondly a theoretical sampling of comparative studies serves to verify generalizations made from our secondary analysis, which is a rather common strategy of theory development within educational research (Eisenhart, 2009).

Results and conclusions

From our secondary analysis of the ProLearn-material we learn that Norwegian novice teachers in primary schools enter a culture with a great willingness to share knowledge - processes that take place on a day to day basis and that involve practical problem-solving like coordinating lesson plans. These exchanges are person-centered and to a lesser extent mediated through knowledge resources. Novice teachers felt an obligation to keep themselves updated, but found it hard to select the relevant knowledge to cope with class-room situations. They missed an infrastructure that would facilitate a translation from collective discourses to individual class-room practices. Our log-data confirmed these self-evaluations, and similar results have been reported in many other studies of Norwegian (Havnes, 2009; Haug, 2010;), Dutch (Orland-Barak & Tillema, 2006) and US-schools (Horn & Little, 2010). Novice teachers participated in different forms of professional communities that were organized within subsections of schools, whole schools or across school boundaries. They received very little feedback on their classroom performance – either from colleagues or school leaders. Thus a community of mutual support reinforced norms of presentism and weakly developed routines for critical inquiries that could make a difference to class-room practices. Compared with our selected literature these findings have to be nuanced as the role of school management, recent educational policies of accountability, and the strength of subject affiliation between teachers at different school levels are intervening factors. Our secondary analysis describes a teacher community in Norwegian schools that is not well understood if we apply a CoP-framework. Our study confirms several other studies about the importance of structural changes at school level in order to sustain teacher communities (Bryk et al. 2009; Talbert, 2010; Tillema & vanderWesthuizen, 2006). Destabilization of discursive patterns may be attributed to these contextual factors or more

global transformations of subject knowledge, teaching platforms – or just individuals as primary movers. In other words there is a need to go behind the metaphor of participation (Sfard,1998).Our study and the reviewed concur in stressing the need for a theoretical and methodological framework for research on teacher collaboration that is sensitive to the interrelations between discursive practices, community relationships, artefactual mediation, enactment of theoretical knowledge and institutional context – and individual creativity. Individual teachers may learn in groups by adopting global ideas that by-pass the community, and that are given legitimacy by being circulated in instructional artefacts. Several attempts have been made to transcend or expand the CoP-framework by grafting it to systemic approaches (Hargreaves et al.,2010 ; Sannino &Nocon, 2008) or restoring the position of the subject (Billett,2008). However in our review, researchers that follow these lines, tend to base their arguments on interactional analysis and a slightly modified version of CoP (Havnes, 2009; Ottesen,2007). They should critically examine the privileging of "micro-genetic studies" – and include multi-level analyses and longitudinal designs in their methodological tool-kit.

A theory for the classroom? - Effects of situated learning approaches on theory-based reasoning

Robin Stark, Dept of Education, University of the Saarland, Germany; Martin Klein, Saarland University Department of Education, Germany; Kai Wagner, Saarland University Department of Education, Germany

Abstract:

The main goal of our project "Theorizing in practice" is to teach competences for theory based reasoning in complex pedagogical situations in teacher training. A complex computer based learning environment will be developed aiming at fostering students' professional vision, i.e. their ability to notice and analyze complex pedagogical situations on the basis of scientific knowledge and reasoning. In this study we tested the effectiveness of three learning conditions (problem based learning, learning through identification of erroneous reasoning, learning by correcting erroneous reasoning). Effects on argumentation knowledge, quality of reasoning and cognitive load were assessed. Results showed that the three conditions are equally suitable and provide significant learning progress in near transfer, while far transfer could not be fostered. Cognitive load was unobtrusive in all conditions. Additional qualitative analysis will provide more insights into constraints and affordances of theory-based reasoning.

Extended summary:

Aims

Several studies in which teacher students were trained using classroom videos show that they have severe deficits regarding professional vision, i.e. the ability to notice and interpret significant features of classroom interactions (Sherin, 2007; Sherin & van Es, 2009). They frequently describe classrooms situations superficially and tend to over generalize situations (Berliner, 1988; Strickland & Star, 2008; van Es & Sherin, 2009). Many teacher candidates also have difficulties analyzing pedagogical situations on the basis of scientific knowledge and reasoning, rather mindlessly rely on subjective theories and harbor unfavorable attitudes toward scientific theories (Stark et al., 2010). This impedes teachers' theory-based perception which is a key factor of theory-based reasoning and action in the classroom (Neuweg, 2007).

These problems will be encountered in our project "Theorizing in practice" that follows the famous dictum of Kurt Lewin that nothing is more practical than a good theory. A complex computer based learning program will be developed aiming at fostering students' abilities to analyze pedagogical situations basing on of scientific knowledge and reasoning. From a didactic perspective this program will constitute an integrated learning environment combining elements of problem-based and example-based learning. Instructional errors will be implemented as a special variant of example-based learning. Typical errors associated with analysis and reasoning in pedagogic situations will be demonstrated and have to be identified and corrected. Positive cognitive and motivational effects were found using similar learning environments in other comparably complex domains (diagnosing in medicine). This study tested the effectiveness of three learning conditions.

Methodology

N = 43 teacher students in the fifth semester were randomly assigned to three different learning conditions. Subjects were given a short (about 400 words) description of two authentic, complex classroom scenarios. Group I (problem-based learning, n = 16) had to develop a situation analysis on their own. They were then given a selection of theories and had to correct and improve their analysis. As a feedback measure they were given an expert-analysis and asked for a written comparison. Group II (learning through correction of erroneous reasoning/analyses, n = 15) had to identify errors in an erroneous analysis on their own. They were then given an expert error-explanation and asked to compare it with their own results. The following steps were analogous to group I. Group III (learning through identification of erroneous reasoning, n = 12) only had to identify errors and compare to the expert error explanation analogous to group II. They were given the expert analysis, but only asked to reflect on it. Learning outcomes were

measured using three post-test scenarios with varying transfer distance (used to measure the quality of reasoning) and a test of scientific argumentation knowledge. Subjects additionally estimated their own training success and their acceptance of the training program. Cognitive load was assessed using a subjective rating scale.

The effectiveness of problem based learning will be compared with learning with instructional errors. Additionally, a comparison between groups II and III should yield new insights into learning with instructional errors. In order to secure internal validity, we controlled for prior argumentation and content knowledge and time-on-task.

Findings

Contrary to our hypotheses no differences in learning outcomes and time-on-task were found between the groups. Overall argumentation quality and argumentation knowledge were almost equal across all groups. However, for all groups, a significant learning progress was found for argumentation knowledge. A significant and practically relevant learning progress over all measuring times was found for two post-test scenarios with lower transfer distance. Far transfer could not be fostered. As a matter of fact, subjects on average scored higher in the second training scenario than in the third post-test scenario. Process data analysis showed no differences between groups over all measurements.

A significant difference in cognitive load was found between the two instructional error conditions. The "correction group" (i.e., group II) reported significantly higher cognitive load. However, there was no correlation between load and learning outcomes. Subjective training success and acceptance of the training program didn't yield any differences between groups, but were significantly correlated ($r = .31$, $p = .33$, p)

Theoretical and educational significance of the research

Our results show that the students improved their argumentation knowledge in all conditions. Contrary to our expectations based on cognitive load theory, the instructional error conditions as a form of example-based learning did not prove superior to problem-based learning. Working memory resources that should have been freed by the use of examples obviously were not utilized to improve learning, in spite of additional instructional support (feedback measure and written comparison). It is not astonishing that only identifying errors is less demanding than additionally correcting them.

Descriptive data show that the third post test scenario (far transfer) was the most difficult. In this scenario subjects were presented with new theories that they had to apply to a new situation. Since all scenarios are considered highly demanding, the results (more than 50 % on average) are regarded as a success from a pedagogical perspective. Since there were no differences between the groups over all measurements, all learning conditions seem to be equally suitable. Regarding theory-based reasoning our subjects showed significant improvements in their ability to give more sophisticated descriptions and analyses of complex classroom situations.

The absence of a significant correlation between subjective training success and quality of reasoning indicates that the students had difficulties estimating their learning progress. In spite of unobtrusive cognitive load scores in all conditions this result can be interpreted as consequence of cognitive overload.

Qualitative analyses will yield further insights into the effectiveness of our learning conditions in general and especially the students' problems with far transfer.

Furthermore, a control group will be assessed to complete the study design. In a follow-up study, an extended training phase is supposed to relieve the far transfer problem and improve overall learning outcomes.

Aspects of qualitative and quantitative measurement of teacher competency

Gabriele Kaiser, University of Hamburg, Germany; Sigrid Blomeke, Humboldt University of Berlin, Germany;
Erich Ramseier, PHBern – University of Teacher Education, Switzerland

The round table will discuss the problem of the measurement of the competencies of future teachers based on various studies on teacher's competency amongst others the international IEA study on teacher education TEDS-M-2008 (Teacher Education and Development Study in Mathematics – Learning to Teach Mathematics). Currently there exist several large-scale studies on the professional knowledge of (future) teachers, however the problem, how to integrate several facets of knowledge and how to integrate evaluations methods from different research paradigms are not sufficiently solved. The contributors to the round table will discuss these questions from various perspectives.

The first aspect the round table will tackle is the integration of quantitative and qualitative approaches. One possible answer lies in detailed item analysis of items for which special groups of students either show unexpected high or low achievements and which yield interesting achievement patterns lying beneath mean differences of various countries. The second problem, which is until now not sufficiently solved, is the integration of different facets of professional knowledge. It will be discussed how it might be possible to integrate pedagogical knowledge into the conceptualizations of teachers' professional knowledge and how to measure it using the data of the TEDS-M-study.

The round table will discuss the problem of the measurement of the competencies of future teachers based on various studies on teacher's competency such as the international IEA study on teacher education TEDS-M-2008 (Teacher Education and Development Study in Mathematics – Learning to Teach Mathematics). Until now the problems, how to integrate several facets of teachers' knowledge and how to integrate evaluations methods from different research paradigms are not sufficiently solved in the existing studies on teachers' professional knowledge. The contributors to the round table will shed light on these questions from various perspectives.

The first aspect the round table will discuss is the integration of quantitative and qualitative approaches.

The first discussant - Erich Ramseier - will use data from the international study on teacher education - TEDS-M – to compare the results from the mathematics content knowledge and the mathematics pedagogical content knowledge of future teachers discriminating the results for future primary and lower secondary school mathematics teachers. Departing from the observation that the study yields varying country results for the different cohorts, for example for pedagogical content knowledge future primary teachers in Norway and Switzerland achieve above the international mean and the German future teachers below the international mean, whereas the results are nearly reverse for future lower secondary teachers. This observation leads to the result that the four scales are very valuable to describe global differences between the knowledge levels of countries. However a separate scaling within Switzerland shows that the national item difficulties differ significantly from the international values. This contribution gives the opportunity to discuss what this tells about the specificity of content knowledge in Switzerland which is reflected in single tasks but not in the scale mean.

The second contribution by Gabriele Kaiser, Martina Doehrmann and Sigrid Bloemeke will use the results of TEDS-M-2008 as well, but propose a different approach to integrate quantitative and qualitative methods. The first quantitative analyses have shown great differences in the solution frequencies of the answers of the future teachers. These differences show the strengths and weaknesses of future teachers from different cultural backgrounds and also of the different routes of teacher education in Germany. Focussing on the German results, there are also items with a similar solution frequency of special groups of future teachers', which can sometimes be explained by referring to a common international core of the specific sub-domain, but which are sometimes quite unexpected. Therefore an interpretative analysis of the answers of the future teachers will be proposed, which may allow to illustrate the strengths and weaknesses of the future mathematics teachers by referring to culture dependent knowledge patterns, e.g. strengths of the groups of higher achieving future teachers in items using symbolic actions or remarkable difficulties of weaker future teachers in this respect.

The third contributor Matthias Baer will discuss the problem how to shed light on teaching competences and will propose a multi-perspective approach to student teachers', novice teachers', and experienced teachers' teaching competences. Since teaching quality is strongly related to students' learning outcomes, the professional quality of teachers plays a crucial role for the development of their students. However, still not much is known on an empirical basis about the effects of teacher education and of experiencing regularly teaching a class on prospective, novice and experienced teachers' competences.

In the round table it is planned to discuss how a light can be shed on emerging as well as already established teaching competences (a) by presenting the multi-method approach we applied in our research project on the acquisition of teaching competences and (b) by giving insights into results of this project. There will be a focus on three of totally eleven data collection instruments: (1) an online-questionnaire for self-estimating one's own teaching competencies, (2) vignettes to trace competences for planning and implementing a school lesson, and (3) videos of taught lessons to discover style and quality of teaching. Furthermore, the surprising fact that teaching competences improved throughout teacher education, but almost no further improvement could be found for the first two years in profession, shall be discussed.

Johannes Koenig and Sigrid Bloemeke will discuss the second problem of the round table, which is until now not sufficiently solved and strongly connected to the first aspect, namely, the integration of different facets of professional knowledge. It will be discussed how it might be possible to integrate pedagogical knowledge into the

conceptualizations of teachers' professional knowledge and how to measure it using experiences of the studies MT21 and TEDS-M. Both studies focused on content knowledge and pedagogical content knowledge in mathematics. According to Shulman and the current discussion on teacher knowledge, general pedagogical knowledge as a third cognitive domain of teacher knowledge has to be taken into account, too. As yet, there has been no attempt to model proficiency in pedagogy.

To close this research gap, TEDS-M data are used. The terminology and the cognitive complexity are used as indicators to describe the difficulty of the general pedagogy items. The distribution of the item parameter estimates allows to cut the scale into two proficiency levels. Frequency distributions of future teachers by teacher education programs point to the content validity of the model. This result will allow to develop further models for the integration of the three theoretically proposed facets of professional knowledge into an overall model.

A Cognitive Model of Concept Mapping as Knowledge Elicitation

Julien Mercier, University of Quebec in Montreal, Canada; Patrice Potvin, University of Quebec in Montreal, Canada; Martin Riopel, University of Quebec in Montreal, Canada; Caroline Girard, University of Quebec in Montreal, Canada

Concept maps are being widely used as assessment and learning tools. One pressing challenge is to elaborate concept-mapping tasks that elicit specific aspects of knowledge in semantically complex domains, depending on the learning or assessment objectives. The objective of this study is therefore to develop and test a cognitive model of concept mapping as knowledge elicitation within a problem-solving task that would inform the design of concept-mapping tasks. Eighteen teachers of varying level of expertise were asked to construct a map representing the knowledge they used in an instructional planning task. Annotated protocols are being coded according to the postulated model. Time-budget analyses will show how frequently and for how long each activity was conducted. Sequential and lag analyses will establish typical sequences of activities. Higher-order processes will be derived from these patterns. New insights about the cognitive task of concept mapping can foster the study of the potential of this process as a technique for knowledge elicitation and assessment for educational and research purposes. These results can also inform the support of the concept-mapping process.

Aims

Since the pioneering work of Novak and Gowin (1984), concept maps are being widely used as assessment and learning tools. Concept maps take the form of node-links assemblies of concepts and relations (Nesbit & Adesope, 2006). Procedures for optimizing the use of concept maps for learning and assessment purposes have been developed and refined in science over the last two decades. In semantically complex learning domains that are less formal than science, these procedures appear relatively underdeveloped. Given the critical impact that professionals in such domains (for example, medicine and education) have in society, helping novices in these fields learn and making sure they reach appropriate levels of expertise is essential. One pressing challenge is to elaborate concept-mapping tasks that elicit specific aspects of teacher knowledge, depending on the learning or assessment objectives. Those concept-mapping tasks must be conceptually and empirically tested in terms of the characteristics of teacher knowledge they elicit (Glaser & Baxter, 2002). By looking at the concept map, the nature of knowledge evoked can be established. To understand why particular features appear and do not appear in the map, the process of concept map construction needs to be examined (see Amadiou, van Gog, Paas, Tricot & Mariné, 2009). The objective of this study is therefore to develop and test a cognitive model of concept mapping by examining cognitive activities using a set of the most basic operations involved in constructing a map in order to (1) see how patterns of operations can describe higher-order concept-mapping strategies and (2) to study the relationship between the concept-mapping process and expertise in the domain. Theoretical framework Building a concept map involves the manipulation of knowledge structures by higher-order cognitive processes (Hilbert & Renkl, 2005). Higher-order cognitive processes have traditionally been conceived of as either discourse processes or problem solving (Hatano & Inahaki, 2000). These processes can be articulated in a complementary manner since discourse production is a coherence-seeking process whereas problem solving is a change-seeking process. In this regard, discourse production processes organize the structures in the map in a way that minimizes incoherence. Problem solving, on the other hand, serves as a control mechanism that manages the concept-mapping task in response to the directions imposed by the task. Discourse production proceeds from the specification of a conceptual representation to the generation of different types of semantic structures (Frederiksen, Bracewell, Breuleux & Renaud, 1990). Discourse production operates on three types of structures: conceptual networks, propositions, and natural language structures. Operations on conceptual networks involve the generation of a frame that is subsequently filled out with descriptive information. Information to be expressed is selected from the vast amount contained in a fully specified conceptual structure. The information to be expressed is then formulated as a set of sequenced propositions. Generic components of the model include the planning of goals and actions, the test of critical conditions for action, the execution of actions, the interpretation of problem states, the evaluation of the problem solution, and the correction of mistakes. The model is contextualised to

concept-mapping by the specification of the procedures planned, the actions carried out, and the elements subject to evaluation and corrections. The construction of a map is partitioned into several steps, such as listing concepts, building partial networks, or building and altering a single map. More specifically, these steps are constituted of a few basic operations: identification of a concept, positioning of the concept in the hierarchy, positioning the concept in a branch, establishment of a relation, and labelling of a relation. All these operations can be planned, evaluated, and corrected.

Research questions

1. What is the relative prevalence of postulated constituents of the concept-mapping process? 2. What is the typical sequence of postulated constituents of the concept-mapping process? 3. What are the higher-order processes that emerge from typical sequences of the postulated constituents of the concept-mapping process? 4. With respect to the first three questions, are there any differences associated with the level of expertise in the domain?

Methodology

Participants are 12 student teachers (6 beginning their baccalaureate, 6 in their final year), 2 teachers with five years of experience, and 4 teachers who have completed a graduate program in teaching. Participants were asked to construct a map representing the knowledge they used in an instructional planning task they realized just before the concept-mapping activity, as part of another study. Participants were instructed to think out loud. Think-aloud protocols were recorded on audiotape. A video camera recorded the concomitant drawing of the map. The protocols were transcribed for analysis, with annotations representing the graphic drawing of the map. Annotated protocols are being coded according to the postulated model. Time-budget analyses will show how frequently and for how long each activity was conducted. Sequential and lag analyses will establish typical sequences of activities. Higher-order processes will be derived from these patterns.

Findings

Preliminary results indicate that the categories derived from the model are adequate for coding the protocols. Complete results will be available in December 2010.

Theoretical and educational significance

New insights about the cognitive task of concept mapping can foster the study of the potential of this process as a technique for knowledge elicitation and assessment for educational and research purposes. Prospective outcomes of this endeavour abound in the field of teaching and teacher education: study of teacher knowledge as it is used in the numerous aspects of teaching practice, use of concept mapping as a knowledge management and communication device in the educational community, use of concept mapping as a learning and/or assessment tool in a variety of settings used in teacher education. These results can also inform the support of the concept-mapping process, both in the case of tutoring situations and in the context of computer tools for scaffolding concept mapping. Research is also needed to develop or refine scoring protocols based on inferences between characteristics of a concept map and the process underlying its elaboration.
