

BOOK OF ABSTRACTS AND EXTENDED SUMMARIES

The Book of Abstracts and Extended Summaries is organised by type of presentation - paper, symposium etc. It is taken directly from the submission software, and thus does not include changes in titles, names or affiliations which have been made in the programme itself.

To search this file, using the pdf search facility in the top mid-right of the screen. It should say Find and you can enter the name or a title and click on Find Next in Current PDF.

PAPER PRESENTATION

Bias factors related to math test performance of Ethiopian students in Israel

Michal Levi- Keren, Tel Aviv University, Kibbutzim College of Education, Israel

The present study examines bias factors which might grant a relative advantage to native Israelis over groups of immigrants in a mathematics achievement test administered to fifth grade students. The bias factor analysis process, aided by quantitative and qualitative data gathering methods, comprised three phases: (1) Using a psychometric procedure called DIF (Differential Item Functioning) to identify differential functioning in test items. DIF was examined in two differentiated groups of immigrants from the FSU and Ethiopia, which were compared to a group of native Israelis with the same ability level in the construct which the test aimed at measuring. (2) Identifying the sources of difficulty leading to DIF, while distinguishing between difficulties that are relevant to the construct measured in the test ("impact factors"), as opposed to those which are not ("bias factors"). (3) Determining whether the item incorporates bias factors. Phase 1 was based on the analysis of the results of a mathematics achievement test administered to a national, representative sample of native Israeli students and immigrant students from the FSU and from Ethiopia. Phases 2 & 3 were made through the judgment of subject-matter experts of those items found to be having DIF, as well as through interviews with immigrant students and "culture experts", who contributed a cultural perspective to the answers of the interviewees.

The paper focuses on the results related to Ethiopian students, which support Vygotsky's socio-cultural approach, emphasizing the influence of culture on the formation of high mental functions, including mathematical thinking. The practical implications of these results are discussed.

In recent years there has been a significant increase in the number of immigrants in many European countries, as well as in Canada, the US and Australia. Israel has absorbed immigrants from the day of its foundation in 1948, including, since the end of the 1980s, large immigration waves from the Former Soviet Union (FSU) and Ethiopia. Mass immigration, in Israel as abroad, tends to include large numbers of children, who, as they join their new country's education system, are forced to cope with many difficulties. In Israel, as elsewhere, follow-up research has been conducted to accompany these integration processes. Studies concerning the academic achievements of immigrant children paint a complex, multi-dimensional picture. While some indicate that immigrant students' achievements level out and, after years, may even come to exceed those of native students, there are other studies that reveal persistent academic achievement. In Israel, it was reported that the academic achievements of immigrants from the FSU and Ethiopia are lower than those of native Israelis, even long after immigration.

Many studies have tried to uncover the sources of immigrant students' academic difficulties. They pointed at a complex array of student characteristics, on both the individual and group level. These may be demographic: relating to the number of years students have spent in their new country, to the socio-economic status of their families, to their school's socioeconomic composition, etc; other characteristics are culture-dependent and therefore relate to language, ways of thinking and values typical of the students' culture of origin. However, since the findings of these studies are not mutually consistent, it is impossible to generalize about the respective impact of these characteristics. Another important component contributing to immigrant students' academic difficulties, however, has to do with learning conditions, including the use of modes of assessment which were occasionally found to be incompatible with the students' learning needs. The assessment measures used supplied only meager information regarding the knowledge the students acquired in their countries of origin. Even the use of testing accommodations, specially developed to improve assessment validity and thus to help the immigrant students skirt these problems, was not always proven to be effective.

The main innovation of this study lies in the attempt to explain immigrant students' difficulties with math tests by focusing on identification and conceptualization of the sources of difficulties they experienced with test items. This approach comprised three phases: (1) Using psychometric procedures to detect test items which are differentially difficult or easy, for two differentiated groups of immigrants from the FSU and Ethiopia which were compared to a group of native Israelis with the same ability level in the construct which the test aimed at measuring.. The measured phenomenon is called DIF: Differential Item Functioning. (2) Identifying the possible sources of DIF, namely, identifying the attributes of the items which caused the difficulty, bearing in mind that there are two kinds of difficulty: those which can be related to the construct being measured (math ability), and therefore reflect true performance differences (impact), as opposed to those which are not, and which are called bias factors .It is the latter type of factors which might distort test results and threaten the validity of the decisions taken on the basis of the test scores. (3) Determining whether the possible source of DIF is relevant to the construct being measured.

Three research questions were formulated, reflecting the three above-mentioned phases: (1) Which items function differentially (i.e., which items are DIF items), regarding the Ethiopian and FSU immigrant students who were tested in math? (2) What are the characteristics of the DIF items that were found to favor the achievement of native born Israelis? (3) Which of those characteristics are bias factors and which reflect true performance differences?

This study is based on a secondary data analysis of findings available from a comprehensive research conducted by Levin et al., in 2002[1]. In this paper, a research design combining quantitative and qualitative methods was used. The identification of DIF (question 1) was based on a statistical technique used to detect DIF items, called Delta-plot. For this purpose a stratified national sample of fifth graders was used, consisting of 530 native Israelis and 559 immigrants from the FSU and Ethiopia, who were tested in math, as part of the earlier mentioned research project. The identification of DIF sources (question 2) and the decision regarding their interpretation (question 3) were made through the judgment of subject-matter experts of those items found to be having DIF, as well as through interviews with immigrant students and "culture experts", who contributed a cultural perspective to the answers of the interviewees.

The study results support Vygotsky's socio-cultural approach, which emphasizes the impact of culture on thinking processes, including mathematical thinking. The salient bias factors among immigrant students from the FSU originate in their unfamiliarity with certain test items, which proved to be alien to their ways of thinking; and also from a lack of sufficient attention to those item-related instructions which appeared in a different typographical format. Immigrant students from Ethiopia, however, tended to have difficulties in manifesting test taking skills differing from those relevant to their indigenous culture. Additionally, the answers they supplied to certain items, in which a concrete situation was presented, were rooted in their peculiar life experience, instead of being anchored in the items' data.

This paper focuses on bias factors related to Ethiopian students, and discusses the theoretical as well as the practical implications of these results (such as providing testing accommodations), that may assist in generating further research aimed at the development of a fairer assessment culture, appropriate to Israel's current multi-cultural reality.

PAPER PRESENTATION

Many questions, few answer(s)? A non response analysis of students' evaluations of teaching.

Bert Brockx, University of Antwerp, Belgium; Pieter Spooren, University of Antwerp, Belgium; Dimitri Mortelmans, University of Antwerp, Belgium

Student evaluations of teaching (SET) are used at many universities to assess teaching quality. The validity and reliability is often discussed in research papers. Several studies that examine different aspects of SET report that a significant number of students do not return their evaluations. This can cause problems concerning the reliability and validity of SET. We do not know of any study that has examined the non-response issue in SET research. In the present paper, an exploratory study on student and course characteristics that might influence a student's decision (not) to participate in course evaluations is presented using multilevel binomial regression models. We find that some student characteristics significantly influence the fact that students complete their SET questionnaires (i.e. course grade, overall grade, gender, and first year of higher education). These findings might have implications for the interpretation of SET results and the use of SET in general. For example, the results show that good students (in terms of having received good grades) are more likely to complete evaluation questionnaires than students who received grades. All stakeholders should take this into account when drawing conclusions about teaching quality based on SET results.

Introduction

Student evaluations of teaching (SET) are seen as the most common means to assess teaching quality at universities (Apodaca & Grad, 2005). A massive amount of research papers have been published on SET (Richardson, 2005). A frequent problem with teacher evaluations is the fact that a significant number of students do not respond to the survey. Layne, Decristoforo & McGinty (1999), for instance, showed that response rates for were 47,8% for online course evaluations and 60,8% for in-class surveys. These results were confirmed by Dommeyer, Baum, Hanna & Chapman (2004).

Due to rather low response rates it might be possible that a selection bias occurs. This could for example mean that students who perform well tend to respond more easily than students who receive low grades. If these students would also have different opinions about the teacher's performance, the selection that occurred could bias the results. It might mean that the results do not reflect the opinion of the complete population but of a selective sample of students. In this paper, we focus on the topic of non response within SET and examine whether course or student characteristics influence a student's decision to participate or not.

Data

The data for the present study were gathered at the University of Antwerp during the fall semester of 2008-2009 academic year by means of the SET -37 course evaluation questionnaire (Mortelmans & Spooren, 2009). 1224 online evaluations were sent to 598 students who were subscribed in 44 courses. As evaluations were administrated through an online system every student was given the possibility to evaluate the courses, opposed to an in-class surveys which requires full class attendance. The response rate was similar to the one reported by Layne, et al. (1999), namely 41,3%.

Method The collected data have a cross classified hierarchical structure. This means that some students evaluated multiple courses by completing several evaluations. The most appropriate analysis method to analyze this data would be a cross classified multilevel binomial logistic regression analysis. However calculating a model with 49 teachers, 609 students, 1238 evaluations and several explanatory variables leads to estimation problems. Therefore, two separate multilevel logit models were estimated, with at the first level the questionnaires and at the second level the students (model1) and, in a second step, the courses (model2). The dichotomous dependent variable ('response') was coded '1' if students participated in the evaluation of a course. Several explanatory variables were added to the model. At the questionnaire level the student's course grade was added, and whether the evaluation was about an elective course or not. At the student level, the overall grade, the student's gender and whether or not it was the student's first year of higher education were added. In the second model we added the course characteristics namely the class size and the required workload.

Results and conclusion

The results show that mostly the student characteristics influence the student's decision to participate in a SET survey. Table 1 shows that female students are more likely to fill in a questionnaire than their male counterparts, also good students (in terms of grades) tend to respond more likely than students who receive low grades. On the other hand, a negative effect is found for students who are in the first year of their university career. The course characteristics show no significant effects, a questionnaire of a course with high or medium workload is not more or less likely to be responded to, than one that required low workload. The same counts for courses with high, low or medium class sizes. The results of this study might have implications for the use of SET. All stakeholders should take into account that the student's performance and gender play an important role in the decision to respond to SET questionnaires. They thus should bear in mind that the sample of students who respond to the evaluations might not be a completely representative sample of the complete population.

PAPER PRESENTATION

The relationship between item type, students' characteristics and media-effect in CBA

Gyongyver Molnar, University of Szeged, Hungary; Krisztina R. Toth, German Institute for International Educational Research, Germany; Beno Csapo, University of Szeged, Hungary

Paper-based assessment reached its limits, however the shift from paper-pencil (PP) to computer-based assessment (CBA) poses new questions. Validity issues regarding media-effect studies belong to one of the key areas. Several studies have been conducted with older students to measure validity (Csapo, Molnar & R. Toth, 2009), however, only a few focused on early childhood education (Choi and Tinkler, 2002). The purpose of this paper is (1) to study the media-effects in a cross-curricular competency field by first grade (age 6-7) students; (2) categorize item formats and students according to their media-dependence. Due to the young age of the target population, the instrument of the study consisted of figural, nonverbal items. The same inductive reasoning test was administered in PP and in CB mode (N=5156 and 313, respectively). The online data collection was carried out with the TAO platform. Student-level differences indicated media-effect, students' achievement was higher in PP (45.33%) than in CB format (32.6%; $t=6.11$, $p<.001$). The highest media-effect was noticeable at items where the answer and distractors contained more figures. Students' socio-economic factors, gender and frequencies of computer-usage did not influence their CB test scores.

Theoretical framework

Technology has fundamentally changed the quality of education, including educational assessment. Technology-based assessment (TBA) opens new areas, raises new issues, offers new assessment methods (see Csapo, Latour, Bennett, Ainley, & Law, 2010), changes the whole assessment process and poses several new questions (see Scheuermann, & Björnsson, 2009). It is no longer doubt that TBA will replace traditional paper-pencil (PP) testing. The transition from PP to TBA in educational context requires a step-by step procedure (Csapo, Molnar, & R. Toth, 2009); the first is the adequate control of media effect during testing. Several media effect studies were carried out in the past few years; however, only a few focused on testing very young students in technology-based environment.

Aims

Administering technology-based tests by very young students poses several challenges; therefore, special attention must be paid to control instrument validity and reliability. The purpose of this paper is to study the media effects in a cross curricular competency field by first grade (age 6-7) students, to control media effect and make detailed comparisons of test results delivered by different media.

In this paper we

- (1) compare pupils' achievement in PP and computer-based (CB) environment;
- (2) categorise the item formats according to their media-dependence; and
- (3) characterise students who achieve better or worse in CB tests.

Methodology

The sample for the PP study was drawn from 1st grade students (age 6-7; N=5156), representative for the school population of Hungary; while the sample for the CB study was drawn from 1st and 2nd grade students (age 6-8; N=313). The instrument of the study was an inductive reasoning test, developed directly for young learners. It consisted of 37 figural, non-verbal items. The same test was used in PP and CB format. Special attention was paid to the paper and screen layout of the test, which were kept as similar as possible. The online data collection was carried out with the TAO (Testing Assistée par Ordinateur) platform via Internet by using computers available at schools. The detailed item analyses were performed by using several means of classical test theory and IRT.

Findings and conclusions

The reliability index of the inductive reasoning test did not differ significantly in PP and in CB environment (Cronbach- $\alpha=.88$ and $.85$, respectively). The comparison of PP and CB test scores indicates significant differences between the achievements based on the media. The average student achievement was higher in PP mode ($M=45.33\%$, $sd=20.07\%$) than in CB format (32.66% , $SD=18.17\%$; $t=6.11$, $p<.001$). Regardless of the item type applied the delivery media caused significant achievement differences. However, depending on the used item format the amount of differences are changing. The highest media effect was noticeable at items where the answer and distractors contained more figures. The influential factor of the delivery media proved to be the strongest ($t=8.24$, $p<.001$). Regarding gender analyses, there

were no achievement differences between the achievement of boys and girls in CB test results. Similar result was found at subtest level as well. Students' socio-economic factors (e.g. number of books, number of PCs, number of mobile phones) did not influence their CB test scores; similarly the common usage of computer and/or internet did not result in higher CB test results.

The delivery media had a significant impact on first graders' achievement regardless of pupils' different background variable the measured cognitive structure, context and item format. The results suggest that if the goal was to develop equivalent summative assessment for the two media, studying the particular differences between the two media using different research condition and research design may support a developmental process towards the improvement of the validity of online assessment. Further research is needed to study the effect of media in other domains, to identify the differences of the cognitive processes relevant in the two media and for controlling the effects of other variables that were not the goal of these studies.

Educational and scientific importance

Paper-based assessment reached its limits. Existing models of assessment typically fail to measure the skills, knowledge and competencies that are increasingly important in the 21st century, and direct feedback is not available after the actual testing. Technology helps to solve this problem. Within a few years large scale international educational assessment programs plan to introduce computer-based assessments of student achievements, therefore, students are expected to be familiar with CB testing. This fact may facilitate the early use of CB testing at schools. However, most cases studies do not focus on pupils' CB testing in an educational context. In connection with media effect control, the detailed analyses of a comparison of PP and CB testing establish scientific bases to improve the efficiency, effectiveness and validity of computerized tests.

PAPER PRESENTATION

Test follow-up: developing productive synergies between summative and formative assessment

David Carless, University of Hong Kong, Hong Kong

The main aim of this paper is to explore how teachers derive formative instructional power from internal school tests. It analyzes potentials and constraints in seeking to enhance student learning capacities from test processes which carry both summative and formative purposes. The paper uses qualitative case study data from six teachers in three elementary schools in Hong Kong involving 31 classroom observations and 26 interviews with teachers. The observations were mainly of test follow-up lessons and interviews probed issues arising from them and other themes related to the interface between testing and student learning. The findings document two particular test follow-up strategies: student self-evaluation of performance on a test; and peer co-operative processes. A common thread across both of these is that they involve active student participation in the post-test learning process. The significance of the study lies in its focus on building productive synergies between summative and formative assessment. Test follow-up can be used to show that test results can look forward to future learning, as well as summarizing previous performance.

Aims Managing the relationship between summative and formative assessment is a major challenge for the enhancement of the learning aspects of assessment. The power and influence of summative assessment often undermines the learning potential of formative assessment. The development of productive synergies between these two functions of assessment represents a potentially powerful way forward. Within this theme, the particular strategy discussed in this paper is post-test follow-up as a means to develop ongoing student learning capacities. The main aims of the paper are: To explore how elementary school English teachers in three selected Hong Kong schools carry out learning-oriented follow-up to internal school tests; To contribute to the development of assessment theory by exploring how summative assessment can be used formatively to support student learning; To analyze the role of context in formative assessment and suggest some features of contextually grounded assessment practices.

Theoretical framework: Formative use of test data The framework for the paper is based on work probing the relationship between formative and summative assessment. Formative assessment is defined as the elicitation and interpretation of evidence, so as to enhance instruction and improve student learning. The formative assessment strategy discussed in this paper is the formative use of a test designed principally for summative purposes (Black et al., 2003), hereafter test follow-up. Test follow-up uses information from tests to advance student learning, so has the potential to contribute to a positive relationship between summative and formative assessment. For test follow-up to be exploited optimally it requires the right kinds of tests: those that are aligned with curriculum aims; those that are instructionally sensitive (Popham, 2008); and those that promote mastery as well as performance (cf. Dweck, 2000). There are a number of challenges for the implementation of test follow-up: frequent classroom testing risks making judgments about student learning rather than suggesting means to improve (Black et al., 2003); it can result in micro-teaching of ways to gain additional marks rather than developing student learning power (Stobart, 2008); and teachers are generally more effective at drawing inferences about student levels of understanding than they are in planning future instructional steps (Heritage et al., 2009).

Methods The research questions guiding the study are: What test follow-up strategies do the teachers carry out? What is the rationale, strengths and limitations of these test follow-up strategies? The research involved multi-site qualitative case studies of teachers implementing test follow-up. Case studies are a particularly useful research strategy to probe the context-dependent nature of classroom implementation of learning activities. The case studies were carried out in English as a foreign language classes in elementary schools in Hong Kong. The unit of analysis in the study was the teacher. Six teachers from three schools were involved over a three-year period. Data sources comprised classroom observations and interviews. Observation is the most direct way of understanding classrooms and so a series of lesson observations were conducted before and after tests. A customized observation schedule was developed to facilitate the collection of relevant information, including: the relationship between lesson content and items in tests; student learning progress and difficulties; and identifiable test follow-up practices. Semi-structured interviews were conducted with teachers to identify their views about assessment and its relationship with classroom practice. Baseline interviews with participant teachers served to understand assessment practices in the school. Post-lesson interviews probed teacher perceptions of relevant issues occurring in observed lessons. The data-set comprises 31 lesson observations and 26 interviews with teachers. Data were analyzed inductively using standard qualitative data analysis procedures, including coding, categorizing and respondent validation.

Findings Classroom observations revealed various test follow-up strategies. Those which carried potential for enhancing student learning mainly involved students as active participants in test follow-up. Peer co-operation was a key element and was exploited in various ways: students working in pairs or small groups to work out answers to challenging test questions or develop correction sheets; and students sharing test preparation or test-taking strategies. Another potentially useful strategy was engaging students in self-evaluation through written reflections on test performance: what they did well, what they were less successful in and how they wanted to improve. Whilst some students wrote relatively trivial comments, such processes had potential to remind students that a test was not just an end-point but part of ongoing learning. Teachers' potential to implement test follow-up effectively related to a complex interplay of multiple factors, including: their background, training and experience; beliefs and understandings related to testing and formative assessment; the extent of satisfaction with existing practices; and the pedagogic priorities in their own school context. Underpinning these elements were various contextual and cultural factors, pertaining to the Confucian-heritage setting of Hong Kong: the expected roles of teachers and students; the dominance of examination-oriented education; and collectivist notions encouraging positive co-operation with peers. **Significance** The theoretical significance of the work relates to the development of productive synergies between summative and formative assessment. By acknowledging the centrality of summative assessment in teachers' and students' lives, but deriving much needed formative impetus, test follow-up can be used to show that test results can look forward to future learning, as well as summarizing previous performance. The study also casts light on the interplay between assessment and educational context via the notion of contextually grounded formative assessment practices which acknowledge the realities of the host setting. Such an orientation honors the existing beliefs of teachers and the associated classroom practices, grounded as they are in a particular socio-cultural setting. It takes a pragmatic view of what is feasible in a specific context, such as Hong Kong, in view of the dominance of examination-oriented education. This starting-point can act as a seed for further development. Finally, the study also carries implications for practice. The findings suggest two main interlinked keys to test follow-up: a) the importance of active student involvement; and b) engaging students in reflecting on their work and performance, including peer learning and self-evaluation.

PAPER PRESENTATION

What do we know about the digital divide in students with an immigrant background?

Oliver Walter, Germany; Martin Senkbeil, Leibniz Institute for Science Education, Germany

In this paper we analyze the 'digital divide', i.e. disparities in the access to digital media, frequency of computer use, and computer literacy, with regard to students with an immigrant background in Germany. Since ICT competencies have an increasing relevance to young people's opportunities on the labour market, especially for students with an immigrant background, we studied the amount of differences on all three dimensions of the digital divide in a sample of 8,874 ninth-graders in Germany. In doing so we distinguished between students of different immigrant generations and different ethnic origin. Our results show increasing levels of computer competency with ascending immigrant generation. With respect to ethnic origin we found deficits for some (e.g., students from Turkey), but not for all migrant groups (e.g., students from Poland). After identifying these disparities, we related them to indicators of structure and process characteristics of the students' family, e.g. socioeconomic status. We found that disparities in computer skills between different groups of immigrants and natives can largely be traced back to differences in access to digital media and to family characteristics. Interestingly, there were different effects of these factors for different immigrant groups. Our results suggest that schools should be aware of the different patterns of the digital divide with respect to immigrant generation and ethnic origin and should try to compensate for them by making an adequate educational offer.

Aims

Many studies have been conducted on the 'digital divide' with regard to social inequalities since the early 1990s. But they often focused only on access to digital technologies and neglected other dimensions as frequency of computer use and computer literacy. Only some research has focused on migrants, especially in Europe. In addition, the existing research on migrants and the digital divide rarely distinguish between different migrant groups (e.g., according to immigrant generation and ethnic origin) and take little notice of differences due to family structure (e.g. socioeconomic status, parental education) and family process characteristics (e.g. family language, family communication) into account.

Therefore, our concern was to study access, use and knowledge of computers and the internet of different groups of immigrant students in Germany and to relate our findings to structure and process characteristics of their families. In particular, we were interested in the following questions:

- (1) What is the digital divide like between natives and students of different immigrant generations?
- (2) What is the digital divide like between natives and students of different ethnic origins?
- (3) Do disparities in computer literacy stem from differences in the access to digital media and from family structure and process characteristics?

Methodology

For answering our research questions we used data of 8,874 9th graders participating in PISA 2006 in Germany. Immigrant background was defined by the students' and parents' country of birth. We distinguished the following groups with respect to immigrant generation: (a) students without an immigrant background: The student and both parents were born in Germany (N = 6,950). (b) 2.5th generation: The student and one parent were born in Germany (N = 491). (c) 2nd generation: The student was born in Germany, both parents were born abroad (N = 731). (d) 1st generation: The student and both parents were born abroad (N = 687). Additionally, we used a second classification differentiating between students whose parents were born in the former Soviet Union (N = 441), Turkey (N = 424), Poland (N = 230) and other countries (N = 801).

Computer literacy was measured by a paper-pencil-test consisting of 14 items ($\alpha = .78$). The other dimensions of the digital divide and the family background of the students were assessed by questionnaire.

Findings

Table 1 shows the results concerning research questions 1 and 2. With respect to computer access there are only some minor differences to students without an immigrant background, especially for students from the 1st and 2.5th

immigrant generation. More pronounced disparities can be found for internet access. There, our results show that 1st generation students have substantially lesser access and that the disparities decrease over generations. In contrast to access we did not find significant lesser differences in frequency of computer use at home and at school. Instead 2nd generation students use computers a bit more often than natives at home. If we look at computer use outside both school and home we also see that the computer is even more often used by students of every immigrant generation than by natives. Even so, 2nd and 1st generation students show distinct deficits in computer proficiency, on average. In contrast to the results for immigrant generation there are greater disparities in access to digital media between groups of different ethnic origin. With the exception of students whose parents were from Poland, immigrant students have significantly lesser access to digital media than natives. Especially a substantial proportion of students from the former Soviet Union and from Turkey do not have access to the internet. The findings for frequency of computer use are similar to the ones we found for students from different immigrant generations: There are no differences in the frequency of use at home and at school, but significantly more students whose parents came from Turkey and other countries use computers outside school and home than natives. In accordance with findings reported above and with the exception of Polish students, students with another than a German origin have lower computer proficiencies, on average.

With respect to research question 3, we found that differences in computer proficiency between groups of immigrant and native students can mostly be traced back to access to digital media, family structure and family process characteristics, although these factors only explain less than 10 percent of the total variance (see table 2 for results with respect to ethnic origin). More detailed analyses point to different mediating mechanisms regarding the development of knowledge gaps between natives and different immigrant groups. Whereas access conditions as well as family structure and process characteristics contribute significantly to explain the disparities for first-generation students, only structure and process characteristics do so for 2nd generation students. The results are similar if we categorize students depending on their parents' country of origin: Family structure and process characteristics are important for Turks, access conditions and family process characteristics are important for those from the former Soviet Union.

Theoretical and educational significance

Our results have some practical implications for the promotion of computer literacy through school activities. Schools have a responsibility to teach students how to competently use a computer and the internet so as to guarantee each student equal opportunities in reaching their future vocation or profession. Schools could, for example, specifically advise parents with an immigrant background, depending on their origin and their children's specific deficits in dimensions of the digital divide, to invest in a computer and internet access at home, or if this is not possible, to provide this through access at school, a library or an internet cafe. Schools should ensure that Turks and second-generation immigrants receive the necessary computer skills. Although these students claim to use a computer frequently they seem not to be able of acquiring sufficient skills on their own. As the parents of Turkish students often lack the necessary education and cognitive skills, schools must take on the role of a mediating agent when it comes to conveying computer-oriented skills.

PAPER PRESENTATION

Multilevel analysis on quadratic relationship between socioeconomic status and math performance

Ningning Zhao, UGent, Belgium

The purpose of the present study is to explore, in a large sample of Chinese primary school students, the relationship between family socioeconomic status and mathematics performance on the base of a multi-level analysis. A rather weak relationship is found between socioeconomic status and performance in the Chinese context. The relationship follows a quadratic curve, implying that students from a disadvantaged family and higher socioeconomic background have a higher probability to attain higher mathematics scores. This can be explained on the base of Chinese cultural beliefs about exams and social class mobility. Moreover, the average socioeconomic status at the school level seems to moderate in the relation between individual SES and academic performance. This suggests that individuals from a disadvantaged family will benefit more from the school with a higher average higher family socioeconomic status than other students who are enrolled in schools with a lower average family socioeconomic status.

1. Introduction

The relationship between socioeconomic status (SES) background and academic performance has received ample attention since the publication of the "Coleman Report" in 1966 (Coleman, Campbell, Hobson, McParland, Mood, Weinfeld and York, 1966). A consistent finding is that students with a high family SES perform better than students with a lower SES. As shown in the Third International Mathematics and Science Study (TIMSS), the influence of family

socioeconomic status on educational performance appears to vary systematically depending on the economical development level of a region (Schiller, Khmelkov and Wang, 2002). Whether the relationship between SES and mathematics performance is different in other countries (developed or developing, various cultural value) is still an open question.

This brings us to the research aims of the present study: (a) to construct a comprehensive SES index based on input from previous studies; (b) to explore the general relationship between SES and mathematics in P. R. China, considering different developmental levels of the region; and (c) to analyze the extent to which aggregated SES at the school level influences student mathematics performance, regardless of students' different individual SES levels. Multilevel analysis was applied to study the impact of variables at the school, class and student level on mathematics performance.

2. Theoretical background

2.1 Measurement of socioeconomic status

SES which was approached in the 1980s stress family income, father's educational level, mother's educational level, and father's occupational status or occupation type (White, 1982). In later studies, additional variables were added to the index; e.g., home resources (Sirin, 2005), home atmosphere or context, number of books in the household, and other resources related to the learning (Caldas and Bankston, 1997; OECD, 2003).

2.2. Varying impact of SES on mathematics performance

2.2.1 Family SES and academic performance

Recently, the meta-analysis of both White (1982) and Sirin (2005) reveals that the direct relation between socioeconomic status and performance might be less strong. White's meta-analysis claimed that the meta-analysis reveals that the average correlation is .299 while Sirin's meta-analysis claimed a correlation value of .343.

2.2.2 SES and performance: the moderating effect of school aggregated SES variables

Previous studies show that higher levels of an aggregated school SES is related to an increase in student performance and in students with a different level of family SES (Perry and McConney, 2010).

3. Method

3.1 Sampling

These twenty schools are located in five Chinese regions reflecting different development levels; and are located in a rural or urban setting. Total school enrolment ranged from 318 to 897 students ($M=547.95$, $SD=140.19$). Sampling strata were based on the location of the school in a specific region.

3.2 Variables

3.2.1 Dependent variables

Mathematics performance level. All the items and cases were calibrated on a continuum scale ranging from grade one to six by Item Response Theory (IRT) programme of BiLog (See Authors, revising). Reliability of the scales (Cronbach's α) was reported to be high: for grade one to grade six respectively .94, .96, .95, .94, .94 and .93. Reported means are: -1.24, -.89, .05, .18, .69, .83.

3.2.2 Independent variables

3.2.2.1 Individual learner's level SES

In a first step, an exploratory factor analysis (EFA) was carried out by applying the WLSM method that is able to deal with eight items for the family information as categorical data (Mplus5.1). The results suggest a two-factor structure in the SES variable. A first factor grouped SES variables focusing on parents' occupation status; a second factor groups SES variables in relation to family wealth.

3.2.2.2 School level SES

Two aggregated SES indexes were calculated at the school level: (1) the average parent's socioeconomic status of the learners attending this school (SCFSES_J) and the average level of wealth of the children in the school (SCFSES_W).

4. Results

4.1 Multilevel analysis of the relationship between SES variables and mathematics performance

4.1.1 Weak relationship between SES variables and mathematics performance

These models only account for 0.41% of the variance in mathematics performance at the individual learner level (.486 vs. .484) (compare model 0 to model 6 in Table 4). This implies that the SES variables under study are not strong predictors of mathematics performance in primary school after controlling for school level variables.

4.1.2 The U-shaped relationship between SES variables and mathematics performance

Another interesting finding from the study is the U-shaped relationship between SES variables and performance in the primary school. This implies that the students with lower SES in China do not always attain lower performance levels, while students with a higher SES level do not always attain higher performance in primary schools. The performance of the students depends on the corresponding family SES level of the student.

4.2 SES and mathematics performance: the moderator effect of school level aggregated SES indexes

4.2.1 Stronger Effect of School level of FSES_J on mathematics performance

In sum, when means of SES at school level are entered into the models, about 22.02% of the total variance in mathematics performance can be explained (.227 vs. .177 see model 8 in Table 4) at the school level.

4.2.2 The moderator effect of school SES on mathematics performance

Figure 2 shows how the mathematics performance of learners with a different level of SES, based on their parents job level (recoded in three categories), varies according to the aggregated SES variable at school level.

The slope of the disadvantaged group with lower individual family SES (FSES_J_R = 1) is less steep as compared to the middle group (FSES_J_R = 2) and the advantaged group (FSES_J_R = 3). This implies that the moderating effect is stronger for learners with a higher individual SES. In general, the higher the school aggregated SES, the higher performance of learners with a higher family SES.

5. Discussion and conclusions

A variety of rationales can be presented to explain these specific findings based on data from the Chinese context. Although the cultural values and political management policies can have a positive impact, it remains nevertheless clear that disadvantaged students run a higher risk for encountering learning difficulties.

PAPER PRESENTATION

Assessment of adult's mathematical competence and the use of mathematics in work and daily life

Timo Ehmke, University of Lueneburg, Germany; Christoph Duchhardt, Leibniz Institute for Science and Mathematics Education, University of Kiel, Germany; Eva Knopp, Leibniz Institute for Science and Mathematics Education, University of Kiel, Germany; Irene Neumann, Leibniz Institute for Science and Mathematics Education, University of Kiel, Germany

The Programme for International Student Assessment (PISA) has drawn attention to the role of mathematical literacy as an important prerequisite for lifelong learning and active participation in society and culture. Many everyday situations require mathematical abilities for sound judgements or important decisions. The aim of this study is to find out how often adults use mathematics in their work and daily life and how this is connected to their mathematical competence. The sample comprises N = 461 adults from Germany (age: M = 44.2 years, SD = 12.2 years). The testing took place by individual sessions in the adults' personal home environment. A Latent-Class-Analysis identified three classes of adults which differ in their profiles of using mathematics in work and daily life. Regression analyses on the adults' mathematical competence showed statistically significant effects for age (beta = -0.19), socio-economic status (beta = 0.26), educational attainment (beta = 0.18) and the interaction between gender and educational attainment (beta = 0.57). Adding the variable "use of mathematics" to the regression model resulted in an additional effect mathematics user profile classes. The findings showed that the use of mathematics in work and daily life is a strong predictor for mathematical competence. This effect is stable even when characteristics of the social background are controlled. Further implications for the life-long learning in mathematics with regard to limitations of the study (sample bias and cross sectional design) will be discussed.

The Programme for International Student Assessment (PISA; OECD, 2003) has drawn attention to the role of mathematical literacy as an important prerequisite for lifelong learning and active participation in society and culture. Many everyday situations require mathematical abilities for sound judgements or important decisions. Mathematical literacy thereby emphasizes the knowledgeable use of mathematics as a tool for solving problems in real-world situations.

The aim of this study is to find out how often adults use mathematics in their work and daily life and how this is connected to their mathematical competence. More concrete we follow two research questions:

- (1) Which profiles can be identified concerning the use of different mathematical concepts in work and daily life?
- (2) Of what kind is the relationship between the adults' use of mathematics in work and daily life, their social status and their mathematical competence?

The sample comprises N = 461 adults from Germany (age: M = 44.2 years, SD = 12.2 years; gender: 55 percent women and 45 percent men). It was taken within a pilot study of the National Educational Panel Study (NEPS) in Germany (Blossfeld, Schneider & Doll, 2009). The testing took place by individual sessions in the adults' personal home environment. Test administrators who had been trained in advance conducted the test according to standardized guidelines. Each session took 90 minutes, and the participating adults were rewarded with a sum of 20 Euros. The test time was divided into 60 minutes for a paper-and-pencil mathematics test and 30 minutes for a questionnaire. The

mathematics test consists of 40 items (Cronbachs' alpha = 0.90) (Ehmke, Duchhardt, Geiser, Grýþing, Heinze, & Marschick, 2009). The questionnaire asks for standard sociodemographics (age, gender, socio-economic status, educational attainment) and also includes a scale on the use of different mathematical concepts in work and daily life (12 items, cronbachs' alpha = 0.86).

A Latent-Class-Analysis identified three classes of adults which differ in their profiles of using mathematics in work and daily life. The adults in the first class (63 percent of the sample) represent the "normal users". They apply elementary mathematics (e.g. fractions) in their work and daily life on average at least once per month. They almost do not use higher mathematical concepts (e.g. trigonometry). The second class (14 percent) comprises "advanced users". They use elementary mathematics as regularly as the first class. Additionally, they use advanced mathematics quite frequently. The third class (23 percent) can be described as "non-users". They report that they very seldom apply mathematics in their work and daily life.

Regression analyses on the adults' mathematical competence showed statistically significant effects for age (beta = -0.19), socio-economic status (beta = 0.26), educational attainment (beta = 0.18) and the interaction between gender and educational attainment (beta = 0.57). Adding the variable "use of mathematics" to the regression model shows an additional effect mathematics user profile classes. Also, this results in a reduction of the effects for the characteristics of social status. This can be interpreted as a mediation effect. In the final model, 35 percent of the variance in the adults' mathematical competence is explained by the characteristics of social status and their use of mathematics in work and daily life.

The findings showed that the use of mathematics in work and daily life is a strong predictor for mathematical competence. This effect is stable even when characteristics of the social background are controlled. Further implications for the life-long learning in mathematics with regard to limitations of the study (sample bias and cross sectional design) will be discussed.

PAPER PRESENTATION

Students' alternative conceptions of tropical cyclone causes and processes

Rod Lane, Macquarie University, Australia; Pamela Coutts, Macquarie University, Australia

Shulman (1987) argued that an important component of pedagogical content knowledge (PCK) is teachers' understanding of common student alternative conceptions, yet little is known about what students believe about many topics in the school curriculum. This paper focuses on an area of the NSW Junior Geography curriculum as the first phase of a larger study designed to investigate Geography teachers' PCK. Common student conceptions of tropical cyclone causes and processes were identified using a variety of methods. Results indicate that middle school Geography students (n=330) hold a range of alternative conceptions related to foundational scientific principles as well as the geographical concepts of location, scale and interaction with the human and natural environment. Implications for the knowledge requirements of Geography teachers are discussed.

Aims/rationale

Shulman maintains that teachers need to ground pedagogy in a detailed knowledge of students' existing conceptions. The first step is to establish the nature of these conceptions. Although there is considerable research on student alternative conceptions in the Science and Earth Science literatures (Reinfreid & Schuler, 2009) there has been little research integrating a focus on scientific processes with the geographical perspectives of spatial distribution, scale, and interaction with the human and physical environment. This study therefore aimed to identify the common alternative conceptions of tropical cyclone causes and processes held by 330 Year 8/9 students studying Geography in 18 Sydney schools. The case study of tropical cyclones was chosen because of: the lack of previous research on student conceptions in this area; the likelihood that students would have been exposed to informal ideas about

tropical cyclones; the ease with which the conceptual building blocks of understanding (such as air pressure) could be identified; and the existence of research indicating such concepts present difficulties for many students because of their abstract nature.

Methodology The mixed-method design consisted of a semi-structured interview (involving drawing tasks, stimulus response activities, and hypothetical/simulation questions) and a questionnaire. The questionnaire, with 40 true/false statements and a confidence scale, provided an indication of the distribution of alternative conceptions across the entire sample. It was assumed that a high confidence level indicated that students were either recalling factual knowledge or drawing on a theorized belief (Vosniadou, Vamvakoussi, & Skopeliti, 2008). The focus of analysis was on the identification of items of low facility where average student confidence was high as these beliefs were likely to represent strongly held alternative conceptions. Seventeen students were subsequently interviewed (with drawing, mapping and stimulus response tasks incorporated) to explore the preconceptions of the participants in greater detail and to validate the findings of the questionnaire.

Data analysis Student drawings, interview transcripts and written responses were coded and patterns of alternative conceptions identified and recorded. Descriptive statistics were generated from the questionnaire responses and items answered incorrectly by more than a third ($n=110$) of the students were then sorted by confidence. Clusters of ideas or item types were identified. Conceptions and beliefs were considered stable if they were used consistently in students' explanations on more than one occasion, for example through their questionnaire responses, written explanations, drawings and answers to semi-structured interview questions (Vosniadou, et al. 2008).

Results Analysis of the drawings, interview transcripts and questionnaire data revealed a number of common patterns and themes. The first grouping of five alternative conceptions related to students' understandings of underlying scientific processes such as sensory based conceptions of felt weight (e.g. air is weightless) and causes of wind (e.g. cold air is the main cause of strong winds) and literal interpretations of models and analogies (e.g. water evaporating from the ocean is a boiling process and clouds are made of steam). The second grouping comprised three categories of beliefs related to geographical perspectives about scale, location and lifecycle of tropical cyclones (e.g. tropical cyclones are phenomenon "about the size of my school"), internal processes (e.g. tropical cyclones "fill-up like a vacuum cleaner, get clogged-up, and stop"); and the relationship/links between different types of natural hazards (e.g. cyclones create tsunamis or are caused by earthquakes). The data also suggest that there are a number of deep-seated alternative conceptions (items of low facility with high average confidence) that are widely held by students (see Table 1 below). For each of these items, students answering incorrectly were either more confident or as confident as those answering correctly (p Table 1: Some firmly-held alternative conceptions)

Statements	% Correct	Confidence
The main reason that the tropics are hotter than the North and South Poles is because they are closer to the sun.	42.73	3
Air is weightless.	63.69	3
The terms "hurricane", "typhoon" and "tropical cyclone" describe different types of storms that occur around the world.	27.68	3
The evaporation of water from the ocean is a boiling process.	56.63	3
Most deaths and injuries in severe tropical storms worldwide are due to objects flying in the air or structures collapsing.	17.61	3

With factual items (e.g. Australia's cyclone season occurs between June and September) or items based on difficult concepts (e.g. Air pressure directly above a body of water increases as the temperature of the water increases), students' average confidence scores were low (40 and 37 respectively).

Interpretation of results and implications for theory The findings indicate that students hold a range of ideas that have the potential to interfere with their depth of their understanding in Geography. Some of these ideas relate to foundational scientific principles, others to the geographical concepts of location, scale and interaction with the human and natural environment. These findings have significant implications for the knowledge requirements of Geography teachers. The research on PCK indicates that knowledge of students' common preconceptions is essential if teachers are to enhance levels of Geographical literacy. Having identified these common categories of student beliefs, the next step therefore is to undertake research to explore Geography teachers' awareness of students' common preconceptions and their use of this knowledge to inform instruction. The results obtained are also consistent with Brewster's (2008) argument that mixed methodological approaches with a strong reliance on structured interviews provide the most reliable diagnosis of students' conceptions. Although the questionnaire provided a reasonable indication of the distribution of alternative conceptions across the sample and clearly highlighted the most entrenched/firmly held naïve beliefs, the semi-structured interviews were required to accurately identify the alternative conceptions of individual participants and provide further meaning to these overall distributions.

PAPER PRESENTATION

Intervention Study on Systems Thinking in Lower Secondary School

Teaching science at the lower secondary level includes the discussion of complex phenomena, such as climate change, genetic engineering and sustainable development. Systems thinking seeks to better understand such phenomena by identifying changes over time and interdependencies between elements. While systems thinking is well established in science and complex topics are found in most secondary-school science curricula, research in science education has shown, that students from primary to higher education have a poor understanding of basic system concepts.

This study examined the effects of introducing systems thinking to 9th grade students. Data on the learning progress of 79 students was collected in a pre- and post-test design, including a second post-test five weeks after the intervention. A competence model was used to develop the content of the intervention and the instruments to measure the changes.

After the intervention, the students showed significant and sustained progress in three competence areas: "model description", "dynamics" and "making predictions". In particular, the students subsequently used more structurally complex relationships, such as causal chains, junctions and feedback loops in their sketches to outline a complex situation. Further, they recognised more non-linear changes and were able to formulate more sophisticated predictions including alternative reasoning, delays and limits of growth than before. The study showed that the main concepts and representations of systems thinking can be successfully taught in a cross-curricular training and that the training also triggers conceptual change by broadening students' reasoning in complex situations.

Teaching science at the lower secondary level includes the discussion of complex phenomena, such as climate change, genetic engineering and sustainable development. In doing so, the aim is not only the acquisition of knowledge but also a better understanding of changes over time and interdependencies between elements. Systems thinking seeks to understand such complex phenomena by identifying boundaries, inputs, outputs, flows as well as parts of a system and how they are connected or working together. Basic concepts of systems thinking, such as feedback loops, delays, nonlinearity and representations such as causal loop diagrams, stock and flow diagrams or time graphs are well established in science.

Whereas complex contents can be found in most secondary school science curricula, systems thinking has not yet been established as a unifying cognitive tool to support students' better understanding. Washington State (USA) is unique in recognising the growing importance of "systems" as one of the cutting-edge concepts and abilities in K-12 Science Standards (Dorn, 2009). Recently, educational standards for systems thinking have also been discussed for public schools in Switzerland.

Research in science education has shown that students from primary through higher education have a poor understanding of basic system concepts (e.g. Sweeney & Sternam, 2000; Sweeney, 2005). Students' reasoning in complex situations is often restricted to linear arguments and to applying linear models to predict changes of any parameter. Considering this, an introduction of understanding complex phenomena by teaching basic concepts of systems thinking and thereby triggering conceptual changes of the students' reasoning in such situations might be challenging.

This study examined the effects of introducing systems thinking to 9th grade students. In particular, the students' abilities to draw a sketch of a complex situation representing interdependencies, their interpretation and calculation of linear and nonlinear changes as well as their level of differentiation in predictions were evaluated.

Data on the learning progress of 79 students was collected in a pre- and post-test design, including a second post-test conducted five weeks after the intervention to evaluate the long-term impact. A working definition of "systems thinking" and a competence model introduced by the Swiss and German research-group SYSDENE was used to develop the content of the intervention and the instruments to measure expected changes. The adoption of a coherent framework – within which contents were drawn from different disciplines – was necessary due to the existence of differing definitions of systems thinking (e.g. Forrester, 1994; Richmond, 1994; Ossimitz, 2000).

The competence model of systems thinking consists of four areas of competence. The first area, "model description", and the second one, "dynamics", are needed for the reconstruction of a system, whereas the other areas, "making predictions" and "assessing action plans" describe the use of the system. As an introduction to systems thinking, the training focused on the areas "model description", "dynamics" and "making predictions". The training consisted of 11 lessons introducing main system concepts and representations, such as causal loop diagrams and time graphs –

applying them to different contents in Geography, Biology and Mathematics. To evaluate the learning progress by means of online and paper-and-pencil tests, existing instruments for measuring systems thinking skills were adapted (Ossimitz, 2000; Bollmann-Zuberbühler, 2008) or newly designed.

The students rated the training as easily accessible and useful. After the intervention, the students showed significant progress in all three areas: "model description", "dynamics", and "making predictions". The training effects persisted until the second post-test. As a consequence of the training, students used more structurally complex relationships, such as causal chains, junctions and feedback loops in their sketches to outline a complex situation. In addition, students recognised more non-linear changes and were able to formulate more sophisticated predictions, including alternative reasoning, delays and limits of growth. Furthermore, some of the students formulated a benefit of systems thinking after the training by declaring that they were better able to identify opportunities for systems thinking in other subjects. The students concluded that it would also be useful to analyse scientific phenomena from different points of view and recognise interdependences in everyday life.

To become an effective systems thinker requires the acquisition of a set of competences and skills. This study showed that the main concepts and representations can be successfully taught in a cross-curricular training. The use of different contents helped students to recognise the benefit of systems thinking as a unifying cognitive tool and as a consequence, they used less linear reasoning and linear models to predict changes. Understanding non-linear relationships such as exponential changes requires specific mathematical knowledge and should best be introduced through experiments and iterative calculations. The study further revealed that a variety of instruments is necessary for collecting data to evaluate the different areas of competence. In particular, new instruments to measure the students' skills to identify dynamic changes were successfully applied. Nevertheless, more efforts are needed to verify the model of competence used in this study.

PAPER PRESENTATION

Collaborative conceptual change in the science classroom: discourse as process & outcome of learning

Erica Sainsbury, University of Sydney, Australia; Richard Walker, University of Sydney, Australia

The processes and outcomes of conceptual change learning were simultaneously evaluated through analysis of the discourse of first year pharmacy students involved in small-group discussion and problem-solving in the topic of "Acids and Bases". Students were videorecorded during weekly sessions, and interviewed on three occasions: before, immediately after and five months after a teaching intervention designed to introduce new conceptual understanding and facilitate the development of contextual discrimination of the meanings communicated by use of particular words in two different scientific communities (chemistry and pharmacy). Interviews were used in order to evaluate the outcomes of conceptual change, and the videorecordings were used to elucidate the processes at work in each group that promoted or constrained conceptual change. The two groups were classified as PC (Persistent Change) and TC (Transient Change) on the basis of the long term learning exhibited at the third interview. There was a clear correspondence between the processes and outcomes in that members of the PC demonstrated productive interactions leading to high levels of intersubjectivity and creation of effective zones of proximal development through extended progressive discourse, while TC members displayed poorly productive interactions, little intersubjectivity and minimal creation of ZPDs. Results were consistent with whole-cohort surveys. A surprising and complex effect of friendship was noted in that the closeness of friendships was not necessarily associated with more productive interactions. The study is important because it describes a conceptual change discourse model which is capable of relating process and outcomes, and offers directions for improving student learning.

Aims

The aim of this research was to explore the application of a discourse model of conceptual change in a first year university classroom. The model was developed on sociocultural principles, and postulates that both the process and outcomes of conceptual change can be evaluated by analysing the discourse of students, both among themselves, and with tutors. Further, the model outlines how student group interactions mediated learning, through promoting different levels of intersubjectivity, and differential creation of zones of proximal development. The study was prompted by a history of observed student difficulties in understanding and communicating meaning when using the same words in different contexts – in this case in the scientific communities of chemistry and pharmacy.

Specifically the study was designed to investigate simultaneously the processes and outcomes of conceptual change learning, where evidence for conceptual change was found when students engaged in patterns of discourse which were appropriate in the context of a particular community, and exhibited explicit contextual discrimination between the two communities.

Methodology

The study was carried out with pharmacy students at the University of Sydney, Australia. Within the compulsory unit Introductory Pharmaceutical Science, students were divided into four parallel workshop groups, undertaking weekly two-hour sessions to consolidate the learning of material on the topic "Acids and Bases" presented in lectures. Within the workshop groups, students worked together in sub-groups of four to six throughout the semester (13 weeks) to complete activities requiring discussion and collaborative problem-solving. Within each workshop, one sub-group was invited to participate in the intensive phase of the study, and two of these groups, comprising eleven students, were subsequently included in the analysis.

The intensive phase involved interviews and videorecordings. The researcher conducted three interviews with each participant: one immediately prior to commencement of the instructional period; one conducted immediately after a four week teaching intervention; and a third interview conducted approximately five months after the teaching intervention, and following a three-month vacation. These interviews represented participants' pre-instruction understanding and attitudes, post-instruction understanding and attitudes, and long-term learning respectively. Group interactions were videorecorded for three weeks in workshops in order to evaluate both verbal and non-verbal behaviours.

Interviews were transcribed verbatim and analysed for content by considering how each participant talked about the concepts under exploration. The discourse of the videorecordings was also transcribed and analysed for the ways in which participants talked about the concepts, and in addition participants' verbal and non-verbal behaviours were analysed in order to describe patterns of collaboration. Questions were also included in the interviews to elucidate the participants' perspectives about the nature of the group interactions to complement observation of behaviours within workshops.

The entire cohort of 190 students was asked to participate in pre- and post-surveys of attitudes, beliefs and knowledge relating to the concepts of "Acids and Bases" in order to investigate the extent to which the selected sample reflected the entire population.

Findings

The two intensive phase groups were selected for analysis because they represented the extremes in patterns of collaboration, which has the advantage of making subtle difference more apparent.

Clear differences were apparent between the groups in the nature and persistence of the learning achieved by their members, with one group (Persistent Change, PC) demonstrating long-term retention of both appropriate discourse and contextual discrimination, and the other (Transient Change, TC) displaying evidence of only short-term learning which appeared to be targeted primarily towards examination performance. Group dynamics and behaviours were also significantly different, with the PC group exhibiting consideration of others and collaborative, learning-focused interactions involving extended and progressive discourse, while the TC group engaged in individualistic and task-focused behaviours which were characterised by less extensive and poorly coordinated discussion. Aspects of interpersonal relationships such as perceived status, together with behaviours such as persistence at tasks, and the nature of interactions with tutors created unique learning trajectories for both individual participants and the groups in which they worked. In summary, the group which demonstrated more productive interpersonal behaviours and group dynamics also demonstrated greater long term conceptual change learning.

An interesting finding was the effect of friendship on group learning. Previous work has suggested that interactions between friends are generally more productive than interactions between individuals who are not friends. However the current results suggest a more complex relationship between friendship and learning. The TC began the study claiming to be close friends, living in community within nearby residential colleagues, whereas the PC indicated that their friendships were less close. However, the closeness of the TC deteriorated significantly as a result of interpersonal competition, whereas the collaborative interactions of the PC appear to have strengthened their friendships.

The results of the cohort surveys were consistent with the findings from the intensive phase in that students demonstrated different extents of conceptual change, but that development of new understandings and some contextual discrimination was generally apparent.

Theoretical and educational significance

This study describes the application of research methods which are capable of providing an analytical and interpretive framework for the simultaneous investigation of the processes and outcomes of conceptual change. It appears to be the first report exploring the interdependence of these two dimensions, and identifies a number of key issues which have the potential either to promote or constrain conceptual change learning. It provides a theoretically rigorous foundation for the development of curriculum and design of learning environments which are capable of enhancing student learning. With respect to processes of change, this study posits a mechanism based on transformation of conceptual understanding through discourse; with respect to outcomes, it offers an alternative to the reliance on examination results.

This study is an important contribution to the development of conceptual change theory through the introduction of a new discourse model, and to conceptual change practice through the model's powerful potential for interpreting the results of empirical investigation. The findings provide new and significant insights into the original questions regarding both the processes and outcomes of conceptual change, and suggest fruitful directions for further research and effective means of improving learning in educational settings.

PAPER PRESENTATION

Changes in preservice teachers' personal epistemologies: A longitudinal study

Jo Brownlee, QUT, Australia; Susan Walker, Queensland University of Technology, Australia; Beryl Exley, QUT, Australia; Annette Woods, QUT, Australia; Chrystal Whiteford, QUT, Australia

Personal epistemological beliefs affect learning and influence the extent to which understanding is developed and meaning is made (Hofer, 2002). Strong evidence exists to demonstrate that pre-service teachers' personal epistemology can have an influence on their learning strategies and learning outcomes (Muis, 2004). Personal epistemologies, therefore, filter how pre-service teachers experience learning in teacher education courses and engage in meaningful approaches to learning (Muis, 2004). Given this, this study examined early childhood and primary pre-service teachers' a) understanding of the relationship between personal epistemologies and beliefs about learning; and b) changes in personal epistemology and beliefs about learning as students progressed through their four year Bachelor of Education course. Data collection occurred in 2007 (Phase 1) and 2009 (Phase 2). At each time point students completed the Epistemological Beliefs Survey (EBS, Kardash, & Wood, 2000) and a subset of students participated in semi-structured interviews. Results from both the questionnaire and the interview data indicated that students' personal epistemologies became more sophisticated over time with significant differences evident between Phase 1 and Phase 2 in students' personal epistemologies and beliefs about learning. Findings from this project on change in personal epistemology and beliefs about learning can inform teacher education programs.

Personal epistemologies affect learning and influence the extent to which understanding is developed and meaning is made (Hofer, 2002). Strong evidence exists to show that pre-service teachers' personal epistemology influences their learning strategies and learning outcomes (Muis, 2004). That is, we know that personal epistemologies filter how pre-service teachers experience learning in teacher education courses and engage in meaningful approaches to learning (Muis, 2004). Given the research evidence showing that personal epistemology influences learning, the study detailed in this proposal investigated a) the relationship between personal epistemologies and beliefs about learning; and b) changes in personal epistemology and beliefs about learning for a group of early childhood and primary pre-service teachers as they progressed through their four year Bachelor of Education degree toward teacher accreditation. ParticipantsThe participants for the study were pre-service teachers in the Bachelor of Education (Early Childhood) and pre-service teachers in the Bachelor of Education (Primary) at a large University situated in a large capital city in Australia. The Primary Cohort attended one of two campuses, a large city-based campus and a smaller satellite campus. Data collection occurred in 2007 (Phase 1) and 2009 (Phase 2). Data collection and analysisAt each phase, the pre-service teachers were invited to complete the Epistemological Beliefs survey (EBS, Kardash, & Wood, 2000). The EBS consists of several subscales, labeled as Structure, Knowledge Construction, Success and Truth. In Phase 1 (2007), 194 Early Childhood pre-service teachers and 131 Primary pre-service teachers completed the EBS. In Phase 2 (2009), 80 pre-service Early Childhood teachers and 131 pre-service Primary teachers completed the survey. At each phase, a subset of the larger cohorts participated in semi-structured interviews to gather qualitative data regarding participants' personal epistemologies and beliefs about learning. Interview responses were compared to establish the extent to which changes had taken place in the pre-service teachers' personal epistemologies over time. At Phase 1 (2007), 15 Early Childhood pre-service teachers and 14 Primary pre-service teachers were randomly selected to be invited to take part. In Phase 2 (2009), 8 Early Childhood pre-service teachers and 5 Primary pre-service teachers from the original interview cohort were re-interviewed. The interviews were scenario-based, and adapted from the work of Stacey et al. (2005) to focus on literacy teaching experiences. The questions were used to encourage reflection and to facilitate articulation of personal epistemologies within the context of the pre-service teachers' fields of study.

Interview questions focused upon beliefs about knowing and beliefs about knowledge to measure personal epistemology. Results Paired sample t-tests indicated that there were significant differences between Phase 1 and Phase 2 on students' responses on the EBS. Specifically, results indicated that 3rd year pre-service teachers were more likely than 1st year pre-service teachers to believe that learning might take time, that knowledge is integrated rather than consisting of a series of facts, and that knowledge is uncertain. However, there were no significant differences on the subscales of Knowledge Construction or Success. Interview analyses revealed changes in personal epistemology and beliefs about learning from Phase 1 to Phase 2. For personal epistemology, four pre-service teachers described practical evaluativistic beliefs at Phase 1 and then complex evaluativistic beliefs at Phase 2. The remaining six pre-service teachers moved from subjectivist to evaluativistic beliefs (n=2 complex evaluativism; n=4 practical evaluativism) at Phase 2. Only three pre-service teachers did not demonstrate any changes, and of these, one pre-service teacher already held sophisticated beliefs at Phase 1, suggesting that further development would not be likely to take place over time due to a ceiling effect. For changes in beliefs about learning, one student moved from a sense making view of learning to a qualitative perspective and one student moved from quantitative to application. Five pre-service teachers did not change their beliefs over time, although it should be noted that three of these pre-service teachers already held qualitative beliefs at Phase 1. Finally, complex evaluativistic beliefs were associated with qualitative conceptions of learning, practical evaluativistic beliefs were linked with qualitative sense-making and application and subjectivist beliefs were related to quantitative conceptions. Implications The findings are important when considering that the core business of teachers relates to learning and knowing. Teachers with more sophisticated personal epistemologies and beliefs about learning are likely to be able to engage in complex problem solving tasks, and argue based on evidence for a "best" solution. Teacher education programs, therefore, need to assist pre-service teachers to promote sophisticated personal epistemologies and qualitative conceptions of learning. A need to help pre-service teachers to reconstruct personal epistemologies is thus highlighted. Such reconstruction may be possible through a focus on explicit reflection on personal epistemologies. Further research is needed to qualify if engagement in explicit reflection on personal epistemologies will progress pre-service teachers' understanding of their personal epistemologies, to calibrate these to a variety of teaching situations, and thus reconstruct their personal epistemologies.

PAPER PRESENTATION

Greek secondary students' early encounters with mathematical proof in Algebra and Euclidean Geometry

Ioannis Kanellos, University Of East Anglia, United Kingdom; Elena Nardi, University Of East Anglia, United Kingdom; Irene Biza, Loughborough University, United Kingdom

Students' early encounters with formal mathematical reasoning are often characterised by tensions between intuitive insight and empirical or deductive inference. In this paper we explore students' early encounters with mathematical proof in order to discuss some of these tensions. To this purpose we draw on the 240 written responses of Year 9 and 10 Greek secondary students to diagnostic tests in Algebra and Geometry. The tests were produced by a group of experienced mathematics teachers, coordinated by the first author in his role as school advisor as well as researcher to this study, and were generated in the light of seminal research in this area by Harel & Sowder (1998) and Healy & Hoyles (2000), on students' emergent proof schemes and proof conceptions respectively. The tests aimed to capture students' perceptions at the time of their first encounters with proof (Year 9) and their evolving perceptions as they approach introduction to formal proof (Year 10). Quantitative (cluster analysis) and qualitative (coding and categorising) analyses of the data, informed by the taxonomies in aforementioned works, are currently in progress. Although preliminary, these analyses suggest that the issues raised by Harel & Sowder and Healy & Hoyles apply to Greek learners at this stage and mark some of the differences between the Year 9 and Year 10 scripts; they also suggest a variation of proof perceptions between Algebra and Geometry and an association between the

sophistication of students' proof schemes and the precision and breadth of mathematical language that these students employ.

Introduction

Students' early encounters with formal mathematical reasoning are often characterised by tensions between intuitive insight and empirical or deductive inference. When asked to determine the truth or falsity of a mathematical statement, or to produce a mathematical argument or proof, students are often perplexed as to what degree they are allowed to rely, for example, on visual insight, are expected to carry out numerous trials or employ the, often elusive at this stage, tools of deduction (Hanna, 2000). In this paper we explore secondary students' early encounters with mathematical proof in order to discuss some of these tensions. To this purpose we draw on a study currently in progress at the Universities of East Anglia and Loughborough in the UK, where the second and the third author are respectively affiliated. The study is being conducted in the secondary education context of Greece, location of the first author's position as a secondary school advisor. In the following we introduce the context, participants, aims and methods of the study and suggest some of its preliminary findings.

Context Greek secondary education is divided in two subsequent stages, the lower (Gymnasium, Years 7-9, ages 13-15) and the upper (Lyceum, Years 10-12, ages 15-17). Proof and proving is taught for the first time in Year 9 in two mathematical topics, Algebra and Geometry. In Algebra, proof tasks in Year 9 often involve the proof of identities such as $(a+b+c)^2 = a^2 + b^2 + c^2 + 2ab + 2bc + 2ca$. In Geometry, proof tasks in Year 9 may involve proving statements such as that every point of an angle bisector is equidistant from the sides of the corresponding angle. Tasks such as these aim to prepare students for a more comprehensive introduction to mathematical proof in the context of the Euclidean Geometry course, as well as the more advanced treatment of Algebra, in Year 10. In Year 9 Algebra students are expected to start exploring properties of real numbers beyond the trial of specific examples and to work towards the expression of generalised properties. In Year 9 Geometry, on the other hand, constructing arguments based on empirical facts is an acceptable practice, at least early on. For example, when students are introduced to the theorems-criteria of congruency for triangles, superimposing triangles is used in order to convince the students of the validity of the criteria. Once convinced, the students engage with proving these theorems in a deductive way. We note that in Years 7 and 8 proof is not present with the exception of the inverse of the Pythagorean Theorem that is used – however without explicit discussion of proof as such – in examining whether a triangle is right-angled or not.

Aims and data collection Our study aims to examine students' perceptions at the time of their very first encounters with proof in Year 9 as well their evolving perceptions as they approach the time of introduction to formal proof in Year 10. To this purpose we administered diagnostic tests in Algebra and Geometry to students of both years and at the beginning of the school year. The tests were produced by a group of experienced mathematics teachers, coordinated by the first author in his role as school advisor as well as researcher to this study, and were generated in the light of seminal research in this area by Harel & Sowder (1998) and Healy & Hoyles (2000), on students' emergent proof schemes and proof conceptions respectively. Students had a normal school period (45 minutes) to work on each test. For example, in one of the six items in the Year 9 Geometry Test, students were given two triangles and were asked to prove that one is right-angled and the other is not. One of the eight items in the Year 10 Geometry test asked the students to divide a line segment in three equal parts via a method of their choice – excluding the use of measurement via a ruler – either explicitly demonstrated and justified in a figure or described and justified in words. One of the twelve items in the Year 10 Algebra Test asked the students to prove that $a^2 + b^2 \geq 2ab$, for real numbers a and b . We collected 240 scripts.

Data analysis and preliminary findings Quantitative (cluster analysis) and qualitative (coding and categorising) analyses of the data, informed by the taxonomies in the aforementioned works, are currently in progress. Students' responses in each item are characterised in terms of a list of proving behaviour features (a synthesis of the features discussed in Harel & Sowder and Healy & Hoyles). These characterisations are entered in a Script \times Features spreadsheet, with each cell containing the characterisation of a student's response to each item in each of the tests. There are two spreadsheets, one for Year 9 and one for Year 10 scripts. Presence or absence of each feature within each item is counted. Cluster analysis of these numerical data will lead to a typology of student proving behavior, namely groups of scripts characterised by the presence or absence of certain features. This typology will be supported by qualitative accounts of the scripts. Although preliminary, these analyses suggest that the issues raised by Harel & Sowder and Healy & Hoyles apply to Greek learners at this stage and mark some of the differences between the Year 9 and Year 10 scripts; they also suggest a variation of proof perceptions between Algebra and Geometry and an association between the sophistication of students' proof schemes and the precision and breadth of mathematical language that these students employ.

PAPER PRESENTATION

Children's preschool SFON, subitizing and counting skills predict mathematical skills 6 years later

Minna M Hannula-Sormunen, University of Turku, Finland; Erno Lehtinen, University of Turku, Finland; Pekka Rasanen, NMI, University of Jyväskylä, Finland; Roland H. Grabner, ETH, Switzerland

Research on mathematical development and number processing, especially the study of early developmental factors, still seriously lags behind the successful identification of the predictors of literacy. This project aimed at charting, longitudinally, numerical development and delineating the early factors producing both later success and failure in school mathematics. In this 7-year longitudinal study of 39 normally developing children, the participants' Spontaneous Focusing On Numerosity (SFON), subitizing-based enumeration and counting skills were assessed at the age of 5-6 years, while their mathematical skills, Raven's non verbal IQ and working memory for numbers were tested at the age of 12 years. Results of path analyses show that subitizing-based enumeration and counting skills predicted uniquely mathematical skills at age 12, while SFON was indirectly, via counting skills related to mathematical skills at age 12. These associations remained significant when working memory and non-verbal IQ at age 12 were controlled for. Working memory was significantly related to mathematical skills at age 12, while IQ was not. Children's SFON continues to be an effective component of mathematical development throughout the childhood years until the end of primary school.

PAPER PRESENTATION

Pre-school children's number and problem-solving concepts compared: UK - Japan.

Jennifer (Ewers-) Rogers, Liverpool Hope University, United Kingdom

International league tables of academic performance show that Japanese pupils consistently outperform English pupils, yet their relative starting points upon starting school are not known. A comparative study investigating early conceptual development was carried out in the UK and Japan examining a range of abilities known to be significant factors generally in school success. 110 pre-school children with an average age 4 years, 55 from each nation were individually assessed in a study matching gender, age, sample size and background. Quantitative data from the results of early number showed that the young Japanese participants significantly out-performed English pre-schoolers on cognitive-linguistic measures at a level approaching significance ($\chi^2 = 3.5$, $p = .056$). They were also able to use more symbolic representation of number ($\chi^2 = 9.52$, $p > .001$). Qualitative data provide further, explanatory detail. The results overall allow consideration and comparison of the philosophy and pedagogy of teaching in the early years with philosophy, pedagogy and educational performance at later stages in the two countries (Alexander, 2001).

Introduction: Global cooperation and competition have expanded interest in comparisons of pedagogy and performance internationally - and particularly of relationships between the two. Tables of academic performance in Mathematics and Science (TIMSS) frequently show pupils from Pacific Rim and Scandinavia achieving the highest results (Mullis, Martin and Foy, 2005). Of note is that Japanese pupils consistently outperform English pupils by the age of 9, despite starting school almost two years later at age 6+. Findings from a range of research areas show that many of young children's early competences are underpinned by the ability to sequence a series of events. Fluck and Henderson (1996) report pre-school children's difficulty in using their counting skills for problem solving, corroborated by a range of recent reports. Problem solving depends upon formal experience in sequencing. While much educational assessment of children takes place within the 'secondary' language mode of writing, relatively little is known about the extent of 'primary' oral ability which allows the construction of meaning from experience as well as direct expression of conceptualisation. The paper reports on a comparative study in the UK and Japan examining early conceptual development and a range of abilities known to be significant factors generally in later school success.

Methodology: To compare children's understandings of number for the relationship between levels of cognitive-linguistic competence and later academic success the tests were conducted at the age at which they approach statutory education. As English children start Primary School at around age 5 years and Japanese children commence Elementary School at 6+ years, tests were administered to participants with an average age of 5 years. Participants 110 pre-school children, 55 from each nation, (56 M and 54 F) aged 40-59 months, were individually assessed (Japanese, $M = 49.09$; English, $M = 50.15$, p Materials: Activities were devised which require participants' to apply their existing knowledge in new situations to reveal the nature and extent of underlying concepts and meta-cognitive abilities. Expression in natural language allowed a valid examination of conceptual knowledge. Reliability was allied to four principles. Firstly that the orally presented tasks eliciting spoken responses were identical in both countries, with materials and content appropriate, 'culturally fair' and reliable (Anastasi, 1988; p.298) in both settings and valid for assessing the cognitive development of very young children. This eliminated using standardised tests, not widely available for this young age-group, and the author developed bespoke tests specifically for this study. Linguistic

accuracy of target questions was measured for reliability and validity at the developmental stage through reverse translation using native speakers. Two tests assessed counting and cardinal number concepts. The Dolls and Stickers game assessed oral number the various ways in which number (numerosity) was conveyed in speech. In the Boxes Game children's graphical/written recordings were examined for clarity in conveying concepts of cardinal number in symbolic form. Ethical safeguards: Ethical safeguards for testing very young nursery/kindergarten participants was considered by the stakeholders and consent obtained through the universities and schools to meet the standards of each country, prior to project clearance and administration. Methods of Analysis: Responses to the Dolls and Stickers task were examined for the correct use of cardinality in orally reporting numbers 3, 1 and 2. A secondary assessment was correct use of the colours yellow, green and red. In the Boxes Game, graphical forms of representing cardinal number were coded as idiosyncratic, pictorial/iconic or symbolic/numeric. Results Statistical tests found a significant difference for all children overall between the means for the oral representation of numbers 1, 2 and 3 in the Dolls game (Cochran Q = 8.19, p df = 2); children were able to represent number 1 orally significantly more easily than the number 2 ($\chi^2 = 5.6$, p) and the number 3 at a level approaching significance ($\chi^2 = 3.5$, $p = .056$) according to the McNamer test. However Japanese participants significantly out-performed English pre-schoolers on cognitive-linguistic measures at a level approaching significance ($\chi^2 = 3.5$, $p = .056$). In the Boxes game the Japanese children made consistently more use of symbolic and numeric representation overall, with greater use made by their older than their younger children: for number 1 ($\chi^2 = 7.38$ $p > .01$); number 2 ($\chi^2 = 7.38$ $p > .01$); and number 3 ($\chi^2 = 9.52$ $p > .001$) Conclusion One of the dangers of intercultural educational comparisons is the temptation to 'borrow' practice. This must be viewed with caution as cultural differences inevitably involve unmatched variables and 'importing' is fraught with danger for teachers and pupils. Instead we need to consider the reasons underpinning effectiveness in a particular educational setting i.e. to consider the social, cultural, political and historical factors and conditions (i.e. the context) and only then can the adoption, or adaptation, of some aspects 'at home' be considered. Comparative studies offer greater insights and understanding of both individual and group functions and potential, and differing degrees of balance between the two. If raising achievement to international levels and improvements in social chances and life chances are to be improved in the UK, then looking outward to other ways of doing and being within early years practice may offer a way forward (Tobin, Wu and Davidson, 1989). Particularly so when Japanese pupils consistently outperform English pupils by the age of 9, despite starting school almost two years later at age 6+, and in view of receiving a concrete and conceptually based curriculum throughout the early years of kindergarten and school.

PAPER PRESENTATION

Exploring Students' Experiences Of Understanding The Threshold Concept Of Function

Max Scheja, Stockholm University, Sweden; Kerstin Pettersson, Stockholm University, Department of Mathematics and Science Education, Sweden

This study explores the nature of university students' experiences of understanding the threshold concept 'function'. Fifteen teacher students taking an introductory course in mathematics were at the beginning of the course asked to reflect in writing on the meaning of 'function'. Subsequent interviews explored in greater detail individual students' conceptual understandings of this concept. At the end of the course, students were again asked to reflect in writing on the meaning of function and then to elaborate further on those written reflections in a qualitative research interview. In a previous study of students' understandings of limit and integral an intentional analysis of the interview transcripts underscored the crucial interplay between understandings developed within an algorithmic and conceptual context respectively. The present study seeks to develop this contextual framework for analysing students' understanding in mathematics by linking the analysis of students' emerging understandings of function to ongoing research on threshold concepts in higher education and more broadly to research on students' experiences of understanding disciplinary ways of thinking and practising.

AIM

The study aimed at exploring the nature of university students' experiences of understanding the threshold concept 'function'.

METHODOLOGY

Fifteen teacher students taking an introductory course in mathematics were at the beginning of the course asked to reflect in writing on the meaning of 'function'. Interviews were then conducted with a subset of the students to explore in greater detail individual students' understandings of this concept. This procedure of asking students to reflect in writing and then to elaborate in interviews on their understandings was repeated towards the end of the course, to investigate any changes in the students' understandings of 'function'. The individual interviews, which lasted between 30 and 60 minutes, were transcribed in full with the students' informed consent. The data—consisting

of the students' written and oral reflections on the concept of function—were analysed within a theoretical framework developed in constructivist research on learning and conceptual change. This framework underscores the importance of understanding individual students' personal motives and beliefs in approaching a learning task and so the analysis focused on discerning students' varying ways of explaining the meaning of the concept of function, and on describing these in terms of contextualised conceptions supporting different understandings of the concept at hand.

FINDINGS

The analysis of the students' written reflections and student interviews is still underway, but preliminary findings indicate that students varied a great deal in their personal understandings of the meaning of function. Looking across the whole data material students seem to express seemingly incoherent, fragmentary and sometimes contradictory conceptions of function. For instance, students talk about function in terms correlations of various sorts (e.g. between time, distance and speed when travelling by taxi etc.) that indicate a common sense view of the concept. Students also bring to the fore conceptions linked to previous learning experiences from earlier school stages, defining function in terms of a simple curve. From these rather fragmented notions of function it is easy to get the impression that students have not yet grasped the conceptual meaning of function. However, from the analysis it was also evident that students' communication of their understandings had to be recognised as part of a dynamic process of coming to grips with a mathematical threshold concept offering certain resistance in terms of understanding. For instance, there was evidence of students' beginning to develop more abstract and conceptually loaded conceptions of function implying a gradual extension of the context for interpreting this mathematical concept. Drawing on previous studies on students' experiences of understanding threshold concepts in mathematics incoherence and fragmentation may in fact form part of a crucial process of developing understanding. Linking these ideas to recent research within the threshold concepts framework on modes of variation, the conceptions identified can be said to represent stages or positions in the process of coming to understand threshold concepts in mathematics. Importantly, these stages are not fixed or isolated. They involve dynamic interpretive processes on the part of the learner, driving the process of coming to understand the threshold concept or, for that matter, subject area. Previous analyses of students' learning of mathematics suggest that a key to understanding lies in the ability to shift contexts. In particular it is through contextual shifts that students may gradually traverse different modes of variation and be made aware of the boundaries of the discipline thus gradually building an awareness of the ways of thinking within mathematics. And in the present study it is this potential for understanding that is emphasised in the analyses of the meanings that students ascribe to the mathematical concept of function.

THEORETICAL AND EDUCATIONAL SIGNIFICANCE

While most of the previous research on conceptual understanding has focused on students' difficulties and shortcomings in coming to grips with mathematical concepts, this study offers an alternative approach to studying students' understanding of mathematics. It focuses, not on misunderstandings, but on the potentiality for learning implied in the range of understandings brought to the fore in a group of teacher students' ways of dealing with the task of explaining the meaning of the mathematical threshold concept of function. Adopting a view on student learning which emphasizes potentiality rather than fallibility has important implications for teaching. From such a perspective, guiding students' efforts to develop conceptual understanding of particular teaching areas does not mean accepting or ignoring apparent mistakes or misconceptions. Rather it means taking them seriously enough to look for ways to help students extend and develop these efforts within contexts that allow important aspects of concepts to be recognized as crucial ingredients in understanding those concepts. Such a perspective, which reveals students' ways of contextualizing concepts and learning tasks, enables teachers to engage, not only with students but also with students' efforts to understand. In that sense it also provides a crucial pathway for linking the students' provisional understandings to ways of thinking endorsed within the discipline.

PAPER PRESENTATION

Use of information sources about socio-scientific issues in elementary school and high school

Maria Joao Fonseca, IBMC - Instituto de Biologia Molecular e Celular, Universidade do Porto and Faculdade de Ciencias, Universidade do Porto, Portugal; Patricio Costa, Faculdade de Psicologia e de Ciencias da Educacao, Universidade do Porto, Portugal; Leonor Lencastre, Universidade Porto, Portugal; Fernando Tavares, IBMC - Instituto de Biologia Molecular e Celular, Universidade do Porto and Faculdade de Ciencias, Universidade do Porto, Portugal

Schools are cornerstones in the promotion of information literacy required for personal and public decision-making about socio-scientific issues, such as biotechnology. However, several reports have evidenced students' and teachers' limited competencies concerning the search and evaluation of scientific information. The purpose of this study was to unveil the relationship between use and trust in information sources about biotechnology among biology teachers and elementary and high school students. Particularly, it aimed to: 1) identify the main information sources used; 2)

understand if and to what extent the use of information sources is influenced by their perceived reliability; and 3) analyze if and how teachers' use and trust in information sources affect students' choices and opinions. Following a quantitative assessment approach through questionnaire implementation, data was collected from 93 teachers and 1196 students. SPSS was used to perform descriptive and inferential statistics (t-tests, ANOVA, and non-parametric statistics). Data analyses reveal that school textbooks, scientific magazines and the television are among the main information sources used by teachers and students. Overall, the respondents' choices appear to be more strongly influenced by the availability and less by the perceived reliability of the sources. Furthermore, there was not an explicit relationship between the use and trust patterns identified for teachers and students. These findings suggest a deficit in information literacy instruction, and indicate the need for strategic interventions, namely involving improved teacher training programs to enhance teachers' own information literacy, and assist them in scaffolding the development of these competencies by their students.

PAPER PRESENTATION

Learning about ecological systems by constructing qualitative models with DynaLearn

David Mioduser, Tel Aviv University, Israel; Ruth Zuzovsky, Tel-Aviv University, Israel

Understanding complex systems has become a challenging intellectual endeavor for scientists and science students as well. For science students, the systems approach and specific concepts in it (e.g., emergence, self-organization, non-linearity) represent a serious learning challenge. Portions of this knowledge appear to them epistemologically counterintuitive, and/or incongruent with the approaches, assumptions and practices characterizing the way they learn Science with the curricula prevalent in educational systems. This presentation focuses on the contribution of Qualitative Modeling (QM) with "DynaLearn" modeling environment, to students' system thinking and understanding of ecological systems. More specifically, on students' ability to: (a) understand and represent complex ecological systems; (b) construct qualitative models of systems; and (c) apply the systemic perspective in different ecological contexts and phenomena. Participants were 25 Junior-High students in two groups, attending a Marine Biology Summer course. Experimental group completed a set of modeling activities using "DynaLearn". Data were collected from students' concept maps and documentation, qualitative models and documentation, and responses to post-intervention questions about different systems and ecological phenomena. Results are clearly indicative of the contribution of qualitative modeling with DynaLearn to students' ability to understand structural and behavioral aspects of the systems under study, to construct qualitative models of the systems, and to apply the gained knowledge when learning about different ecological systems.

Understanding complex systems has become a challenging intellectual endeavor for scientists and science students as well. The development of systemic approaches since the early years of the previous century, opened ways of thinking about and studying phenomena in the world unveiling aspects, interrelationships and processes that were overlooked by traditional science. For science students, the systems approach and specific concepts in it (e.g., emergence, self-organization, non-linearity) represent a serious learning challenge. Portions of this knowledge appear to them epistemologically counterintuitive, and/or incongruent with the approaches, assumptions and practices characterizing the way they learn Science with the curricula prevalent in educational systems.

This report is part of a larger study conducted with Junior High-School students aiming to assess the contribution of Qualitative Modeling (QM) with "DynaLearn" modeling environment, to students' system thinking and understanding of ecological systems. DynaLearn (DL) supports the construction of models in a succession of Learning Spaces - from simple representations (entities and relationships), toward more complex representations (quantities, quantity spaces, direct and proportional relationships, feedback loops, conditions and assumptions).

This presentation focuses on the contribution of QM with DynaLearn to students' ability:

- to understand and represent complex ecological systems;
- to construct qualitative models of systems, and
- to apply the systemic perspective in different ecological contexts and phenomena.

Method

Participants were 25 High School students in two groups, attending a summer course in Marine Biology comprising short lectures, lab activities and a field trip. In addition as treatment variable, the experimental-group (DL) completed a set of modeling tasks using DynaLearn, while the control group (C) that did not use DynaLearn did a Web-based inquiry-task.

Data collection was conducted using 3 instruments:

- Students' concepts maps and documentation - both groups.
- "Challenging questions" questionnaire - both groups.
- Students' models and documentation - experimental group.

Concept mapping: Done twice by DL group (pre- and post-intervention) and once by C group.

Modeling tasks: students constructed a series of models using DynaLearn's learning spaces 2, 3 and 4. Following each modeling activity, they documented their experiences answering questions about their models, the modeling process and the insights gained from one modeling step to the next.

Results

Question 1: On the contribution of qualitative modeling with DynaLearn to students' ability to understand and represent complex ecological systems

Students' concept maps were analyzed focusing on the following variables:

- Overall configuration of the system's representation - e.g., hierarchical or Net-type.
- Foci - focus on structural static properties or on dynamic aspects (processes and causal relationships).
- Guiding organizing principle: e.g., formal-classification principles or ecological-systems' principles.
- Type of relationships: e.g., mainly structural or referring to causal processes and chains.
- Scientific accuracy: on a scale from high to low level of accuracy.

A brief account on some results follows:

Pre- post- experimental group concept maps comparison:

- Increase (40% > 71%) in Net-type, and decrease (60% > 29%) in hierarchical, types of representations
- Increase (60% > 86%) in the use of ecosystemic organizing principles and decrease (40% > 14%) in using formal-classification organizing principles
- Increase in representing structural relations (10% > 29%) and mixed structural/process relationships (60% > 71%)
- Slight decrease in scientific accuracy (80% > 70%)

Concept map comparison between experimental and control groups:

- None of the representations in the C group was Net-like
- Less ecosystemic representations in the C group (DL-86% vs. C-54%)
- Most representations in the C group were of structural type (DL-29% vs. C-62%)
- Less representations in the C group combined structural/process relationships (DL-79% vs. C-38%)
- Less scientific accuracy in C group's representations (DL-71% vs. C-23%)

Question 2: On student's ability to construct qualitative models of an ecological system

Brief summary of results for three of the variables considered:

- Students understanding of the phenomena modeled

At first, half of the students phrased their modeling aim as specific questions, e.g.,: How much effort the patella exerts when attaching to the rock in varying intensities of waves.

At the end of the modeling activities most students (80%), defined phenomena in more generic and systemic ways, i.e., The relationship between crabs, barnacles and patella; The effect of jellyfish on the Israeli marine shore.

- Understanding types of relationships in the system

Values for this variable include the relationships: single/unidirectional; parallel /unidirectional; one-to-many; causal-chains; feedback-loops. Along the modeling activities we observed:

- Decrease in single/unidirectional relationships (40% > 10%)
- Decrease in parallel/unidirectional relationships (20% > 10%)
- Increase in one-to-many relationships (0% > 10%)
- Increase in chain-relationships (30% > 50%)
- Increase in feedback-loop relationships (0% > 20%)
- Insights related to complexity and the worth of modeling for learning

Qualitative analyses of student's documentation unveil their perception of complexity and the contribution of modeling for understanding it. Examples of insights: "The modeling activity enabled predictions"; "The modeling activity enabled to understand the dynamics of the system"; "The modeling activity allowed studying many variables and many relationships"; "The modeling activity taught me that some changes have long-term and far effects – If you touch one thing, everything can change".

Question 3: On the contribution of QM to student's ability to understand different phenomena and systems

"Challenging questions" were administered to both groups after the intervention. Students had to apply the knowledge gained to provide descriptions, explanations, and predictions concerning a marine ecosystem. Sample results:

- The average total score by DL students was much higher than that of the C group (78.3% vs. 45.8%).

- DL students outperformed C students (DL-59% vs. C-36%) in understanding different types of relationships in ecosystems
- On predicting changes that might occur in a system in response to an interference (external agent, change in conditions), most students in the DL group (60%) succeeded in delineating long chains of events, vs. none in the C group.

In summing up the results, it is clear that from the perspective of systems thinking, the modeling activity affected students' perception of systems in a more dynamic and comprehensive way.

PAPER PRESENTATION

Developing optimization as a reasoning strategy for dealing with socio-scientific decision-making

Nicos Papadouris, University of Cyprus, Cyprus; Costas Constantinou, University of Cyprus, Cyprus

This paper reports on an exploratory investigation of high-school students' ability to use an optimization strategy for processing information in socio-scientific decision-making tasks. We have developed specially designed curriculum materials for this investigation. We have implemented these materials with two groups of high-school students (N=28) over a course of nine ninety-minute sessions. Prior to and after the teaching intervention we collected data through open-ended tasks, that asked students to either address specific socio-scientific decision-making situations or evaluate the appropriateness of given decisions regarding those same situations. Each student responded individually while 10 students also participated in follow-up interviews. Data analysis demonstrated a significant shift towards more analytic and thoughtful decision-making approaches, after the teaching intervention. Specifically, most students spontaneously selected to apply the targeted optimization strategy and provided appropriate justifications for their decisions. Additionally, there was a substantial reduction in the number of students who either resorted to non-compensatory approaches that excluded some of the criteria or employed invalid approaches for synthesizing all the available information. Finally, there was a significant increase in the percentage of students who were able to elaborate reasoning flaws characterizing commonly invoked decision-making approaches. These data provide encouraging indications for the possibility of devising learning environments for promoting students' decision-making reasoning strategies, which is an important component of science learning. At this stage, we are in the process of revising the curriculum materials using the data that emerged from its implementation and we plan for a controlled experiment to investigate the effectiveness of this approach.

Introduction

Decision-making skills are widely recognized as a central aspect of scientific literacy and, hence, an important aim of science teaching. However, research on teaching and learning about decision-making, within science education, has been very limited. This is evidenced by the rather poor research base on students' initial ideas and the difficulties they encounter when engaged with socio-scientific decision-making tasks and also by the lack of teaching innovations in this area. This paper is part of a research project that seeks to develop and validate curriculum materials for a certain aspect of decision-making. Specifically, they are focused on the reasoning component of comparing the possible solutions so as to identify the most appropriate one and they seek to help students develop a specific optimization strategy that could serve this role. The learning materials have been implemented in the classroom environment so as to evaluate their potential effectiveness and identify possible ways to revise them. Below we briefly describe the learning materials, we discuss methodological issues relevant to their implementation and we present empirical results from the evaluation of their potential effectiveness.

Overview of the learning materials The learning materials are primarily web-based and they have been designed using the STOCHASMOS platform. Students work in groups, following a guided inquiry approach. They are assigned the role of consultants that should advise the government on the most appropriate technology to be used, in conjunction with the existing oil-fired power stations, in order to provide a specific amount of electrical energy. There are three possible solutions: installing wind parks, installing photovoltaic parks or converting some of the existing stations so as to use natural gas. Students are provided with information on the possible solutions and relevant criteria, which they need to process so as to formulate an evidence-based decision. Throughout their engagement with the learning environment, students are guided to (i) recognize the complexity stemming from the presence of both strengths and weaknesses in all three solutions, (ii) appreciate the need for systematic data processing that synthesizes the entirety of the available data and (iii) gradually develop and elaborate a specific optimization strategy as a possible way to meet this need. In brief, this strategy involves, converting raw data into a single scale, adjusting for the possible variation in the importance of the criteria, through the assignment of weights, and using the adjusted scores to obtain overall weighted values and determine the most appropriate solution.

Methods

The curriculum materials have been implemented in the context of a summer science club. Participants were 28 high-school students (aged 16-17) and the teaching intervention lasted nine ninety-minute sessions.

Prior to and after the teaching intervention we collected data through seven open ended tasks. In four of them students were asked to address specific decision-making situations relevant to the selection of the site for installing a water desalination plant. Students were provided with information linking the given criteria and the possible solutions, which they were asked to process and formulate a detailed suggestion as to the most appropriate solution. In the remaining tasks students were given certain suggestions relevant to these same situations and they were asked to judge their appropriateness. Students responded individually and ten of them (36%) also participated in follow-up interviews so as to gain further insights into their reasoning.

Students' responses were processed in order to document the qualitatively different ways of dealing with decision-making situations and the positions they adopted in judging the appropriateness of given decisions. The comparison of the students' responses prior to and after the teaching intervention, using non-parametric tests, provided encouraging indications as to effectiveness of the curriculum materials. In addition to this, the interview data allowed us to identify and document the main reasoning difficulties undermining students' attempt to address decision-making situations.

Findings Prior to the teaching intervention none of the students was able to synthesize the available information by weighing the strengths and weakness of the rival solutions in a systematic and valid manner. Most of them employed non-compensatory approaches that only relied on some of the relevant criteria and precluded tradeoffs among the various solutions. For instance, one such response was: "I would suggest Sotera. It is the best on two out of the three criteria". Those who attempted to synthesize the data employed flawed approaches, such as the direct comparison of the advantages and disadvantages of the rival solutions using the raw data without adjusting for the variation in the corresponding metrics. In addition to this, only 25% of the students were able to identify reasoning flaws in the decisions they were asked to reflect on. These findings provide empirical support to the position that such reasoning skills do not typically emerge as a spontaneous outcome of conventional science teaching or maturation.

After implementing the learning materials, the majority of students (76%) spontaneously selected to address the given tasks using the optimization strategy (figure 1). Most of the remaining students sought to integrate all the available information, though in an error-prone manner. One such example involves arbitrarily dismissing the magnitude of the difference among rival solutions on certain criteria as "insignificant". In addition to this shift in the percentage of students who were able to apply holistic decision-making approaches, most of them (87%) were also able to elaborate reasoning flaws inherent in the given decision-making approaches.

Concluding remarks The results from data processing suggest that students' interaction with the learning materials facilitated the shift towards more analytic and holistic approaches that consider tradeoffs among the strengths and weaknesses of possible solutions. In addition to this, it has helped them appreciate flaws inherent in commonly invoked decision-making approaches. These encouraging indications are directly related to the need for an emphasis shift in science teaching from only addressing content to also integrating objectives related to reasoning strategies. At this stage, we are in the process of revising the activity sequence, based on the available data, so as to further increase its potential and we plan for a controlled experiment to investigate the effectiveness of this approach.

PAPER PRESENTATION

Characterizing the language of students' written explanations in TIMSS' science items

Birgitta Frandberg, Chalmers University of Technology, Sweden; Anita Wallin, Faculty of Education, Sweden; Per Lincoln, Chalmers University of Technology, Sweden

Abstract. This study describes certain lexical features of the language used by Swedish grade 8 (aged 15) students answering science items in TIMSS 2007. The language of the students' freely formulated written responses to science items can be seen as an expression of the conventions of a specific discourse within science education in secondary school. The specific discourse is assessment by written tests. Data from TIMSS offers an opportunity to investigate the language used by a large group of students, carefully sampled. Drawing from systemic functional linguistics, we estimated the degree of technicality of the explanations from a sample of 1938 written answers. Answers were on average 14 words long and varied between 1 and 77 words, the average amount of science terms were 1,64, with a range of 0 to 9. There was a difference in use of science terms between achievement groups, with the explanations from the group of high achievers having the highest level of technicality. Although the girls, on average, use more words, their answers do not include a larger number of science terms. The use of science terms in the answers varies

according to the use of science terms in the items. The results indicate a discourse of tests and explanations in science education where students are not expected, and therefore not practiced, to use a specialized language.

Aim

When science education is viewed as processes of socialization constructed by discourse and interaction, the language used becomes a central issue for research (Kelly, 2008). Language is in socio-linguistic research regarded not just as a tool but also as constitutive of meaning and social context. (Dimopoulos, Koulaidis, & Sklaveniti, 2005; Halliday & Martin, 1993; Lemke, 1990; Veel, 1998).

The discourse of science and school science is regarded as particularly difficult due to among other things its grammatical and lexical features and ultimately how it constructs meaning (e. g. Lemke, 1990). The view of the central role of language in science education has resulted in a large body of research in spoken and written language used by teachers and students in science classrooms and in textbooks of science (Halliday & Martin, 1993; Hatzinikita, Dimopoulos, & Christidou, 2008; Lemke, 1990). However, written explanations in answers to test items from large samples of students are not well investigated from a linguistic perspective.

Studies of texts and text use in some Swedish compulsory classrooms have revealed science education as a predominantly oral activity (af Geijerstam, 2006), and high achieving students was shown to produce more technical texts compared to those written by low achievers. The sample in the study was however small, and there was a call for studies of larger groups.

The subject of this study is the language used in a specific discourse within science education, the discourse of assessment by written tests, with scientific explanations for natural phenomena. The aim is to describe the extent of adaption of student language to the register of the language used in school science, in the area of matter and transformation of matter. Student responses to five items were analyzed regarding some lexico - grammatical features seen as typical for scientific language. The main questions are: How can the language used by students in explanations of phenomena in the specific scientific/school scientific context of written tests be described in relation to lexico-grammatical features as science terms, nominalizations and passive verbs in the register of scientific language? Does the language used differ between girls and boys, or between groups of students of different success in TIMSS 2007, and between separate items with respect to these same features?

Theory and Method

To identify features typical for scientific language we relied on the notion of register and linguistic code from the theory of systemic functional linguistics (Halliday & Martin, 1993). Features useful for this study are the use of specialized terminology, frequent use of nominalizations, and frequent use of verbs in passive voice. We used student answers from the Swedish part of TIMSS 2007. Only answers with an explanation were analyzed. In order to answer the questions of the study, the explanations were grouped in different ways, according to gender and according to obtained achievement scores in TIMSS 2007.

Five items from TIMSS 2007, year 8 (aged 15), were selected. These were the ones that most directly addressed the subject area of matter and processes involving changes of matter and at the same time requested responses freely formulated by the students.

The total number of words in each explanation, the number of different science terms and total science terms used in each explanation were counted. According to Martin (1993) technical or science terms can be of three kinds; words which have a meaning in everyday language and rendering a new meaning in science, words used as technical in related fields, and words indexical of a field. In this study we categorized a word as technical when it can be assigned to any of the above-mentioned groups. Additionally, the ratio of total science terms to total number of words in each answer was calculated. In the following is used the term technical density.

Findings

Preliminary results in short: The explanations in the sample are between 1 and 77 words long, with a mean of 14,7. Girls produce on average longer explanations than boys on all items, with a mean no of words for explanations from girls 15,44 compared to 11,97 for boys. The difference is statistically significant. The number of science terms in explanations produced by students is on average 1,64, varying between 0 and 9, and technical density (science terms/total words) is on average 0,1166. The technical density of answers varies according to the technical density of items. Number of different science terms used by all students varies between the items, from 34 to 51. Mean technical density does not vary with statistical significance between girls and boys, despite the difference in length of answers. High achievers on the total TIMSS 2007 produce answers with statistically

significant higher technical density than low achievers. High achievers in total use twice as many different science terms as low achievers.

Relevance

The discourse of tests in science education is significant in that it often is the ground for grading of students and therefore an important issue to know more about. If students are to be offered possibilities to learn science it is necessary for teachers and teacher educators to be aware of the difficulties linked to the written language of scientific explanations. Further research into differences shown between achievement groups with respect to technicality is suggested.

PAPER PRESENTATION

Relations of students cognitive abilities, learning-related attitudes and GPA at Grade 3, 6 and 9

Sirkku Kupiainen, University of Helsinki, Finland; Jarkko Hautamäki, Helsinki University, Finland; Natalija Gustavson, University of Helsinki, Finland; Jukka Marjanen, University of Helsinki, Finland; Pekka Rantanen, Haaga-Helia University of Applied Sciences, Finland; Mari-Paoliina Vainikainen, University of Helsinki, Finland

The study is part of a longstanding research project on the formation and fostering of learning to learn competence as part of educational effectiveness. The present paper is based on the first data from a longitudinal large-scale assessment study in Southern Finland, collected in spring 2010, encompassing all the municipality's Finnish-speaking 1st, 3rd, 6th and 9th graders (à 2000 students). The objective is to look at changes in the role the different cognitive and affective factors play in 3rd, 6th and 9th graders' school achievement. The data comprises results from eight cognitive tasks covering reasoning skills, reading comprehension and mathematical thinking, together with a large array of affective scales, covering dimensions relevant for learning and school work. The preliminary findings of SEM reveal that 1) the explanatory power of the factors measured in the assessment vis-à-vis school achievement increases in step with grade; 2) the role of affective factors – OR students' ability to manifest them – increases with age; 3) the weight of learning enhancing attitudes increases along school careers vis-à-vis achievement. The study provides empirical data on the development of general cognitive skills and students' learning-related attitudes and beliefs across the middle school years, and on students' developing accuracy in manifesting them in self-report questionnaires. The study also provides teachers with knowledge regarding the role of diverse affective factors for students' learning, which can and should be taken into account in an age-appropriate way at school.

Introduction

The study is part of a longstanding research project on the formation and fostering of learning to learn competence in formal educational setting as part of a quest for measuring educational effectiveness (Hautamäki & al. 2002; 2006; 2010). The overarching point-of-view is developmentally informed educational psychology of schooling (Olson, 2003). The present paper is based on an ongoing large-scale study, covering four age cohorts of students in a municipality in Southern Finland. This first stage of a forthcoming longitudinal study comprised the assessment of the learning to learn competence of all the municipality's Finnish-speaking 1st (not included in this study), 3rd, 6th and 9th graders (7, 9, 12 and 15-year-olds, approximately 2000 students per cohort). Aims The research objective of the current paper is to look at changes in the relative role the different cognitive and affective factors play in 3rd, 6th and 9th graders' school achievement. Actual research questions are: 1) How well does students' school achievement reflect their cognitive competence as evinced in the assessment vis-à-vis the various affective factors that direct the use of these cognitive abilities toward the expectations and demands of the school and/or can be interpreted by the teacher as doing so, and 2) Are there structural changes in the relationships between these three factors –cognitive competence,

learning and school related affective factors, and GPA – between grade 3, 6 and 9 students and if so, how should they be interpreted. Data The data, collected in spring 2010, comprises results from eight cognitive tasks in three main domains (reasoning skills, reading comprehension, mathematical thinking) together with some twenty five affective scales from self-reported questionnaires, covering dimensions relevant for learning and successful school work (e.g., academic self concept, interest, learning strategies, means-ends-beliefs, learning motivation, self-efficacy) for each age cohort of 3rd, 6th and 9th graders. The cognitive tasks and the affective scales have been used earlier in several large-scale cross-sectional and one longitudinal study and altered slightly from cohort to cohort to accommodate the developmental stage of the students. The cognitive tasks can be scaled via common items and calibrated to Piaget's theory of cognitive development based on earlier studies. Data regarding students' socio-economic background and school achievement was collected concurrently, together with parental and teacher data on grades 3 and 6. Methodology The cognitive scales for the three age cohorts will be compared and combined applying Rasch scaling (Bond & Fox, 2007). To answer the main research questions, structural equation modelling will be used (AMOS) supported by other appropriate statistical methods (PASW Statistics). Preliminary findings At this point, Rasch scaling has been executed only for the 9th grade data, revealing excellent coverage across all ability levels for almost all the cognitive tasks. Moreover, the one tasks based directly on Piaget's theory revealed the expected 'qualitative jump' with the items requiring full formal operational thinking mastered by just a fraction of the students at grades 6 and 9 (due to the complexity of the task it was not included in the 3rd grade test booklet). The preliminary findings of the SEM analyses (AMOS) reveal that 1) the explanatory power of the factors measured in learning to learn assessment vis-à-vis school achievement increases in step with students' school careers (.37 vs. .41 vs. .45); 2) the role of affective factors – OR students' ability to 'know' or interpret themselves and to answer the respective questionnaires (see Harter 1999) – increases with age; 3) at least in this study, while at grade 6 negative attitudes play a clear role vis-à-vis school achievement, especially for girls, at grade 6, 'positive' factors (agency, learning orientation) take the role of definitive priority for both boys and girls. Overall, the model explains better girls' achievement than boys', which seems to reflect the longstanding gender gap in educational achievement in Finland – at least as it is marked by teachers. Theoretical and educational significance With three cross sectional views on students who could theoretically be (and to a great degree actually are) from the same families, assessed with cognitive tasks and questionnaires built to be comparable across grades through common items, the present study allows for as close an approximation of a developmental view on cognitive skills central to learning at school and after it, which can be used for hypotheses building for the next stage of the longitudinal study. Likewise, it provides a similar opportunity to look at the development of students' learning-related attitudes and beliefs, and of students' developing accuracy in manifesting them in self-report questionnaires. On the theoretical level, the study can be seen as a valuable contribution for the quest for a developmental model of schooling which has guided learning to learning research from its beginning. At the practical educational level, the study can be seen to directly provide teachers with new theoretically based knowledge regarding the role for students' learning of diverse affective factors which can and should be taken into account in an age-appropriate way when trying to foster both curricular achievement and students' readiness for lifelong learning.

PAPER PRESENTATION

‘Yes, We Can’: Linking Teachers’ Networks and Student Achievement through Collective Efficacy

Nienke Moolenaar, University of Twente, Netherlands; Peter Sleegers, University of Twente, Netherlands; Alan Daly, University of California, San Diego, United States; Daniel Van Amersfoort, Open University, Netherlands

Educational reform efforts aimed at increasing student achievement have embraced collaborative practice as a means to intensify teacher interaction in support of improved instruction and student learning. While recent studies suggest the importance of strong teacher networks for school conditions that may benefit student achievement, empirical evidence of the direct effect of teacher networks on student learning is weak. The goal of this study was to examine the relationship between schools' social network structure and student achievement and the potential mediating role

of teachers' collective efficacy beliefs. Data were collected from 775 teachers of 53 elementary schools in a large educational system in the Netherlands. Student data were obtained at the school level, representing the results of 1383 sixth grade students on a nation-wide standardized final test administered one month after the collection of the teacher data. Using social network analysis and multiple regression analysis, we analyzed data from a quantitative teacher survey in combination with school level student achievement data. The teacher survey consisted of a Likert-type scale on perceived collective efficacy and social network questions on work-related and personal advice. A direct effect of social network structure on student achievement could not be evidenced. Yet, findings suggest an indirect effect of social network structure on student language achievement through collective efficacy. Highly dense teacher networks are associated with strong teacher collective efficacy, and in turn, strong teacher collective efficacy was related to school level student achievement.

Theoretical framework

Around the globe, educational researchers, practitioners, and policy-makers are showing interest in the potential of networks to foster systemic improvement in instructional quality and student achievement. Research suggests that relationships among teachers are important in building strong school communities (Penuel, Riel, Krause, & Frank, 2009), and that strong teacher networks can give teachers a sense of belonging and efficacy (Grodsky & Gamoran, 2003). In line with this argument, educational social network studies often emphasize the potential importance of teacher networks for school change, educational reform, and student achievement (Moolenaar, 2010). However, while recent studies suggest the importance of strong teacher networks for school conditions that may benefit student achievement, empirical evidence of the effects of teacher networks on student learning is limited. Recent research suggests that the relationship between student achievement and teacher collaboration, while important for instructional improvement, 'is likely indirect' (Goddard, Goddard, & Tschannen-Moran, 2007). As main benefits of collegial relationships that may affect student achievement, scholars refer to feelings of equally shared responsibility for positive outcomes, alignment of expectations for students, increased feelings of effectiveness (Little, 1987), and raised sense of efficacy (Bandura, 1993). Collective efficacy is a concept that amalgamates these benefits as it expresses shared perceptions of a group's ability to achieve collective goals (reflected in the motto 'Yes, we can'). Perceived collective efficacy is both associated with teacher collaboration (Ashton & Webb, 1986) and student achievement (Goddard, 2002). As such, collective efficacy may be a mechanism that can explain how configurations of teacher networks affect student achievement. To test this assumption, this paper is aimed at examining teachers' collective efficacy as a plausible mechanism that explains the suggested relationship between teacher network structure and student achievement.

Method
Context and sample. Our study takes place in the Avvansa School District, a large educational system of 53 elementary schools in the Netherlands. Data on social networks and collective efficacy were gathered from 775 educators (teachers and principals), reflecting a response rate of 96.8 %. **Social networks.** We examined teachers' work-related and personal advice networks in the sample schools using social network analysis. To assess the work related advice network in the sample schools, the educators were asked to answer the question: 'Whom do you go to for (work related or personal) advice?'. We examined density and centralization of the advice networks among educators within each school. These social network characteristics were calculated using UCINET 6.0 (Borgatti, Everett, & Freeman, 2002). **Collective efficacy.** Perceptions of collective efficacy of the school staff were measured with five items (Goddard, 2002). This instrument was translated and adjusted to the Dutch context of elementary education. The scale was designed to assess faculty perceptions of collective efficacy. For example, in one item teachers were asked: 'Teachers in this school are able to get through to difficult students'. **Student achievement.** We included student achievement as in mathematics and language on a standardized test that was administered to 1383 sixth-grade students of the sample schools (age 11-12). The nation-wide standardized Final Primary Education Test is considered to be a reliable and valid measure of student achievement (Cito, 2009). **Results** Based on the findings from multilevel analysis (see Table 1), we could not confirm a direct effect of teachers' social network structure on student achievement at the school level of analysis. Neither the density, nor the centralization of advice networks was found to directly affect student achievement in mathematics or language. However, findings suggested the density of work related and personal advice networks affected teachers' perceptions of collective efficacy, which in turn was associated with increased student achievement. Dense networks appear to support and nurture teachers' confidence in the capacity of their team to impact students' learning and achieve school goals. As such, collective efficacy served as an intervening variable that may explain how dense social networks among educators may ultimately benefit student achievement.

Significance Increasing student performance through strong professional teacher communities is high on the agenda for educational leaders across the globe. In this paper we suggest that the benefit of strong teacher networks for student achievement lies in its potential to foster teachers' collective efficacy beliefs. By offering shared experiences, creating a feeling of collectivity, and providing the opportunity to exchange expertise, strong teacher networks nurture teachers' beliefs in the capacity of their team, which in turn was associated with increased student achievement. A potential route to school improvement therefore may be to grow strong ties among teachers, cultivate their collective belief in 'yes, we can', and as a result, harvest increased student achievement.

PAPER PRESENTATION

Handling school inspection and their results: Differentiation of school types

Sebastian Wurster, Humboldt Universitat zu Berlin, Germany; Holger Gaertner, Freie Universitaet Berlin, Germany

The current state of research on the effects of school inspection is heterogeneous: intended and unintended effects are reported. Based on a theory of Ehren and Visscher (2006) this paper focuses on the hypothesis that several types of schools exist that deals in different ways with the inspections and its results. According to the school type feedback of results should be school specific. For the identification of these types German schools in the federal states of Berlin (N= 283) and Brandenburg (N= 278) were examined. Latent class analysis revealed four types of schools. The "active schools" are characterized by a high activity level, good inspection results and extensive communication and reflection of the results. The "unsatisfied schools" are distinguished by a substandard inspection result, low activity level and negative perception of the inspection procedure. The "(self-) satisfied schools" received an excellent result. The quality of inspection procedure is estimated very positive. The activity level is low. These schools seem not to have reasons to act. The „reactive schools" got a substandard result. Characterizing for this type is a low activity level except for a high preparation activity before the inspection proceeded. Although the result is not outstanding, the result and procedure are accepted. The findings suggest a differentiated inspection procedure (especially the feedback) and acting of the support systems depending on the type of school, to assist school development best.

Extended Summary

Aims

Recently school inspections have become an important instrument in managing education. They were implemented for two reasons: to improve and to control school quality. To this day empirical findings do not provide a clear answer to the question whether inspections have a positive or negative impact on school quality improvement (de Wolf & Janssens, 2007).

This paper focuses on the hypothesis that schools deal in different ways with school inspection and its results. A theoretical framework was developed by Ehren and Visscher (2006) to systemize different impacts of school inspections and to explain the different effects. Feedback should be given differently depending on the type of school. For low innovation capacity schools inspection feedback should include clear instructions for action. In contrast for high innovation capacity schools school inspection should only feedback strengths and weaknesses to promote an autonomous development.

The research questions for this study are the following:

- How do school principals and teachers perceive school inspections and inspection reports?
- And if there are differences: Can we identify types of reaction patterns to school inspection?

Methodology

The empirical part of this paper uses a survey (October 2008) that is based on the views of principals and teachers concerning the impacts of school inspections. The survey includes questions concerning the acceptance and benefits of inspections and the communication and reflection of the results. Besides, it looks on the use of support, changes in schools activities, negative consequences and quality of inspectors diagnostic. Additionally, the results of the inspections were used to characterize types of schools according to the hypothesis above. To identify these types a Latent Class Analysis (LCA) was conducted. To select the appropriate latent class model information criteria and bootstrap analysis were applied.

The data base includes N=391 German schools in the federal states of Berlin (N= 176) and Brandenburg (N= 215) that were inspected in school years 2006/07 und 2007/08. The two states have a similar inspection proceeding. The overall response rate was 70% (Berlin 60% and Brandenburg 76%). An analysis of non-participants revealed no differences between the schools taking part and those not taking part with respect to either student performance or their evaluation by inspectors.

Findings

Four types of schools can be derived from the results.

1. The "active schools" (approx. 25%) are characterized by the highest self-reported activity level, good overall inspection results and extensive communication, reflection and dissemination of the results. The schools in this class have also the highest external support demand level to accomplish actions. Despite time stress these schools show a high acceptance of inspection. The inspection results are accepted as well as the perceived diagnostic validity of the inspection process.
2. The „reactive schools"(approx. 21%) got a substandard result. Characterizing for this type is a low activity level except for a high preparation activity before the inspection proceeded. Distinctive for this type is little communication and reflection of the results. These schools are lowest on dissemination and results processing. Although the result is not outstanding, the result and procedure are accepted. Also the benefits of inspection and the diagnostic validity of the inspection team are estimated sufficient.
3. The "(self-) satisfied" (approx. 26%) received an excellent result and communicate the feedback school-wide. The quality of inspection procedure (feedback, perceived diagnostic validity, low perceived time constraints) is valued very positive. The activity level instead is low. These schools seem not to have reasons to act.
4. The "unsatisfied schools" (approx. 29%) are distinguished by the worst overall inspection result and negative perception of the inspection procedure, diagnostic validity and also negative and undesirable consequences. Activity level is low and the results are little communicated and reflected within the school. A high time charge for little perceived use is described. The class of unsatisfied schools can be divided into two subtypes. Characteristic for both subtypes is the substandard overall inspection result and the negative perception of the inspection process. But Subtype 1 (ca. 23%) shows a high level of self-reported activity, intended action and action planning. Schools of this type receive few external supports. In contrast Subtype 2 (ca. 14%) has the lowest activity of all types and low dissemination and results processing.

Theoretical and educational significance of research

The described types of schools involve the theoretical model proposed by Ehren and Visscher (2006). A differentiated inspection procedure (especially the feedback) and acting of the support systems and school supervision authority, depending on the type of school, seems to be needed to assist school development best.

PAPER PRESENTATION

Why school norms and teacher cooperation do NOT pay off in terms of student learning

Eckhard Klieme, Deutsches Institut für Intern. Pädagogische Forschung, Germany; Brigitte Steinert, German Institute for Internat. Educat. Research, Germany; Jan Hochweber, DIPF, Germany

The school has been considered "the unit of change" in educational systems. Improvement programs focus on professional development, collaboration, and school culture (e.g., shared norms and achievement orientations) – eventually changing classroom teaching and learning. However, while effects of teaching on student learning are well

understood (Baumert et al., 2009; Klieme et al., 2009), there is less rigorous knowledge about school processes, and effect sizes are much smaller.

This paper reports on a representative study of language development in ninth grade, $n = 209$ schools, 1579 teachers, 9980 students. HLM models specify the impact of school level (achievement orientation, strength of competence goals, cooperation among German language teachers) and classroom level factors (structure, teacher support, cognitive challenge, frequency of opportunities for language learning).

Professional goals and collaboration had an effect on structure and frequency of learning opportunities. Teacher support and cognitive challenge had an impact on student motivation and achievement, respectively. This pattern supports the theory of basic dimensions of teaching quality. Professional activities at the school level, however, seem not to focus on those aspects of school/teaching quality that can make a difference for student learning.

Theoretical background

The school has been considered the unit of change in educational systems. Since the 1970s, the Anglo-American field of school improvement has endorsed this idea (Chrispeels & Harris, 2006, p. 295). Improvement programs regularly focus on professional development, collaboration, and school culture (e.g., shared norms and achievement expectations) – eventually changing classroom teaching and learning.

However, effects of school level variables on student learning tend to be rather small. Meta-analyses of school and instructional effectiveness prove that individual prerequisites of learning and individual activities bear more significance to the students' learning results than the characteristics and processes of instruction, and even far more than school process characteristics (Hattie, 2009; Seidel & Shavelson, 2007; Scheerens & Bosker, 1997).

Research Questions

Drawing on a school achievement study that is representative for Germany we assess in how far differences in the development of achievement and learning motivation in the subject of German in ninth year students can be explained by differences in the professional norms and practices (school level) on one hand, instructional quality and teaching practices (classroom level) on the other hand. Also, we want to study the pattern of relations between school and classroom characteristics.

Research Method, Design, and Hypotheses

This paper reports on a representative study of language development in ninth grade, $n = 209$ schools, 1579 teachers, 9980 students, in Germany. HLM models specify the impact of school level (achievement expectations, strength of educational goals, cooperation among German language teachers) and classroom level factors (structure, teacher support, cognitive challenge, variability of teaching methods). In each school, two classes from the same year were assessed. Students were assessed both at the beginning and the end of the school year. Change in achievement and change in motivation, estimated from IRT models and classical test analysis, respectively, are used as dependent variables. Data were analyzed with a series of three-level models, allowing for an analytical dissection of school, class and individual levels.

At the classroom level we identified three basic dimensions that had already been ascertained in earlier studies (e.g., Klieme, Pauli and Reusser (2009); Baumert et al., 2009; Pianta & Hamre, 2009):

- (1) clear, well-structured teaching, (structuredness)
- (2) a supportive learning climate that is oriented towards the students (teacher support) and
- (3) challenging, cognitively activating demands (cognitive challenge).

Student perceptions of lessons were used to assess these constructs. We also took into account a fourth scale for questions regarding the variability of teaching methods used in the classroom.

Following the learning and teaching theory assumptions of Klieme, Pauli and Reusser (2009) we expect supportive teacher behavior to be crucial to the development of motivation, while cognitively challenge should be important for achievement development. Both of these criteria are likely to be positively influenced by well-structured instruction. Contrary to the three basic dimensions that become effective as „deeper characteristics of instruction“, the fourth scale pertinent to the variability of teaching methods constitutes a "surface characteristic" of teaching, and we do not expect this scale to bear an effect on learning development.

The following predictors are applied at the school level: achievement expectations of the German teachers, norms that are shared among the German teaching staff (here: the strength of language-related educational goals) as well as

cooperation among the German teaching staff. These aspects of professional culture are generally assumed to influence the quality of instruction and also cognitive and motivational learning processes.

Results

First, the impact of school level variables on instructional quality and teaching practices was analyzed using a series of three-level HLM-models. Each dimension of instructional quality and practice was analyzed (I) without controls and (II) controlling for gender, SES, migration status, and cognitive ability, both on the student and (as a compositional variable) on the class level, plus school type on the school level.

Teacher cooperation at school level had a significant positive gross effect on perceived structure and variability of instructional methods, while strength of educational goals at school level had a negative gross effect on structure and variability. However, all these effects vanished once controls were introduced, with strong effects of school type masking most other effects.

Second, the impact of instructional quality and teaching practices on students' achievement growth and change in motivation was analyzed using another series of three-level HLM models. Once again, models were run (I) without controls and (II) with control variables on all three levels. It turns out that none of the school level predictors (teacher cooperation, strength of educational goals, and achievement expectations) had an effect on achievement or motivation.

However, two of the class level indicators of instructional quality had an impact on student learning, as predicted. The indicator of cognitive challenge bears a significant and also sizeable effect on the increase in achievement, at both the individual and the classroom level. Also, teacher support has a significant effect on the development of student motivation on the classroom level. As expected, the variability of learning opportunities, considered to be a "surface characteristic", neither impacts student achievement nor student motivation.

Discussion

At the level of classroom instruction, the study supports our model of instructional quality which assumes three basic dimensions, with cognitive challenge being the most important predictor of achievement growth, and teacher support being the most important determinant of motivational development. However, these effective aspects of instructional quality do not correlate with aspects of professional culture at school level (i.e. cooperation, achievement expectations and strength of educational goals). The school level factors do have an impact on instructional practices, but this impact is on variability of teaching methods and perceived structure – i.e. on those aspects of instructional quality and practice that do NOT have an effect on student learning. This pattern explains why professional culture at the school level does not pay off in terms of learning.

Thus, the theoretical assumption that school quality, and more precisely the professional norms and cooperation among teaching staff, mediated by instructional quality, influences student learning, receives no support from the DESI data. The practical consequence for school development reads as follows: Professional development at school level should carefully and explicitly aim at those aspects of classroom practice that have been shown to be important for student learning, rather than, e.g., sharing many teaching methods among colleagues, which as such does not stimulate student learning

PAPER PRESENTATION

Does Instructor Affective Support Matter for Undergraduate Students?

Gonul Sakiz, Marmara University, Turkey

Research indicates the need for assessing the connection between students' functioning in schools and perceived affective dimensions of learning environments (Turner, Meyer, Midgley, & Patrick, 2003). Although considerable research has examined the role different types of teacher support on students' functioning in learning environments, insufficient emphasis has been placed on the affective dimensions of teacher support. In the current study, the construct of Teacher Affective Support, first developed by Sakiz (2007), were improved, renamed as Instructor Affective Support, and administered to 367 undergraduate students enrolled in a teacher training department of a major teaching and research university in Istanbul. Associations among perceived instructor affective support, academic enjoyment, academic anxiety, academic hopelessness, and academic effort were tested using a structural model. Direct and indirect influences of given variables were examined. Perceived instructional support directly and/or indirectly influenced academic enjoyment, academic anxiety, academic hopelessness and academic effort. Overall, the structural model explained 42% of the variance in academic enjoyment, 24% of the variance in academic

anxiety, 65% of the variance in academic hopelessness, and 77% of the variance in academic effort behaviors of junior college students.

Research has indicated the need for assessing the relationship between students' functioning in schools and perceived affective dimensions of learning environments (Turner, Meyer, Midgley, & Patrick, 2003). Although considerable research has examined the role teacher support plays in early adolescents' functioning in schools, insufficient emphasis has been placed on the affective dimensions of teacher support. Because a primary goal of education is to increase students' learning capacities and advance their academic accomplishments, schools must begin by providing environments in which students feel safe, cared for, and valued. If teachers can establish affective learning environments in classrooms by internalizing and modeling affective behaviors, students first observe, then start imitating, and, eventually, internalize these behaviors which lead to greater experience of belonging and academic and emotional fulfillment in classrooms. Therefore, more attention should be directed to examining teacher affective support in learning environments. Research, up to date, has documented the influence of different components of teacher affective support on student outcomes in various developmental levels. For example, Buyse, Verschueren, Doumen, Van Damme, and Maes (2008) reported that emotionally supportive learning environments involving teacher warmth, respect, and interest in students moderated between externalizing and internalizing behaviors of kindergarten students and their relational functioning (conflict and closeness) in classrooms. A recent study by Rudasill, Gallagher and White (2010) showed that classroom emotional support involving teacher characteristics such as warmth, kindness, respect, and concern for students had a significant moderator effect between children's temperament (attention and activity level), measured when children were 4-and-a-half-years-old, and their reading and mathematics achievement levels in third grade. Stipek et al. (1998) reported that the affective learning climate in mathematics classrooms, involving variables such as teacher interest in students, respect, and valuing, was the most powerful indicator of students' academic motivation in fourth- through sixth-grades and positively related to students' learning goal orientation, help-seeking and risk-taking behaviors, and positive emotions. Similarly, Reedy, Rhodes and Mulhall (2003) found that teacher characteristics like interest in and concern for students decreased early adolescents' depressive symptoms and increased their self-esteem over the years, from sixth- through eighth-grades. Although we know a little bit about the influence of several teacher affective characteristics on K12 students' academic, emotional and motivational behaviors, those teacher characteristics have not been explored all together until recently. Sakiz (2007) combined all affective characteristics under one category. Following an extensive analysis of theory and research, the characteristics and behaviors of teachers providing affective support to their students were determined as caring, respect, kindness, concern for and interest in students, valuing, recognizing, treating fairly, holding high expectations, encouraging, listening, and warmth. In that study, teacher affective support emerged as a significant predictor of middle school students' sense of belonging, academic emotions, academic self-efficacy, and effort in mathematics. In the current study, the potential influence of teacher affective support on college students' emotional and motivational outcomes were explored. First, Teacher Affective Support Scale was improved and renamed as Instructor Affective Support Scale. Confirmatory Factor Analysis was performed and a satisfactory fit was obtained (Figure 1). For the exploration, a structural model was developed. It was hypothesized that perceived instructional support would increase college students' academic enjoyment and academic effort and decrease academic anxiety and academic hopelessness in a wide range of courses.

Participants and Procedure

Three hundred and sixty-seven undergraduate students enrolled in a teacher training department of a major teaching and research university in Istanbul, Turkey, responded to the questionnaire. From the participating students, 126 (34%) were in their first year, 83 students (23%) were in their second year, 67 students (18%) were in their third year and 91 students (25%) were in their fourth year in the programme. The average age of the students in the study was 20.82 (SD = 1.76), ranging from 17 to 32. A greater number of female students (n=220, 59.9%) than male students (n=128, 34.9%) participated. Nineteen students (5.2%) did not respond to the gender question. Students responded to the survey items with respect to the course they were taking at the time of the survey administration. Data Analysis Descriptive, reliability, missing data, and normality analyses were conducted using Statistical Package for Social Sciences (SPSS). Structural equation modeling (SEM) was performed using AMOS statistical software package. Within two-step modeling, the original structural model was respecified as a measurement model and tested for its adequacy in the first step. The latent constructs in the hypothesized structural model were represented by their items as measured indicators and were allowed to intercorrelate during the examination of the measurement model. A priori alpha level was set at .05 for all estimations.

Results

Psychometric Properties of the Final Measure The internal consistency reliability estimates for each scale was determined as follows: The reliability estimates for the Instructor Affective Support Scale (13 items, $\alpha = .956$), Academic Enjoyment Scale (3 items, $\alpha = .909$), Academic Anxiety Scale (4 items, $\alpha = .752$), Academic Hopelessness

Scale (2 items, $\alpha = .777$) and Academic Effort Scale (5 items, $\alpha = .744$) were all in a satisfactory range. Structural Model The hypothesized model provided an adequate fit to the given data (Table 2) [$\chi^2(308, N = 367) = 872.319, p = .00$, CFI = .977, TLI = .978, RMSEA = .071 (with 90% CI lower bound = .065 and upper bound = .076)]. As shown in Figure 2, instructor affective support was significantly positively related to academic enjoyment [$b = .650, p < .001$]. Overall, the structural model explained 42% of the variance in academic enjoyment, 24% of the variance in academic anxiety, 65% of the variance in academic hopelessness and 77% of the variance in academic effort behaviors of junior college students. Indirect effect analysis also showed the significant impact of instructor affective support on student outcomes. The results improved our understanding of the factors influencing college students' emotions and motivation. Instructor affective support needs to be studied further with the participation of students in different fields. Gender effect should also be explored.

PAPER PRESENTATION

Group work at university: Insights into the interplay of students' emotions and appraisals

Karen Kimmel, RWTH Aachen, Germany; Marold Wosnitza, RWTHUniversity Aachen, Germany

This paper stresses the critical role of emotions in group work and examines how university students' emotional orientations towards a real-life group assignment relate to their cognitive, motivational, management, assessment and interpersonal appraisals of the task. For this purpose, students' emotional orientations (measured by a newly developed instrument) and group work appraisals were conceptualized as multi-dimensional, interrelated and emerging. Matched questionnaire data of 338 teacher students reveal that students' emotional orientations are strongly associated with multiple dimensions of the task. More precisely, findings show how students' appraisals of specific dimensions of the task predict positive and negative emotional orientations towards the group assignment. In sum, for a holistic understanding of students' emotional experiences of group work, it is critical to systematically examine these in light of their appraisals of distinct dimensions of the task. Overall, such insights may enhance educational practice and ensure that group work is perceived as emotionally rewarding by students.

PAPER PRESENTATION

Exploring patterns of task specific goal setting and motivation regulation

Allyson Hadwin, University of Victoria, Canada; Elizabeth Webster, University of Victoria, Canada; Stephanie Helm, University of Victoria, Canada; Lindsay McCardle, University of Victoria, Canada; Mariel Miller, University of Victoria, Canada

The purpose of this study was to examine the evolution of motivation regulation and goal setting by undergraduate students over 9-weeks in an academic semester. Weekly online reflections were coded for (a) goal quality, and (b) type of academic challenge experienced that week. Students self-evaluated goal attainment from the previous week and rated their efficacy for achieving the goal they set this week. Findings indicated that motivational challenges (particularly willpower) were the most frequent challenges students encountered over the course of a semester. When students confronted motivational challenges, they tended to set low quality behavioral goals that were met with future motivational and goal management challenges. However, over the course of an academic semester, students developed increased confidence in their abilities to achieve goals, self-reported higher goal attainment, and set goals of higher quality in terms of specificity and proximity.

Self-regulated learning (SRL) refers to a learner's deliberate planning, monitoring, and regulating of cognitive, behavioral, and motivational-emotional processes towards completion of an academic task/goal. SRL can be thought of as conducting experiments about one's own learning. Students identify a challenge or problem, hypothesize about how and why the problem occurred, and set some goals to address the problem. To achieve goals, learners make plans and set procedures in action concurrently self-monitoring and collecting informal data about progress and processes. These data inform regulatory adjustments to studying now or on future tasks (Winne & Hadwin, 1998). However, a paucity of research has examined the challenges students perceive during studying, or the ways they respond to and adapt to those challenges over time. Motivation in Self-Regulation. Winne and Hadwin (2008) posit that students regulate motivational state much like they regulate other aspects of learning. They recognize a discrepancy between products and evaluations relative to affective or motivational standards they hold and follow one of three possibilities to regulate motivational state: they change conditions, operations, or standards. From this perspective goals and standards are entwined with motivational states. Research on motivation regulation has found that college students identify using a wide variety of motivation strategies in response to hypothetical learning scenarios (Wolters, 1998). However, there is a need for research measures that capture dynamic regulation as it develops over time in authentic learning tasks (Winne et al., 2002; Winne & Hadwin, 2008; Zimmerman, 2008).

Specifically, research should examine: (a) how students monitor and regulate motivational challenges during authentic learning activities, and (b) how students respond to and adapt to motivational challenges over time. Goals for SRL. Goals are fundamental for self-regulatory cycles because they define standards for planning, choosing strategies, monitoring, evaluating, and regulating learning. Goals also provide insight about: (a) how learners interpret tasks in relation to their beliefs, (b) what they value, and (c) what they can do. Goals are fundamentally dependent on the first phase of SRL. How students translate assigned goals into their own goals is partly determined by their task understanding. Misalignments can lead to setting goals that are vague, inappropriate, or lacking specificity needed to guide work on the task. To support SRL, goals must provide accurate and appropriate standards for establishing plans, selecting study tactics, and monitoring and evaluating progress. Findings to date indicate that students can learn to set better goals for SRL; the goals are: (a) anchored in shorter blocks of time defining what would be achieved in a 1-2 hour study session (temporal properties); (b) process oriented; and (c) specific in identifying standards, processes, and strategies to be achieved or enacted (specificity) (Gendron et al., 2009; Zimmerman, 2008). In post-secondary learning contexts, students are usually tasked with setting their own goals and translating distal assigned goals and tasks into manageable proximal goals that can be used to guide studying and learning activities on a daily basis. However, there is a paucity of research that examines the quality and effectiveness of self-set goals for regulating learning in authentic university tasks and contexts. The purpose of this study was to examine the ways students regulate their learning in the context of motivational challenges. Specifically, this study examined weekly online goal setting as a strategy for regulating motivation by examining the following research questions: (a) What kinds of motivational challenges do students encounter over a semester and how prevalent are those challenges compared to other cognitive, goal management, and time planning challenges students encounter? And (b) how do students regulate motivational challenges in terms of the goals they set?

Methods.

Participants included 43 undergraduate students (20 female, 23 male) enrolled in a first-year, graded elective course (ED-D 101: Strategies for University Success). Students completed online reflection-planning notes each week. A document template was posted listing each question, and providing space for responses. Students saved each reflection with a new date. Online reflections might be considered a type of structured diary measure of SRL (Schmitz & Wiese, 2006). Reflections were used as a tool to promote active self-regulation. Students were asked to focus on academic learning in any of their discipline related courses. They were not limited to a particular course or any particular type of challenge. Reflection was prompted by a series of questions. The first part of the reflection prompted students to: (a) reflect on the previous week's strategies, (b) self-evaluate goal attainment on a scale of 0 (goal not achieved) to 10 (goal fully achieved), and (c) describe one thing they struggled with in their learning this past week. The second part of the reflection prompted students to: (a) state one goal for studying/learning this upcoming week, and (b) rate their confidence for accomplishing that academic goal this week on a scale of 0 (not at all confident) to 10 (extremely confident). Data were collected weekly for 9 weeks.

Findings.

Goals were coded for quality on four attributes including specificity about: (a) the target for the goal, (b) a temporal period for achieving the goal, (c) a standard, and (d) an action or process to be engaged. Challenges were coded with five general categories emerging including: cognitive, motivational, goal management/planning, managing self or environment, or no challenge at all. Conditional probability matrices were used to examine patterns in week-to-week goals and challenges. Findings revealed that students engaged in cycles of maladaptive motivation regulation. Motivational challenges (particularly willpower) were the most frequent challenges students encountered over the course of a semester. When students confronted motivational challenges, they tended to set low quality behavioral goals that were met with future motivational and goal management challenges. However, over the course of an academic semester, students developed increased confidence in their abilities to achieve goals, self-reported higher goal attainment, and set goals of higher quality in terms of specificity and proximity.

Discussion.

One challenge for future research is to explore the effectiveness of technologies for illuminating adaptive and maladaptive patterns in motivation regulation over time. Findings in this study demonstrate that documenting goals, efficacy, and challenges and self-evaluating goal attainment may not be sufficient to break the cyclical patterns in goal setting quality, type, and challenges encountered

PAPER PRESENTATION

Effects of a Tutorbased Learning Strategy Training for Students

Cornelia Gutmann, Ulm University, Germany; Tina Seufert, Ulm University, Germany

To help first-year students in their phase of orientation the University of Ulm provided a four weeks "Trainingscamp", where students have the possibility to repeat and consolidate their mathematical skills and got an introduction for learning strategies. The students ($n=198$) worked together in tutorials of about twelve people. Before the Trainingscamp the tutors have been trained to teach mathematical skills as well as cognitive, metacognitive and motivational learning strategies. One part of the tutorials received a semester-ongoing training for the same learning strategies as at the Trainingscamp. In an empirical study we wanted to find out whether the Trainingscamp in fact had positive effects on students motivation and their learning strategy use as well as possible longitudinal effects. The unexpected and disappointing results showed that at the very beginning of the course of studies the training leads to partly highly significant negative effects concerning motivational aspects and strategy use development. Over the course of semester the group with the ongoing strategy training recovered significantly concerning motivation and strategy use but not for metacognitive strategy use. Nevertheless, the results reassured us that strategy training is not detrimental per se. Rather, the timing of such a training seems to be crucial: after the first and unavoidable "shock of realism" students could be helped to reflect on expectations, motivational and emotional reactions. Based on this they could be prompted to use especially metacognitive and meta-motivational strategies to better cope with failure and high demands.

Introduction

At university first-year students have to deal with many new affordances: generally, they have to deal with an increasing amount of issues, get used to less interactive lesson formats like lectures and have to learn in a more self-regulated way. Moreover, from a motivational point of view students often feel like the little fish in the big pond (Marsh, 2005), i.e. they have a new reference group and instead of feeling superior, competent and self-confident they are worried about mastering the given requirements. To help students in this phase of orientation several universities provide programs where specific competences like mathematical skills are repeated and consolidated. Before the semester starts at Ulm University a four weeks "Trainingscamp" has been invented where students had the possibility to repeat and consolidate their mathematical skills and got an introduction into important learning strategies. They visited lectures about mathematics and have to write an "exam" at the end. To deepen and to exercise the subject matter from the lectures and the strategies the students ($n=198$) worked together in small groups of about twelve people together with a student tutor every day during the Trainingscamp. The tutors have been trained to teach mathematical skills as well as cognitive, metacognitive and motivational learning strategies. After the trainingscamp all students had tutorials in addition to their math lectures during the first semester. One part of those groups received an ongoing training in their tutorials for the same learning strategies as at the Trainingscamp. These groups have been compared with tutorials without this additional training (trained and untrained tutorials: $n=44$).

Method

In an empirical study we wanted to find out whether the Trainingscamp in fact had positive effects on students motivation and their learning strategy use. Moreover, we analyzed whether the additional strategy training during the semester had longitudinal effects on motivation and their learning strategy use. With repeated measures, before (t_0) and after the Trainingscamp (t_1) as well as after the first semester (t_2) we measured motivational and strategical aspects. Specifically, we assessed students current motivation for math (QCM; Rheinberg, Vollmeyer & Burns, 2001), motivational orientations with subscales from the inventory for capture of study- and achievement motivation (SELLMO; Spinath et al., 2002). Students self-reported strategy use has been assessed by the German version of "The Motivated Strategies for Learning Questionnaire" (MSLQ; Pintrich et al., 1991). Additionally, we assessed several parameters like spatial abilities and math grades that were used in the ANCOVA for comparing the trained and untrained group.

Results

With respect to motivational aspects and strategy use the analysis with repeated measures from t_0 to t_1 revealed an unexpected and disappointing result. For motivational scales we found that students current motivation and avoidance motivation remained stable, whereas their learning goal orientation decreased significantly ($F(1,197)=14.95$, $p<.001$). The strategy use can be divided in cognitive, metacognitive and concentration/persistence aspects. While we found almost no changes over time for the cognitive strategies, despite the fact that students used (superficial and less effective) repeating strategies significantly more after the trainingscamp ($F(1,197)=4.50$, $p<.05$). However, the students of the tutorials with additional strategy training during the first semester at least partly recovered from the first tremendous decrease in motivational orientation and strategy use: the ANCOVAs revealed that they reported more motivation for math than the untrained control group after the same period of time ($F(1,197)=4.38$, $p<.05$).

Summary and Discussion

We analyzed the effects of a tutorbased learning strategy training on the development of strategy use and motivation for first-year students. Results showed that besides the well-meant program for basic mathematic skills and a first introduction into learning strategies the students lost learning goal orientation as well as their approach motivation, used more ineffective repeating and less metacognitive strategies and reported losses of persistence and concentration. Overall, they developed a – from a theoretical point of view – unfavorable learning behavior. In our view it seems plausible that the highly challenging math course even potentiated the "fish-in-the bowl-feeling" of students and led to a desperate behavioral pattern of superficial but "fast" learning. However, by implementing an additional training during the first semester we have been able to stop the negative development for cognitive and motivational strategies (the tutors focused on these strategies because of their familiarity with them), but not for the metacognitive strategies. Nevertheless, the results reassured us that strategy training is not detrimental per se. Rather, the timing of such a training seems to be crucial: after the first and unavoidable "shock of realism" students could be helped to reflect on expectations, motivational and emotional reactions. Based on this they could be prompted to use especially metacognitive and meta-motivational strategies to better cope with failure and high demands.

PAPER PRESENTATION

The development in motivation in early secondary school and later exam participation and results

Ineke van der Veen, University of Amsterdam, Netherlands; Thea Peetsma, University of Amsterdam, Netherlands

This study focuses on the relationship between the development in motivation in early secondary school and later exam results and changes in the school career of students in the lowest type of secondary school in the Netherlands. For decades educators have been concerned about the decline in achievement, motivated behaviour and motivational beliefs of children after the transition from primary to secondary school. We can expect that the decline in motivation of students in the lowest school type can be more extensive, as the percentage of early school leavers is highest there: almost three times higher than in higher school types.

Participants were 335 16-year old students of six pre-vocational secondary schools in the Netherlands who attended the fourth and final year. When these students were in the first year of secondary school they participated in a longitudinal study, filling in a self-report questionnaire for four times during regular class time.

The analyses showed that not the change but the level of motivation in the first year predicted future exam results. For instance, the effort students made for maths in the first year was positively related with maths exam results in the fourth year of secondary school. Another finding was that students who did not change schools, had a higher general well-being and a more positive development in general well-being than students who did change schools.

PAPER PRESENTATION

Student Engagement in the Engineering Classroom

Jonathan Hilpert, Indiana University Purdue University Fort Wayne, United States; Jenefer Husman, Arizona State University, United States

The purpose of this study was to examine the relationship between instructor practice and student engagement in the engineering classroom. Our results provide a description of how engineering professors' instructional practices – such as activating student prior knowledge and engaging students in authentic learning activities – might relate to student motivation and cognitive engagement. Our results provide information about the types of instructional practices that might promote knowledge building, collaboration, perceived instrumentality for coursework, and self-efficacy.

Student engagement in learning is important because students who are meaningfully engaged are more likely to construct strong knowledge structures (Corno & Mandinach, 2004). Engagement is a multi-dimensional construct with behavioral and cognitive components (Corno & Mandinach, 2004; Fredricks, Blumenfeld, & Paris, 2004). Cognitive engagement is a psychological state in which students are monitoring their own learning, which entails weighing alternative view points of a topic, and employing useful strategies for rehearsing, organizing, and elaborating on new information (e.g. Sinatra & Nussbaum, 2004). Behavioral engagement is when students are involved in meaningful learning activities that demonstrate good quality of effort. Many instructional techniques can be used to facilitate deep engagement including conducting experiments, debate, authentic problem solving, and developing self explanations (Ormrod, 2010). Many of these techniques promote weighing alternative points of view, comparing prior knowledge with previously un-encountered information, and contrasting ideas to resolve discrepancies. In general, these cognitive processes allow for more links between cognitive structures, allowing for easier retrieval and more flexible use of information.

Teacher Practices

Deep student engagement, both behavioral and cognitive, is often facilitated through effective instructional practices (Blumenfeld, Kempler, & Krajcik, 2006). Students are considered engaged when evidence of meaningful participation in collaborative and knowledge building tasks are present. Students are cognitively engaged when they participate in activities that allow them to explore all possible sides of an issue or concept, rehearse, organize, and elaborate on information, and meet their skill level as learners. These can range in level of student autonomy from structured guided practice to autonomous problem based learning (Rosenshine, 2003)

Student Perceptions

Effective teacher practices are just one side of the equation, and there is a need for research that explores teacher/student dynamics in STEM classrooms (Heller, Beil, Dam, & Haerum, 2010). In order to navigate learning environments provided by professors, students must be motivated to consider and engage new information. Students who perceived new information to be valuable and who expect to perform well at a given learning task (Wigfield & Eccles, 2001), and are thus more likely to engage, both behaviorally and cognitively. Commonly referred to as multi dimensional mediational models of learning (e.g. Linnenbrink, 2007), engagement is hypothesized to mediate the relationship between student motivation and learning (Dole & Sinatra, 1998)

Purpose of the study

In the fall of 2009 we began an evaluation of a professional development program at a large southwestern university in the United States designed to promote constructivist teaching practices in freshman engineering classrooms. The purpose of this study was to examine instructor practices in the engineering classroom. We wanted to determine which types of instructional practices resonated with students and resulted in higher levels of students' self reported cognitive and behavioral engagement.

Method

Preliminary observations were conducted in eleven engineering classrooms at a large public university in the southwest. During the observations detailed running records and evaluations of the of the courses were taken. The topics of the courses included, Programming in C++, Introduction to Mechanical and Aerospace Engineering, Programming in Java; Informatics; Engineering Design; Digital Design, and Society and Technology.

Participants

Participants were eleven freshman engineering educators. Eight of the instructors were male, and three of the instructors were female. All of the instructors were experienced engineering educators at the university. 349 engineering students, enrolled in the observed courses, were also surveyed (demographics pending).

Measures

Student Perceptions of Classroom Knowledge-building (SPK): The SPOCK subscales (Shell et al., 2005) were administered to assess students' knowledge building (cognitive engagement) and collaboration (behavioral engagement).

Perceptions of Instrumentality (PI): The PI scale (Husman, Derryberry, Crowson, & Lomax, 2004) was administered to determine perceived instrumentality of a particular college course selected by the participant.

MSLQ Self-efficacy (MSLQSE): The MSLQ self-efficacy subscale (Pintrich, Smith, Garcia, & McKeachie, 1994) was administered to assess students' confidence in their ability to complete the coursework.

Reformed Teaching Observation Protocol (RTOP). Moment to moment running records and evaluations of the courses were taken using a modified version of the RTOP, a research tool designed to evaluate instructor practices in science classrooms.

Analysis/Results

A series of one way ANOVA's were conducted across instructors to determine if significant differences existed between instructors for student self reported Knowledge Building, Collaboration, and Perceived Instrumentality. Results indicated there were significant differences across instructors for students self reported Knowledge Building [$F(9,338) = 4.23$ $p < .001$] Collaboration [$F(9,338) = 4.78$, $p < .001$], and Perceived Instrumentality [$F(9,338) = 4.38$, $p < .001$].

Based on follow-up pairwise comparisons, running records for instructors whose students mean scores were significantly higher than two or more of their colleagues were examined to determine what instructional strategies may be related to student responses. Miles & Huberman's (1994) recommendations for coding qualitative data were followed. Coding indicated instructors with high mean scores 1) presented material in small steps, 2) provided feedback via individual contact with students, and 3) employed instructional techniques that promoted meaningful communicative interaction among students revolving around content.

The students' who reported the highest mean scores were in classrooms where their instructors demonstrated evidence of activating student prior knowledge before instruction and actively engaging students in learning activities when presenting new information. Common strategies were isolated

Discussion

Engineering instructors who helped students activate relevant prior knowledge may have been better able to motivate students to engage by helping them to see how new information builds on old information and is related to future goals such as completing a class project or learning how to solve engineering problems. Engagement in the classrooms existed on a continuum from low to high. On the low end, instructors simply talked about new ideas, presented power point slides, or drew diagrams on the board. On the high end, instructors provided opportunities for peer interaction, novel problem solving, and guided practice. These techniques seem to have promoted deep cognitive engagement among students.

PAPER PRESENTATION

Analysing students' intention to change academic procrastination based on the Transtheoretical Model

Carola Grunschel, Bielefeld University, Germany; Lena Schopenhauer, Bielefeld University, Germany; Stefan Fries, University of Bielefeld, Germany

Academic procrastination is a highly prevalent phenomenon among students. According to previous research, a majority of students wishes to reduce academic procrastination. However, it has not been investigated whether these students intending a behaviour change differ from those not intending a change. The goal of this study was to address this question on the basis of the Transtheoretical Model (TTM) of change. Behaviour change is viewed as a result of passing five discrete stages. The variables self-efficacy and pros of change are assumed to increase, and cons of change to decrease across the stages. In an online survey (N=380 students, 266 female) participants' categorization to the stages of change, academic procrastination, students' motivation to change, and the TTM variables were assessed. Almost half of the students indicated implementing their intentions without procrastinating. The others had either not thought of a behavioural change, or were merely intending a change. The goodness of categorization was supported by significant differences between the stages concerning students' academic procrastination and motivation to change. The expected differences between the stages regarding self-efficacy, pros and cons of change were also significant. Hence, these results deliver in combination with the stages of change the groundwork for developing effective interventions.

Motivational developments in primary school: A longitudinal study on group-specific differences

Lisette Hornstra, University of Amsterdam, Netherlands; Ineke van der Veen, University of Amsterdam, Netherlands; Thea Peetsma, University of Amsterdam, Netherlands; Monique Volman, University of Amsterdam, Netherlands

This study is aimed at examining developmental patterns in motivational beliefs (task value and self-efficacy) and motivated behavior (effort), as well as related developments in academic achievement during the last four years of primary school. Because parental socialization practices with regard to school can differ for boys and girls, or for children from different ethnic or socio-economic backgrounds, developmental differences in motivation between these groups were examined. Participants were 712 primary school children. These students filled in a self-report questionnaire with scales on task value and self-efficacy five times between 3rd and 6th grade. Their teachers rated each student on effort during each measurement. Achievement scores on math and reading comprehension were collected from the schools. Results showed an overall decline in task value, while self-efficacy and effort remained stable. Developments in motivation were related to developments in reading comprehension achievement, but not math achievement. Some differences in developmental patterns were found between boys and girls, and between students from different ethnic or socio-economic backgrounds, indicating the importance of distinguishing these different groups.

Aims

Research has consistently found a decline in students' motivation for school during the secondary school years (e.g., Fraine, Damme, & Onghena, 2007; Gottfried, Fleming, & Gottfried, 2001; van der Veen & Peetsma, 2009). There are also some indications that this decline is already apparent in primary school (e.g., Nurmi & Aunola, 2005; Spinath & Spinath, 2005). Considering the large impact of motivation on achievement (Eccles, Wigfield, & Schiefele, 1998), this decline can be considered worrisome. The number of studies that have focused on developments in motivation during primary school is however rather limited. Especially longitudinal studies on motivation that also examine related developments in academic achievement are needed. Also, studies that address differential developmental patterns of motivation and achievement between different groups of students are scarce. There are several reasons to assume motivational patterns may differ for students with different background characteristics, such as different socio-economic and ethnic backgrounds. Most of these reasons have to do with different socialization practices and differences with regard to the values and behaviors parents encourage in their children (Verkuyten, Thijs, & Canatan, 2001). In their review, Hughes, et al. (2006) described how encouraging a positive ethnic identity in minority children is positively related to self-esteem, academic orientations and outcomes. Also, it was found that ethnic minority parents are more likely to have higher expectations for their childrens' academic potential (van der Veen, 2003). On the other hand, ethnic minority students as well as students from a low socio-economic status (SES) background are more likely to feel a disidentification with school, to feel more incompetent (Verkuyten et al., 2001), and they are more likely to be faced with lower expectations from their teachers (van den Bergh, et al., 2010). Also differences between boys and girls may be expected due to differences in parents' socialization practices for boys and girls (Meece, Glienke, & Burg, 2006). There is a large body of research on gender differences in motivation, especially regarding motivation for math. However, there are still a lot of contradictory findings on gender differences in motivation (Pajares & Graham, 1999; Pajares & Valiante, 2001; Skaalvik & Skaalvik, 2004). Moreover, it is especially unclear whether there are developmental differences in motivation between boys and girls (Meece et al., 2006). In motivation research, a distinction is often made between motivational beliefs such as task value (beliefs about the importance and relevance of school tasks) and self-efficacy (expectations about competence to perform on a task), and behavioral outcomes of motivation (e.g., the amount of effort a student puts into his or her schoolwork). The proposed study will examine developmental patterns of motivation, i.e. task value, self-efficacy, and effort, during the second half of primary school and will focus on differences in these developmental patterns between students from different socio-economic and ethnic backgrounds as well as gender differences. In the proposed study, the following research questions will thus be addressed: 1a How do task value, self-efficacy, and effort develop during the second half of primary school? 1b How do these developments differ by gender, social and ethnic background? 2a How do the developments in task value, self-efficacy, and effort relate to developments in academic achievement? 2b To what extent does this differ by gender, social and ethnic background?

Methodology

712 primary students participated in this study: 50% were boys and 50% girls. Twelve percent of the students were from non-Dutch (mostly Turkish or Moroccan) background, and 15% had a low, 50% a medium and 34% a high SES background. The students filled in a self-report questionnaire five times: the first in the 3rd and the last in the 6th grade. At the first measurement the students were on average 9 years old. The questionnaire included Likert-type scales (range 1-5) on task value and self-efficacy. During each measurement, teachers also rated each student on effort. School records on students' gender, ethnic background and socio-economic status (SES) were collected as well as achievement scores on math and reading comprehension. The data were analysed using multivariate Latent Growth Curve Analyses (LGCA) with Mplus (Muthén & Muthén, 2007). The rate and level of growth of the different variables were examined and related to each other. To investigate differences in the rate and level of growth of the different variables and whether the relationships of the level of growth in academic achievement with the other variables in the model differed between the groups, a multi-group LGCA was performed with groups being boys vs. girls, students from Dutch-background vs. students from non-Dutch background and students from low, medium and high SES.

Results and conclusion

The data of the first three measurements have been analysed. From 3rd to 5th grade students showed an overall decline in task value while their self-efficacy and effort remained stable (see figure 1). We did find differences in developmental patterns between groups of students based on gender and social and ethnic background. For instance, we found that girls showed lower initial levels of self-efficacy and effort, but the same rate of growth as boys. Furthermore, high SES students showed higher initial levels of effort than middle or low SES students, but no differences in growth rate. Also, Dutch-background and ethnic minority students did not differ in their initial level of self-efficacy, however, ethnic minority students showed a significant increase in self-efficacy, while Dutch-background students showed a significant decrease. The development in reading comprehension was best explained by the development in self-efficacy. Figure 1. Overall developments in self-efficacy, task value and effort from 3rd to 5th grade. * Outcomes of measurement 4 will become available in November 2010, outcomes of measurement 5 in July 2011.

The results indicate the importance of examining developments in both motivation and achievement. These outcomes also show the importance of differentiating between groups of students based on gender and background differences, as these groups showed different developmental patterns in motivation. Further research will be aimed at finding out which factors of the learning context contribute to these developments in primary students' motivation for school.

PAPER PRESENTATION

Characteristics of students with specific educational needs in mainstream primary education

Marjon Bruggink, Windesheim University of Applied Sciences, Netherlands; Sui Lin Goei, VU University Amsterdam, Netherlands; Hans Koot, VU University of Amsterdam, Netherlands

The research reported in this paper wishes to specify the characteristics of students with specific educational needs (whether they are academic or behavioural), as perceived by their teachers as in need of more care, in mainstream primary education in The Netherlands. Data were collected on 151 students in mainstream primary education in The Netherlands, who were designated by their teachers as needing more care or a different approach, regarding academic achievement (mathematics and reading), self-competency, externalising and internalising behavioural problems, executive functioning and student-teacher relationship. The results are important for teachers to discriminate between groups of students with different sets of educational and pedagogical needs, whether they are classified or non-classified special educational needs, and accordingly to adapt their instructional, pedagogical and managerial strategies to the needs of these students. This paper addresses an issue/topic that directly impacts the quality of (inclusive) education as well as educational results.

Context and aim

The research reported in this paper wishes to specify the characteristics of students with specific educational needs (whether they are academic or behavioural) in mainstream primary education in The Netherlands. The results are important for teachers to discriminate between groups of students with different sets of educational and pedagogical needs and accordingly to adapt their instructional, pedagogical and managerial strategies to the needs of these students. This paper addresses an issue/topic that directly impacts the quality of education as well as educational results.

Nowadays, throughout Europe, teachers in mainstream education face major challenges teaching a very heterogeneous population of students with a diversity of academic and behavioural needs due to the policy of including children with special educational needs in mainstream education. There is a growing trend towards the inclusion of all students, including those with emotional and behavioural disorders (EBD; Mastropieri & Scruggs, 2004;

McLesky, Henry, & Hodges, 1999). Inclusion was mentioned among the five major challenges with regard to quality and education in the European countries (Working Committee on Quality Indicators, 2000).

In the Netherlands this shift towards more inclusion and integration is called 'appropriate education' and it involves meeting the needs of every student, including students who need extra care. Although the Dutch government has focused on diversity and adaptive teaching for many years since the nineties of the past century, recent research of the Dutch Inspection of Education reported that 40% of the teachers in mainstream primary education do not adapt their instruction effectively to the needs of their students. This is probably due to a number of factors. For teachers it is often difficult to specify the special needs of students who need extra care and instruction (Smeets, 2007). Furthermore, most teachers designate only the students with classified diagnoses and disorders as having special educational needs, and needing special facilities and education, and therefore focus exclusively on the problems and deficits of a student's learning. Last but not least, teachers lack a variety of differentiated instructional strategies and interventions to accommodate the needs of students in learning.

The research reported wishes to specify the sets characteristics of students with specific educational needs in mainstream primary education in The Netherlands. Dutch research of Smeets, Van der Veen, Derriks and Roeleveld (2007) and Van der Veen, Smeets and Derriks (2008) shows that teachers label approximately a quarter of their students to show some form of "problem behavior" or "in need of care". To our knowledge, no research has yet been done on the specific sets of student characteristics of students of whom the teacher thinks they have specific educational needs. The main research question of this study is as follows: What are the characteristics of students with specific educational needs in Dutch mainstream primary education, according to their teacher? This study is the first of a set of three studies on specific educational needs, based on the perception of their teacher, in mainstream primary education in The Netherlands.

Method

Participants were 151 students from grade 5, 6 and 7, whom the teachers designated as having specific educational needs from 14 schools in mainstream primary education in the Netherlands. Teachers were asked to designate students as having specific educational needs in their classrooms, according to the following definition: "Students who need more pedagogical, instructional and/or managerial care or a different approach to meet the educational goals that have been set for them". Data were collected in April-June 2010, regarding: 1. General information: such as sex, grade, family background and recent academic achievement in mathematics and comprehensive reading. 2. Externalising and internalising problem behaviour: teachers filled in the Problem Behavior at School Interview (PBSi, Erasmus, 2000), an instrument that measures externalising and internalising behaviour in school contexts. 3. Executive functions: teachers filled in an inventory about executive functions (Brief, Smidts & Huizinga, 2010) such as inhibition, cognitive flexibility, emotional regulation, taking initiatives, working memory, planning, tidiness. 4. Relationship with the teacher: teachers filled in inventory about types of student-teacher relationship (LLRV, Koomen, Verschueren & Pianta, 2007), such as conflict, independence and closeness. 5. Self-competence of the student (CBSK): students filled in a self-competency scale.

Results

89 (58.9%) were male and 62 (41.1%) were female. 20% were classified as having an official diagnosis (such as dyslexia or adhd); 30% were low achievers in mathematics and comprehensive reading. The data were analysed by given means (sd) in comparison to means (sd) of the normgroup. Second, high-achievers and low-achievers on mathematics and reading were identified. Third, male and female were compared on academic achievement and all of the scales from the inventories. Finally, we identified students with special educational needs and (sub)clinical scores regarding behavioural problems, interaction problems and executive functions. Correlations between the (sub)clinical scores and the other scales are computed.

Preliminary results show the following:

- Compared to the norm group students with specific educational needs have lower self-concept;
- Students with specific educational needs regarding externalising and internalising behaviour do not differ significantly from student without specific educational needs; students with specific educational needs score higher on depression;
- Boys with specific educational needs score significantly higher in mathematics than girls with specific educational needs. The average score in comprehensive reading of girls is somewhat higher than the average score of boys, but not significantly;
- Boys with specific educational needs have significantly more conflicts than girls with specific educational needs. They also have more problems regarding inhibition, tidiness and evaluation of their own behaviour. These boys score higher on the scales adhd, odd and cd and significantly lower on pro-social behaviour than girls with specific educational needs;

Conclusion and discussion

Results will be discussed in terms of classified special educational needs versus specific educational needs as perceived by the teacher. Furthermore, the discussion will focus on how the teacher can meet the pedagogical, instructional and managerial needs of these students by designing individual education plans for classroom instruction.

PAPER PRESENTATION

Why do parents employ private tutors for their children? Psychological perspectives on a global issue

Judith Ireson, Institute of Education-London, United Kingdom; Katie Rushforth, Institute of Education-London, United Kingdom

Parental involvement in their children's learning takes a variety of forms including face to face interaction and more distal influencing of children's activities outside the home. This paper addresses parental factors that influence children's participation in extra lessons and private tutoring to support learning and achievement. It explores parents' views of learning, their sense of efficacy in helping their children with schoolwork and the pressures and preventive factors that influence the employment of tutors. Information was collected through a questionnaire survey of 1170 parents whose children were in year 6 (age 10-11 years), year 11 (age 15-16 years) and year 13 (age 17-18 years) and from interviews with 58 parents. Findings indicate that parents' views of the importance of effort in learning are associated with children's participation in extra classes and private tuition. At home, parents support their children's learning and the majority of parents felt that this was sufficient to enable their child to do well in school. Parents recognised their own limitations and weighed their child's needs against the intellectual capital in the family, time available and relationship issues. The majority of parents employed tutors to help their children do well in tests and examinations and the pressure to seek extra help was keenly felt in areas where there were high stakes tests for selective secondary schools. These findings show that psychological factors deserve consideration when seeking to understand factors that influence the demand for private tutors.

Aims

Theoretical perspectives that have been used to explain the worldwide demand for private tutoring, or 'shadow education' tend to emanate from economic, educational or comparative perspectives (Bray, 2003; Dang and Rogers, 2008). These perspectives focus on factors at a macro level that influence demand such as the quality of national education systems, the extent of competition through high stakes testing for places in secondary schools and higher education, and the economic advantages gained from higher level qualifications. While these factors are significant, this paper argues that more proximal, psychological factors also play a part in parents' decisions to employ private tutors and therefore deserve greater consideration in the research literature. As there is very limited research on psychological factors that relate specifically to private tuition, this study turns to theoretical perspectives on learning and motivation including the seminal work of Dweck (1999) showing that learners' conceptions of intelligence as a fixed or malleable entity are associated with different views of the role of effort in learning. It also draws on the work of Hoover-Dempsey, and colleagues (Hoover-Dempsey, Battiato, Walker, Reed, DeJong and Jones, 2001; Green, Walker, Hoover-Dempsey and Sandler, 2007) who found that parents are more likely to be involved in their children's education and homework if they believe they should be involved, believe they can help and perceive that their children and their teachers want them to be involved. In relation to the employment of private tutors, financial demands and pressures from a selective education system may also influence parents as they weigh up the need to employ a private tutor.

Methods

The data for this paper was collected as part of a larger project that obtained information from students in schools in England and their parents. A stratified sampling strategy was employed through the distribution of questionnaires to students in 30 primary and 28 secondary state maintained schools, which were selected to represent a range of demographic areas. In total, questionnaires were returned from 2468 students and 1170 parents. Students, who were in year 6 (age 10-11 years), year 11 (age 15-16 years) and year 13 (age 17-18 years), took questionnaires home for their parents to complete, and completed questionnaires were received from 474 parents of year 6 children, 359 year 11 and 357 year 13. Interviews were also held with 58 parents. Parent questionnaires contained items on extra lessons and private tuition provided for their child and reasons for arranging these, help given with schoolwork, views on learning and effort, and demographic information. Interviews focused in more depth on the reasons for employing private tutors and parents' attitudes towards private tuition.

Summary of key findings

The main reasons given by parents for employing a private tutor were to improve their child's performance in tests and examinations and to increase understanding of the subject. In the sample as a whole, the majority of parents (65%) disagreed that their child's ability set a limit on their achievement and 71% agreed that with enough hard work their child could get high grades. A five-item scale of parents' views of learning was constructed and found to be associated with children's participation in private tutoring. Most parents of year 6 children (64%) felt that the family provided enough help, but this proportion was lower in year 11 (51%) and year 13 (53%), indicating that some parents had a lower sense of efficacy with more advanced aspects of the curriculum. Parents recognised their own limitations and weighed their child's needs against the intellectual capital in the family, time available and emotional constraints. They cited their own difficulties with specific content and lack of familiarity with the modern curriculum and methods as reasons for employing a tutor and, in a few cases, spoke of strained relationships with the child if they tried to help. Pressure to employ a tutor was evident in certain parts of the country where there were high stakes tests for selective secondary schools. Parents themselves perceived a demand for extra tuition and children also approached their parents if they felt they were not making sufficient progress. Evidence suggested that a combination of psychological and educational factors influenced parents' decisions.

Significance

This paper presents the first systematic study of the conceptions and motivational factors that play a part in parents' decisions to seek extra lessons and private tutors for their children. It demonstrates that greater consideration should be given to psychological factors in the private tutoring literature, alongside the economic, cultural and educational factors that have received attention to date. Parental views of learning would benefit from more detailed examination within countries, to reach a more nuanced understanding than is offered by the prevailing tendency to draw broad contrasts between Eastern and Western cultures.

PAPER PRESENTATION

Conceptual Change in Adopting the Nationwide Special Education Strategy in Finland

Helena Thuneberg, university of helsinki, Finland; Jarkko Hautamaki, Helsinki University, Finland; Mari-paoliina vainikainen, University of Helsinki, Finland; Raisa Ahtiainen, University of Helsinki, Finland; Touko Hilasvuori, University of Helsinki, Finland

The study analyzed conceptual change in the ongoing nationwide special education reform in Finland. The number of students having an official special education decision was 8% of the students in basic education in the year 2007. For half of them education was organized in segregated special classes or schools – this despite the country's commitment to the Salamanca statement, UNESCO 1994. To intervene this development, the Ministry of Education launched a new Special Education Strategy, SPES (Nov 2007). Our data consist of four documents from the municipalities (n=235, i.e. over half of the total amount) obtained in four time-points. Comparison of the special and strategy term representations between the time-points revealed that the amount of the special®-expressions significantly decreased and in the same amount the strategy-terms increased. Similarly the therapeutic/ symptom/medical terms were replaced by pedagogical terms. After one and half years of the process, at the first level of implementation: non use, orientation, preparation, were still about 22% of the municipalities, at the second level: mechanical use, routine, were 60% and at the third level: refinement, integration and renewal, were 18% of the municipalities. The conclusion is that they have advanced in applying the SPES in the intended goal-direction. However, from the systemic-discursive perspective, adopting concepts from an external input in a top-down process is not straightforward and, thus, it is quite probable that meanings vary considerably between the different discourses.

1. Introduction

The goal of this study is to add new knowledge in the stock of evermore important topic of understanding the implementation of educational reforms. We take advantage of an extensive reform in Finland, comparative in importance and extent to the foundation of Finnish Basic Education. A new Special Education Strategy (SPES) was launched in Finland by the Ministry of Education in 2007. There was the need for reconsideration of the system, because the number of the official special education referrals had been growing uncontrollably for years being 8% in the year of 2007 (Statistics 2007). For half of those students education was organized in segregated special classes or schools – this despite the country's international commitments (e.g. the Salamanca statement, UNESCO, 1994) to promote inclusion and a common school for all. To solve this contradiction the new strategy emphasizes inclusion and the "neighborhood school principle".

2. Aims of the study

The main research objectives were: (1) to analyze the conceptual change in the Special education strategy knowledge construction process. The change trend in municipality documents of four time-points was assumed to reflect the

educational reform process in the field in general, by giving an overall picture of the reform advancement in the national level; (2) to identify the variation between the municipalities and to roughly classify the municipalities according to their stage of implementation of the strategy. The systemic-discursive perspective (cf. Luhmann) was applied in order to understand the mechanics of the concept integration. For conceptualizing the change process we used, among others, the expansive learning model (cf. Engeström. 1989).

3. Methodology

Data: the municipality documents. Four documents were obtained from the municipalities: 1. The initial applications (December 2007) for the Ministry of Education, which included an organization plan for special education, 2. The more specified plan (June 2008), for the Board of Education, 3. The intermediate report (April 2009) for the Board of Education and 4. The municipality's plan of education (September 2009) for the Jyväskylä University and the board of Education.

Method: For the first aim, the identification of the change trend, we applied the content analysis and quantification of the main SPES concepts in the document data in four time-points during one and half years. The reliability of the analysis was strengthened by the on-going expert team discussions. By a simple search-function of Microsoft Word, the term occurrences were identified, analyzed in their contexts and calculated. For the second aim, to assess the advancement and direction of the process, the documents were categorized using the criteria of stage of implementation (Hall & Loucks, 1977). Because intensified support was a new concept, its emergence and elaboration in the documents was considered as a valid indicator for the level of development.

4. Results

The first objective, the conceptual change trend: 31 concepts with totally 63 592 occurrences were identified. The result was that the amount of the special[®]-expressions (related to the existing system) significantly decreased and the strategy terms (promoting the new strategy) increased between the two four time-points, but the difference leveled in the two last-timepoints. Similarly the therapeutic/ symptom/medical terms were replaced by pedagogical terms, but again the difference leveled from the rapid spurt towards to the last time-point.

The second objective, the variation between the municipalities: After the process had been going on almost for two years, at the 1st level: non use, orientation, preparation, were still about 22% of the municipalities, at the 2nd level: mechanical use, routine, were 60% and at the 3rd level: refinement, integration and renewal, were 18% of the municipalities. The frequent observation was that at the first level overrepresented were either (a) very small municipalities, which might be due to the fact that they had less personal and other resources available, and less experience about similar projects. They were often those, who want but cannot yet, or (b) those municipalities, which had just before the launch of the SPES and reorganized their special education system. They were those, who can, but do not want. The municipalities at the second level of implementation could be characterized of knowing and doing, but in a superficial manner, i.e. the principles were not yet genuinely integrated. For the third level was characteristic that inclusive practices were self-evidently in use, but even that was not enough anymore and the municipalities were modifying their practices and refining their systems.

5. Conclusion

The conclusion is that the cities and municipalities had advanced in applying the SPES in the intended goal-direction – but they did and do it in their own pace and way. From the systemic-discursive point of view, concept spread is not a straightforward process and, thus, it has been shown that now when the strategy concept labels seem largely to be spread in the field, they more or less bear different meanings, from subtle nuances to more profound differences. The meanings have modified and now are varying within the sub-systems (e.g. among teachers/school health care professionals/ psychologists/school administration) and are deviating more or less from the originals. Although in order to assure a common language, we need to emphasize the precise usage of concepts and opening of the meanings in multi-professional conversations, from the systemic-discursive perspective we are inclined to think that "the incommensurability of the discourses" (Königswieser & Hillebrand, 2005) is profound. That is why the wisest thing seems to be to support the local initiative and recreation of the concepts from the starting points of the discourses of concern, which is in line with Olson's (2003) emphasis on the importance of the local interpretation and the need for administration to take the local conditions into account for a real change to occur. This comes close to that, which in literature has been referred by the concept of logical generalization (cf. Barnett, D. & al.) a compromise of research and local school practice.

PAPER PRESENTATION

The Psychology of Containment: Schools and the Mis/use of Diagnostic Categories

Penny Van Bergen, Macquarie University, Australia; Linda Graham, Macquarie University, Australia; Naomi Sweller, Macquarie University, Australia

In this study we examine the ages and rate at which Australian boys and girls in the state of New South Wales are being enrolled in special schools for emotional disturbance (ED) and behavioural disorder (BD). Our aim was twofold: first, to determine whether any diagnostic changes have occurred in the relationship between age and special school enrolments (that is, the trends in enrolment) across the last decade, and second, to compare these enrolments by gender. We find that boys are over-represented in both ED and BD, but, critically, substantially more so in 2007 than in 1997. These findings suggesting a changing pattern of diagnosis unrelated to prevalence in the population. Implications for subsequent school functioning are discussed.

Challenging behaviour has been identified as one of the most significant issues confronting Australian schools (APPA, 2008; Ferrari, 2009a). Diagnoses and the use of segregated settings for emotional disturbances (ED) and behavioural disorders (BD) have each spiralled (Graham & Sweller, in press), to the point where one third of special schools in the state of New South Wales are now reserved specifically for students classified as "ED/BD" (NSW DET, 2009). Nonetheless, in targeting "at risk" students for support, current educational responses can both stigmatise certain groups and hasten their alienation with the school system (Norwich, 2007). Moreover, whilst international research has long pointed to disproportionate representation of African American students and boys in 'non-normative' categories of special education (Hosp & Reschly, 2001; Oswald, Best, Coutinho & Nagle, 2003; Wehmeyer & Schwartz, 2001), little is known about the profile of Australian students being diagnosed.

Method

Our study draws on annual government school enrolment data published by the New South Wales Department of Education and Training (NSW DET). First, the number of students enrolled in special schools with diagnoses of emotional disturbance (ED) or behavioural disorder (BD) was calculated, broken down by age and gender. Next, a series of curve estimation analyses were used to estimate linear and quadratic trends in the percentage of students enrolled in a special school with either ED or BD diagnoses at each age.

Results

For special school enrolments due to diagnoses of emotional disability (ED), significant linear and quadratic trends in age were observed. This was the case for both boys and girls, and in both 1997 and 2007. Interestingly, however, whilst trends did not differ by the year of inquiry, the nature of these trends was different for girls than for boys. For boys, the combined linear trends, $F(1, 11)s > 4.94$, $ps F(2, 10)s > 9.50$, $ps F(1, 11)s > 28.63$, $ps F(2, 10)s > 13.11$, ps rate of the rise in enrolments across age. There was no clear peak or fall in enrolments, but instead a pattern of very low enrolments to age 12, followed by an acceleration of enrolments between the ages of 12 and 17 (see Figure 1).

For special school enrolments due to diagnoses of behavioural disorder (BD) age trends are less clear; changing with both gender and year of inquiry. For boys, there is a significant linear trend in 1997, $F(1, 11) = 6.39$, $p > .05$, indicating a consistent rise in enrolments across age. In 2007, however, the trend is quadratic, $F(2, 10) = 4.07$, p number of special school enrolments for BD are much larger in 2007 than in 1997.

For girls there is a significant linear trend in 1997, $F(1, 11) = 5.47$, $p F(1, 11) = 14.01$, $p F(2, 10) = 6.60$, p

Discussion

Consistent with international trends showing over-representation of particular groups of students in special education, the ED and BD enrolment data show that boys are entering segregated schooling earlier than girls and at a greater rate. Moreover, the gender discrepancy in BD diagnoses increases between 1997 and 2007. Although a gender discrepancy in might be expected in some categories of disability, where genetic and other indices do suggest genuine gender differences, these differences cannot fully explain the rate of over-representation shown for ED and BD, the findings of over-representation in special education based on race and geographical location, or the changing profiles of ED and BD diagnosis over the decade from 1997 to 2007. Moreover, we note that boys are even more highly over-represented than the international literature suggests (e.g. see Oswald et al., 2003). Thus, we suggest that such variation reflects differences in processes of identification, categorisation and enrolment, and not in the incidence of disability (OECD, 1999).

These findings have considerable implications, with claims that segregated settings are becoming "holding areas for students that regular schools are either unable to or unprepared to work with" (Dempsey, 2007, p. 76; also see Graham & Spandagou, in press), or, worse, that students are in many cases graduating to juvenile justice centres

(Bouhours, 2006; de Plevitz, 2006; also see Graham, Sweller & Van Bergen, in press). We suggest that this is a problem increasingly likely to affect boys.

PAPER PRESENTATION

Teacher Resilience: Conceptualisations, research and practice

Susan Beltman, Curtin University, Australia; Marold Wosnitza, RWTHUniversity Aachen, Germany; Caroline Mansfield, Murdoch University, Australia

One challenge for the future of education in a global/networked society is the quality and resilience of teachers in changing times. Specifically, there is concern in many countries about the high attrition rates of early career teachers. This paper presents a systematic review of literature related to teacher resilience. The review underpins a larger research project aiming to enhance the resilience of early career teachers by embedding evidence-based practice within pre-service teacher education programs. A shift in thinking from attrition to resilience offers the potential for more positive, effective interventions to occur. Definitions of resilience include the ability to "bounce back" after experiencing difficult events, and it is often conceptualised as an outcome of the interaction of risk and protective factors. A search of databases such as ERIC and ProQuest revealed over 250 articles linked to key words such as 'resilience' and 'burn out' published from 2000 onwards. The selected papers are analysed according to their research methods, key empirical findings, and suggestions for practice. The paper will provide an overview of how resilience has been conceptualised, strengths and limitations of current research and suggest directions for future research. The findings have significance for those interested in the construct of resilience, teacher retention and attrition, and pre-service teacher education programs.

Aims

One challenge for the future of education in a global/networked society is the quality and resilience of teachers in changing times. Specifically, there is concern in many countries about the high attrition rates of early career teachers. While many studies have examined why teachers leave the profession, some recent research has, more positively, focused on what sustains teachers and explores teacher resilience. Resilience is often conceptualised as an outcome of the interaction of personal and contextual risk and protective factors. Definitions highlight the ability to "bounce back", and to thrive, rather than just survive, in the face of challenges. This paper reviews recent empirical studies, discussing how teacher resilience has been conceptualised and investigated, key risk and protective factors for teachers, and recommendations for enhancing teacher resilience. It underpins a larger research project aiming to enhance resilience of early career teachers by embedding evidence-based practice within pre-service teacher education programs.

Methodology

The review was conducted in three phases. Phase 1 involved an extensive search of education, social science, psychology and health science data bases, publisher data bases, key journals and web sites for empirical papers in the area of teacher retention and resilience. Searches used key words such as 'resilience' and 'burn out', were limited to material published from the year 2000 and resulted in 260 items. Phase 2 involved closer scrutiny of phase 1 results to determine the empirical studies published in peer-reviewed journals specifically concerning both teacher resilience (n=45) and beginning teacher retention (n=36). In Phase 3 a thorough review of the remaining 50 papers was conducted summarising the aim of each paper, how resilience was conceptualised, the participants, the methodology, key findings and implications. Tables were then constructed to provide an overview of these key factors across all papers.

Findings

The paper will present key findings of the literature in relation to conceptualisations of resilience, the research methods used, risk and protective factors for teacher resilience, and the implications for various groups. Conceptualisations of resilience in the papers revealed some common ideas. For example, resilience is a dynamic process or outcome that is the result of interaction over time between a person and the environment. Of the selected papers, 13 had "resilience" or "resiliency" in their titles. Twenty-three papers explicitly discussed resilience, although not all defined it. The other 27 papers focused on resilience related constructs such as teacher self-efficacy, burn out, coping strategies and social supports. With regard to research methods, most studies were conducted in the USA (n=17) and with early career teachers (n=21). Sample size varied from 1 to 3235 participants. Methodological approaches used were classified as qualitative (n=29), quantitative (n=12) or mixed methods (n=9). The largest proportion (n=23) of studies used qualitative methods with fewer than 30 participants. A variety of data sources was used with interviews the most common (n=34). The papers were also analysed to identify the key factors for teacher resilience. Twenty-five separate personal and contextual challenges were identified with the most common challenge being classroom management and disruptive students (n=11). Challenges impacted on teachers' stress, self-efficacy,

motivation and future career intentions. There was a sense of frustration that the same challenges have been known for years. Not all challenges were seen as problematic, with some teachers found to be ready for, and actively seeking, new challenges. Thirty papers reported particular personal characteristics assisting teachers to thrive. These included personal attributes (such as persistence and a sense of humour), self-efficacy, coping skills, interpersonal and teaching skills, professional growth, self-care and qualifications. These characteristics were often inferred from interviews and observations, rather than measured. A number of papers highlighted the importance of altruistic motives and noted that teachers were not primarily motivated by extrinsic rewards. Forty papers referred to contextual supports. These were: school/administrative support, mentor support, the school students, support of peers and colleagues, pre-service program, and support of family and friends. School structures were supportive for new teachers when leadership was strong, open, supportive, and well-organised, resources distributed fairly, and encouraging feedback provided. School students had not been envisaged as a category of support but in challenging schools teachers had a deep respect for the way their students dealt with difficult circumstances and felt a powerful responsibility and commitment to them. The literature reported implications for stakeholders including employers, schools and teacher educators. Developing and retaining resilient teachers required changes or adjustments for pre-service programs, schools and employing authorities.

Theoretical and educational significance of the research

The findings have significance for those interested in the construct of resilience. Despite being framed in the language of different theoretical perspectives, the findings of the studies supported the notion of resilience as a dynamic, complex, idiosyncratic and cyclical construct. The findings are also significant for schools and employing bodies. Papers included suggestions for creating supportive structures, induction programs, school principals, and casual teachers. A few authors raised the issue of financial bonuses for teachers who perform well. Some suggested that as teachers' motivations are primarily altruistic, "financial perks", an extrinsic motivator, seem unlikely to dramatically impact on recruitment. Others argued that not all beginning teachers were planning a lifelong career in the profession, so providing opportunities for challenges with appropriate rewards, might extend their time in the profession. Recommendations for pre-service teacher education programs were made regarding the role of the practicum, staff support, and support from fellow students. In conclusion, the paper contributes to theoretical understandings of the nature of resilience in the context of teaching. Reviewing current empirical research has shed light on the complexity of the personal and contextual challenges and supports faced by teachers, and on the benefits of focussing on developing resilience in the multiple contexts of teachers' preparation and work. Longitudinal studies with larger samples and intervention studies would add to this emerging area of research.

PAPER PRESENTATION

Finding valued relationships: beginning teachers networking to meet their professional needs

Alison Fox, University of Cambridge, United Kingdom; Elaine Wilson, University of Cambridge, United Kingdom

This paper explores the networking activity of three beginning Science teachers during a school – university based Post Graduate Certificate of Education year-long course in the UK. We examine how three beginning teachers establish and sustain effective relationships which support their development as a teacher and ensure that they remain in the profession. An ethnographic-based approach was taken, with the researcher also acting as tutor to the trainees. This approach allowed us to collect longitudinal data about developing relationships. Data collection included network diaries, (web-log) e-journals, interviews, a mapping activity and interviews with school-based teacher mentors. The findings reveal that when beginning teachers are proactive networkers they are more likely to solve emerging problems and feel more in control within the school context. Furthermore how and with whom the new teachers networked revealed that informal social networks are significant.

Aims

This study builds on earlier published work inquiring into the role of others to teacher development in school – university partnership teacher education. While it has been shown that beginning teachers draw on a range of people to support them in their development, in more or less proactive ways, the processes of relationship development are not well understood. This work address the question 'how do beginning teachers find and develop effective relationships?'.

Theoretical underpinnings

The study adopts a network theory approach which is underpinned by the idea that personal or ego-centric networks can reveal significant social connections (Wasserman and Faust, 1994; Nardi et al, 2000). Social network analysis methods are used to frame from where advice is sought, what information is gained, how informal support is used and where collaboration enacted. These methods are usually applied to known and bounded networks but we have

applied them in an exploratory way to beginning teachers' evolving networks. We were already aware that valued relationships were likely to be found beyond the formal in-school mentor and in-Faculty tutor links (Fox and Wilson, 2009). This ego-centric network theory approach was useful to explore inductively the processes of networking used to meet beginning teachers' perceived professional needs.

Methodology

An ethnographic approach was taken to be able to follow and explore with beginning teachers the development of their relationships over time. The methods used produced large amounts of rich data and involved intense researcher activity, given a dual role of the researcher acting as both tutor and researcher, so a limited sample of beginning Science teachers were asked to volunteer to be involved in the research study. Three PGCE trainees (two male - one female; two career changers – one recent graduate) were selected to be followed through their one year PGCE course. The course pattern involved beginning teachers working in two contrasting placement schools, with feedback given on observations of their teaching by the tutor in each of the three school terms, and their maintaining a reflective e-journal, shared with the university based tutor. Additionally the beginning teachers agreed to keep a diary of their network activity and to be interviewed three times over the course about their networking activity, generating a visual representation or network map (Fox et al, 2007) at each interview. Mentors were also invited to reflect on the trainees networking on each school visit.

An integration of these data sources (allowed individual relationships to be tracked for each beginning teacher, to reveal factors (affordances or barriers) that contributed to the development of the most valued relationships. Value was considered in the light of the trainee's perceived needs.

Findings

Although all three beginning teachers were able to identify and talk about their professional needs, they showed different levels of proactivity in working with others to meet these needs. To some extent their proactivity was dependent on the school cultures they found themselves in and to some extent related to their own sense of identity as a developing teacher. Frank developed a rich, cross-school network in his second placement, the result of such networking activity leading him to talk about a sense of belonging, which helped him decide to commit to teaching. For Frank relationships with staff through social football activity was particularly crucial in allowing him to develop not only as a Science teacher but resulting in him also contributing to teaching in the PE department. Claire, who came into teaching with a particular view of how she wanted to support learning in her classrooms, found that her view was not shared in the school cultures of either school she was placed in during her training. Individuals were flexible to support her in developing her practice in her first school but she needed to seek out like-minded individuals quite effortfully in her second school and was, at one point, very close to deciding to leave the course. Based on reflection on her experiences Claire chose her first teaching post carefully, having developed a clear idea of what she wanted a workplace to provide. Nigel was much less proactive about relationship building beyond the use of formal links and he was not always able to match the expectations of him in developing his practice. We reflect on the factors that affected his more limited use of networking. These findings are set within the backdrop of a wider data set, which also indicates the interplay of school culture and individual agency.

Significance

It appears that beginning teachers can take considerable responsibility for meeting their needs through relationship building and that this is in fact important in terms of their socialisation into the teaching profession. In making connections with others who are 'like-minded' beginning teachers are likely to gain both professional and personal support. The challenges are that this requires effort in school cultures in which trainees are not yet embedded and in what might seem quite serendipitous ways. Whether to share a lift, strike up a conversation after professional studies sessions or decide where to spend break times appear significant decisions to the likelihood of developing effective relationships. There is arguably perhaps a role for schools and teacher educators to make these choices explicit, to discuss networking as an explicit tool for professional development and to facilitate opportunities for teachers to meet in conducive social ways to support such networking. Whilst clues have been given through accounts from Frank, Claire and Nigel as to how to find 'like minded' individuals and develop valued relationships, more research is needed to understand the processes of support being given in these relationships.

PAPER PRESENTATION

Can teacher educators learn from pupils: first exploration of pupils views on good teachers

Anouke Bakx, Fontys PABO Eindhoven, lectoraat L&I., Netherlands

This article reports on a first exploration of pupils' views on qualities of primary school teachers. A questionnaire (N = 2,516) was used to measure pupils' perceived teacher qualities. Results show that eleven different categories with teacher qualities can be distinguished. The three most important categories mentioned by Dutch pupils are (1) teachers' personality-related qualities; (2) didactic skills and guidance; and (3) authority. Involvement of pupils in the description of teacher quality might lead to an enriched view on teacher quality. It might lead to a perspective on teacher quality in which personality-related qualities play a larger role, compared to the present Dutch view on teacher quality.

Introduction

In 2005, the Dutch Ministry of Education decided that schools should introduce integral personnel management to stimulate teachers' development and create opportunities for career development in education. Indeed, a new reward-system offers possibilities for differentiation within the teaching profession. However, it should be clear what is defined as 'a good teacher' (teacher quality) and how 'very good teachers' can be distinguished from 'average good teachers'. In this study the concept of teacher quality concerning primary education has been explored.

Teacher quality

Defining 'very good teachers' seems to be complex. There is no general consensus upon this concept (e.g. Berliner, 2001; Waldrup, & Fisher, 2003; Palmer, Stough, Burdinski, & Gonzales, 2005). Effectiveness studies on teacher quality show that didactic and pedagogic quality combined with communicative competence are essential in order to gain good results with pupils (eg. Hattie, 2009; Marzano, 2003; Ryan & Deci, 2000; Scheerens, 2007). The same aspects for teacher quality emerge from descriptive studies on teacher quality, together with 'teachers' knowledge'. This concerns an integrated expertise of specific content knowledge, didactical and pedagogical knowledge and skills (Beijaard, Verloop, & Vermunt, 2000; Darling-Hammond, 1999; Stronge, 2007). Other studies show that teachers' personality characteristics might be important in relation to teachers quality (Cornelius-White, 2007; Hattie, 2009; Timmering, 2009), but there is no consensus on the role of personality in teachers' quality (Borich, 1988).

In 2006 the Dutch government adopted a law concerning the 'basic quality of teachers'. Seven teacher competencies have been described, which are used within the entire educational field within the Netherlands (www.lerarenweb.nl): (1) interpersonal competence; (2) pedagogic competence; (3) subject knowledge and methodological competence; (4) organisational competence; (5) competence for collaboration with colleagues; (6) competence for collaboration with the working environment; and (7) competence for reflection and development (www.bekwaamheidsdossier.nl/cms/bijlagen/SBLcompetence_primary.pdf). These seven teacher competences concern a 'basic level' or a starting point for junior teachers. This competence-view on teacher quality does not entirely comprehend all qualities as reported in international research. Amongst others, subject knowledge and personality-related qualities form no specific part of the Dutch view on teacher quality. Next to this, the seven competencies do not specify what a 'very good teacher' is. In the Netherlands, policy makers are responsible for the formal definition of teacher quality, as used in teacher education. Dutch teachers have been involved in this definition process. However, primary school pupils have not been involved in these kinds of exercises. They are never asked 'what is a very good teacher?'. Pupils spend much time with their teachers within the classroom and might be seen as important 'stakeholders'. Our research question is: What are good teachers according to primary school pupils? The aim of this study was to broaden the perspective on teacher quality, involving pupils.

Method

A questionnaire for pupils was constructed, containing one question: 'What is a good teacher?' (see also Figure 1). To help the pupils, three questions were given: (1) What does a good teacher? (2) What is a good teacher like? (3) What should a good teacher be able to do?

Respondents

In total 2,515 pupils from 31 primary schools in the Netherlands have participated in this study. They anonymously completed the questionnaire as part of a lesson activity. The pupils' age varies from nine to twelve years old.

Data-analysis

All together 18,750 'qualities' of good teachers have been mentioned by the pupils. Two researchers - independently of each other - have placed all the qualities into data-sheets. All together, 131 different qualities have been reported, which have been combined into categories. These categories with qualities have been compared and discussed by the two researchers. Final categories have been constructed based on consensus of the two researchers.

Results

Eleven different categories of qualities of good teachers can be distinguished. According to pupils the most important quality of teachers concern personality-related qualities like humour, being nice and being kind. Next to this, didactic skills and guidance are mentioned. Pupils state that good teachers perform well concerning explaining, motivating, teaching in general, structuring the educational activities and offer differentiation. Third, authority is reported by the students: this refers to a certain degree of strictness, honest punishments and remaining silence in the classroom.

Conclusion

There is no consensus on the definition of teacher quality for primary school teachers. The concept of teacher quality varies within the different countries of the European Union (Snoek et al., 2009), probably due to the specific cultures. In the Netherlands, teacher quality is specified by seven competencies. Pupils state that personality-related qualities are the most important for good teachers. Humour, being kind and nice are important, next to the didactic skills and guidance. These last two qualities also appear as important qualities from effectiveness studies on teacher quality. Third, authority was mentioned by the students. This aspect, as well as subject knowledge is no part of the seven Dutch competencies for teachers. Pupils' view on teacher quality might enrich our perspective on quality of primary teachers.

PAPER PRESENTATION

Satisfaction with the academic studies in first-year students: Only a matter of academic performance?

Julia Karbach, Saarland University, Germany; Kathrin Kaub, Saarland University, Germany; Corinna Reichl, Saarland University, Germany; Nicolas Becker, Saarland University, Germany; Hans-Werner Bedersdorfer, Saarland University, Germany; Roland Bruenken, Saarland University, Germany; Frank Spinath, Saarland University, Germany

Over the last years, a number of studies have investigated the level of academic study satisfaction (ASS) in university students. Most authors agree that ASS is a variable of particularly high relevance because it is associated with the physical and mental well-being of students as well as with premature university dropout. Recent studies have suggested that ASS is a multidimensional construct including the satisfaction with (1) the contents of the academic program (ASS-content), (2) its terms and conditions (ASS-conditions), and (3) the process of coping with academic stress (ASS-coping). While the role of university-related variables (e.g. the quality of courses) and motivational student-related variables (e.g., vocational and academic interests) for the prediction of ASS is already well documented, less is known about the potential role of more general student-related variables (i.e., academic performance, social behavior, overall life-satisfaction, personal significance of the studies). Data from a sample of 381 first-year students indicated that academic performance was a strong predictor for all three aspects of ASS. ASS-content was also predicted by social integration, overall life-satisfaction, and the personal significance of the studies.

In addition, overall life-satisfaction predicted ASS-conditions and social behavior was most relevant for ASS-coping. Thus, our findings suggest that general student-related variables are important components for the prediction of ASS. While the influence of academic performance seems to be relatively general, the predictive value of the variables social behavior, overall life-satisfaction and personal significance of the studies is more specific and varies for the three dimension of ASS.

Aims

In students of all ages, the satisfaction with their academic studies is associated with their physical and mental well-being. In university students, this academic study satisfaction (ASS) is generally considered as an indicator for the quality of universities and therefore plays an important role in the process of recruiting prospective students. Moreover, it is one of the key variables with respect to premature university dropout. Conceptually, the construct ASS is based on the person-environment fit theory (French, Caplan, & Harrison, 1982), which assumes that the degree of satisfaction depends on the fit between a person's needs and abilities and the potential and demands of the environment, respectively. Earlier publications suggested that ASS is a multidimensional construct, including the three sub-dimensions satisfaction with (1) the contents of the academic program (ASS-content), (2) its terms and conditions (ASS-conditions), and (3) the process of coping with academic stress (ASS-coping) (Spieß et al., 1996; Westermann et al., 1996). With respect to predictors of ASS, a number of studies point to the importance of university-related variables, such as the quality of courses and facilities as well as motivational student-related variables, such as academic motivation and vocational interests (e.g., Hiemisch, Westermann, & Michael, 2005; Schiefele & Jacob-Ebbinghaus, 2006). The predictive value of these variables was different for the three components of ASS and could be increased for all of them when both university-related and motivational student-related variables were considered in the same model (resulting in up to 53% of explained total variance). However, so far there is not much evidence for the role of more general student-related variables, such as academic performance or overall life satisfaction, that have been emphasized in a theoretical framework proposed by Apenburg (1980). Although he did not assess any sub-dimensions of ASS, he assumed that the level of general ASS is best predicted by (1) the students' academic development (i.e., their academic performance), (2) their social behavior and integration (i.e., interaction with their environment), (3) overall life-satisfaction (assumed to be relatively stable over time), and (4) the personal significance attributed to their studies (assumed to be highly variable between students). Apenburg claimed that the area of academic development is the strongest predictor for ASS, whereas the predictive value of social behavior and integration may be more variable. Thus, the aim of the present study was twofold: First, we tested the predictive value of the Apenburg model for the three dimensions of ASS (ASS-content, ASS-conditions, ASS-coping). Second, we investigated whether the four components in the model (academic development, social behavior and integration, overall life satisfaction, significance of the studies) are of differential predictive value for the three dimensions of ASS.

Methodology

A total of 381 first-year students from Saarland University pursuing a teaching certification ($n=289$) or enrolled in the Bachelor of Science for psychology ($n=92$) were included into the study. Participants completed the study-satisfaction questionnaire (Spieß et al., 1996; Westermann et al., 1996) and a test battery including measures for each one of the four components proposed by Apenburg (1980): (1) Academic performance (academic self-concept, self-efficacy, German high school GPA), (2) social behavior and integration (perceived social support, mental stability/anxiety), (3) life satisfaction (self-regulation, general life satisfaction, hours/week of part-time employment), and (4) the personal significance attributed to their studies. We tested the three-dimensional structure of ASS and the predictive value of the general student-related variables on these dimensions by means of confirmatory factor analyses using structural equation modeling.

Findings

Our data showed that the three dimensions of ASS are correlated ($r=.31-.43$) but clearly separable constructs. Significant predictors for ASS-content were the academic self-concept, overall life satisfaction, the personal significance of the studies, German high school GPA, and the amount of part-time employment (43% of explained total variance). ASS-conditions was best predicted by a model including the academic self-concept, German high school GPA, and the amount of part-time employment (11% of explained total variance). Finally, the academic self-concept, anxiety, and German high school GPA were reliable predictors for the ASS-coping (42% of explained total variance). Theoretical and educational significance of the research. The findings of our study support the view that study satisfaction is indeed a multidimensional construct. Though these dimensions are related, the predictive value of general student-related variables for each one of them was different. Consistent with Apenburg (1980), academic performance (academic self-concept, German high school GPA) served as general predictor that was relevant of all three dimensions of study satisfaction. In contrast, we also identified variables with specific predictive value: Overall life satisfaction was only related to ASS-content, while anxiety only was a significant predictor for ASS-coping. Part-time employment had a negative impact both on ASS-content and ASS-conditions. In sum, the general student-related

variables investigated in this study proved to be reliable predictors for all three aspects of ASS. The general role of academic development on the one hand and the specific role of social integration on the other hand are consistent with the Apenburg framework (1980). As a next step, it seems worth investigating whether combining general student-related variables with the previously investigated university-related and motivational student-related variables will add incremental validity to the prediction of ASS, and whether the predictive value of these variables changes over the course of one's studies.

PAPER PRESENTATION

Effects of citizenship education on citizenship of students: A review study

Ellen Geboers, University of Amsterdam, Netherlands; Femke Geijssel, University of Amsterdam, Netherlands; Wilfried Admiraal, University of Amsterdam, Netherlands; Geert ten Dam, University of Amsterdam, Netherlands

Abstract

For this paper proposal a literature review was carried out on the effects of citizenship education in secondary schools on students' citizenship. Although in many Western countries schools are obligated to provide citizenship education, the effectiveness of different forms of citizenship education is still unclear. This paper focuses on 28 articles in which effects of citizenship education are described. After the assessment of the studies' research designs, effects of different types of citizenship education are analyzed and critically assessed in relation to the citizenship practices of young people. The effects are analyzed in terms of social tasks that students need to fulfill in their daily lives and types of competences. Citizenship education in the classroom appears to teach knowledge, skills, attitudes, reflection and behavior, primarily on democratic principles. The conclusions about the effects of citizenship education are discussed as well as the quality of the studies which have been analyzed.

Introduction

Active participation in modern society requires citizenship knowledge, skills, attitudes and reflection on social issues. Citizenship is learned during life course through participation in different social practices. School is not only one of those practices that are part of young people's everyday life. It is an institution that by means of citizenship education explicitly aims at facilitating and optimizing the learning processes of citizenship. Ideally, the school is a place for young people to accumulate democratic experiences and reflect upon these experiences. In almost all European countries as well as in Canada, Australia, and the US citizenship education is introduced in the curriculum. Imperative in introduction is the assumption that schools can play a role in citizenship development. However, the question remains whether this assumption is tenable because no research has systematically reviewed the literature on this topic. A democratic, pluriform society predominantly requires that citizens be prepared to make their own critical contributions. In a political interpretation of citizenship, youngsters are primarily seen as future citizens and are prepared, for example by enhancing civic knowledge for political voting. However, associating citizenship with the civil society, involves young people's everyday lives in which they interact with others (family, work, and school) (Biesta, 2007). Citizenship education, in both the political and the social domain, should be aimed at stimulation of the critical capacities of young people to enhance the quality of their participation (Ten Dam & Volman, 2004; Lawy & Biesta, 2006). The currently proposed paper focuses on the effects of citizenship education including the political and the social domain of the contemporary discourse of citizenship. We examine whether this broad conceptualization of citizenship education is reflected in and supported by the results of empirical studies.

Methodology

The international articles in this paper cover the period of 2003-2009. We performed a systematic search procedure including four steps. In the first step, data bases of the digital library of the University of Amsterdam were examined

using the following keywords: 'citizenship or civi*' and 'education', and 'competence', and 'knowledge', and 'skills', and 'attitudes', and 'reflection', with * used as a joker. This step was repeated three times, as a rerun of each search led to slightly different results. The following data bases were examined: Eric (Educational Resources Information Center); PsycINFO; Catalogue of the University of Amsterdam; PICARTA; Web of Science; Academic search premier and Scopus (abstract and citation database of peer-reviewed literature). In the second step we added the database ScienceDirect and examined the new combination of databases with the following keywords: 'citizenship or civi* education' and 'competenc*', and 'knowledge', and 'skills', and 'attitudes', and 'reflection', and 'democra*', and 'youth development', with * used as a joker. In August 2009, a third step included a rerun of the earlier searches to update our output. In this third step Scopus was excluded as this database was no longer available. The fourth step included a check of the reference lists. We performed a selection procedure in two stages. In stage 1, we evaluated the abstracts with the following criteria to include an article: Manuscripts published between 2003 and 2009; Journal articles that were available online; Journal articles which were based on empirical research; Journal articles which have been published in peer reviewed journals; Studies with participants referring to students in the age of thirteen to sixteen years, i.e. the first stage of secondary education, and Studies with a focus on citizenship or citizenship education. In stage 2, the full-texts of the articles were checked for these criteria. Moreover, articles without a problem definition or research question were removed. A total of 28 studies concerning effects of citizenship of students and the role of secondary education were included. Two aspects of these 28 articles were categorized: citizenship education and students' citizenship. The type of citizenship education is categorized in: curriculum in school, curriculum out of school, pedagogical climate and extracurricular activities. The reliability of this classification equals Cohen's κ ; 0.94 (two coders). To classify students' citizenship, we applied the conceptual framework of citizenship of youngsters of Ten Dam, Geijssels, Reumertman, and Ledoux (2010). In this framework, citizenship of youngsters is specified into citizenship competences and citizenship behavior regarding the social tasks that youngsters need to fulfill. With social tasks, we used the following categories to study the effects on the student level: acting democratically (political), acting democratically (social), acting in a social responsible manner, dealing with conflicts and dealing with differences (with a Cohen's κ ; (two coders) of 0.90). With competences and behavior the following categories were used: knowledge, attitudes, skills, reflection, and behavior (with a Cohen's κ ; of 0.90). Finally, we categorized the research design of each study in terms of a cross sectional design, longitudinal design, quasi-experimental design with control group, quasi-experimental design without control group, review study design, and a qualitative exploratory design (with a Cohen's κ ; of 1).

Results and conclusions

In the final paper the descriptive statistics and cross tables will be presented and moreover, if possible, effect sizes were calculated to gain an insight of the magnitude of the effects reported in the reviewed literature applying Cohen's f and d . In empirical studies on citizenship, the political domain of citizenship, and not so much the social domain, appears to be emphasized. So, citizenship education today seems primarily aimed at learning to act democratically and to a much lesser extent at learning to act in a socially responsible way and dealing with differences. Moreover, students' attitudes towards citizenship are mostly studied as an effect of citizenship education. Citizenship education in the classroom appears to teach knowledge, skills, attitudes, reflection and behavior on democratic principles. In the literature there is hardly any attention paid to the ability of young people to deal with conflicts. With regard to the teaching strategies, organizing an open and democratic classroom climate in which discussion and dialogue takes place appears to be effective in the development of citizenship of young people in secondary education. Furthermore, the literature review shows important shortcomings in the methods used to examine youths' citizenship development in an empirical way. With these conclusions, the review study will challenge educational scientists to increase the empirical base of citizenship education and to allow more informed decision-making regarding citizenship education in policy and practice.

PAPER PRESENTATION

How accurate and stable are parents' and teachers' judgments of children's test anxiety?

Constance Karing, Universitat Bamberg, Germany; Tobias Dorfner, Bamberg University, Human Sciences, Germany; Cordula Artelt, Bamberg University, Germany

Although test anxiety is one of the most common types of anxiety in children and has got a negative impact on school performance, only few studies have investigated parents' and teachers' judgment accuracy of children's test anxiety. However, the few existing cross-sectional studies found a rather low accuracy of teachers' or parents' judgments of children's test anxiety. To our knowledge, so far no study has examined the stability of teachers' and parents' judgment accuracy in the domain of test anxiety. Against this background, the present study investigates mothers' and teachers' judgment accuracies of children's level of worry and emotionality in the school subjects of German and mathematics and the stability of the accuracy of these judgments over a period of one year. Data were obtained from a sample of 74 German language and 73 mathematics teachers, 830 mothers and their 5th and 6th grade children in

the context of the BIKS study. For the whole group our analyses revealed that, on average, mothers tend to underestimate children's worry and overestimate children's emotionality in both subjects and at both measurement points, whereas German language and mathematics teachers tended to overestimate children's emotionality as well as worry at both measurement points. However, when looking at the children with high test anxiety, we found both mothers and teachers consistently underestimate children's worry and emotionality in both school subjects. Furthermore, our results showed stability coefficients of low to medium size over a period of one year for mothers as well as for teachers.

Theoretical framework.

Test anxiety is one of the most common types of anxiety in children between the ages of 9 and 12 and it often persists into adolescence (e.g. Suhr-Dachs & Döpfner, 2005). Moreover, several studies have demonstrated that academic achievement is negatively influenced by test anxiety (e.g. Seipp & Schwarzer, 1991). But according to Liebert and Morris (1967), test anxiety is not a homogenous trait. It can be distinguished into two components: worry and emotionality. Previous studies found that worry was stronger negatively related to school achievement than emotionality (e.g. Schwarzer, Seipp & Schwarzer, 1989). Thus, it seems advisable to assess both components of test anxiety. Furthermore, given that students develop subject-specific competences, control- and threat expectations during the course of school years, they can also develop subject-specific test anxiety. Thus, it seems beneficial to assess students' test anxiety referring to unique school subjects. Given the high prevalence rate of test anxiety among children and the negative impact of test anxiety on school performance, it is worthwhile to investigate the accuracy of parents' and teachers' judgments of children's level of test anxiety. The few existing studies found a low accuracy of teachers' and parents' judgments of children's test anxiety (e.g. Lukesch-Toman & Helmke, 1979; Spinath, 2005). However, these studies neither examined test anxiety in specific school subjects nor did they differentiate between the two components of test anxiety. Furthermore, they investigated judgment accuracy only at one measurement point. Although stability coefficients of medium size over a period of six months were found for elementary school teachers' judgment accuracy of students' school achievement (Lorenz & Artelt, 2010), no study has examined the stability of teachers' and parents' judgment accuracy in the domain of test anxiety.

Aims.

The present study addresses the following research questions: a) How accurately do teachers and mothers judge children's level of worry and emotionality in the school subjects of German and mathematics?, b.) How valid are their judgments for children with high test anxiety?, c.) How stable are teachers' and mothers' judgment accuracies over a period of one year?

Methods.

In our analysis, we used data from 74 German language and 73 mathematics teachers, 830 mothers and their children at grade 5 (t1) and grade 6 (t2). The students attended 40 secondary schools (lower, middle and higher track) in Germany. Children's emotionality and worry in the school subjects of German and mathematics were measured at t1 and t2 by means of two short scales for each school subject, each consisting of 3 items. Students were rated at t1 and t2 by their teachers and mothers by using the same items. Students whose emotionality and worry scores were at least one standard deviation above the mean were labeled as high test anxiety group. Difference scores between children's ratings and teachers' or mothers' judgments were computed to determine whether teachers and mothers are accurate in judging the level of children's worry and emotionality in German and mathematics. To examine the stabilities, we calculated correlations between the difference score at t1 and the difference score at t2 for both components of test anxiety.

Results and Discussion.

Our analyses for the whole group revealed that, on average, German language and mathematics teachers tend to overestimate children's emotionality as well as worry at both measurement points. This is consistent with previous research on elementary school teachers' judgment accuracy of general test anxiety (e.g. Spinath, 2005). Furthermore, mothers tend to overestimate children's emotionality, but they tend to underestimate children's worry in both subjects and at both measurement points. These inaccurate judgments may not only represent a diagnostic problem, they can also be regarded as an indicator of disturbed family communication or a lack of mothers' interest in their children. However, when looking at the children with high test anxiety, we found both mothers and teachers consistently underestimate children's worry and emotionality in both school subjects. An underestimation of children's worry cognitions and emotionality however, can lead to a delayed help. Furthermore, for both groups, our results showed stability coefficients of low to medium size over a period of one year for teachers as well as for mothers. The implications of these findings for research and practice are discussed.

Scientific significance. Up to now, there is no study known to us that examined teachers' and parents' judgment accuracy of subject-specific test anxiety simultaneously and thereby distinguished between worry and emotionality. Furthermore, no study has addressed the stability of teachers' and parents' judgment accuracy in the domain of test anxiety. Moreover, it seems to be useful to assess both components of test anxiety in different subjects, given that our results indicate that possible interventions aiming at fostering judgment accuracy might need to vary depending on school subjects, anxiety components as well as judges.

PAPER PRESENTATION

Developing a learning centered model for designing and managing study programmes

Tobias Jenert, University of St. Gallen, Switzerland

So far, research as well as development concerning teaching and learning in higher education have focused primarily on learning in the context of individual courses. Modern theories of adult learning, however, suggest that a course of study be seen more holistically, stressing students' persistent development within various in- and out-of-class learning experiences. Therefore, not only courses but also study programmes should be designed and managed according to pedagogical principles, with the aim to provide a consistent framework in which educationally purposeful learning activities can take place. The need for pedagogically founded principles for programme design is amplified by the Bologna reform which aims at redesigning study programmes but provides only administrative guidelines. The study presented in this paper addresses this issue by developing a comprehensive model for the design and management of study programmes according to pedagogical principles. The model is labeled learning centered as it starts out from students' perceptions of specific programme features. Conducting case studies in different study programmes, (1) students' perceptions and practices of studying were reconstructed together with (2) the structure of each programme as well as (3) programme designers' educational intentions. The resulting model for programme design and management comprises two dimensions. A leadership dimension, in which educational goals are developed and justified, and an ownership dimension in which students and teachers act according to their perceptions and intentions. The model provides strategies for programme designers and managers to purposefully align both dimensions.

Research on teaching and learning in higher education has first and foremost centered on individuals - i.e. students' and teachers' approaches to learning and teaching - as well as methods (Entwistle, McCune, & Scheja, 2006). As a consequence, concepts on how to improve and innovate education at higher education institutions (HEI) have mainly stayed on the level of individual courses, e.g. trying to implement new teaching and learning methods (Aineley, 2008). Yet, there are both theoretical as well as practical reasons to argue for a broader perspective on student learning and, as a consequence, reach beyond the course-level and focus on entire study programmes: Over the last thirty years or so, learning theories have increasingly been stressing the importance of (a) social-material contexts (McInerney & van Etten, 2002) as well as (b) learners' subjective experiences. This suggests that a course of study should not be regarded as a mere addition of more or less independent courses but rather as a holistic learning experience leading to persistent individual growth of the learners. In this understanding, a study programme comprises the total of a student's educationally purposeful social-material experiences at a HEI, both within and outside the classroom (Hu & Kuh, 2002). A second reason why educational researchers and designers should take a closer look at the design of study programmes lies in the Bologna process: The introduction of the European Credit Transfer System as well as the

low-tiered study structure force HEI to systematically craft their programmes' internal structure. Due to the fact that there are virtually no pedagogical concepts concerning the design of study programmes, these design processes have so far been dominated by administrative considerations, largely neglecting students' experiences and their resulting action strategies within the programme structures (Winter, 2009; Hildbrand et al., 2008). It can be concluded that there is a lack of knowledge on how to design study programmes in a pedagogically purposeful way. The aim of the study underlying this proposal is to develop a comprehensive model for designing and managing study programmes. The model is labeled learning centered as it starts out from understanding learners' perspectives on specific programme design features. Therefore, students' perceptions of different programmes are investigated as well as their educationally relevant action strategies in coping with the programme environment, e.g. selection of learning activities, attribution of resources for learning, and social interactions with peers. Thus, relevant design dimensions are identified providing programme designers with a tool to judge how their design decisions impact on students' perceptions and strategies. Methodologically, the study is grounded in a cultural psychological framework (Bruner, 1990; Shweder, 1991) influencing both, the theoretical model as well as the empirical research. When investigating the causes of human action, cultural psychology considers the characteristics of socio-material contexts, and people's (social) meaning-making within these contexts (Shweder, 1991). For modeling the interrelations between design features and students' actions within study programmes, this means to reconstruct and to link three major aspects: (1) The intentions the programme designers had in mind when crafting an existing study programme (e.g. objectives and expectations). That way, the educational purpose of a study programme is determined. (2) The resulting programme structures including the curriculum (module structure, obligatory and elective elements, workload, dominant teaching, learning, and assessment methods, etc.), extra-curricular features (support of internships, student associations, etc.), and general support (introduction to studying, counseling, etc.). (3) Students' perceptions (perceived programme objectives, feasibility of the programme structures, etc.) and their action strategies concerning the programme features (selection of elective courses, attribution of resources for learning, coping strategies, social behavior towards peers, etc.). Concerning the empirical research, qualitative case studies (Travers, 2001) were conducted to empirically elaborate the programme design model. The cases were sampled according to the method of "maximal structural variation" (Kleining & Witt, 2000), combining different types of university and disciplinary cultures. Thus, relevant aspects of programme design can be identified irrespective of organizational or disciplinary characteristics. Data stems from expert interviews with programme designers, document analysis, and focus groups with students. All data was analyzed with qualitative content analysis (Flick, 2009; Mayring, 2003). The findings of the study show that often students neither know what they are supposed to learn during their studies nor how to organize their study in order to accomplish certain outcomes. Yet, when students are insecure, "hidden curricula" (Bergenhengouwen, 1987) are constructed, often leading to undesirable behavior from an educational point of view. This problem is addressed by proposing a pedagogically oriented model for the design, management, and further development of educational programmes in higher education. The model consists of two major dimensions: (1) The programme leadership dimension comprises the normative foundations of an educational programme. Processes within this dimension are, among others, the definition of desirable educational outcomes by identifying and weighing different stakeholders' respective influences as well as the identification of educational activities suitable for developing and assessing the desired outcomes. In contrast, (2) the programme ownership dimension addresses teacher's and student's actual expectations and practices. Programme ownership means that teachers and students know and accept the intended programme outcomes, understand how to best accomplish them, and are ready to act accordingly. Thus, programme management aims at aligning normative concepts on the leadership level and actual practices on the ownership level. To accomplish such an alignment, (a) teachers and students must be involved into the developmental process on the leadership level, (b) a permanent position for the management of a programme has to be established acting as a contact person and communicator, and (c) permanent support for teachers and students must be available to actuate the desired practices of teaching and studying. The model provides a conceptual framework for educational design that reaches beyond the course level addressing the students' experience of higher education in a more holistic way. The specific potential of this model is its grounding in students' perceptions stressing student learning as the key responsibility of programme design and management.

PAPER PRESENTATION

Developing children's narrative identity in primary school

Eero Ropo, University of Tampere, Finland; Maiju Huttunen, University of Tampere, Finland

In this paper we report results of an intervention in which the main aim was to develop student identity in primary schools. Theoretical framework of the study is based on empirical studies of identity formation of young people. The intervention was executed in a second grade primary school class from a suburban environment. Two teacher students spent 2,5 months with the class developing and experimenting teaching materials and methods, interviewing

and observing the pupils. Pupils' work sheets, writings, drawings and other products were the data collected for the analyses. All data were analyzed qualitatively using narrative approach.

Results showed that the ten weeks long intervention program was long enough to produce changes in pupils' outcomes. For instance, written and drawn narratives of identity became longer and more detailed during the teaching period. Differences between boys and girls were also found. Implications for school education will be discussed in the paper.

In this paper we report results of an intervention in which the main aim was to develop students' narrative identity in primary schools. The study is part of a larger research project on identity and knowledge construction (Know-Id) started in 2010. In main project our purposes are twofold. First, we want to understand the identity formation processes both in school and university contexts. Second, we aim at developing teaching and learning environments to enhance identity development.

Identity as concept has a long history (see e.g. Holstein & Gubrium 2000; Shotter & Gergen 1989, Baumeister 1986). Identity, as part of personality, is often related to such concepts as values, personal or social development, moral development, and citizenship education (Veugelers 2007). In education developing student personality, self, or identity as a goal is almost self-evident. However, it has been found that school education does not seem to support student identity development optimally (Lannegrand-Willems & Bosma 2006).

Identity development in adolescence has most often been studied from the psychological point of view, as part of personality or self, although it is often hypothesized that identity relates to individuals' subject matter preferences and choices in the school, motivation for learning and studying, and many other aspects of knowledge selection, processing and construction (see e.g. Ropo 1999). Recent studies on identity development in the schools typically have focused on specific groups, such as adolescent girls (Spreckels 2008; Eckert 1993), boys (Georgakopoulou (2005), or young people in general (e.g. Ferrer & al. 2008). Some intervention studies have also focused on modifying or affecting the identity development (Kerpelman & al. 2008; Montgomery & al. 2008).

In this study we approach identity from narrative perspective. Main reasons for this framework are that we, like many other researchers, view narrative as the major process through which identity develops and is formed (e.g. Pasupathi & McLean 2010, xxi). Narrative is also regarded as a method to express and describe the identity of a person. It is evident that personal narratives have their roots in the early childhood when children start to refer to personally experienced past events using one or two word expressions (Fenson et al. 1993; Reese 1999). Children's narratives get little by little richer when they are able to construct increasingly complex stories about the past events. This development continues in adolescence (Fivush, Haden & Adam 1995). It is found that these stories are not only about what has happened, but also about the meanings of the past event for both the narrator and one who is commenting the story. It has been found that the nature of mother – child relationship is at least partly related to how many evaluative aspects children's stories have (McAdams 1996). We hypothesize that it is through these kinds of narrative processes that children's personal, social and cultural identity is formed and developed.

Methods

A second grade primary school class from a suburban environment in Finland was chosen for the study. Two fifth year primary teacher students spent 2,5 months with the class as practice teachers developing and experimenting instructional methods, interviewing and observing the pupils. The research group designed the teaching methods collecting afterwards pupils' work sheets, writings, drawings and other products into each pupil's individual portfolios. Pupils were also asked to write autobiographical narratives and to draw pictures of themselves in the beginning and end of the teaching period. All narratives and other materials pupils produced during the project period were analyzed qualitatively using narrative approach.

Results

Results showed that the ten weeks long intervention program was long enough to produce changes in pupils' outcomes. For instance, pupils' written and drawn narratives became longer and more detailed during the teaching period. The titles of the assignments were typically such as "write a story of yourself who am I", "draw a picture of yourself", "tell me about your family", etc. Pupils seemed to become more aware of their roots and family history, life courses of their family members. Recognizing own emotions and feelings were also practiced and getting to know one's close and larger living environment was part of the study. All the results will be reported in more detail in the paper.

Detailed results showed that girls' narratives are richer and more detailed than boys, but during the project boys' narratives developed the most. In addition to that the most interesting result of the study was that the children whose

identity and self-esteem seemed to be weakest developed the most. Also the parents of the pupils participated in the project for instance by providing information on family roots.

Implications for the formation of narrative identity will be discussed in the paper. We will also discuss the goals of school curriculum, and identity ideals that schools seem to have concerning what the society prefers and what is a good citizen. It was found that already 8-year old children recognize what society wants from them and what kind of citizens are good citizens.

PAPER PRESENTATION

Implementing hands-on experience in project management education

Shai Rozenes, Ruppin Academic Center, Israel; Ida Kukliansky, Ruppin Academic Center, Israel

The project management discipline is expanding within many engineering activities. This discipline can facilitate successful accomplishment of an engineering project. Therefore, academic institutes all over the world teach the "project management" program. This study presents a novel approach that educates engineering students to become successful project managers based on contextual learning. This approach embeds a practical project within the project management program. The student has to implement the academic know-how into the embedded project. The study utilizes a questionnaire – a quantitative tool to measure the students' attitudes to the preferred and the actual learning environment. The learning environment was divided into five categories: student supportiveness, independent learning, integration between the practical activities and theory classes, guidance contribution and difficulties in reality. The results show that the actual rank in about 60% of the questions was identical or even higher in comparison to the preferred rank. About one fourth of the questions revealed that the preferred rank was higher than the actual rank by 1. The relatively small gap between actual and preferred learning environments indicates that the students were satisfied with the educational process.

Introduction

The field of project management has been developing in recent years within many engineering activities. Therefore, many academic institutes all over the world teach the "project management" program. One of the theoretical anchors of the project management program teaching process can be contextual learning, that adapts the learning process to the experiences and interests of the learner, emphasizing higher-level thinking, knowledge transfer across academic disciplines, and collecting, analyzing and synthesizing information and data from multiple sources and viewpoints (Smith, 2000). The aim of this study is to present and evaluate a novel approach, based on contextual learning that educates engineering students to become successful project managers combining academic know-how with the practical project. This approach considers the main knowledge required in the field of project management (Meredith & Mantel, 2006).

Method

Participants The participants were 82 third year students (53 males and 29 females) at the Industrial Engineering and Management (IEM) department at the Ruppin School of Engineering. **Procedure** The education process combines project management academic theory and practice. The program is conducted as a workshop in which all participants participate in discussions, while performing genuine assignments. Student teams choose a real life project as a case study to facilitate the learning process. This project is presented, during the workshop, to illustrate the implementation of project management tools and techniques within their organizational environment. The program outline, fourteen weekly sessions of four hours, is shown in Figure 1 (Appendix). The software package used is MS Project software, a very popular worldwide package. The lecturer monitors the process by the following guidelines: (a) Supervisory meetings are scheduled for every alternate week; (b) Progress reports are prepared by the team for each meeting; (c) The supervisor discusses progress with the students referring to the schedule. The project supervisors assess the process by the following guidelines: (a) Progress reports: the supervisor receives progress reports at each meeting. The reports are assessed throughout the semester. (b) Final reports: the project team writes an engineering report that describes the entire progress with a scientific approach. (c) Viva: each and every project team member is examined by the IEM staff to prove his/her knowledge. **The questionnaire** The instrument used for evaluating the learning environment included a questionnaire in a preferred and actual form. The preferred form, showing students' personal perceptions of their preferred learning environment was filled out by the students at the beginning of the PM course and the actual form was filled out at the end of the course. Our instrument on the actual and preferred forms was built according to the Science Laboratory Environment Inventory (SLEI) questionnaire (Fraser et al., 1995) that was validated among 7000 university students in several countries. The questionnaire includes 35 questions on a Likert scale of 1 (strongly disagree) to 5 (strongly agree), divided into five categories: (a) Student supportiveness – Extent to which students know, help, and are supportive toward each other (b) Independent learning – Extent to which

students learn by themselves, including acquaintance with designated software c) Integration – Extent to which practical activities are integrated with theory d) Guidance – Extent to which guidance contributed to the students e) Difficulties - Extent to which the student has difficulties in reality The Cronbach's alpha coefficient showing the reliability of the questionnaire was 0.83 for the preferred form and 0.78 for the actual form. Results The mean, median and the standard deviations (SD) of the 82 participants by categories for the preferred and actual form of the questionnaires are summarized in Table 1. The averages of the "Student supportiveness" category were higher than in the other categories in both forms of the questionnaire.

Table 1. Questionnaire Summary

Category	Actual form	Preferred form	Mean	Median	SD	Mean	Median	SD
a)	4.21	40.66	4.47	50.44	b)	3.42	40.39	3.74
c)	3.95	40.55	4.21	40.51	d)	3.64	40.49	3.91
e)	3.42	30.40	3.94	40.45				

The average difference between actual and preferred ranks in the entire questionnaire was only 0.33 (about one third unit). Figure 2 (Appendix) depicts the joint distribution of the responses by categories, showing the ranking in the preferred and actual form of the same question. It can be seen that the preferred rank in all the categories is slightly higher than the actual rank. Other studies have shown that students rank their attitudes to the preferred learning environment higher than the existing one (Dorman, 2008). The actual rank in about 60% of all the questions was identical or even higher in comparison to the preferred rank. About one fourth of the questions revealed that the preferred rank was higher than the actual rank by 1.

Discussion

This paper presents an academic project management program that can be used in globally, and which prepares students to become future project managers, implementing practical aspects by using a real life project within the organizational framework. Positive students' attitudes are important because they strengthen motivation and interest, and thus promote meaningful learning of the topics in project management. The results show that the majority of students were satisfied with their learning environment; their actual form rank was at least like the preferred form rank. The relatively small gap between actual and preferred learning environments shows the student's satisfaction with the educational process based on contextual learning.

PAPER PRESENTATION

Effects of structured analyses on theory based reflection

Anne Levin, Universitat Bremen, Germany

The perspective of experts is influenced by their beliefs and orientations. Therefore teachers pedagogical attitudes and beliefs are of practical significance for teaching (Bromme, 1992). To support student in developing skills in theoretical based analysis an instruction based structure to guide students through the process of analyzing and reflecting given authentic situations was developed. Two experimental studies were conducted to test the differential effects of three modes resp. two modes of instruction on the acquisition of elaborated theoretical knowledge. During the first experiment teaching-students were instructed to analyze relevant situations in terms of theoretical conditions resp. to generate solutions for a given problem. students in teacher training (n = 153) were randomly assigned to one of two experimental conditions and one control group: structured analysis I (structured analysis and interpretation referring to own experiences and assumptions followed by analysis and interpretation based on a theoretical concept); structured analysis II (structured analysis and interpretation based on two different theoretical concepts); unstructured analysis (control group). Results show moderate to high positive effects on learning outcomes (concerning the acquisition of more elaborated knowledge). Structured analyses had also small effects on the number of given references to theoretical concepts. There was no difference found between the two experimental groups. The second study (n = 61) used an incomplete two by two design (structured vs. unstructured instruction and inexperienced (first-year students) vs. experienced students (in at least the fourth year)). Structured analyses as well as the experience (Master vs. Bachelor student) had big effects on the number of given references to theoretical concepts during the process of analyzing as well as on the justification of proposed solutions.

The perspective of experts is influenced by their beliefs and orientations. Therefore teachers' pedagogical attitudes and beliefs are of practical significance for teaching (Bromme, 1992). The ability to analyze situation and to reflect one's own actions and intentions referring to extensive pedagogical content knowledge has significant relevance for teachers who want to become experts in their field (Bromme 1992, Berliner, 2001). This assumption of Bromme and Berliner is supported by studies that prove, that teachers who are more successful in conducting cooperative learning in classes display pedagogical attitudes and beliefs which are more elaborated and complex (Haag & Dann, 2001). The ability to reflect one's actions and underlying beliefs and orientations are critical for developing expert knowledge. As Bromme and Tillema put it: "Becoming a professional is not a process of substituting theory by experience, but a process of fusing theory and experience." (Bromme & Tillema, 1995). The results of a questionnaire (involving 144 students of education of the Technical University in Berlin (Levin, 2010)) showed, that students of education have significant problems in referring to theories and theoretical models while analyzing specific cases or interpret examples of teacher-students interactions. One major reason for avoiding a deeper reflection was a stated lack of procedural knowledge that leads to a helplessness according to the ability to structure the process of analysis and reflection. To support students in developing skills in theoretical based analysis we developed an instruction based structure to guide them through the process of analyzing and reflecting given authentic situations. Two experimental studies were conducted to test the effects of three modes resp. two modes of instruction on the acquisition of elaborated theoretical knowledge. Two hypotheses were tested: Structured analysis should lead to higher effects on learning outcomes than unstructured analysis. Students using structured analysis I should be able to elaborate theoretical knowledge in a deeper way than students using structured analysis II due to linking theoretical knowledge to their previous knowledge. During the first experiment students in teacher training who were taking part in a lecture of educational psychology were instructed to analyze relevant situations in terms of theoretical conditions resp. to generate solutions for a given problem. Students in teacher training $n = 153$, (Levin, 2010) were randomly assigned to one of two experimental conditions and one control group: structured analysis I (structured analysis and interpretation of a presented situation referring to own experiences and assumptions followed by analysis and interpretation based on a theoretical concept); structured analysis II (structured analysis and interpretation of a presented situation based on two different theoretical concepts); unstructured analysis (control group) - unstructured analysis and interpretation based on two different theoretical concepts. During four sessions (periods between the sessions ranged from two to three weeks) students worked on four different situations. Results were openly discussed. Two weeks after the last intervention a test was written (irrelevant for the passing of the following examination). Results show moderate to high positive effects on learning outcomes (concerning the acquisition of more elaborated knowledge). Structured analyses had also small effects on the number of given references to theoretical concepts. There was no difference found between the two experimental groups. Inquiries showed excessive demands due to the structured instruction. Therefore the structure was revised in order to improve comprehensibility. Time to work on the authentic situations was expanded. Two hypotheses were tested: Structured analysis should lead to a significant rise of references to theoretical concepts compared with the unstructured group. Students of the master course were expected to excel students of the bachelor courses according to the number of stated references on theoretical concepts (during the process of analyzing the situation and of the justification of proposed solutions). The second study ($n = 61$) used an incomplete two by two design (structured vs. unstructured instruction and inexperienced (first-year students) vs. experienced students (in at least the fourth year)). The BA courses (parallel courses, same teacher, same schedule and content) were randomly assigned to one of two conditions: structured analysis II (structured analysis and interpretation of a presented situation based on two different theoretical concepts) and unstructured analysis (control group) - unstructured analysis and interpretation based on two different theoretical concepts. During three sessions (sessions were held weekly) students worked on three different situations. Results were openly discussed. Two weeks after the last intervention a fourth situation was analyzed. Structured Analyses as well as the experience (Master vs. Bachelor student) had big effects on the number of given references to theoretical concepts during the process of analyzing as well as on the justification of proposed solutions.

PAPER PRESENTATION

The Effects Generative Testing Methods on Text Retention and Text Comprehension

Kim Dirkx, Open University, Germany; Liesbeth Kester, Open University of the Netherlands, Netherlands; Paul A. Kirschner, Open Universiteit, Netherlands

Retrieval by means of multiple-choice, free-recall or short-answer tests has shown to be a very effective study strategy for long-term retention of facts from expository texts. Because today's education emphasizes meaningful learning rather than rote learning, the present research investigated the effects of two generative testing methods namely summarizing and concept mapping on retention and comprehension compared these methods to free-recall and restudy. Students (N=250) were given a Biology text and either reread it, or took a test on the material. A final test was administrated after 5 minutes (i.e., measure short term retention) or one week (i.e., measuring long-term retention). Before the experiment, students were trained in restudy or one of the three testing methods. In addition, prior knowledge, verbal ability and working memory were measured to correct for individual differences. Preliminary results show an superior effect of tests versus restudy on delayed retention. Summarizing seems to benefit long term comprehension. Final results will be presented during the Earli of 2011.

Students often prepare for an exam by rereading their notes or the textbook (Karpicke, Butler, & Roediger, 2009). This study strategy, has proven however, not to be the most effective study strategy for long-term retention (Callender & McDaniel, 2009; Roediger & Karpicke, 2006). A better strategy for that purpose is testing or the act of retrieval (Karpicke et al; Roediger & Karpicke). This so-called memory effect of testing or testing effect has often been investigated since its first mention in the literature (e.g., Glover, 1989).

The traditional testing effect research has investigated the effect of tests in laboratories with educationally irrelevant material such as lists of words or unrelated word pairs and used recognition, cued-recall, or free-recall tests to measure retention (Butler & Roediger, 2007; Karpicke & Roediger, 2007, 2008, see McDaniel, Roediger, & McDermott, 2007; Roediger & Karpicke, 2006). From those more traditional experiments, free recall has shown to be an highly effective testing method. The effectiveness of free recall has been ascribed to the need for retrieval without cues. Retrieval without cues has been suggested to enhance the retrieval effort thereby enhancing memory traces and consequently long-term retrieval (Glover, 1989). Roediger and Karpicke suggested that the limit interest in the testing effect and the lack of incorporation in education is a result of the limited range and usability of materials used in the more traditional testing effect experiments. More recent testing effect research has acknowledged that problem and investigated long-term memory retention of material actually used in education such as foreign vocabulary words, expository texts and materials from test preparation books with educationally relevant tests, such as, multiple-choice, short-answer or essay tests. Here we want to take this line of research one step further.

Due to changes in educational demands, secondary education emphasizes the obtainment of higher cognitive skills such as comprehension and application. In result new testing methods, that enable assessment of such skills, are being implemented in schools. Two such testing methods are concept mapping and summarizing. Here we call them generative tests. Students need to generate without cues what they remember. In contrast to free recall concept mapping and summarizing explicitly require students to organize the information and draw relations between concepts/ideas/facts.

The question investigated in the present research is whether an testing effect can be found using these generative testing methods. Concept mapping and summarizing require students not only to recall information but also to (hierarchically) organize the recalled information. Free-recall, in contrast, asks students to write down everything they remember from, for example, a text without paying attention to wording or text structure. In line with the testing effect research, it is hypothesized that recall by means of free-recall, concept mapping, and summarizing will lead to better delayed (after one week) retention compared to restudy, and that restudy will yield higher immediate (after 5 minutes) retention. Moreover, it is expected that concept mapping and summarizing will enhance comprehension more than free recall because these generative testing methods require students to make inferences and relations between the information they learn.

Data collection runs from October 20th 2010 till December 10th 2010. In total 250 Dutch sophomore secondary school students, taking biology courses for two to three hours a week, will be included. We will present in this summary the result of a subsample of 35 students that already finished the complete experiment. A randomized 4 x 2 factorial design with between-subject factors learning strategy (restudy, free recall, summarizing, concept mapping) and retention interval (5 minutes, 1 week) is used. Prior knowledge, reading comprehension and working memory capacity are tested prior to the start of the experiment to determine the potential effects of individual student characteristics. During the experiment participants read a 500 word text on metabolism from an often used Biology textbook. The students either take a test or restudy the text during 10 minutes. After 5 minutes or one week a final short-answer test of 17 items (both retention and comprehension questions) is administered.

Preliminary data of 35 students are displayed in the appendixes. Restudy leads to very high short-term recall levels (after 5 minutes), but this advantage of restudy disappears after one week (long-term recall). In addition, after one week all three test groups had higher recall scores than the restudy group. This indicates a testing effect (see figure 1). The preliminary data was cautiously analyzed using Kruskal Wallis with Condition (restudy after 5 minutes or one week, free-recall after 5 minutes or one week, concept mapping after 5 minutes or one week, summarizing after 5 minutes or after one week) as grouping variables. Results showed that the conditions significantly differed from each other ($H=15.394$; $p=.031$). A Mann Whitney U test showed that there is a tendency for the superiority of summarizing on long-term recall compared to restudy ($p=.064$). Figure 2 shows that there are only small differences in retention between the four strategies. Summarizing and restudy seem to be just as effective on the short term and free recall and concept mapping seem to be a little less effective. Long term retention is much higher in the test conditions. In figure 3 it is seen that students in the summary condition yielded far higher comprehension test scores both after 5 minutes, and one week compared to the other conditions. In contrast to what was expected, concept mapping seems no more effective than free recall.

The results of the complete sample ($N=250$) will be available in December 2010. We are pleased to present and discuss final results, during the Earli 2011 in Exeter.

PAPER PRESENTATION

Dialogical interactions in mathematics: Promoting achievement in a global world

Ricardo Machado, Universidade Nova de Lisboa, Faculdade de Ciencias e Tecnologia, Portugal; Margarida Cesar, Universidade de Lisboa, Instituto de Educacao, Portugal

Having access to knowledge, and knowing how to use it, is essential to avoid social exclusion (Cesar & Oliveira, 2005). Mathematics assumes an important role in students' schooling paths. But students often develop negative social representations about mathematics that shape their underachievement and are also shaped by it (Gorgorio & Planas, 2005; Machado, 2008). Communication plays an essential role in mathematics learning (Sfard, 2001). Collaborative work can be used as a mediation tool to facilitate mathematical knowledge appropriation and the development of students' abilities and competencies (Cesar, 2009).

This study is from the Interaction and Knowledge research project. Its main aims were studying and promoting collaborative work in formal educational scenarios. Assuming an interpretative approach, action-research projects were developed in around 600 mathematics classes (5th to 12th grades, 10/11 to 17/18-year-olds) all over Portugal. We focus on an 8th grade class, from a school near Lisbon, chosen as a paradigmatic example. The main participants were these students ($N=21$), the teacher/researcher and two other observers. Data were collected through questionnaires, tasks inspired in projective techniques, an instrument to evaluate students' abilities and competencies, observation, documents and students' protocols. Data were treated and analysed through a narrative content analysis (Clandinin & Connelly, 1998) from which inductive categories emerged.

The analysis of some students' solving strategies and mathematical thinking illuminates the potentialities of collaborative work to promote more positive social representations about mathematics and students' mathematical performances. We illustrate the interactive interplays that facilitated those changes through the analysis of students' paths.

Having access to knowledge, and knowing how to use it, is essential to avoid social exclusion (Cesar & Oliveira, 2005). According to Sfard (2008), thinking is communicating. It is important to face students with opportunities to develop those complex mental functions, particularly through their access to mathematical mental tools (Cesar, 2009). But although being important in students' schooling paths, they often develop negative social representations about mathematics that shape their underachievement and are also shaped by it (Gorgorio & Planas, 2005; Machado, 2008). As social representations are a dynamic, multi-faced and dialogic construct (Markova, 2005), they can inform us about how the others interpret the context and situations that they are experiencing, particularly in their learning process within mathematical classes. As communication plays an essential role in mathematics learning (Sfard, 2001), it is important to create thinking spaces (Perret-Clermont, 2004) where students develop complex mental functions (Vygotsky, 1934/1962) through dialogical interactions (Renshaw, 2004). They share their argumentations and points of view. In these spaces/times (Cesar, 2009), students give meanings to the words, to their actions and to those of others with whom they interact (Bakhtin, 1929/1981). Thus, teachers need to benefit their practices in order to develop students' reflective and critical participation. Assuming the collaborative work, namely in peers, as a daily practice and establishing a coherent didactic contract is a way to promote students' access to (mathematical) knowledge and the development of their abilities and competencies (Cesar, 2009). Working in peers also facilitates students' transitions (Zittoun, 2006), namely their access to the mathematical knowledge they learned in different contexts, scenarios, and/or situations – an essential step towards empowering students mathematically (Cesar, 2009).

The problem that originated this study are students' negative social representations about mathematics and their impacts in students' (under)achievement and in their school and social inclusion. The research questions we address in this paper are: (1) Which are the 8th graders' social representations about mathematics at the beginning of the school year?; (2) Which changes do we observe in those social representations during the school year?; and (3) What are the impacts of collaborative work on students' social representations about mathematics, in their (mathematical) knowledge appropriation and in their mobilization and development of abilities and competencies?

This study is from the Interaction and Knowledge research project. Its main aims were studying and promoting collaborative work in formal educational scenarios. Assuming an interpretative approach (Denzin, 2002), action-research projects (Mason, 2002) were developed in around 600 mathematics classes (5th to 12th grades, 10/11 to 17/18-year-olds) all over Portugal. We focus on a class (8th grade), from a school near Lisbon, chosen as a paradigmatic example of an illiterate and poor multicultural context in which students usually failed and dropout of school. The main participants were these students (N=21), the teacher/researcher and two other observers. Students worked collaboratively during the whole school year, in dyads and small groups. Data were collected through questionnaires (September and June), tasks inspired in projective techniques (September, January and June), an instrument to evaluate students' abilities and competencies (September), observation, documents and students' protocols (whole school year). Data analysis was based in a narrative content analysis (Clandinin & Connelly, 1998) from which inductive categories emerged (Cesar, 2009), allowing to trace students' learning paths and the mathematical knowledge they mobilized.

The analysis of some students' solving strategies and mathematical thinking illuminates the potentialities of collaborative work to promote more positive social representations about mathematics and students' mathematical performances. For instance, how some students' engaged in mathematical activities they were unable to face until then and how that empowerment contributed to their inclusion. It also illuminates the role of dialogical interactions in students' access to mathematical knowledge, in the development of complex mental functions and (mathematical) abilities and competencies such as making, testing and explaining their own conjectures.

PAPER PRESENTATION

Teachers and peers: processes of exclusion and inclusion in children's preschool groupings during lea

Peter Kutnick, The University of Hong Kong, Hong Kong; Antonella Brighi, University of Bologna, Italy

This study poses that interactive learning and social inclusion should be studied in both child-adult and child-peer cognitive/learning contexts, in order to develop an understanding of children's co-constructive processes of knowledge within the pre-school. Most knowledge of effective pre-schools is based upon teacher-scaffolded interactions, but a majority of children's learning time is spent without a teacher present.

Our study aims to: identify types of child- and teacher-oriented groupings that characterize cognitive/learning activity among 4 year-olds in pre-school; describe the activities that children undertake in these groupings; and assess learning groupings for types of learning activity, cognitive challenge social inclusion/exclusion.

25 pre-school classrooms were selected and observed in England and in Italy. A mapping system characterized cognitive/learning activity undertaken in various groupings of 4 year-olds and found these groupings were differentiated by number per group, composition of group, activities engaged and cognitive challenge. 103 maps identified 536 groupings. Analyzing the groupings by descriptive and inferential statistics, two distinct pedagogic worlds were identified: large, teacher-oriented groups of children, and small peer-oriented groups. In the teacher-oriented groups children were involved in learning activities in a socially inclusive context – where boys and girls, friends and non-friends interacted under teacher direction. Peer-oriented groups tended to be solitary or socially exclusive – accentuating gender differences in task choice, learning partner and cognitive challenge of activity. Findings suggest that cognitive/learning tasks may be undertaken in either of these pedagogic worlds, but different social activity involved may imply dissimilar pathways of teacher-oriented, inclusive or gendered exclusive knowledge construction.

INTRODUCTION

Most western countries offer universal pre-school access to 4 year-olds; identifying that this experience will enhance a child's cognitive and social development and facilitate entry to primary school. Recent studies of pre-school experience have found that effective pre-schools have high levels of teacher-pupil interaction within a socially inclusive learning environment; and this combination of interaction and inclusion are strongly associated with ease of primary school entry and learning. Effective pre-school studies, though, mainly focus on teacher-scaffolded activity, teacher-child interaction and associated inclusion. The studies separate this activity from free play – within which cognitive and social interaction is likely to be associated with social exclusion among children.

Within the study reported here, we focus on cognitive/learning time in pre-school classrooms. We note, though, that during cognitive/learning time teachers spend most of their time with children but children spend most of their time away from a teacher and in the presence of peers. While there have been excellent descriptions of cognitive/learning time co-constructed between child and teacher, there is little consideration of child-peer cognitive/learning time and the processes of inclusion/exclusion associated within this time.

This study poses that there may be distinct pedagogic worlds (related to child-adult and child-peer activity) that can be identified during cognitive/learning time and that interactive learning and social inclusion should be studied in both child-adult and child-peer cognitive/learning worlds in order to develop an understanding of children's co-constructive processes of learning within the pre-school.

AIMS:

Our study aims to: identify the types of child-oriented and teacher-oriented groupings that characterize cognitive/learning activity (4 year olds in pre-school); describe the activities that children undertake within these groupings; and, assess these groupings for types of learning activity, cognitive challenge and social inclusion/exclusion.

METHODOLOGY:

Pre-schools were selected as characteristic early education settings in local communities in England and Italy. Ethical permission was granted before the study began. A total of 25 pre-school classrooms (children mean age was 4 years) were selected and observed during the summer term. Each classroom was visited 3 or 4 times, allowing for a representative sample of cognitive/learning activities.

Instrument:

'Mapping' (Kutnick, Blatchford & Baines, 2002; 2006) allowed observation of number, type and composition of groupings per classroom as children undertook learning activities. Each map provided group-level summaries of: those involved in learning activities, types of activity, level of cognitive challenge and interaction. Groupings observed clearly differentiated between 'teacher-oriented' (defined as a grouping of children that undertook an activity with the teacher present) and 'child-oriented' (groups undertook a teacher structured activity mainly without teacher presence). Within each grouping maps also identified: grouping size, gender and friendship composition; who composed the groups; whether an adult was present and his/her role; and quality of interaction and communication. A total of 103 maps identified 536 groupings. Analysis considered the total number of groups (N=536), and used descriptive and inferential statistics (Pearson Chi Square Analyses, Anova) to assess differences between groupings.

FINDINGS:

Teacher- and child-oriented groups:

Observations found a clear distinction between teacher- and child-oriented groups. Teacher groups displayed an inclusive mix of sex (boys and girls) and friendship (friends and acquaintances) and were composed of 6-9 children interacting with the teacher on teacher-assigned tasks. Child groups worked either individually or in small (2-3) groupings and were homogeneously composed of boys- or girls-only and were friends-only while they undertook teacher-assigned learning tasks. Analyses found that children undertook their cognitive/learning activities in separate pedagogic worlds; a teacher-oriented world being interactive and inclusive and the child-oriented world being active and exclusive.

Interaction/communication:

Communication differed by teacher- and child-orientation. About 38% of teacher and child groups exhibited joint interaction with communication. Scaffolded interactions were most likely in teacher-oriented groups. 35% of activities exhibited parallel interaction. There was a high proportion of solitary activity without communication exhibited only in child-oriented groups.

Activity:

Teacher-oriented, inclusive groups undertook activities associated with preparation for entry to schooling (mid-high cognitive challenge). Child-oriented, exclusive groups undertook sex-differentiated activities; this exclusivity was also associated with different activities for male and female groups and different levels of cognitive challenge. Boys undertook mid-low cognitive challenge activities of large and small construction and scripted toys. Girls undertook mid-high and high challenge activities of art, 3Rs and pretend play.

SIGNIFICANCE:

Effective pre-schooling is said to draw upon teacher scaffolded interactions and inclusive pedagogy to promote cognitive/learning and preparation for primary school. Yet, our mapping analysis identified that much of children's cognitive/learning time is directed by teachers but undertaken without the presence of a teacher. Mapping of cognitive learning activities of 4 year-olds revealed much action and interaction within their groups, but these activities took place in two (separate) pedagogic worlds which characterized both England and Italy. The teacher-

oriented world was interactive and inclusive; groups composed of 6-9 children who worked with the teacher and included boys and girls, friends and acquaintances. Teacher-oriented groups undertook mid-high cognitive activities oriented towards preparation for entry to primary school. The child-oriented world was composed of groups that undertook teacher structured cognitive/learning activities; these groups were interactive but were limited in size and characterized by homogeneity of sex, friendship. Child-oriented activities had different gender orientations – girls pursued school preparatory activities and boys pursued scripted actions with toys and manipulative objects. Gendered activities were also differentiated by level of cognitive challenge.

We explain learning within inclusive and exclusive pedagogic worlds by drawing upon 'first generation' activity theory. We note that cognitive/learning activities were undertaken in an 'interactive social environment' but children's interactions were 'mediated' by culturally defined orientations of child-adult and child-peer groups. Moreover, as most pre-school children spend their cognitive/learning time away from the presence of a teacher, we suggest that interactive learning mediated in this socially exclusive context may characterize the orientation to learning that children are likely to carry into their primary school. We suggest that further studies are required to further ascertain how pre-school learning experience can be made more inclusive.

PAPER PRESENTATION

Studying the quality of communication in emerging self-managing student team companies over time

Johanna Poysa-Tarhonen, University of Jyväskylä, Finland; Jan Elen, Katholieke Universiteit Leuven, Belgium; Pasi Tarhonen, Honeywell Inc., Finland

This paper looks at the development of the quality of communication in self-managing student team companies over time to better understand how relatively large student teams (n=16-19) gradually develop. In the study, shifting levels of interpersonal dynamics serve as indicators of the quality of communication in student teams. The study contributes to current knowledge by following a temporal perspective on change in groups and addresses unpredictability and complexity as a fundamental feature of teams' functioning. This research, reporting on four videotaped team meetings of three student teams, collected during their first year as entrepreneur students, utilizes a mixed method approach as a combination of quantitative analyses and qualitative interpretations by combining statistical and time-series model identification methods (statistical process control) and qualitative content analysis. The results enabled accurate information of the significant patterns of interactions over the process and how these different patterns unfold in micro-level in teams. The results arising out of the study might be helpful for teachers/team coaches to craft targeted support for teams to better e.g. mitigate or prevent negative incidents or series of events to occur in the consequence of team development.

To better succeed and to stimulate employee commitment, an increasing number of modern knowledge-intensive work organizations are establishing teamwork-based working models and less hierarchical, self-managing working practices (Knights & McCabe, 2003). The self-managing work team can be characterized as a collective that has the authority to decide how members' efforts will be organized, monitored and managed to accomplish the team's work (Hackman, 1995; van der Vegt, 2010).

This research examines three emerging, self-managing student team companies (co-operatives) within a business school context and specifically looks at the development of the quality of communication in these teams over time. The aim of the study is to better understand how relatively large teams (n=16-19) gradually develop. This understanding may be used to coach (beginning) self-managing teams in their learning process. In the study, shifting levels of interpersonal dynamics (Losada, 1999) over time serve as indicators of the quality of communication in student teams. The study contributes to current knowledge by following a temporal perspective on change in groups and addresses unpredictability and complexity as a fundamental feature of teams' functioning (e.g. Arrow et al., 2004). It is expected that details of the nonlinear interactions in teams cannot be predicted and that patterns of group behaviour can best be studied by focusing on the evolution of group behaviour, e.g. by identifying changes in regard to the shifts to qualitatively different patterns of interactions in groups.

Data were obtained from four videotaped team meetings of three heterogeneous teams, collected at regular intervals over their first academic year as entrepreneur students. Teams' meetings were videotaped using a 360° camera that allowed observations of all the participants simultaneously. To better understand emerging teams' performances a mixed method approach was adopted that implied the combination of quantitative analyses and qualitative interpretations. First, to study the quality of communication, the videotaped team meetings were coded at phrase level in regard to three pairs of variables (positivity/negativity, inquiry/advocacy, other/self) that Losada (1999; Losada & Heaphy, 2004; Fredrickson & Losada, 2005) had identified to imply significant qualities of communication in terms of interpersonal dynamics in business teams. Next, the amount of different pairs of variables was calculated and

compared to ratios of high-, medium- and low-performance teams as identified by Losada (1999). This first phase of analysis marked each code with a time stamp. Second, the data was aggregated in one-minute intervals and time series analysis was conducted on these data. The one-minute interval ratios were first inverted and normalized to calculate the mean value of the combination of three abovementioned pairs of variables at points in time. To identify changes in the patterns of group interactions, the data were processed further by using statistical and time-series model identification methods (statistical process control, see e.g. Wheeler & Chambers, 2000; Oakland, 2002). The aim was to identify statistically significant states from the time series data that were biased strongly towards extremes (e.g. highly positive or negative states) or indicated statistically significant state changes (e.g. a clear change from positive to negative). Third, to fully understand teams' behaviours the extreme states and state changes were traced in the discussion data. These data served as meaning units to analyze the contents and actual meanings of communication among team members during the significant states (e.g. Graneheim & Lundman, 2004).

The results showed that in all the three teams the quality of communication in regard to the interpersonal dynamics stayed relatively identical (medium-level) over the measurements if compared to Losada's (1999) classification into high-, medium- and low-performance business teams. In all the teams the results indicated clear state changes in teams' behaviours basically with respect to three forms of patterns: violations (uncontrolled variations in team's performances, be they positive or negative), continues flows of violations (oscillation behaviour) and (biased) trends (be they positive or negative). Interpretations in these qualitatively different patterns exhibited regularities in terms of qualitative themes that had to do particularly with the beginning, self-organizing teams' functioning, such as the processes of coordination and self-organization (e.g. Druskat & Pescosolido, 2002), and the micro-practices of power in peer-led teams (e.g. Davis, 2008). The results enabled accurate information of the significant patterns of interactions over the process and how these different patterns unfold in micro-level in teams. This may be helpful e.g. for teachers/team coaches to craft targeted support and interventions for teams e.g. to mitigate or prevent negative incidents or series of events to occur in the consequence of team development.

PAPER PRESENTATION

Individual and group level expressions of social skills as predictors of satisfaction & performance

Michele Notari, PHBern, Switzerland; Baumgartner Adrian, PHBern, Switzerland

The study looks for empirical answers to the following question: To what degree are self-rated individual social skills and the distribution of social skills within learning groups predictive for group member's satisfaction with group performance and quality of collaboration? Data collection took place in a project based learning curriculum of pre-service teachers. Two questionnaires were used, one at the beginning and one at the end of the learning cycle which lasted for one semester. The investigation of 60 learning groups (N = 155 teacher training students) revealed the

following results: Self-rated social skills on the individual level were for the most part non-significant predictors for the satisfaction with group performance and the quality of collaboration. A different picture emerged on the group level: Groups in which members show a high and/or amongst themselves homogeneous expression of specific social skills (i.e. exchange orientation, prosocial behavior, leadership) are more satisfied and collaborated better than groups with high and heterogeneous expressions of skills.

Executive Summary

Commonsense dictates that individual social skills are relevant ingredients for successful collaborative learning. However, we could find hardly any studies who tried to identify empirically and systematically the social skills most predictive of group performance and collaboration. Furthermore, those few studies have relied almost exclusively on the individual, neglecting that group success and collaboration is as much dependent on individual skills as on the skill configuration within the whole group. In our own study, we have chosen a project-based (PBL) learning curriculum as a context to analyze collaborative learning processes. In PBL learners have to organize themselves as a group, negotiate goals, assign responsibilities, communicate and resolve emerging conflicts (Eastman & Owens Swift, 2002). It is expected that students practice and refine these skills during the collaboration process (Peterson, 1997).

Research design

Research questions:

Which individual social skills are associated with group process variables (i.e. satisfaction with performance and quality of collaboration) in a collaborative project-based learning setting?

What configurations of social skills within learning groups (i.e. heterogeneous vs. homogeneous distribution and low vs. high expression of a skill) are associated with differences in group process variables?

At the start of the PBL curriculum students completed a questionnaire (t1) self-assessing various social skills. According to Peterson (1997) and Heuermann and Krutzkamp (2003) the questions concerned perceptions of personal social skills. At the end of the project students were given a second questionnaire (t2) tapping their satisfaction with the course of the project and their judgement about the quality of collaboration during the project.

Self-assessment of individual social skills (t1)

The questionnaire contained 16 self-referential statements which students rated on a four-point scale (totally agree – do not agree at all). The 16 statements were reduced to five factors using principal component analysis. The five factors explained 66.9% of total variance. All factor scales had acceptable internal consistencies (Cronbach's Alpha): exchange orientation (i.e. being able to cooperate, compromise, resolve conflicts etc.): (Cronbach's Alpha = .685), prosocial behavior: (Alpha = .600), initiative: (Alpha = .705), leadership: (Alpha = .627), assertiveness: (Alpha = .652).

Group process variables (t2)

Students rated six process variables (i.e. satisfaction with performance, efficiency of collaboration, clear division of responsibilities, clarity of leadership, mutual support giving, group harmony and ability to bring in one's ideas) on a four-point scale (totally agree – do not agree at all).

Analyses

In our research design individuals are nested within learning groups. As we were interested in the predictive power of individual level (level 1) and group level (level 2) variables on satisfaction and quality of collaboration, a multilevel analysis approach was pursued using the hierarchical linear modelling software HLM 16.2 (Raudenbush, Bryk & Congdon, 2004). This was done for all outcome variables for which the intraclass correlation coefficient (ICC) demonstrated significant level 2 variance (all other outcome variables were analysed with linear regression models). The basic regression equation was as follows:

level 1: outcome = $\gamma_0 + \gamma_1$ (individual social skill) + r

level 2: $\gamma_0 = \gamma_{00} + \gamma_{01}$ (mean social skill) + γ_{02} (SD social skill) + γ_{03} (interaction mean x SD) + u₀

$\gamma_1 = \gamma_{10} + u_1$

The social skill expression on level 2 consisted of group members average skill level (mean), variability of skill level within groups (SD) and the interaction between mean and variability.

Selected results

Individual social skills as predictors of satisfaction and quality of collaboration

Of the five social skills we investigated only two demonstrated predictive value. Students high in leadership skills saw their groups as less mutually supportive ($B = -.18$, $p = .065$) and students high in assertiveness thought they had been less capable of bringing their ideas into the project ($B = -.31$, $p = .009$).

Configuration of social skills within groups as predictors of satisfaction and collaboration

Members from groups in which the individual exchange orientation is high (mean) and at the same time homogeneously distributed (SD) report a more efficient collaboration ($B = -2.77$, $p = .048$) and a clearer division of responsibility ($B = -2.32$, $p = .061$) than other groups. Other meaningful effects were found for prosocial behavior and leadership: Group member's satisfaction with performance ($B = -2.04$, $p = .098$) and with the efficiency of collaboration ($B = -2.02$, $p = .033$) is lower when prosocial behavior within the group is high but heterogeneously distributed. At the same time these groups show a clearer division of responsibility ($B = -2.86$, $p = .030$). Groups high in leadership skills (irrespective of the distribution of this skill) report more efficient collaboration ($B = .55$, $p = .008$) and a clearer division of responsibility ($B = .35$, $p = .090$).

Conclusions

The associations emerging on the individual and the group level were not identical which hints at the necessity of considering both. Groups in which most members show a high individual level of a specific social skill (i.e. exchange orientation, prosocial behavior, leadership) fare better than groups with low individual expressions of these skills. Detrimental to the group process seems to be an uneven distribution of a specific social skill combined with an overall high level of the skill within the group. Astonishingly not many effects on the individual level were related to satisfaction and quality of collaboration. This is evidence for the context-dependency of social skills (Rose-Krasnor, 1997), i.e. whether a specific social skill is beneficial for collaboration in project-based learning depends on the group one is placed in and on the social skills levels of one's group members.

PAPER PRESENTATION

Back and Forth between Reading and Writing: Experienced Teachers Study with Wiki

Yael Poyas, Oranim College of education, Israel

This research study examined three groups of teachers ($N=52$), studying literature in the Wiki environment, within the framework of an M.Ed. program at an academic college of education in Israel. The Wiki environment was chosen because it is interactive, hypertextual, collaborative, available hands-on, transparent to all those using it, and particularly appropriate in a textual environment. Learners' satisfaction with this method, their attitude to it, the speed of their writing, as well as the processes of the texts' formation were examined. The data were gathered by means of the Wiki features, and also derived from the participants' feedback and from the lecturer's ongoing notes in the field. The learners' satisfaction was generally on a high level, and the group's product was satisfactory; however, the students encountered difficulties that should be taken into account during the planning of Wiki-assisted teaching. The results reveal variance among the learners due to differences in their mother tongue and their cultural background; their willingness to accept the Wiki environment's characteristic features was influenced by their specific professional perspective, previous learning habits, and by the prevalent academic norms. The way the topics for writing were chosen affected the process by which the written texts were finalized.

The paper analyzes findings of a three-year research of Wiki-assisted teaching. The Wiki environment is interactive, cooperative and multimodal, enabling collaborative writing of texts among participants, as well as follow-up of the written product's development and each learner's contribution. The integration of Wiki environments and a 'Wiki pedagogy' (Ruth & Houghton, 2009) is rapidly gaining ground in institutions of higher education. When using ICT, two cultural factors, among others, must be taken into account: a) the learners' perceptions of teaching and learning (Alsunbul, 2001; Farabaugh, 2007; Wang & Beasley, 2008); b) academic norms regarding knowledge (Lyndsay, 2006; Wang & Beasley, 2008). The present study examined the impact of learners' characteristics on their readiness to accept Wiki pedagogy features, in three courses for teachers during three consecutive years.

The Study Participants:

The groups of teachers were taking M.Ed. literature courses in the years 2007-2009. Most of the learners in the three groups were women, reflecting the situation among teachers in Israel as a whole. The learners' age ranged from 26 to 63 years, while half of them were over 41 years old. groups200720082009Arabs972Jews101410Total192112 Apart from the national and linguistic variance, the teachers shared other characteristics such as experience in the field,

commitment to their workplace, a relatively advanced age, and the teaching of humanities and social studies. Description of the courses: The class work was mostly whole group discussions in Hebrew. The aims of Wiki integration were the following: a) to encourage a literary discussion with maximum participants; b) to increase collaboration among colleagues; c) to turn learners' interpretations into a subject of study in the course; d) to develop a motivating group project. The task: The task in the three courses was identical - to write an entry about a selected topic, connected to the literary work studied, relating it to entries written by colleagues, supplementing or expanding them. The tasks differed in the following preconditions: the way the topics were chosen – by the lecturer or by the learners; the levels of involvement in the processes of assessment – mere recommendation to assess colleagues' work or an explicit request to do so.

Research questions: 1. What patterns of the teachers' use of Wiki were exposed, in relation to their age, culture and mother tongue and task characteristics? The hypothesis was that the younger Hebrew speaking teachers would collaborate earlier than others. 2. Which attitudes did the teachers display to the writing and the study in the Wiki environment? The hypothesis was that the culture of teaching at their schools and in academia would influence the experience and the attitudes, as well as the level of difficulty the learners encountered. Data collection: The data were gathered from three sources: 1. Data provided by the Wiki environment. 2. Feedback by the participating teachers. 3. The lecturer's reflective diary. a) The Wiki environment provided information about the dates when the participants contributed to the editing of the entries and the 'discussion' pages. b) The entries were surveyed at three different points of time throughout the course, to examine the development of the writing, adherence to the subject of the entry and amount of information included, their organization and structure, and the number of links to their colleagues' pages and to other Internet pages. c) The 'discussion' pages were examined to ascertain a) the participants and b) the contents of the feedback. d) The written and oral feedback provided by learners throughout the course enabled an exploration of the learners' attitudes.

Findings and Discussion

Most learners expressed satisfaction with the activity in the Wiki environment (87%). Reasons mentioned: 1. The ongoing connection between the writing process and the lessons increased involvement during the course. 2. Exposure to colleagues' entries, provided food for thought. 3. Comments, written on the 'discussion' pages, helped and guided writing. Learners mentioned they were proud of contributing to knowledge beyond the limits of the specific course (60%). The preliminary apprehension at the Wiki transparency was replaced by a sense of sharing: you are not alone in the Wiki environment. Age and professional status: Unlike our hypothesis, teachers' age was not a decisive factor in their willingness to participate in the Wiki environment. It was affected more strongly by their perception of themselves as teachers with a social status and authority: They said it was not appropriate for them to reveal the process of their writing and partial work. Academic culture: The study confirmed our hypothesis that long-term academic habits of learning and teaching would affect participants' writing. Academic norms influenced their willingness to guide and criticize their colleagues' work. Evaluation was perceived as the lecturer's role. When required to react, the learners avoided criticizing their colleagues' entries on the 'discussion' pages. Most of the learners (80%) mentioned that they wished to preserve the exclusiveness of their entries and to prevent colleagues' intervention in their pages. Culture and language: Approximately half of the Arab learners postponed their activity in the Wiki environment and were in need of linguistic assistance in the editing of their entries. Some of them said they felt helpless when facing the multidirectional and unstructured task, which demanded interpretive daring - more so than their Jewish colleagues. Choice of topic: The way topics were chosen affected the pace and process of writing. When topics were learners' choice, learners began writing more rapidly and enthusiastically, but slowed down during the course, owing to new challenges arising in the group's discussions and in colleagues' entries. When topics were lecturer's choice the stage of entry took longer and the writing became more assiduous towards the end of the course. This affected the likelihood of exploiting the learners' entries during classroom discussions. The findings show that when teaching in the Wiki environment cultural, linguistic and professional components should be taken into account.

PAPER PRESENTATION

Global Learning Environments – Integrating Virtual and Actual Sites for Teaching

Ken Stevens, Memorial University, Canada; Barbara Craig, Victoria University, New Zealand

Teachers are increasingly likely to teach in the spaces between schools as well as within the institutions to which they are appointed. Moreover, teachers are interacting with learners beyond the confines of the traditional school day. Teachers in some parts of the world are providing instruction beyond traditional classrooms in networks of schools that are located beyond major centres of population. In other places they are collaborating in networks of schools in inner city urban communities. Small, geographically isolated and large inner city urban schools alike are finding new opportunities in a global networked society. Using new digital technologies (Web 2.0) in the delivery of teaching and learning creates possibilities for teachers today to network and collaborate beyond their institutional walls (Granic, C'ukusic & Walker, 2009; O'Brien, Varga-Atkins & Qualter, 2008). Research on rural and urban learning networks is based on the convergence of two conceptual frameworks: (i) open and closed schools and (ii) horizontal and vertical integration. The convergence of these two frameworks guides the transfer of knowledge and skills from teacher education designed for teaching in traditional, physical, classrooms to include virtual teaching and learning based on a matrix of conceptual, pedagogical, technological and organizational change (Stevens, 2007). A process of teacher education is outlined in which teachers are prepared for the integration of actual (or physical) classes with virtual learning environments as schools are networked. The implications for teaching and learning in a global networked society have institutional, policy, financial and pedagogical implications.

This research is based on the convergence of two conceptual frameworks: (i) open and closed schools and (ii) horizontal and vertical integration. The convergence of these two frameworks will guide the transfer of knowledge and skills from traditional teacher education, focused on single classrooms, to open learning environments that include both inter-institutional teaching and learning and local and global community engagement. The two frameworks will be interpreted within a matrix of conceptual, pedagogical, technological and organizational change (Stevens, 2007). Schools as we have known them are autonomous institutions with their own teachers, their own students and their own cultures. Schools in each community to a considerable extent duplicate what schools are doing in other communities with students being taught by teachers assigned to teach face to face to whole classes, small groups and, in some cases, individually. There is nothing remarkable about this model of the school and it is an accepted part of the global educational landscape. Perhaps the most remarkable feature of this model of the school is that it remains largely unchallenged. This will be considered to be a "closed" model of the school. The "open" model is based on schools academically and administratively integrating with one another and with other institutions for at least part of a school day. Information and communication technologies facilitate the linking of classes in schools to share teaching, learning and resources. New digital technologies encourage learners to take control of their own learning, connecting them to experts locally and globally and allowing participation in virtual spaces. The open model challenges the closed model of the school by questioning the need for appointing all teachers to schools, rather than, in appropriate cases, some teachers being appointed to networks of schools (Ertl & Plante 2004). It questions the appropriateness of learners engaging solely with their peers within their own, physical classrooms and, it questions the very notion of a school itself. The open model of the school is grounded in the application of information and communication technologies to teaching and learning and the construction and deconstruction of virtual classes. In the open model of the school teaching and learning takes place electronically between as well as in classrooms. In the open model teaching and learning involves collaboration and connections between students, between students and teachers, students and experts, and, more often than not, beyond the confines of their own classrooms, their own school and their own country. In the closed model, teaching takes place only in classrooms.

The electronic linking of schools across dispersed sites to create academically and administratively integrated educational structures that support traditional, on-site teaching and learning, can be conceptualized as "horizontal integration" (Stevens & Stewart, 2005). By extending this model at the local or community level through connecting digitally with selected homes, services, libraries and businesses, "vertical integration" can be achieved. By vertically integrating homes into sites (local schools) that are horizontally integrated into federated teaching and learning structures (school district intranets), intellectual and skill capacity building can be leveraged. This model challenges the traditional concept of the school that is open only certain hours of the day and certain weeks of the year.

There are implications of the shift from closed to open classes and in the horizontal and vertical integration of schools for global learning (Barab, et. al., 2001). Schools can be extended in terms of time, space, organization and capacity.

This will be demonstrated on the basis of New Zealand research in inner city urban environments (Craig & Coman, 2009) and from Canadian research in rural communities (Hawkes & Halverson, 2002; Stevens & Stewart, 2005). The New Zealand research considers the pedagogical advantages of aggregating 6 urban high schools into a learning network and connecting them to wider opportunities through a bridge onto the Kiwi Advanced Research and Education Network (KAREN).

There are implications for the professional education of teachers for schools that have the capacity to engage with global learning environments (Green & Hannon, 2007; Lai, 2005; Scardamalia & Bereiter, 2006). New Zealand and Canadian research identifies specific technology gaps, teacher preferences for training approaches as well as new ways of relating to learners, to learners' parents, to networks and to communities that have implications for teacher professional development. Five implications will be analyzed in concluding this paper and will, hopefully, generate discussion that will inform current and future research.

PAPER PRESENTATION

Overcoming the Unshared Knowledge Barrier by Fostering Awareness of the Partners' Meta-Knowledge

Tanja Engelman, Knowledge Media Research Center, Germany; Friedrich W. Hesse, Knowledge Media Research Center, Germany

The present experimental study focuses on two problems occurring in computer-supported collaborative learning situations: First, it has been empirically proven that groups mainly discuss shared information, that is, information that is already known to all group members, while unshared information, that is, information that is known to only one member, is often neglected. However, such unshared information could be task-relevant. Therefore, taking unshared information into consideration should be fostered. Second, Wegener's theory of transactive memory system points out that groups perform better when the group members are informed about their collaborators' knowledge. However, acquiring correct knowledge about what others know is difficult. An approach for solving these two problems is introduced which provides the group members with the collaborators' meta-knowledge structures and underlying information by means of digital concept maps. The study compares 20 triads with spatially distributed group members that had access to their collaborators' meta-knowledge maps with 20 triads collaborating without these maps. Results on overcoming the unshared knowledge barrier showed, as expected, that the triads being provided with such maps started sooner to discuss unshared information, applied more of their collaborators' unshared information, and processed unshared information more deeply. Results on fostering group performance, however, demonstrated in contrast to Wegener's theory that being informed about the collaborators' meta-knowledge is not sufficient to increase computer-supported collaborative problem-solving. These results are discussed with regard to the results of comparable prior studies that had provided the group members additionally with their collaborators' concrete task-relevant knowledge.

Collaboration over distance becomes increasingly important. However, computer-supported collaboration still causes a lot of problems. Beside all the problems occurring in group situations, the group members also have to deal with problems of computer-support. The present empirical study focuses on two problems: First, empirical studies (e.g., Stasser et al., 1995) demonstrated that groups mainly focus their discussion on shared information, that is, information that is already known to all group members, while unshared information, that is, information that is known to only one member, is often neglected. However, such unshared information could be task-relevant. Therefore, taking unshared information into consideration should be fostered. An effective approach for solving this communication bias is role allocation (e.g., Stasser et al., 2000): Each group member is allocated to a role and is explicitly informed about the collaborators' expertise. In the present study, a different approach was investigated that makes the collaborators' expertise salient by fostering awareness regarding the collaborators' meta-knowledge structures and underlying information. Second, not knowing what the others know causes collaboration problems (Engelmann & Hesse, 2010). According to Wegner (1986), a transactive memory system provides a group with information about where in the group, that is, in which individual memory, specific knowledge is stored. Via communication a group member has access to the collaborators' knowledge. Empirical results showed that an effective transactive memory system increases group performance (e.g., Liang et al. 1995). Although, it is important to know what the collaborators know, it is not easy to acquire such knowledge, especially for newly formed groups participating in a computer-supported collaboration. A proven approach for a solution to this problem is to provide the group members access to the representations of the collaborators' knowledge and its underlying information by means of digital concept maps (e.g., Engelmann & Hesse, 2010). However, to date, it is not clear whether this tool for fostering knowledge and information awareness is effective because it makes the collaborators' concrete task-relevant knowledge available or because it makes the collaborators' meta-knowledge available. According to Wegener's theory of transactive memory system, it should be sufficient to be informed about the others' meta-knowledge to increase the group performance. Therefore, in the present study, a tool for fostering awareness regarding the collaborators' meta-knowledge structures is investigated with respect to its effect on computer-supported collaborative problem-solving. In the present empirical study, 20 triads with spatially distributed members who had access to their collaborators' meta-knowledge and underlying information both represented in digital concept maps were compared with 20 triads collaborating without seeing their collaborators' maps. Participants were 120 university students from different fields of study. The gender composition in the triads between the conditions was constant and the acquaintance among the group members was controlled. The group members were required to rescue a fictitious kind of spruce forest. The information units were evenly distributed among the three group members. Each participant had access to several unshared information units and with one member or with both members shared information units. After an individual phase in which each group member was asked to become familiar with her/his own knowledge and information, both represented via a digital concept map, they were requested to collaborate to solve the problems. To do this they had to compile their knowledge and information by creating a group concept map. Only in this collaborative phase were they able to speak with each other by using Skype. In the control condition, the group members had access to both their own working window containing their own knowledge and information, as well as to their shared working window for creating the group map. In the experimental condition, the group members had additionally access to their collaborators' working windows containing their collaborators' meta-knowledge structure and underlying information. Results on overcoming the unshared knowledge barrier showed, as expected, that the triads having been provided with the collaborators' meta-knowledge maps started sooner to discuss unshared information, applied more of the collaborators' unshared information, that is, they included more often unshared information of their collaborators in the group map, and processed unshared information more deeply. In contrast to our hypotheses, being informed about the collaborators' meta-knowledge is not sufficient to foster computer-supported collaborative problem-solving. The conditions did not differ regarding the group performance, although the results of the group maps analyses indicate that the two conditions used different strategies while creating their maps. To sum up, having access to the collaborators' meta-knowledge structures fosters sharing of unshared information and leads to better processing and application of unshared information. In addition, it results in the use of a different strategy regarding group map creation. However, in contrast to Wegener's theory of transactive memory system, the results gave evidence that it is not sufficient to know who knows what in the group, that is, to be informed about the others' meta-knowledge in order to increase group performance in computer-supported collaborative problem-solving tasks. These results are discussed with regard to the results of prior studies that provide the group members additionally with their collaborators' concrete task-relevant knowledge. Further analyses and studies are planned for finding the reasons for why knowing the collaborators' meta-knowledge is not sufficient.

PAPER PRESENTATION

In quest of a framework for blending physical and virtual manipulatives in science experimentation

Georgios Olympiou, University of Cyprus, Cyprus; Zacharias Zacharia, University of Cyprus, Cyprus

In this study we aimed to investigate the effect of experimenting with Physical Manipulatives (PM), Virtual Manipulatives (VM), and a blended combination of PM and VM on undergraduate students' understanding of concepts in the domain of Light and Color. A pre-post comparison study design was used for the purposes of this study that involved 70 participants assigned to three conditions. The first condition consisted of 23 students that used PM, the second condition consisted of 23 students that used VM, and the third condition consisted of 24 students that used the blended combination of PM and VM. In the case of the blended combination, the use of VM or PM was selected based on whether it provides an advantage/affordance that the other medium of experimentation (PM or VM) cannot provide. All conditions used the same inquiry-oriented curriculum materials and procedures. Conceptual tests were administered to assess students' understanding before, during, and after teaching. Results revealed that the use of the blended combination of PM and VM enhanced students' conceptual understanding in the domain of Light and Color more than the use of PM or VM alone.

Aims Recent research studies have documented the need for the development of a framework that portrays how Physical Manipulatives (real world physical/concrete material and apparatus) and Virtual Manipulatives (virtual apparatus and material that exist in virtual environments, such as computer-based simulations) could be combined in order to enhance students' learning through science experimentation (Authors, 2010; Jaakkola et al., 2010). The purpose of this study was to contribute towards the development of such framework. Specifically, we set as our learning objective the improvement of students' conceptual understanding and proceeded with the development of a framework that blends PM and VM affordances/advantages according to the effect they have on students' conceptual understanding. In doing so, we identified through prior research the PM and VM affordances that were found to support students' conceptual understanding and created blended combinations of PM and VM for all of the study's experiments. The research question of this study was: Should the use of a blended combination of PM and VM be preferred over the use of PM or VM alone, when the enhancement of students' conceptual understanding through laboratory experimentation is at task?

Methodology

A pre-post comparison study design was used for the purposes of this study that involved 70 undergraduate students, who were enrolled in an introductory physics course that was based upon the Physics by Inquiry curriculum (McDermott et al., 1996). The participants were randomly separated into three conditions. The first condition was assigned 23 students to use PM, the second condition was assigned 24 students to use VM, and the third condition was assigned 24 students to use the blended combination. The students in all conditions were randomly assigned to three-member groups as suggested by the curriculum of the study. Blending PM and VM was based on each medium's unique advantages/affordances that were identified through prior research. In other words, PM or VM were selected whenever they had an affordance/advantage over the other medium for each one of the experiments involved in this study. The combination, as such, varied across the study's experiments according to the learning objectives that each experiment aimed to serve. The curriculum used in this study involved the 3 sections of the module of Light and Color of the Physics by Inquiry curriculum, namely, introduction to light and shadows, colors in painting and colored light. As far as the material/manipulatives used for conducting the experiments of the curriculum, the use of PM involved physical material, whereas, the use of VM involved the Virtual-Lab Optilab (see Figure 1; Hatzikraniotis et al., 2007). The duration of the study was 13 weeks. All conditions were facilitated in the same laboratory environment that hosts both conventional equipment and a computer network arranged at the periphery. Students met once a week for one and a half hour. The time-on-task was the same for all conditions. INSERT FIGURE 1 ABOUT HERE Previously validated conceptual tests were administered to assess students' conceptual understanding before, during and after the study (see Figure 2). All tests contained open-ended questions, which were scored and coded blind to the condition in which the student was placed. The reliability measures were above 0.93

across all tests. INSERT FIGURE 2 ABOUT HERE The data analysis involved both quantitative and qualitative methods. The quantitative analysis involved: (a) one-way ANOVA for the comparison of the pretest scores of the three conditions on each test, and (b) one-way ANCOVA for the comparison of the posttest scores of the three conditions on each test. The qualitative data analysis focused on identifying and classifying students' conceptions concerning light, shadows, colored paint and colored light. The analysis followed the procedures of open coding (Strauss & Corbin, 1996).

Findings and Discussion

The ANOVA procedure indicated that the three conditions did not differ in pretest scores across all of the study's tests. However, the ANCOVA procedure revealed differences among the study's three conditions. Bonferroni-adjusted pairwise comparisons suggested that students' posttest scores in the PM alone and VM alone conditions were significantly lower (pLight & Color concepts that were introduced through the curriculum material of this study, more than the PM or VM conditions did. The qualitative analysis confirmed the findings of the quantitative analysis. Specifically, the PM&VM condition was found to have, in all posttests, the highest prevalence for each scientifically-accepted conception and the least for each misconception. The fact that the use of a blended combination of VM and PM, which is grounded on a framework similar to the one developed in this study, appears to be more conducive to learning through laboratory experimentation than the use of PM and VM alone, challenges the already established norms concerning teaching and learning through experimentation in the science classroom. Specifically, it challenges the laboratory experimentation as we experienced it through PM or VM, in a way that calls for its redefinition and restructuring, in order to include blended combinations of VM and PM.

PAPER PRESENTATION

Chaining single versus dual format representation to improve mental model building from animation

Jean-Michel Boucheix, University of Dijon, LEAD-CNRS, France; Richard Lowe, School of Education, Curtin University, Australia; Dian Kemala Putri, University of Djakarta, Indonesia

The goal of the experiment presented in this paper was to test whether mental model building from animations could be improved by using external simplified representations of the dynamic process, such as static key frames are in effect 'small scale models'(Johnson-Laird, 1998). We chained similar or different pairs of representations to examine the effect of various couplings on learning from a complex animation of an upright piano mechanism. Across a presentation, the presence and temporal location of a series of static pictures showing the key step of the dynamic process and of the animation were manipulated. Four versions of the presentation with different representational couplings were compared across four groups in a learning task given to 82 participants. In each version, information was delivered in two learning stages. In the first version, a series of 6 Static pictures (St) depicting key steps of the mechanism were simultaneously presented during the learning stage 1 then followed by presentation of the Animation (An) during the learning stage 2: St+An. In the second version, the presentation order was reversed An+St. The two other versions were controlled modalities using a single format, respectively St+St and An+ An. Results of comprehension post-tests indicated significantly higher mental model scores the dual format versions than for the single format versions. The findings are discussed in terms of working models.

Building internal 'runnable' mental models (Mayer, 2005) that are of high quality from an external animation requires managing high levels of processing demands. Johnson-Laird (1998) argued that in order to be manipulable in working memory, mental models need to be "simplified representations" or "small-scale models" of the external world. The experiment presented in this paper examined whether the building of mental models from animations could be improved by chaining them with external simplified representations of the dynamic referent content. Previous studies have used simplified formats such as a series of static pictures or animation segments to depict the key steps of an

animation (e.g. Kriz & Hegarty, 2007; Arguel & Jamet, 2008; Rebetz, & al., 2009; Béétrancourt & Morand, 2010). However, in most studies, key steps were presented alone (with text), or at the same time as the animation. Results were not consistent, showing no or slight comprehension differences between the tested versions. In this study, we used an alternative approach to test the effect of the presentation of simplified external representations, on learning from a complex animation. We manipulated the presence and the temporal location of (i) a series of static pictures and (ii) the corresponding animation. A complex animation of an upright piano mechanism was used without text (Figure 1). Four pairings of presentations were compared. In each presentation, the information was delivered in two learning stages. In the first version, a series of 6 Static pictures (St) depicting key steps of the mechanism were simultaneously presented during the learning stage 1 then followed by presentation of the Animation (An) during the learning stage 2: St+An. In the second version, the presentation order was reversed An+St. The two other versions were controlled modalities using a single format, respectively St+St and An+ An. Higher quality mental models were predicted in the St+An, and to a less extent in the An+St condition, than in the single format conditions. In the St+An condition, we expected that in the first learning stage, learners would build a mental model of the mechanism operation by making inferences between the static key steps via active comparison and mental manipulation of the various pictures in the series. In the second learning stage, learners would use the presented animation to check this mental model. Feedback from the animation would allow them to adjust their representation previously built in stage one. In the An+St condition, learners could apply a first model built in the learning stage one to perform inferences between the static pictures in learning stage two. In the single format conditions, there are no such opportunities to 'test' the first-stage mental model against an alternative representation.

Method

After testing for spatial abilities and prior knowledge, the 82 participants (undergraduate students) were randomly assigned to four groups (two dual-format and two single-format conditions). The material was composed of a series of static pictures and an animation of the upright piano mechanism. During the learning period, each participant studied how the piano mechanism worked from the depictions provided. Total learning time was fixed at 3'30", with 1'45" for each stage (An or St) of the learning session. A cross movement post-test was a direct measure of the recall of the local motion of each component. On a single picture of the upright piano, learners moved crosses on the screen using the computer mouse to show the direction and amplitude of each piano component's movement. The second post test was a comprehension measure of the quality of the mental model of the piano operation. Participant had to write a precise explanation of 'what happens for each component of the piano when a pianist presses the key and then releases it'. Results Figure 2 shows the performance (% of correct answers) for each post-test. test and mental model quality test, for each type of presentation. A repeated measures ANOVA showed mainly a significant interaction between the type of presentation and the two post-tests, $F(3,78) = 6.52$, p Univariate analysis showed a significant effect of the type of presentation for the mental model score, $F(3,74) = 4.44$, $p = .006$, Eta square = .15. Scores for St+An and An+St were higher than scores for St+St and An+An, $F(1,74) = 10.01$, $p = .002$. Univariate analysis for the local motion score showed no effect of the type of presentation, $F(3,74) = 0.85$, $p = .046$, Eta square = .03.

Discussion and future work In learning from animation, the use of manageable representation of the dynamic process improves mental model building quality. We showed that dual external format presented sequentially were more efficient than single format. "Small-scale models" such as static key frames, should not be used as substitutes instead of animations, but as "working models" to learn more from animations. In future work, eye tracking recording will be used in order to investigate how learners "work-with" dual versus single formats.

PAPER PRESENTATION

Emotional effects in multimedia learning

Steffi Heidig (Domagk), University of Erfurt, Germany; Jan L. Plass, New York University, United States; Eunjoon Rachel Um, The New York Times, United States; Helmut M. Niegemann, University of Erfurt, Germany

In contrast to cognitive factors, emotional variables are rarely discussed in multimedia learning research. However, emotions can affect cognitive processing and are assumed to affect learning mediated through motivation, learning strategy use and the use of cognitive resources (e.g., Pekrun, 1992). Based on a study by Um, Song, and Plass (2007), we examined the effects of positive emotions on learning. Additionally, we investigated motivational and cognitive factors mediating the effect of emotions on learning. As Um et al. (2007) further showed that an appealing design of a multimedia learning material may induce positive emotions in learners, we applied a 2x2-design, using both a mood induction procedure and the design of the learning material as methods to manipulate the learners' emotions. The results indicate that an appealing design was able to induce positive emotions and facilitate comprehension. In contrast to Um et al.'s (2007 study, transfer performance has not been affected by positive emotions or design. A further analysis on the mediating motivational and cognitive factors aims at providing insight on the effects of emotions on learning.

Theoretical framework

Research on multimedia learning so far has mainly focused on cognitive factors, especially on balancing the amount of cognitive load induced by the design of the learning environment (e.g., Mayer, 2009; Plass, Moreno, & Brýnken, 2010). Emotional factors however, have so far largely been neglected, although they have been shown to affect cognitive processing and problem solving (e.g., Bless, 2001; Isen et al., 1984). The cognitive-motivational model (Pekrun, 1992) further predicts learning effects of emotions that are mediated by cognitive and motivational mechanisms such as intrinsic motivation, learning strategy use and the use of cognitive resources. In the context of multimedia learning, Um, Song, and Plass (2007) showed that positive emotions during learning facilitated intrinsic motivation as well as comprehension and transfer performance. Their results further indicate that an aesthetically more appealing design may induce positive emotions compared to a less appealing one. In the present research aimed to replicate and extend that study we explore the effect of an aesthetically appealing design on learners' emotions, and the effect of emotions on motivation and learning. In accordance with the cognitive-motivational model on the effects of emotions (Pekrun, 1992), we further introduced learning strategy use and task-irrelevant thinking as dependent variables as there are assumed to mediate the effects of emotions on learning. Methodology Design

A 2x2 factorial design was applied, manipulating the participants' emotions externally to the learning task by presenting short films in the beginning of the study (positive vs. neutral) or internally by varying the design of the learning material (positive vs. neutral). The neutral learning material was designed in a black and white layout, whereas the positive learning material featured warm colors and baby face cues.

INSERT_TABLE_1 Data Sources

The participants were 121 college students (85.3% female). The mean age was 21.98 years (SD=2.13). The participants were randomly assigned to the 4 treatment groups: positive emotions/positive design (PEPD, n=31), positive emotions/neutral design (PEND, n=30), neutral emotions/positive design (NEPD, n=30), neutral emotions/neutral design (NEND=control, n=30).

Materials

A multimedia learning environment on immunization served as learning material (positive or neutral design; Um et al., 2007). Online questionnaires included the Positive Affect Schedule (PAS) from the Positive and Negative Affect Schedule (PANAS) to assess the participant's emotional state, a 7-item-scale to assess intrinsic motivation, 23 items for learning strategy use, 15 items on task-irrelevant thinking as well as a learning test including comprehension and transfer tasks.

Procedure

After a short instruction, the participants were presented either the positive or the neutral film in order to externally induce emotions and answered the PAS. This was followed by the learning period (positive or neutral design). The participants then answered the PAS for the second time, the intrinsic motivation-, learning-strategy- and task-irrelevant-thinking-scale and the learning test. Results Manipulation Check

A ONEWAY ANOVA revealed a main effect for the external emotion induction on the PAS, $F(1, 119)=13.60$, $p\&\eta^2=.10$. Participants who were presented the positive film reported more positive emotions than subjects who watched the neutral film.

INSERT_TABLE_2 Does an aesthetic design of a multimedia learning material induce positive emotions?

ANOVAs for repeated measures on the PAS scores (after film, after learning) of each experimental group showed that

- externally induced emotions decreased over time (PEND-group: $F(1, 29)=26.57$, $p\&\eta^2=.48$),
- an aesthetic/positive design helped to maintain positive emotions (PEPD-group: $F(1, 30)=2.08$, $p=.16$),

- positive emotions were induced by the aesthetic design of the learning material (NEPD-group: $F(1, 29)=5.57$, $p=.03$, $\eta^2=.16$),
- the control group remained at a neutral emotional level ($F(1, 29)=.21$, $p=.65$).

Therefore, an aesthetically appealing design seems to facilitate positive emotions during learning. Do positive emotions facilitate learning outcomes?

A two-factor ANOVA revealed no main effect for positive emotions on comprehension, $F(1, 117)=.91$, $p=.34$. However, it showed a main effect for design on comprehension, $F(1, 117)=7.00$, $p=.01$, $\eta^2=.06$. Learners that were presented an aesthetically appealing learning material performed better on comprehension tasks than learners that were presented with a neutral design. Further, a second two-factor ANOVA indicated neither a main effect for positive emotions on transfer, $F(1, 117)=3.65$, $p=.06$, nor a main effect for design on transfer, $F(1, 117)=.02$, $p=.85$. Hence, the four groups did not differ in their transfer performance. Do cognitive and motivational factors mediate the effect of emotions on learning?

Preliminary correlational analyses showed relations between the learner's emotions and motivation, learning strategies as well as task-irrelevant thinking. Further, multiple regression models indicated an effect of these variables on comprehension and transfer. We did not provide any numbers yet, as we are going to analyze these relationships using structural equation modeling and present the results.

Discussion

In sum, the results of the study indicate that the presentation of an aesthetically appealing learning material may induce positive emotions and facilitate comprehension. A facilitating effect of positive emotions and design on transfer as reported by Um et al. (2007) could not be fully replicated in the presented study. Both studies however, show first evidence that emotional factors may play a decisive role in multimedia learning and should therefore been taken into account when designing multimedia learning materials. Further, SEM-analyses are going to provide insight in mediating factors between emotions and learning. More research is needed to examine the role of emotions in complex learning processes, and appropriate aesthetic design factors for an emotional multimedia design.

PAPER PRESENTATION

Effects of Gaps in Worked Examples on Motivation and Complex Skill Acquisition in Medical Education

Lena Hofmann, University of Munich, Germany; Karsten Stegmann, Universität Landau, Germany; Matthias Siebeck, University of Munich, Germany; Frank Fischer, Universität München, Germany

An important competence of medical doctors is the communication with patients, especially in breaking bad news (BBN) situations. Protocols like SPIKES (Baile et al., 2000) provide steps how to appropriately communicate BBN situations. According to common competence definitions, it is not sufficient to have knowledge on the SPIKES. In addition, the application of knowledge (including the underlying motivation) is necessary as well. Worked-out examples have been broadly applied to support acquisition of applicable knowledge and learners are usually highly motivated to learn with worked-out examples. Research has shown that especially self-explanations during learning with worked-out examples are related with learning. Self-explanations have been successfully triggered by adding gaps into the worked-out example and ask learners to anticipate the next steps. Videos can be used as worked-out examples especially when no predetermined solution is available. In our study 159 medical students learned the complex skill of delivering a cancer diagnosis which is linked to coping with negative emotions. We examined the effect the completeness of video-based worked-out examples (complete vs. with gaps) on knowledge acquisition, motivation and complex skill acquisition regarding BBN. We found a positive effect of the video-based worked-out example in general on motivation but not on knowledge acquisition. Furthermore, students that worked with

incomplete worked-out examples (with gaps) were significantly better in the complex skill of BBN than those who worked with complete worked-out examples.

An important competence of medical doctors is to adequately communicate with patients, especially in breaking bad news (BBN) situations. Protocols like SPIKES (Baile et al., 2000) provide steps how to communicate BBN situations. According to competence definitions it would not be sufficient to have knowledge on the SPIKES. In addition, the application of knowledge (including the underlying motivation) is necessary as well. However, situations like BBN are connected with negative emotions that may reduce the motivation to perform the learned skill. Medical doctors who feel high anxiety or shame regarding BBN may rather try to be quick and superficial instead of prudent. Worked-out examples have been broadly applied to support acquisition of applicable knowledge and learners are usually highly motivated to learn with worked-out examples. They can serve as expert models and are especially helpful to enhance problem solving skill when combined with self-explanations (Crippen & Earl, 2007). Self-explanations can be implemented in gaps within incomplete worked-out examples and have shown to support the quality of self-explanations for near and medium transfer (Stark, Mandl, Gruber, & Renkl, 1999). There is an immense body of evidence that worked-out examples enhance knowledge acquisition and self-efficacy under certain conditions (Renkl, 1997). Videos can be used as worked-out examples especially when no predetermined solution is available because diversity is demonstrated with complex content in context (cf. McLaren et al., 2006). However, whether worked-out examples affect the acquisition of complex communication skill and whether motivation to apply the knowledge is positively affected is rarely examined yet.

Research question

To what extent does the completeness of video-based worked-out examples (complete vs. with gaps) affect knowledge, complex skill and motivation in the context of medical education?

Method

In a one-factorial pre-post design we implemented a video-based worked-out example and varied the completeness (complete vs. with gaps). 159 medical students at the LMU Munich were randomly assigned to one of the two conditions. The learning session on BBN is a mandatory module of the Medical Curriculum Munich (MeCuM). Learners were asked to read a 2000 words summary on the SPIKES (15 minutes).

Learning material and task. 30 minutes were given for the video-based worked-out example that lasts 11 minutes. This video showed a simulated BBN situation where a medical student in the role of the doctor delivers a cancer diagnosis to a patient. It was segmented into 11 episodes. For each episode, learners could open an analysis of the doctor's acting according to the SPIKES and suggestions how to do better.

Independent variables. In the incomplete condition, four episodes were stopped before the doctor took action. Learners were asked to write down how they would proceed. After they had submitted their solution, learners were asked to compare their procedure with the solution suggested by the expert.

Dependent variables. BBN-related motivation was measured before and after the worked-out example using four items with a 5-point Likert scale with sufficiently high reliability. Knowledge regarding BBN was measured before and after the worked-out example with a video-based test. In this test, the learners watched three video-based examples without instructional explanations from two different simulated BBN cases. Learners were asked to describe how they would act after each episode. The answers were coded with a coding scheme based on SPIKES with the amount of steps listed according to the SPIKES as the indicator for knowledge on this procedure. To exclude effects of the different BBN cases we z-standardised the scores separately and included the order as a random factor in the statistical analysis. The BBN skill was measured on the following day. Each student was allocated a 10 minutes time slot to deliver a cancer diagnosis in a realistic scenario to simulated patient (SP). Deliveries took place in individual sessions and were videotaped. After 10 minutes the students got feedback from the SP (10 minutes). The quality of BBN conversations was coded with a coding scheme based on the SPIKES. Inter-rater reliability was sufficiently high. The amount of steps listed according to the SPIKES served as measure for the complex skill regarding BBN.

Results

We found a general positive effect of the video-based worked-out example on BBN-related motivation. No effects of the completeness of the worked-out examples were found. With respect to knowledge acquisition we did neither find an effect of the worked-out example nor an interaction effect with completeness. The completeness had a positive effect on complex skill acquisition with respect to BBN. Learners who learned with gaps in their worked-out examples showed a significantly higher skill during the BBN simulation in the transfer scenario with the SP.

Discussion

Our results provide evidence that video-based worked-out examples can foster complex skills regarding communication in the context of medical education. While the knowledge seems to be acquired just by reading the text on SPIKES, the worked-out examples facilitated the motivation and skill regarding BBN. The gaps increased this effect regarding the skill, which might be due to the usage of self-explanations. Finally, incomplete video-based worked-out examples seem to be a good preparation for simulation-based learning with SP.

PAPER PRESENTATION

Interactivity in multimedia learning: Using the INTERACT model to structure and inform research

Jan L. Plass, New York University, United States; Steffi Heidig (Domagk), University of Erfurt, Germany; Ruth N. Schwartz, New York University, United States

Since the introduction of computers as tools for learning, interactivity has been much discussed as holding strong promise for educational use (e.g., Hannafin & Peck, 1988; Bransford et al., 1999; Renkl & Atkinson, 2007). But does interactivity in fact improve the quality and effectiveness of learning environments? Empirical investigations to date have yielded mixed results (e.g., Moreno & Mayer, 2005; Moreno & Valdez, 2005; Schwan & Riempp, 2004). Two critical factors seem to have played a part in producing these inconsistencies. First, definitions and theoretical treatments of interactivity have not been consistent (e.g., Betrancourt, 2005; Kennedy, 2004; Sims, 1997; Moreno & Mayer 2007). Similarly, approaches to operationalizing this construct in research have varied widely (e.g., Moreno & Mayer, 2005; Schwan & Riempp, 2004). In response, we propose a standardized definition as well as a process approach for operationalizing interactivity. The Integrated Model of Multimedia Interactivity (INTERACT) describes a system of six interdependent components of interactivity (Domagk, Schwartz, & Plass, 2010). The relationships and feedback among these components comprise interactivity. Because the components can be individually considered and systematically varied, the application of INTERACT as a model for investigating interactivity can facilitate more rigorous empirical investigations, comparisons between studies, and the derivation of broad principles for the design of interactive learning environments. Additionally, constructs such as learner control, guidance, and feedback, commonly discussed with regard to interactivity, can be reconsidered using the INTERACT model.

Since the introduction of computers as tools for learning, interactivity has been much discussed as holding strong promise for educational use (e.g., Hannafin & Peck, 1988; Bransford et al., 1999; Renkl & Atkinson, 2007). But does interactivity in fact improve the effectiveness of learning environments? Empirical investigations to date have yielded mixed results (e.g., Moreno & Mayer, 2005; Moreno & Valdez, 2005; Schwan & Riempp, 2004). Two critical factors seem to contribute to these inconsistencies. First, definitions and theoretical treatments of interactivity have not been consistent (e.g., Kennedy, 2004; Sims, 1997; Moreno & Mayer 2007). Similarly, approaches to operationalizing this construct in research have varied widely (e.g., Moreno & Mayer, 2005; Moreno & Valdez, 2005; Schwan & Riempp, 2004). In response, we propose a standardized definition as well as an approach for operationalizing interactivity. The Integrated Model of Multimedia Interactivity (INTERACT) describes a system of six interdependent components of interactivity (Domagk, Schwartz, & Plass, 2010). The relationships and feedback among these components comprise interactivity. Because the components can be individually considered and systematically varied, the application of INTERACT as a model for investigating interactivity can facilitate more rigorous empirical investigations, comparisons between studies, and the derivation of broad principles for the design of interactive learning environments. Defining Interactivity

Formal definitions, although varying widely (e.g., Kennedy, 2004; Moreno & Mayer, 2007), agree that interactivity requires two fundamental conditions: (a) at least two participants, and (b) reciprocity. Accordingly, we define interactivity in multimedia learning as follows:

Interactivity in the context of computer-based multimedia learning is reciprocal activity between a learner and a multimedia learning system, in which the [re]action of the learner is dependent upon the [re]action of the system and vice versa.

This emphasizes the dynamic relationship between the learner and the learning system, acknowledging that a multimedia learning environment per se cannot be interactive, but can only include features with the potential to engage the learner (Kennedy, 2004).

Operationalizing Interactivity

Beyond definition, the concept of interactivity must be operationalized to support systematic investigations. Previous attempts at classification have focused on systems and affordances (Sims, 1997, Schwier & Misanchuk, 1993). Some recent approaches, though considering the learner, continue to emphasize the medium rather than cognitive processes evoked (Moreno & Mayer, 2007; Kalyuga, 2007). Although Kennedy's learner-focused model of interactivity (2004) stresses both behavioral and cognitive activities, it is not far-reaching enough. Neither individual differences of the learner nor affective aspects are considered, and the mental model is viewed as an end product only, rather than as part of the continuous feedback loop. The INTERACT model takes a systemic approach, including both the learner and the learning environment, focusing on interactivity as a process, and introducing the critical components of affect and individual differences, which have not previously been integrated into discussion of interactivity. Additionally, INTERACT views the mental model as part of an integrated feedback process: Knowledge structures result in, but also lead to, changes in behavior, cognition, and emotion.

The INTERACT-Model

The Integrated Model of Multimedia Interactivity (INTERACT) includes six principal components which together make up an integrated system: the learning environment, behavioral activities, cognitive/metacognitive activities, motivation and emotion, learner variables, and the learner's mental model. The interactivity process is represented by the feedback loops connecting these components. Each of these components is theoretically based and will be discussed in more depth during the presentation.

Insert Figure 1

Applying INTERACT

The INTERACT model is both theoretically and practically significant. Together, the elements of the INTERACT model and the relationships among them represent the complex and dynamic interplay between a multimedia learning system and a learner. The identification of these six specific components, and the feedback loops that describe the flow of the interactive process, introduces into the construct of interactivity the conceptual clarity needed to interpret and compare previous findings as well as to guide future research on interactive learning environments. For example, the most commonly discussed types of interactivity—learner control, guidance, and feedback—can be understood and illuminated using the INTERACT model. Finally, on a practical level, INTERACT can provide educators and educational designers with a process approach that allows them to design and evaluate effective interactive components for multimedia instruction.

PAPER PRESENTATION

Knowledge and Clinical Decision Making by Novice, Intermediate and Experienced Midw

Jill Scevak, University of Newcastle, Australia; Nerida Ambler, University of Newcastle, Australia

Quality of Prior Knowledge and Clinical Decision Making by Novice, Intermediate and Experienced Midwives This study reports an investigation of knowledge growth and structure in novice and intermediate student and experienced midwives. Fifteen student midwives were asked to reflect on their first and last (20th) birth and twelve experienced midwives were asked to reflect on their last birth. All verbal protocols were coded for type of knowledge recalled based on a coding scheme developed for the study. The theoretical basis of the coding scheme was derived from the research literature that the development of expertise is strongly linked with the growth of sophisticated knowledge structures. Non-parametric statistical tests (Wilcoxon Signed Ranks & Mann-Whitney) were used to examine the group differences across the coding categories. The SOLO Taxonomy (structure of the learning outcome) was used to examine group differences in the structure of knowledge. Results indicated that the experienced midwives were more likely to have a more sophisticated structured knowledge base. The results suggest an important role for prior knowledge and its structure in explaining the differences between the groups in the quality of their clinical decision making, implications for nurse education and professional development are discussed.

Midwives are faced with potential clinical problems in every delivery they attend and their ability to deal with these problems in a competent way is important for safe and effective midwifery practice. The major aim of nurse educators and university nursing schools is to develop midwives with good clinical problem solving abilities. The study of clinical problem solving used by nurses, medical doctors and students has attracted much attention in the research literature and the focus of these research studies has been on the differences between expert and novice problem solvers (Boshuizen & Schmidt, 1992). To account for these differences factors such as clinical experience (Norman, Trott, Brooks & Smith, 1994; Tabak, Bar-Tal & Cohen-Mansfield, 1996), structure and use of knowledge for problem solving (e.g. Patel & Kaufman, 2000; Hassebrock & Prietula, 1992; Boshuizen & Schmidt, 1993) and reasoning processes used in processing clinical data for diagnosis (e.g. Leprohon & Patel, 1995; Patel, Groen & Arocha, 1990) have been examined. A major theme arising from this literature is the importance of the structure and use of knowledge for problem solving. Differences in the quality of knowledge structures amongst expert and novices accounted for the differences in the quality of their decision making (Freeman, 2003; Simpson & Know, 2003; Fox-Young, 2002; Danerek & Dykes, 2001). The relationship between the quality of knowledge structures and quality of decision making has been demonstrated in number of studies (e.g. Rikers, Schmidt & Boshuizen, 2002; Gilhooly, 1996; Bordage, 1994; Grant & Marsden, 1987). For example Boshuizen and Schmidt (1992, 1993) used the verbal protocol method and were able to discriminate between the quality of knowledge structure used by medical doctors at varying levels of expertise in their diagnosis. They found that recall of case relevant information was found to be non-linear, with both experts and novices recalling less information than intermediates. Experts reasoning was based on higher-order propositions or 'encapsulated clinical knowledge' whereas novices and intermediates reasoning was based on data acquisition and elaboration. Rikers, Schmidt & Boshuizen (2002) found that experts process clinical cases almost entirely in an encapsulated mode. While the research literature would suggest that the quality of prior knowledge distinguishes experts from novices in the quality of problem solving little of this research has been extended to the practice of midwifery. The aim of this study is to examine the acquisition of midwifery competence and associated knowledge, skills and attitude by midwives in the practice of midwifery through analysis of the development and application of prior knowledge in clinical decision making by student and experienced midwives while performing a normal vaginal delivery. The study used a mixed methods research design first; a verbal protocol method was used to gather data about the prior knowledge used by midwives in their decision making during a normal vaginal delivery. Transcribed verbal protocols were then coded for the type and quality of knowledge using a coding scheme developed for the study. Coded protocols were subjected to a frequency counted and non-parametric tests (Wilcoxon Signed Ranks Test & Mann-Whitney Test) were used to examine group differences across the coding categories. Fifteen student and twelve experienced midwives were asked to reflect on their actions and decision-making processes in a normal vaginal delivery they had recently performed through structured interviews (the sequence of questions followed the chronology of the birth process). Student midwives were interviewed twice, after their first and last (20th) normal vaginal delivery assessment. Student midwives were classed as novices at the beginning of their training and as

intermediate at the end of their training. Intra-subject performance was examined to analyse the changes in use of prior knowledge and decision-making processes associated with the development of midwifery competence. Protocol analysis was used to identify the differences in the use of relevant knowledge, its structure and clinical decision making processes between student and experienced midwives were also analysed. The results of the study found that differences in the quality of prior knowledge and the structure of knowledge used in decision making distinguished between novices, intermediates and experts. In addition, a change in the quality of prior knowledge and structure of knowledge used in decision was evident in the transition from novice to intermediate. These findings have important implications for the training of midwives and for the professional development of midwives. To improve clinical decision making in midwives the aim of the curriculum should encourage the development of a well-structured knowledge base in the context of midwifery through the process of critical reflection.

PAPER PRESENTATION

Academia as Multiple Workplaces: Re-location, Re-location, Re-location

Lynn McAlpine, University of Oxford, United Kingdom

Increasingly PhD graduates who imagine traditional academic positions are unable to find such jobs; they end up in fixed-term appointments as post-doctoral fellows or researchers on others' grants. Few studies document their experiences and most that do draw on data from the late 1990s and early 2000s. This longitudinal study reports on the experiences of a small number of social science researchers in two universities in the UK during 2008-2010. A biographical identity-trajectory perspective results in a rich portrayal of work-life intersections and the role of re-locations as integral, yet disruptive, to their academic work.

Purpose

This paper examines longitudinally the workplace experiences of social sciences post-docs and researchers hired on other's grants. It raises questions about the long-term impact of the increasing fragmentation of academic work. Perspectives Like others examining academic experience (Colbeck, 2008), this study uses an identity perspective. Identity-trajectory (McAlpine et al, in press) incorporates a biographical view of identity: personally distinct past experiences influence present intentions and engagement in academic work as well as future imagined possibilities. Essential to this view is the interweaving of personal values, intentions and responsibilities in how work is approached and experienced. Further, by exercising ongoing agency (Archer, 2000) despite social and physical constraints (Billett, 2009), individuals have some ability to decide which aspects of the practices they encounter they will engage in. Yet unexpected constraints (as well as serendipity) may lead elsewhere.

Methods

The approach draws on a long tradition in research on teaching, that of narrative inquiry (Clandinin & Connelly, 1990). Essential to this approach were participant narratives describing how they constituted their identities (Sfard & Prusak, 2005) at different points in time. These participant narratives could then form the basis for researcher-constructed narratives that amongst other things: made connections between events; represented the passage of time; and showed the intentions of individuals (Coulter & Smith, 2009). Data sources and analysis Six social science researchers in two UK universities completed demographic updates several times over a year, recorded in logs a weeks' activity once a month for several months, and were interviewed approximately one year after data collection began. In the following year, a similar cycle was repeated. Researcher-generated case narratives were constructed through successive re-reading of each participant's multiple accounts; these case narratives preserved the unique features constituting each identity-trajectory through time. Then, these case narratives were re-read seeking emergent themes, with reference as appropriate to the original participant accounts.

Results

While intellectual passion and work-life intersections emerged as themes, what is highlighted here are multiple forms of relocation. These relocations, often involving the intersection of the workplace and the personal, resulted from appointments that were of relatively short duration (1-1.5 years). Relocations represented shifts that could be social, geographical, linguistic, cultural or intellectual. A particular disruption was the intellectual relocation that often occurred as individuals moved into new appointments. Participants were often doing research in a new field, perhaps with little connection to their own interests. These relocations disrupted the development of their identity-trajectories, particularly their sense of their own expertise and ability to contribute.

Significance

Increasingly, social sciences PhD graduates cannot expect to find a traditional academic job immediately post-graduation (UK CGE, 2009) in fact, may wait five years (Nerad et al, 2006). Concurrently, the number of social science

researchers in the UK and the US is growing (UK CGE, 2009; Horta, 2008). The emergence of the theme of relocation in this study reinforces Krause's (2009) assertion of the increasing fragmentation of academic work and leads to questions as to the long-term implications on knowledge construction of fixed-term academic work.

PAPER PRESENTATION

Pedagogical horizons for action in supporting students' future orientation in higher education

Terhi Skaniakos, University of Jyväskylä, Finland; Leena Penttinen, University of Jyväskylä, Finland; Marjatta Lairio, University of Jyväskylä, Finland

The topic concerns the development of career guidance practices within higher education. We are introducing an idea of pedagogical horizons for action. The aim is to provide a pedagogic model, which is useful in understanding the students need and future oriented career questions, and educational contexts, in which the guidance is provided to support the students knowledge, awareness and competence of work life. The aim of the model it to map out the possibilities of creating and enhancing students' and teachers' perspectives of work orientation, by which we refer to three specific aspects: personal relation to work life (awareness, attitude), professional skills (both generic and specific), and employment skills. The model is based on theoretical scrutiny of the "future orientation" presented by Savickas (2005) and "horizons for action" by Hodgkinson and Sparkes (1997), and combined with the pedagogical understanding of teaching and guidance in higher education context. From the perspective of university students, there are several kinds of contexts in which the career questions are made. These constitute individual horizons for action. In addition to the individual dimension it has been our aim to add a pedagogic perspective to the model. It provides with a broader educational context to the same phenomenon. The students' future questions and the possibilities of work life orientation are presented in relation to different educational contexts and activities. In addition to presenting the model, we will discuss its applications and make suggestions for the development of guidance and pedagogical practices in higher education.

The topic of this paper concerns the development of career guidance practices within higher education, especially from the perspective of work life. We are introducing an idea of pedagogical horizons for action. The aim is to provide a pedagogic model, which is useful in understanding both, the students' needs and future oriented career questions, as well as the educational contexts, in which the guidance is provided to support the students knowledge, awareness and competence of work life. The model enables to map out the possibilities of creating and enhancing students' and teachers' perspectives of work life orientation, by which we refer to the understanding of the career and work life contexts in general. Furthermore, we have theoretically classified the concept into three specific categorisations: 1) personal relation to work life (awareness, attitude), 2) professional skills (generic and specific), and 3) employment skills (knowledge of labour market, job seeking skills etc.). The model of pedagogical horizons for action is based on theoretical scrutiny of the "future orientation" presented by Savickas (2005) and "horizons for action" by Hodgkinson

and Sparkes (1997), combined with the pedagogical understanding of teaching and guidance in higher education context. Students' future orientation is approached from a holistic life design perspective (Savickas & al. 2009). This draws attention to the particular career concerns which individuals are impelled to ask themselves. According to Savickas (2005), positive answers to these questions can reinforce students' ability for career construction. From the perspective of university students, there are several kinds of contexts in which the career questions are made. These constitute individual horizons for action (Hodkinson and Sparkes 1997). Both, personal habitus and the opportunity structures of the labour market influence to these actions. From the individual perspective, the horizons for action can both limit and enable our understanding of the possibilities of career choices we can make. The work of Savickas and his colleagues (2009) also brings life-long, holistic, contextual and preventive dimensions to the development of the model. In addition to the individual dimension it has been our aim to add a pedagogic perspective to the model. It provides with a broader educational context to the same phenomenon. The students' future questions and the possibilities of work life orientation are presented in relation to different contexts, including teaching and supervision, tutoring, career guidance, peer support, mentoring, internships, student exchange, work experience and leisure time activities. These contexts can be seen as spaces which can enhance students' work life orientation, and in which the students interact with the teachers and other staff members, as well as peer students, and gain learning experiences. Thus the understanding of the constitution of pedagogical horizons of action is crucial in development of both, pedagogics and guidance in higher education. The model of pedagogical horizon for action in supporting students' work life orientation in higher education is introduced in the basis of the above presented theoretical framework. In addition to the actual model, we will discuss its applications and make suggestions for the development of guidance and pedagogical practices in higher education.

PAPER PRESENTATION

Learning Of Medical Expertise: Development Of Conceptual Comprehension And Clinical Reasoning Skills

Mirjamaija Mikkilä-Erdmann, University of Turku, Finland; Ilona Ahopelto, University of Turku, Finland; Henna Vilppu, University of Turku, Finland; Mari Murtonen, University of Turku, Finland; Erkki Olkinuora, University of Turku, Finland; Pekka Kaapa, University of Turku, Finland

The purpose of this study was to investigate, how medical students develop their comprehension and reasoning skills concerning the central cardiovascular system. Medical teaching aims to educate physicians who are capable of linking theoretical medical knowledge to practical clinical skills. This requires both deep biomedical understanding and knowledge how apply it in clinical contexts. Hence, the research questions in this study were: 1. what kind of conceptions concerning cardiovascular system do students have during their first and second study year? 2. How do these conceptions change? 3. How is the level of biomedical understanding related to the clinical reasoning skills? The participants of this study were 119 medical students. A pretest-posttest -design was used. Students were investigated during their first and second study year. Our results indicate that the quality of preconceptions concerning cardiovascular system among first and second year medical and dental students varies a lot. Most of the students had relevant understanding, but also a substantial number of misconceptions, such as "serial loops" were diagnosed also after the instruction. The level of biomedical understanding seems also to be connected to the success in clinical reasoning. Students who had improved their biomedical understanding the most reached the highest scores in the clinical reasoning task and vice versa. Our study will enhance theoretical understanding of the longitudinal development of medical comprehension.

PAPER PRESENTATION

Promoting self-regulated learning strategies by web-based journals in medical studies

Kristin Schmidt, University of Freiburg, Germany; Andreas Lachner, University of Gottingen, Germany; Sabine Rey, University of Gottingen, Germany; Bjoern Stucke, University of Gottingen, Germany; Cornelius Froemmel, University of Gottingen, Germany; Matthias Nuckles, University of Freiburg, Germany

In this study we investigated the potential of web-based learning journals to encourage self-regulated learning in medical studies. The study is a part of a joined interdisciplinary research project of the department of medicine at the University of Göttingen and the department of Educational Science at the University of Freiburg. A key element is the implementation and evaluation of a web-based learning journal. Learning journals are a method to reflect on one's learning processes and learning outcomes during the course of, for example, a lecture or seminar. In our present study, we contrasted two different versions of web-based journals: a metacognitive version encouraging the application of metacognitive strategies and a cognitive version stimulating the elaboration of learning contents. 86 medical students produced several journal entries as follow-up work to a four-week medical course. They were randomly divided into one of four different conditions of a 2 (metacognitive journal) x 2 (cognitive journal) quasi-experimental design. Results showed that the metacognitive journal supported the generation of learning goals and the monitoring and reflection of learning processes. The cognitive journal stimulated the usage of cognitive strategies such as elaboration of learning contents. Using web-based journals in medical education seems to be promising to stimulate beneficial strategies involved in self-regulated learning.

Introduction

Self-regulated learning is the ability to control and influence one's learning processes positively: The learners take personal initiative, apply powerful strategies to attain individually valued learning goals and monitor their understanding in order to detect and eliminate possible comprehension problems (Schraw, 1998; Zimmerman, 2002). Self-regulated learning skills are indispensable in all academic studies and especially in medical education. Studying medicine requires memorizing thousands of facts, looking at disease pattern from different theoretical perspectives, thereby relating theoretical concepts to clinical symptoms and practical experience. In order to master these manifold and complex demands, medical students need high competences in self-regulated learning.

In this presentation, we present a joint interdisciplinary research project of department of medicine at the University of Göttingen and the department of educational science at the University of Freiburg, in which we investigate the educational potential of web-based learning journals in medical studies. The study we present here is a pilot to a series of studies, in which we will successively implement and investigate combinations of different types of instructional support. The heart of our project is a web-based journal. It encourages students to adopt self-regulation to their learning processes. In the first phase of the three-year project, different versions of the web-based journal will be implemented and investigated by quasi-experimental field study designs. In the second phase, medical students will be offered a training in self-regulated learning strategies in addition to the web-based journal. It will be investigated whether combining indirect strategic support in terms of the web-based journal will be enhanced by direct support in terms of the strategy training. In the last phase of the project, the lecturers will be offered a teacher training that shows them ways how to encourage their students to apply self-regulated learning strategies.

Against this background, the present study focused on the comparison of two different versions of the web-based learning journal: a metacognitive version and a cognitive version. This comparison was inspired by the observation that different conceptualizations of journals are discussed in the existing research literature (see, e.g., Nýckles, Hýbner & Renkl, 2009; Schmitz & Wiese, 2006). The metacognitive version provided medical students with prompts for the planning of learning goals as well as for the monitoring and evaluation of learning processes and outcomes. The cognitive version encouraged the students to elaborate and organize the learning contents thoroughly. Organization and elaboration was stimulated by prompting the students to explain a medical topic to a fictitious layperson, for example, a patient. We expected that introducing a fictitious audience would help the students to better relate newly learned medical concepts to their prior knowledge and reorganize the contents in order to make them intelligible to a layperson.

In our present pilot study, the main research question was, whether the two web-based journal versions would support medical students in eliciting the learning processes and strategies as expected. We further asked the students to indicate their satisfaction with the web-based journal.

Methodology

Participants were randomly divided into one of four conditions of a 2 (cognitive journal) x 2 (metacognitive journal) quasi-experimental design. We asked the students to write a journal entry once a week during the learning unit "ophthalmology and otolaryngology" that lasted about one month. Eighty-six students of medicine with an average age of 24.89 (SD=4.25) participated in the study. They were in the fourth year of their medical education. Dependent variables were the frequency of cognitive and metacognitive strategies and the degree of acceptance of keeping a learning journal regularly. The extent to which different subcategories of cognitive and metacognitive strategies were present in the students' journals entries was rated on Likert-type rating scales. The strategies were rated by two independent raters (ICC = .80 to .92).

Results

The data analysis showed that students in the metacognitive conditions applied more metacognitive strategies (i.e., planning, monitoring and regulation) than students without metacognitive support, $F(1,82)=40.17$, $p\&\eta^2=.33$. On the other hand, students in the cognitive conditions used more elaboration and organization strategies and the students without cognitive support, $F(1,82)=22.93$, $p\&\eta^2=.22$. A more detailed analysis revealed, that students with cognitive support more often than the other groups attempted to relate theoretical concepts and own practical experiences. The results from the acceptance questionnaire, on the other hand, suggested that the medical students to some respect perceived a goal conflict between achieving a good grade in the examination and acquiring practically applicable knowledge through journal writing. Many of them acknowledged the usefulness especially of the cognitive journal version, but they suspected that the task of explaining a topic to a layperson such as patient might not be efficient as preparation of an exam that contained mostly multiple-choice questions.

Conclusion

In summary, these results suggest that web-based journal writing can be a useful method to support essential self-regulated learning strategies in medical studies. Medical students, who were provided with metacognitive support, elicited a raised number of planning, monitoring and evaluation strategies in their journal entries. Students with cognitive support better elaborated and integrated theoretical concepts with personal experiences from their practical training. On the other hand, the results also show that introducing a web-based journal as a singular intervention may not be fruitful in the long run. Students' statements from the acceptance data suggest that additional measures such as a strategy training may be useful, especially to inform the students about the advantages of deep-level learning strategies in acquiring sustained and applicable knowledge. Also, offering training interventions for the lecturers could be fruitful, for example, to inform them about alternative assessment methods that (compared to multiple-choice tests) are more compatible with deep-level learning strategies.

PAPER PRESENTATION

ICT Pedagogy for Multigrade Schools: Modernization of an ancient school type

Andrea Karpáti, UNESCO Centre for Multimedia in Education, Hungary; Pal Molnar, Eotvos Lorand University, Hungary

Multigrade schools are partially divided school spaces coordinated by a teacher who manages two classes that learn different disciplines at different levels during the same time period. The 19th school type prevails in rural areas around Europe and often produces lower than average student achievement and professional burnout among teachers. The paper presents results of a teaching experiment that involved the development of a new, ICT-supported learning environment with collaborative microworlds and individualised learning spaces, an interdisciplinary, multi-age curriculum and a new teacher training model called Mentored Innovation.

Pre- and post hoc interviews and focus group discussions with school principals, local stakeholders and selected students and results of experimental teaching documented in lesson plans, teaching blogs and teachers' e-portfolios revealed significant changes in methodology and professional self-perception and motivation of teachers. Schools integrated the enhancement of digital literacy for students and adults in the village. Head teachers introduced a distributed leadership style and shared knowledge practices to raise staff motivation and prevent burnout. However the level of ICT resources remained low, innovative pedagogy resulted in a significant raise in digital literacy both for staff and students. Professional networking with similar institutions resulted in peer learning and adaptation of methods conceived in other small village schools. This study proved that Multigrade schools may be effective if

teachers reconstruct their learning environment through ICT applications, profoundly change curricula and methods to suit their special learning conditions and teach students as a multi-age, multi-skills community.

Introduction and aims

Multigrade education is an organizational method of primary level education for communities with a small number of school age children situated mainly in rural settlements with low income families, and consequently, limited local financial resources for education. Teaching and learning occurs in partially divided school spaces coordinated by a teacher who manages two classes that learn different disciplines at different levels during the same time period. A decrease in child birth, and the number of school age children during the last few decades resulted in an increase in their number all around Europe. (NEMED, 2008)

According to biannual Hungarian national assessments, the knowledge level of pupils in small village schools with a staff of 2-3 primary educators is significantly lower than the national average (Imre, 2009). The integrity and self-esteem of small villages are closely linked to these schools, therefore, between 20007-2009, an ICT supported pedagogical model was collaboratively developed and piloted by teachers of these schools and educational researchers of ELTE. The paper presents findings about the way this identity building exercise affected ICT literacy and methodology of teaching, learning and communication in Multigrade schools.

Methodology

Based on principles of the Trialogical Learning Theory, (Paavola, Lipponen and Hakkarainen, 2004), we invited Multigrade teachers to form a knowledge building community, learn ICT supported communication skills and co-develop their new curriculum with researchers. We designed a Mentored Innovation Model for ongoing peer support through a knowledge construction environment enriched with Web 2.0 solutions. (Kárpáti and Munkácsy, submitted). While models of dialogical coaching that utilized models owned by instructors to form new knowledge structures in teachers have repeatedly failed, working around a shared knowledge objects (collaborative art projects and performances, development of lesson plans and digital teaching aids) in a trialogical relationship was introduced for in-service teacher education.

A new type of ICT-supported learning environment was set up where collaborative microworlds (for practice, creation, assessment and communication) and individual learning spaces were interconnected. Discipline-based curriculum for grade level teaching was replaced by integrated arts and science modules that promoted multi-age, multi-level, interdisciplinary learning.

First, the new learning infrastructure and methodology was piloted first with 21 schools (a stratified sample of the 605 Hungarian Multigrade institutions). Pre- and post hoc interviews and focus group discussions were conducted with school principals, local stakeholders and selected students. Experimental teaching was documented in lesson plans, teaching blogs and teachers' e-portfolios. (Karpáti and Dörner, 2009, 2010) In the second iteration, student performance was assessed. (Results will be reported in Karpáti and Munkácsy, in press). The presentation focuses on the first study and describes the ICT supported pedagogical model for Multigrade schools.

Conclusions

Survey results are summarized using the list of criteria of the innovative, progressive school (Ilomäki and Lakkala, 2010):

a. Content of the vision of the school and the integration of ICT in this vision

The school's mission is to revive, actualize and disseminate local culture and thus contribute to the sustainability of life in a small agricultural settlement. ICT use blended in smoothly with this vision. Social Web applications were found much more important for learning than in average size Hungarian schools.

b. Leadership type

With a staff of 2-4 teachers, leadership is naturally distributed and village inhabitants – parents, business owners, political leaders – are actively involved in shaping the fate of their only cultural institution beside the church. The principal acts as a catalyst, peacemaker and manager of change. Computer supported communication and information sharing helps shape and structure often emotional and contradictory face-to face encounters.

c. The culture of knowledge work in the school

Shared knowledge practices include regular brainstorming sessions involving partner schools via Skype, networking with parent groups and businesses to realize collaborative ICT projects (producing digital teaching aids about local attractions or problematic "hot topics", WebQuests, internet based "Ask the Expert" sessions, collaborative narrative and image production like "Wandering Tales" started in one village and passed on to the next to continue, etc.)

d. Level of ICT resources

Accessibility and sufficiency of resources is a major issue with all Multigrade schools in Hungary. ICT tools in use are "second hand", therefore, teachers' ICT competence and use is restricted. Thanks to pedagogical training, the

educational value of existing infrastructure is much higher than presumed. Surprisingly, students' ICT competence and use is also around the national average as parents readily make considerable financial sacrifice to provide tools and internet access for their children.

e. Working practices of the teacher community

In the national survey, professional isolation was mentioned by teachers as a major burnout factor. In the post-hoc survey, members of the Gardonyi Network perceived themselves as part of a community of practice. One year later, the community is still active and supports, through donations and professional assistance, one of the schools that fell victim to the red mud flooding caused by an aluminum factory in October 2010 in Hungary.

f. Pedagogical practices and ICT

Conceptions about the pedagogical use of ICT were jointly developed by Multigrade teachers and their mentors. The number of learning activities that utilize ICT has grown significantly.

Significance of the study

This study proved that Multigrade schools may be effective if teachers reconstruct their learning environment through ICT applications, profoundly change curricula and methods to suit their special learning conditions. Students should be taught as a multi-age, multi-skills community and not a set of clashing grade level classes imposed upon each-other in the undivided learning space. Innovation in this educational setting means the courage of being different from the mainstream pedagogical models. Our teaching model was selected by UNESCO for dissemination in Africa in 2009. Here, Multigrade schools present an economic way to provide schooling in rural areas where students are numerous but teachers are scarce.

PAPER PRESENTATION

Opening up learning through improvised use of technology

Patrick Dillon, University of Eastern Finland, Finland; Teemu Valtonen, University of Eastern Finland, Finland;
Mikko Vesisenaho, University of Eastern Finland, Finland; Ruolan Wang, University of Nottingham, United Kingdom

The aim of the work reported in this paper is the use of improvisation and ICT as vehicles for improving the transfer of skills in learning. Improvisation is a process that can be an effective vehicle or 'carrier' for transferable skills. It deals with the problem of how to cross boundaries between formal and informal learning and learning in different environments and educational sectors.

Improvisation of learning is an activity of collaboration, transformation, and discovery. Important skills are likely to develop via the concurrency of various activities, for example: Breaking out of the well-rehearsed patterns of learning behaviour that might hold learners back professionally, socially, or personally. Attending to the 'how' and not just the 'what' of learning. Communicating more effectively, collaborating more fully, and attending to listening, responding, and building with others. Working with everyone and everything available in a continuous, creative process.

In this paper we will outline: (i) a method for identifying improvisations that have creative and innovative potential; and (ii) a method for consolidating improvisations into a flexible, adaptive and transferable technique. We will illustrate the methods through concrete examples of improvisations based on informative cases and propose some tools, pedagogies and strategies for cross-sectoral transfer of skills via improvisation and use of ICT.

The aim of the work reported in this paper is the use of improvisation and ICT as vehicles for improving the transfer of skills in learning. Improvisation is a process that can be an effective vehicle or 'carrier' for transferable skills. As such, it deals with the problem of how to cross boundaries between formal and informal learning and learning in different environments and educational sectors. The paper reports work in progress at The Information and Communication Technology Research Group (Tietotekniikan opetuskäytön tutkimus- ja kehittämisyksikkö) (ToTY) at the University of Eastern Finland, the Visual Learning Lab (VLL) at the University of Nottingham and the School of Education at the University of Birmingham.

Improvisation is commonly associated with jazz and theatre (King, 1997; Martin et al. 2002) and it is used in management and business (Brown & Duguid, 1991; Crossan & Sorrenti, 1997; Pasmore, 1998). Improvisation means the coincidence of creative, emergent and collaborative activities. Research has shown that whereas people can use ICT imaginatively (e.g. in social networking) they seldom recognise its educational potential. Through our work in improvisation with (mobile) text-based and audio-visual ICTs, we are defining new patterns of use and new relationships amongst learners, technological tools, information and society. We are developing strategies for self-validation and transfer of skills so that the contribution that improvisation makes to learning becomes personally meaningful through the use of ICT and integral to lifelong learning.

In most traditional learning environments, learners are expected to build cumulatively on what they already know and can do (constructivism). Or they are taught directly what to do and given limited latitude to take the risks with learning. Either way, learners are unlikely to perform 'out of track', rather they repeat existing behaviour patterns, passively playing out the roles they have already learned. We are interested in facilitating improvisation as a means to create playful and collaborative learning environments within more formal educational structures (Loi & Dillon, 2006; Dillon & Loi, 2008).

Lobman and Lundquist (2007) use the term 'unscripted learning' to describe scenarios of improvisational learning. They argue that both teachers and students are essentially improvisers and performers. Improvisational performance in learning is the key to creativity, and fine-tuning creativity between teachers and students is crucial to knowledge acquisition and construction. As creativity is an essential ingredient in any effective teaching and learning situation, another question that needs to be addressed is how can we create an environment where improvisation can be encouraged and captured, and where creativity can flourish? Teachers obviously play an important role as they are on the front line working with students. Improvised learning with unanticipated outcomes should be possible in all educational settings.

Improvisation of learning is an activity of collaboration, transformation, and discovery. Important skills are likely to develop via the concurrency of various activities, for example: Breaking out of the well-rehearsed patterns of learning behaviour that might hold learners back professionally, socially, or personally. Attending to the 'how' and not just the 'what' of learning. Communicating more effectively, collaborating more fully, and attending to listening, responding, and building with others. Working with everyone and everything available in a continuous, creative process.

In this paper we will outline: (i) a method for identifying improvisations that have creative and innovative potential; and (ii) a method for consolidating improvisations into a flexible, adaptive and transferable technique. We will illustrate the methods through concrete examples of improvisations based on informative cases and propose some tools, pedagogies and strategies for cross-sectoral transfer of skills via improvisation and use of ICT.

The outcomes of this research will provide: (i) policy makers with a framework to encourage and support ICT as a vehicle for improvisation within and between educational sectors; (ii) teachers with tools pedagogies and strategies to encourage and support ICT and improvisation; (iii) individual learners with transferable skills that may be utilised and adapted throughout their educational and professional lives.

PAPER PRESENTATION

The role of strategic theories in learning using computer-based representations

James Aczel, The Open University, United Kingdom; Jonathan San Diego, King's College London, United Kingdom

This paper examines how learners interact with variations in representations presented in a computer environment. In particular, it explores how analysis of learning in terms of the notion of strategic theories can provide insight into learners' cognitive processes when using such representations. The study reported here looked at problem-solving using concurrent mathematical representations (numbers, graphs, algebra). For each task, the set of representations was presented in one of three instantiations. These were: Static (non-moving, non-changing, non-interactive);

Dynamic (animated, following keyboard inputs); and Interactive (directly manipulable using a mouse). A variety of data was collected from 18 participants: learners' shifts in attention were recorded using an unobtrusive eye-tracking device and screen capture software; keyboard and mouse actions were logged automatically; utterances and gestures were video recorded; and notes and sketches were recorded in real-time. This rich data was analysed in an integrated way, with the aim of characterising learners' strategies. The results show that participants tend to use multiple strategies over the course of task completion, and that the number and type of representation influence the strategies used. It is argued that this form of strategic analysis offers a systematic way of understanding learning journeys.

Aims

Computers are offering learners new ways to interact with visual representations, and to make links between these representations; yet learners' traditional difficulties with representations often remain (Dunham & Osborne, 1991); and indeed dynamic, linked and interactive representations may carry their own additional difficulties (Ainsworth, 2006). At the same time, developments in technology for real-time capture of gestures and utterances (Blake & Scanlon, 2002), eye-tracking (Hansen et al., 2001), and notes and sketches (Mann et al., 2008) mean that it is now possible to capture rich data on learners' interactions with representations. However, the very richness of this data presents problems. Firstly, software to coordinate and integrate the analysis of these different multiple streams of data is only recently beginning to appear. Secondly, the processes of rendering, collating, synchronising, transcribing, coding, and comparing such data are time-consuming. Finally – and this is the focus of this paper – it is not at all clear how best to bring theory to bear on the analysis of this data to provide genuine insight into learners' cognitive processes. This paper explores how analysis of learning in terms of the notion of strategic theories (Aczel, 2006) can provide insight into learners' cognitive processes when using variations in computer-based representations.

The representation study

In order to explore the sense that learners make of multiple mathematical representations when problem-solving, a study was conducted in which a set of representations was presented in one of three instantiations. These were: Static (non-moving, non-changing, non-interactive); Dynamic (animated, following keyboard inputs); and Interactive (directly manipulable using a mouse). A variety of data was collected from 18 participants: shifts in attention were recorded using an unobtrusive eye-tracking device and screen capture software; keyboard and mouse actions were logged automatically; utterances and gestures were video recorded; and notes and sketches were recorded in real-time. A strategic theory approach

A number of theoretical explanations for the difficulties with representations identified in the research literature can be discerned, and some of these could be examined using the data collected in the study. We chose to explore a "strategic theory approach" to analysis (Aczel, 2006), in which learners are seen as having "concerns" (problems of special interest in a given context); they conjecture "strategic theories" (attempts to address the concerns); and then they subject these strategic theories to some kind of "error-elimination", typically a sifting or testing process. Learning then is portrayed in terms of processes of discontinuous trial-and-improvement of strategic theories under the selection pressures provided by concerns.

Application of the strategic theory approach

The data was analysed in an integrated way, with the aim of characterising participants' strategies. The results show that participants tend to use multiple strategies over the duration of task completion, and that the number and type of representation given influence the strategies used. For example, it was seen that participants may often choose a strategy dependent on the particular form of mathematical representation with which they have started (e.g. a line graph). Should this attempt fail, participants may attempt to improve this strategy by combining it with another form of representation (e.g. numbers). Participants were also seen constructing their own representations ("re-representing strategies"). In addition, the eye-tracking data showed that participants sometimes constructed representations with their eyes ("imagining strategies"). By identifying the different kinds of strategies being used at particular times, the points at which strategies were abandoned or refined, and the frequency of chosen strategies, a pattern of activity can be constructed for an individual participant over the duration of a task (e.g. Figure 1). By comparing such patterns between tasks and between participants, it might be possible to identify significant commonalities and differences. It was found that the relationships between performance, strategy and time spent on task are complex. It was also found that strategy choice can be influenced not just by the representations given but also by the participant's prior knowledge and concerns. The data hints that participants change strategies when they experience difficulty in using a strategy; when their attention shifts to a different mathematical form; when they experience difficulty in visualising mental images; when a strategy imposes excessive cognitive load; and when they fail to link multiple representations. Instantiation also appears to influence participants' use of strategies. For example, participants given Static instantiations tended to spend more time using imagining strategies than participants given Dynamic or Interactive instantiations. Static and interactive instantiations tended to encourage graphical strategies; dynamic instantiations tended to encourage algebraic strategies. Dynamic and interactive instantiations tended to encourage re-representation. More research is clearly needed to test the findings over a larger sample of participants and tasks. However we would suggest that this form of analysis offers a systematic way of understanding learning journeys.

PAPER PRESENTATION

Social-problem Solving, Family Background and School Achievement at the ages of 8–18

Laszlo Kasik, University of Szeged, Hungary; Jozsef Balazs Fejes, University of Szeged, Hungary

The main aim of the research was to describe the developmental level of social-problem solving (SPS) at the age of 8, 12, 15 and 18 (N=1146). We also examined the relationship between SPS, social-interest realisation abilities (SIR: cooperation, competition, help and leadership), family background and school achievement. One questionnaire was adapted (SPS; for children, parents, teachers), and the investigation of SIR was assessed with a questionnaire developed by ourselves (for children, parents, teachers). These instruments proved to be highly reliable. We also used a list of variables of family background and school achievement. The relationship between the values of SPS-factors of children and parents is the strongest in all groups. Based on the total values, three factors (negative problem orientation, rational problem solving, avoidance) show increasing tendency with age, contrary to positive problem orientation and impulsivity. Gender differences can be found especially among children between 15 and 18. The relationship between SPS- and SIR-factors is significantly stronger with age (e.g. positive correlation between cooperation, help and positive problem orientation and between competition and impulsivity; negative correlation between leadership and avoidance). The SPS-factors are influenced the most by family type, less by mothers' educational level, and the least by net income. In the youngest group, school success (grade average) already shows high positive correlation with SPS-factors (with SIR-factors, too), and these values increase with age. In the two older groups, the highest values can be found between rational problem solving and mathematics and biology, between impulsivity and history and literature.

Background

International literatures agree that social competence is a very important factor for both individuals' inner balance and a satisfactory social co-existence. According to the well-established psychological view, social competence is a complex system of various social, emotional, cognitive (both inherited and learnt) abilities and motives (Rose-Krasnor, 1997). Within social competence social-problem solving and social-interest realisation (cooperation, competition, help, leadership) abilities are very important factors (Fylfj, 2009). On the basis of international research results, social environment (e.g. family, peer relationship, school) determines strongly the development of social competence and the correlation between social and cognitive development is very significant with age (Grusec & Hastings, 2007). Therefore, their improvement is a major task of institutionalised education. However, it is not known how social-problem solving and social-interest realisation abilities develop, and what kind of relationships are between the social abilities, cognitive area and family background in Hungarian context.

Aims

The main aim of the research was to describe the developmental level of social-problem solving (SPS) at the age of 8, 12, 15 and 18. We also examined the relationship between SPS, social-interest realisation abilities (SIR: cooperation, competition, help, leadership), family background and school achievement. Results are to be used as the basis for a complex development programme.

Methods

Sample, data collection

Subjects were 1146 children (and their teachers and mothers – only a few fathers sent back the questionnaire). The size of the age and gender subsamples was approximately the same. Data collection took place in Spring 2010.

Instruments

The questionnaire of the functioning of social problem solving was adapted from D'Zurilla, Nezu and Maydeu-Olivares (2002). This Likert-type questionnaire assesses the five factors of social-problem solving: positive and negative problem orientation; impulsivity; rational problem solving; avoidance. Social-interest realisation abilities were assessed with a Likert-type questionnaire developed by ourselves. Based on the theoretical background (socio-anthropological, human ethological, social psychological), some dimensions were defined within these abilities. Then factor analysis was done, on the basis of which the dimensions formed a lot of factors (e.g. interest, relation between give and take, time and winner, approach and rule). In the case of both questionnaires, besides children's own evaluations, teachers and mothers also evaluated the functioning of abilities. These instruments proved to be highly reliable (SPS: 0.86–0.94; SIR: 0.83–0.92). Furthermore, we had a list of background variables at our disposal about all participants (e.g. mothers' educational level; family size and type; net income; grade average as school achievement).

Results

Development of SPS and SIR

The correlations between the raters are very different on both SPS ($r=0.22-0.68$, p Based on the total SPS-values (mean of the three raters), positive approach to social problems is more typical of 8- and 12-year-old children than of older children. On the other hand, the interpretation of the solution of relations and situations problematic for oneself as a negative phenomenon is the most typical of the two older groups. Students belonging to the two older age groups show a bigger tendency to define problems, to decide before solving, to the rationality concerning realisation, to a multi-perspective interpretation, and to take into consideration more solution possibilities. Decisions and realisations based on emotions are characteristic of the 8- and 12-year-old children. Problem avoidance and postponement of solution is more frequent among the 15- and 18-year-olds than among younger children.

In the case of total SIR-values, 4 factors from 6 show increasing tendency with age (interest; contribution and share; period and winning; equal opportunity, conflict of interests, exclusion) and the difference between the two older and the two younger groups is significant (p

Relationship between the examined aspects

The relationship between the SPS- and SIR-factors is significantly stronger with age ($r=0.25-0.79$, p The SPS-factors are influenced the most by family type and family size, and less by mothers' educational level. Net income is the environment variable that has the smallest effect on the assessed components of social-problem solving.

In the youngest group, school success (grade average) already shows high positive correlation with SPS-factors (with SIR-factors, too), and these values increase with age. In the two older groups, the highest values can be found between rational problem solving and mathematics and biology, between impulsivity and history and literature.

Conclusion

According to our results (1) the inner correlations of the factors of social competence are already strong in the early years, and these correlations increase with age; (2) the family characteristics play a major role in the development of social-problem solving, and (3) correlation between the social and cognitive psychic areas is strong and gets stronger with age. These results strengthen unequivocally international research experience in the same domain. On the basis of these results, an experimental programme will be launched in 2011. Nevertheless it has to be taken into consideration that respondents were mothers. Numerous surveys show that mothers' opinions about cooperation and competition are different from those of fathers.

PAPER PRESENTATION

Home Learning Environment and Emotional Development in the Preschool Years:A Child Centered Approach

David Richter, German Institute for Economic Research, Germany; Simone Lehl, University of Bamberg, Germany

Although the preschool years are of great importance for children's cognitive and emotional development, up to now little is known if and how children's home learning environment promotes their socio-emotional development over typical background variables (e.g. gender). Therefore, the present paper focuses on the influence of child and family background variables as well as the home learning environment on the development of children's physical aggression. Data are drawn from the interdisciplinary German research study "BiKS-3-8". The sample comprised 547 children ($M = 3.7$ years) from 97 preschools. The developmental trajectory of children's physical aggression was rated by preschool-teachers in the first, second and third preschool year.

For data analyses, the recently developed growth-mixture modeling (GMM) method was used. GMM allows the identification of unobserved subpopulations and their different latent trajectories with longitudinal data. This approach was especially useful for the present study because recent research on the development of aggression clearly identified subgroups of children differing in their developmental trajectories (e.g., Joussemet et al., 2008).

The results show, that the development of aggression is not linear and displays not the same pattern for all children as three different latent classes were identified ("all-time-low", "all-time-high", and "declining"). In addition to the typical positive influence factors like being a girl, having an older mother, or growing up with siblings, positive influences of the home learning environment were identified.

The current educational climate in Germany focuses strongly upon preschool children's cognitive development and raises questions about how to promote emergent literacy and numeracy in preschools and families. Although these preacademic skills and their promotion are immensely important for children's academic success, emotional and social development requires equally careful nurturing. Especially the preschool years are of great importance for children's emotional development. At this age children learn in interaction with adults to regulate and to express their emotions appropriately.

Emotional competence is crucial not only in its own right but for positive outcomes in both social and academic domains (Denham, 2006). First, the components of emotional competence help children to ensure effective, successful social interactions which are crucial predictors of later mental health and well-being (Denham & Holt, 1993; Robins & Rutter, 1990). Second, emotional competence also supports cognitive development, academic achievement, and school adjustment through its contributions to social competence and self-regulation (Blair, 2002; Carlton & Winsler, 1999; Greenberg & Snell, 1997). Summing up, social and emotional factors often uniquely predict academic success, when other factors, including earlier academic success, are already taken into account (Carlton, 2000; Pianta, 1997; Shields et al., 2001). Promoting young children's social development seems therefore to be crucial for children's academic achievement.

Up to now, little is known if and how children's home learning environment promotes their socio-emotional development. Especially the influences of domain-specific, more cognitive, aspects of the home learning environment are rather unclear. Therefore, the present paper focuses on the influence of child and family background variables as well as the home learning environment on the development of children's physical aggression.

The interdisciplinary German research group "BiKS" deals in two longitudinal studies with the development and the educational career of children aged 3 to 12 years. The sample of "BiKS-3-8" comprised 547 children ($M = 3.7$ years; 48.3% female; 19.5% migration background) from 97 preschools. The developmental trajectory of children's physical aggression was rated by preschool-teachers at six different measuring points in the first, second and third preschool year. Items were derived from a German questionnaire, which measures socio-emotional behaviour of preschool children (Tietze et al., 1981), and from a German adaption (Göttert & Asendorpf, 1989) of the California Child Q Set (CCQ; Block & Block, 1980), which was used very successfully in the German longitudinal study LOGIK (e.g., Asendorpf, Denissen, & van Aken, 2008). Items were selected to measure children's actual behaviour (e.g., my child easily argues with other children). The response scale ranged from 0 (disagree) to 3 (strongly agree). Considering that only three items were aggregated, Cronbach's alphas were satisfactory (Cronbach's $\alpha \geq .70$). The project collected a wide range of data on the background of the children, their families and the preschool settings they attended in order to investigate the cognitive development of the children, the influences of their background, home and preschool as well as the formation of educational selection decisions.

For data analyses, the recently developed growth-mixture modeling (GMM) method was used. GMM allows the identification and prediction of unobserved subpopulations and their different latent trajectories with longitudinal data. Therefore, this approach was especially useful for the present study because recent research on the development of aggression clearly identified subgroups of children differing in their developmental trajectories (e.g.,

Joussemet et al., 2008). Specifically, GMM relaxes the single- population assumption of conventional latent-growth models. Instead of considering individual variation around a single mean growth curve, the growth-mixture model allows different classes of individuals to vary around different mean growth curves within each latent class (Muthéén, 2004). In addition, the conditional probability of an individual child belonging to a specific latent class can be estimated.

For the development of aggression analyses identified three different latent classes. The majority of the children (77.6%) belonged to a class with very low starting values ($mI = 0.34$, $p\ mI = 1.81$, $p\ mI = 2.23$, $p\ mS = -0.60$, p

The results show, that socio-emotional development (i.e. the development of aggression) is not linear and displays not the same pattern for all children. Depending on their family background, children show different developmental trajectories. In addition to the typical positive influence factors like being a girl, having an older mother, or growing up with siblings, positive influences of the home learning environment were identified. This evidence provides a positive view on early literacy and numeracy promotion.

PAPER PRESENTATION

The impact of teachers' judgments on primary school students' achievement

Gwenaëlle Joet, Université Pierre Mendès France, France; Nadia Leroy, UNIVERSITE DE GRENOBLE LSE, France; Pascal Bressoux, Université Pierre Mendès-France, France

According to the researches in the educational domain, teachers have a critical role, in part because they are asked to produce judgments about the abilities of their students. These judgments can be defined as inferences, made by the teacher, on the abilities of their students from several pieces of information (Bressoux & Pansu, 2003). They can be explicit or implicit, and seems to be strong predictors of students' achievement (Alvidrez & Weinstein, 1999). In our work on French fourth-grade children, we proposed to evaluate the effect of teachers' judgments (expressed at three different moments during the school year) on students' achievement (at the end of the year), taking into account a dynamic aspect that is the evolution of judgments during a school year. In other words, the main purpose of this research is to focus on the dynamic aspect of teachers' judgments and to estimate the effect of the variations of teachers' judgments on students' achievement (math and French language). Hierarchical linear modeling (HLM) and growth curve analyses (Singer & Willett, 2003) will allow to i) estimate the growth trajectory of teachers' judgments and ii) use these growth trajectories to estimate the impact of teachers' judgments variations on students' achievement.

Many researchers, educationalists or members of educational systems wonder long-past about academic learning determinants. Although several variables have been shown (for example, students' socioeconomic level, self-perceptions or gender) to be related to students' achievement, a better understanding of the reason why some students succeed academically while others fail is needed.

The purpose of this study is to assess the influence of teachers' judgments in mathematics and French (mother tongue) on students' academic performance. The teacher is the main referent for students and the best able to make a judgment on their abilities. Previous researches on self-fulfilling prophecies have shown that teachers' judgment about their students' abilities had an influence on students' performance through the influence of their behaviors towards them. This phenomenon is better known as "Pygmalion Effect" (Rosenthal & Jacobson, 1968), and many studies in educational domain agree that a more positive judgment provides more opportunities for learning and therefore, a better achievement (see Good & Brophy, 2000). Although many of these studies used varied methodologies, most of them have conceived teachers' judgments as fixed at a given point of time (generally at the beginning of the school year), rather than as a dynamic process meaning that teachers' judgments may vary over time during the school year.

The main purpose of this research is to focus on the dynamic aspect of teachers' judgments and to estimate the effect of the variations of teachers' judgments on students' achievement (math and French language). Using multilevel growth curve models (Singer & Willett, 2003), we will i) estimate the growth trajectory of teachers' judgments and ii) use these growth trajectories to estimate the impact of teachers' judgments variations on students' achievement.

Participants and procedure:

Participants in the longitudinal study were 373 students in fourth-grade (CM1). Students were from 24 classes in 18 schools in towns near Grenoble (France). All students remained in the same class during the school year. The teachers (19 women and 5 men) expressed their judgments about their students' abilities in mathematics and French three times during the school year (October, February and June). They completed items on a questionnaire for each student

for the three waves of data. We assessed how teachers perceived their students' capability asking them to indicate their opinion about students' behavior in the classroom, their performance level and their potential in French and mathematics. Each teacher has been asked to rate his/her judgments regarding the academic value of his/her students, on a Likert-type scale from 0 (very low) to 10 (very good), for each student in the classroom (e.g. please assign a score indicating the performance level of the student X in French). For each field, we then constructed a mean score from the three dimensions: behavior in classroom, performance level and potential. This mean score gives us an average measure of teachers' judgments about the abilities of each student (psychometrics properties of the scores were assessed).

Achievement:

We collected students' end-of-year achievement scores obtained at a French and mathematics test in grade 3 and grade 4. Students' test scores at the end of grade 3 were used as a control variable (initial achievement), while test scores at the end of grade 4 were used as "final" achievement. The participating classes had heterogeneous achievement levels both in French and mathematics, and students were not placed in any group or class according to their ability levels. We were thus able to compare the influence of teachers' judgments as a function of the students' academic level at the end of the previous school year to see if the average achievement level of individual classes was a factor that may have contributed to variations in students' achievement later in the year.

Statistical modeling of the data and preliminary results:

In a first step, we ran multilevel growth curve models (Singer and Willett, 2003) in order to estimate teachers' judgments growth trajectory over time. In other words, we first studied the variations in teachers' judgments over the time period under study. In a second step, we will evaluate the influence of these variations in teachers' judgments on students' achievement, in mathematics and French. As our sample consisted of heterogeneous fourth-grade classes across multiple school contexts, we use a multilevel statistical approach (Raudenbush & Bryk, 2002) to test in what extent variations in achievement could be explained by both individual-level student characteristics and classroom-level contextual factors. Controlling for individual variables, we will include in our models teachers' judgments variations (i.e., the intercepts and slopes estimated in the growth curve models).

The statistical treatments are in progress. Preliminary results showed that there is a positive and significant influence of average teachers' judgments expressed during the school year: more positive judgments provide a higher students' achievement both in mathematics and French. We also estimated that there are variations between teachers in judgment growth rate over the school year. We now have to test if these growth rate variations in teachers' judgments (i.e. whether judgments improve or declines over time) influence students' achievement.

PAPER PRESENTATION

Perceptions of the Learning Environment and Elements of Burnout Among Medical Students

Topi Litmanen, University of Helsinki, Finland; Kirsti Lonka, University of Helsinki, Finland; Sofie Loyens, Erasmus University Rotterdam, Netherlands

Medical students experience high levels of distress while studying, which has consequences for their well-being as well as academic performance. The goal of the present study was to explore which perceived aspects of the learning environment contribute to exhaustion and lack of interest (or cynicism), which are the key elements of burnout. Participants were 673 medical students, who filled in the MED NORD-questionnaire. A structural equation modelling approach was adopted to test the relationships between students' perceptions of the learning environment, lack of interest, and exhaustion. A satisfying fit of the model with the data was found. Results showed that exhaustion had the strongest relationship with workload. In addition, workload was an important determinant, and satisfaction acted as a protective factor for lack of interest. Interestingly, worry had a negative relationship with lack of interest, indicating that high levels of worry reduce lack of interest. Based on these results, student's well-being might be increased with focusing on their experiences of workload as well as their commitment with future work.

Studying in higher education requires long-term commitment and offers students extensive challenges. Those who are most likely to discontinue their studies are the ones who experience high levels of anxiety and lack of interest (Mäkinen et al., 2004). Compared to students in other academic fields, medical students experience higher levels of anxiety and depression. Among medical students, burnout is strongly related to dissatisfaction with the learning environment (Dyrbye et al., 2006). Exhaustion and cynicism are the core dimensions of burnout (Maslach & Jackson, 1981), with cynicism closely resembling lack of interest. The learning environment is hence an important factor, since it can either promote or protect for burnout and attrition. The goal of this study was to examine how students' perceptions of the learning environment are related to exhaustion and lack of interest in one's studies.

Methodology

Participants

Participants were 673 medical students (70% male, 30% female) from three medical faculties in Finland. The mean age was 24. 55% of the participants were in their pre-clinical stage (1st or 2nd year) and 45% were in their post clinical stage (3rd or 4th year).

Materials

The MED NORD (Lonka et al., 2008) questionnaire was used. It measures several aspects related to student well-being and orientation. Perceptions of the learning environment were measured by 15 items that formed the scales Disengagement, Receiving feedback, Workload, Worry, and Satisfaction (Dahlin et al., 2005). Exhaustion was measured by four items (Maslach & Jackson, 1981) and Lack of interest (the used items were very close to cynicism) by two (Mäkinen et al., 2004). Items concerning perceptions of the learning environment were rated on a 4-point Likert scale ranging from 1 (not at all true) to 4 (totally true), and the items concerning Exhaustion and Lack of interest were measured on a 5-point Likert scale with the same scale labels.

Statistical analysis

A structural equation modelling approach was adopted to test the relationships between students' perceptions of the learning environment, lack of interest, and exhaustion. Hypothesized structural relationships among the variables were established and the structural model was tested. The tested model included five latent variables concerning the perceptions of learning environment: Worry (with 3 observed variables), Satisfaction (4), Disengagement (4), Workload (2) and Feedback (2). The model included correlations between these variables and these five latent variables predicted the latent variables Exhaustion (4) and Lack of interest (2).

Results

Analysis of the hypothesized model resulted in a CFI of .92, a TLI of .90, and a RMSEA of .05. These indices indicated a rather good fit of the specified model with the data. The χ^2 analysis, $\chi^2(169, N = 673) = 440.2, p$

Table 2 presents the structural relationships between the latent variables. Workload appeared the only significant predictor of exhaustion, whereas lack of interest was significantly determined by worry, workload, and most strongly by satisfaction. These findings imply that perceived workload puts students at risk for exhaustion as well as a lack of interest, which may lead to burnout. Feelings of satisfaction can prevent students from losing interest in one's education. Interestingly, worry holds a negative relationship with lack of interest, meaning that high levels of worry reduce students' lack of interest. It seems that those students, who do care about their studies, have not become cynical. However, their feelings of worry and uncertainty still make them less satisfied, as reflected in the negative correlation between worry and satisfaction.

Theoretical and Educational Significance of the Research

On the basis of the current study, students' well-being might be increased by tackling their experiences of high workload. It also appears important to find ways to increase students' satisfaction with their program and how it prepares them for their future professions.

Future research will investigate whether these relationships vary for students in different stages of education. In addition, the influence of the instructional format (i.e., a Problem-Based Learning curriculum versus a traditional, lecture-based) will be further explored.

PAPER PRESENTATION

Students' Attitudes Towards Modes Of Evaluation

Mordechai Miron, Tel Aviv University, Israel

The purpose of the study was to determine the attitudes of Israeli students toward different modes of evaluation. The sample consisted of 346 students who were enrolled in six different faculties at Tel Aviv University. Students reported the frequency at which they encountered three modes of evaluation: objective tests, essay-type tests and written papers. A 66-item questionnaire was devised to establish students' preferences for different testing methods. The data revealed that essay tests were the most common mode of evaluation and objective tests were encountered least often. The students expressed a favorable attitude toward each mode of evaluation. The analysis of the data indicated that significant differences were found among students enrolled in different faculties.

Since the mid-1960s, students' influence on decisions affecting university life has increased in many countries, particularly in the area of instruction. Their influence on academic decision-making was partially generated through standard questionnaires in which students rated the effectiveness of university instruction. However, these evaluation measures rarely included information on student perceptions of the relative merits of various test procedures (Mabry, 1997). Students have firm attitudes toward different modes of testing and evaluation. These attitudes should not be ignored, because there can be little doubt that test performance is influenced to some extent by students' positive or negative perceptions regarding the tests they take. Murchan (1989) concludes that the format of testing has a great impact on how and what teachers teach, and students learn. Research findings revealed that students' perceptions of assessment significantly influence their approach to studying (Struyven, Dochy, & Janssens, 2005). Different types of tests also tend to determine the students' approach to learning. Drew (2001) found significant differences in students' perceptions of essay tests as compared to their perceptions of multiple-choice formats. Zeidner (1987) found that students prefer the multiple-choice format to an essay type examination in almost all dimensions of his inventory (perceived difficulty, anxiety, complexity, success expectancy, feeling at ease). There was only one dimension in which students thought that essay exams were more appropriate; namely, for the purpose of presenting one's knowledge in the subject matter (Zeidner, 1987). The purpose of the present study was to determine the extent of use of different modes of testing on the university level and to explore the attitudes of Israeli students toward these modes. Three questions were examined empirically: 1. To what extent were different modes of tests used at the university? 2. What were the students' attitudes towards these modes? 3. Were the students' attitudes towards evaluation modes related to the academic faculties in which they were enrolled?

Method

Sample The population consisted of 346 undergraduate students enrolled in six different Tel-Aviv University faculties: Exact Sciences (N= 24), Medicine (N=57), Life Sciences (N=62), Social Sciences (N=68), Humanities (N= 100), and Law (N=35). **Instruments and procedure** The questionnaires used in this study aimed to investigate three different types of evaluation commonly used at the university: objective tests (multiple-choice questions), essay-type tests, and written papers. In order to ascertain the frequency of use, the students were asked to rate each of the three evaluation modes on a 3-point scale. In order to determine student preferences, a 66-item questionnaire was devised, consisting of three 22-item subscales (objective tests, essay-type tests, and written papers) rated on a 5-point Likert scale. The questionnaires were administered during class periods, and respondents were guaranteed anonymity.

Results

1. To what extent were different modes of tests used at the university? The data indicated that essay tests were the most commonly used mode of evaluation, whereas objective tests were the least frequently used.
2. What were the students' attitudes toward these modes? The results revealed a favorable attitude toward each of the three modes. Though students held favorable attitudes toward all three types of evaluation, papers scored the highest, objective tests were less preferred, and essay tests scored lowest.
3. Were the students' attitudes toward evaluation modes related to the academic faculties in which they were enrolled? The order of preferences differed from faculty to faculty. In the humanities, the order, from most preferred to least, was papers, objective tests, and essay tests, whereas in the social sciences, the order was papers, essay tests, and objective tests. Medical students preferred objective tests and did not strongly differentiate between the two other evaluation modes. In most faculties, essay tests were the least preferred mode of evaluation.

Discussion and Conclusions

The purpose of the study was to investigate the frequency of use of the three different modes of evaluation in an Israeli university and to examine the attitudes of university students toward these modes: essay tests, objective tests and written papers. Essay tests were reported to be the most common mode of evaluation encountered by the students, whereas objective testing was the mode experienced least frequently. The predominance of essay tests may reflect university professors' reliance on familiar evaluation modes, thus perpetuating testing practices to which they

were exposed during their own studies. Without specific training on grading and assessment, educators draw primarily on their own experiences as students in determining the grading policies and practices they employ (Stiggins, 2005). evaluation. Students in this sample indicated a favorable attitude toward each of the three modes of evaluation. More than thirty years ago, Shapira and Etzioni-Halevy (1973) noted that the Israeli student tended to conform and had a generally moderate approach toward the university. Students approved of the university's structure, functions, and instructional and evaluation methods. The present study substantiates these findings at least with regard to evaluation modes. Future research should investigate other samples and instruments in order to validate the current results. Though students favored all three types of evaluation, papers scored highest, followed by objective tests, and essay tests scored lowest. These results do not corroborate Zeidner's (1987) and Boud and Falchikov's (2007) findings that students preferred multiple-choice items. The differences may stem from the testing experiences to which students in the different samples had previously been exposed. The findings indicate that students in different faculties differ in their attitudes toward modes of evaluation. It seems that studying within the framework of a scientific discipline and of a certain professional orientation may influence students' attitudes and expectations, including their attitudes toward the different modes of evaluation (Kellaghan & Madaus, 2003). This study may offer university professors valuable information in the area of testing. Testing practices should receive further cautious exploration. Although students' perceptions may be erroneous, students are the consumers of our instructional processes and thus cannot be disregarded. Furthermore, our testing instruments and subsequent grading policies have far-reaching effects on future generations of students. [1] In this paper, evaluation, testing and assessment are used interchangeably.

PAPER PRESENTATION

Learning culture as a prerequisite for an institution-wide approach to educational development

Taiga Brahm, University of St. Gallen, Switzerland; Anja Gebhardt, University of St. Gallen, Switzerland; Tobias Jenert, University of St. Gallen, Switzerland

Over the last two decades, the discussion about innovating teaching and learning at higher education institutions (HEI) has concentrated on various core concepts: such as an increased focus on learning outcomes as competencies and more student-centered teaching. These concepts form part of what Barr and Tagg (1995) have termed the "shift from teaching to learning". However, very few approaches have been proposed so far in the scholarly literature on how to actually transfer such normative concepts into the practice of teaching and learning at HEI. In order to sustainably develop the practices of teaching and learning at HEI, it is necessary to comprehend the prerequisites for educational development. The construct of "learning culture" can be seen as a possible concept to explicate these prerequisites. The aims of this study are to propose an institution-wide approach to educational development at HEI and to present a comprehensive instrument to diagnose learning culture as a starting point for educational development. The findings of the study include a first version of the Learning Culture Inventory for HEI. The students' version of the instrument encompasses 12 scales for the individual, 12 for the pedagogical interactions and 5 for the organizational dimension. With the institution-wide approach to educational development and the Learning Culture Inventory, this study can provide the basis for sustainable developmental initiatives to innovate teaching and learning at HEI.

Currently, a number of discourses are going on about how to best organize teaching and learning at higher education institutions (HEI). Over the last two decades, the discussion about innovating teaching and learning at HEI has concentrated on various core concepts: such as an increased focus on learning outcomes as competencies and more student-centered teaching. These concepts form part of what Barr and Tagg (1995) have termed the "shift from teaching to learning": a call to alter the current instruction-centered practices and move towards innovative practices of teaching and learning. Students are expected to become active, motivated, and self-responsible learners who eagerly engage in learning processes rather than "consume" precast knowledge. Teachers are supposed to support student learning by acting as coaches who consult learners in their mostly self-regulated learning activities (Clifford, 1999; Zimmerman, 2002). However, very few approaches have been proposed so far in the scholarly literature on how to actually transfer such normative concepts into the practice of teaching and learning at HEI (for an exception see e.g. D'Andrea & Gosling, 2005; Blackmore, 2009). To accomplish large-scale (i.e. institution-wide) as well as sustainable change, the role of educational development at HEI has to change as well (Gosling, 2009).

In order to sustainably develop the practices of teaching and learning at HEI, it is necessary to comprehend the prerequisites for educational development. The construct of "learning culture" can be seen as a possible concept to explicate these prerequisites. The aims of this study are to (a) propose an institution-wide approach to educational development at HEI and to (b) present a comprehensive instrument to diagnose learning culture as a starting point for educational development.

The methodology of the study is twofold. In a first step, the institution-wide approach to educational development as well as the concept of learning culture as a three-dimensional construct has been elaborated. In a second step, the construct was operationalized to develop a quantitative instrument for diagnosing learning culture at HEI. Educational development as an institution-wide endeavor. While there is ample research on how engaging teaching and learning methods can be used within course settings (e.g. Biggs, 2003), little is known about the preconditions for sustainable and large-scale changes of the prevalent practices at HEI. Addressing individual teachers and innovative learning designs at the course level (as it is often the case nowadays, cf. Dany, 2007) may actually lead to innovative practices and showcases; often, however, their impact on student learning remains minimal compared to the total of learning experiences students undergo during their time of study. Additionally, changes on the course level can be overlaid by factors which are not within the scope of the individual teacher and tend to be discontinued after the innovation phase when initial funding is no longer provided (Hannan & Silver, 2000) or when the learning culture is not adequate. Therefore, we argue for an approach to educational development at HEI focusing not only on teachers and the course level but addressing the whole institution to arrive at more sustainable changes in the teaching and learning practices. Such an institution-wide approach includes (a) faculty development, i.e. the support of faculty in the design of and teaching in innovative learning environments, (b) curriculum development on the program level such the students' whole learning experience within a study program is considered, and (c) strategic development on an institutional level (Jenert & Brahm, 2010). As a starting point for such an institution-wide approach to educational development, we suggest to diagnose the existing learning culture at the HEI. It encompasses all the aspects within a HEI that impact on students' learning processes and includes (1) a personal, (2) a pedagogical interactions and (3) an organizational dimension. The personal dimension comprises individual characteristics of learners considered relevant for formal and non-formal learning processes, i.e. their motivation to study. The pedagogical interactions dimension focuses on teachers' and learners' actions in the context of (non)-formal learning settings at HEI, e.g. the tasks, methods, and roles defining the actual design of a learning environment. The organizational dimension focuses on how teaching and learning is positioned within a HEI (as compared to e.g. research as their other main activity besides teaching). Consequently, this dimension comprises all those factors that are subject to (strategic) decisions on the institutional level and at the same time impact student learning, e.g. socialization to higher education for both students and faculty.

The Learning Culture Inventory for HEI. Developing the instrument, we started out by gathering and developing items for the different dimensions of learning culture (see below). In a first screening, these items were shown four experts in order to evaluate comprehensibility of the wording as well as the suitability for HEI. Next, for the first validation of the instrument, 1001 students and 225 faculty members at a Swiss university were surveyed. Over the following 6 months, the questionnaires have been used with about 3000 students in three different universities in Germany, Austria, and Switzerland. To analyze the data, exploratory factor analyses, and reliability analyses were used.

The findings of the study include a first version of the Learning Culture Inventory for HEI. The students' version of the instrument encompasses 12 scales for the individual, 12 for the pedagogical interactions and 5 for the organizational dimension. The assumed basic factor structure of the instruments could be confirmed. The reliability of most scales was reasonable (Cronbachs Alpha can only be reported for some scales in this abstract), e. g. for extrinsic motivation to study $\alpha = .853$ and hope as a positive emotion $\alpha = .820$ on the personal dimension; competition between students $\alpha = .759$ and formative evaluation of students performance ($\alpha = .727$) concerning pedagogical interactions, and systematic student introduction to studying ($\alpha = .787$) on the organizational dimension.

Both, the institution-wide approach to educational development and the learning culture instrument, are relevant for research and practice. While the instrument provides a possibility to diagnose the learning culture at a HEI, the institution-wide approach can subsequently be used as a (theoretical) guideline for HEI on how to implement organizational structures for educational development. Taken together, this study can provide the basis for sustainable developmental initiatives to innovate teaching and learning at HEI.

PAPER PRESENTATION

Investigating tertiary education students' attitudes toward Statistics

Tasos Barkatsas, Monash University, Australia

Undergraduate and Postgraduate students' attitudes toward statistics were investigated by using the Survey of Attitudes Toward Statistics (SATS), along with a number of supplementary variables such as: gender, confidence in mathematics and confidence in statistics. Initially an exploratory Principal Components Analysis (PCA) with Varimax and Oblimin rotations was conducted and internal consistency reliability estimates were calculated, followed by various t-tests, correlations and a MANOVA. All correlations among subscales were low except for the correlation

between the Difficulty and the Value subscales. No statistically significant gender differences were found but there were statistically significant differences between the "mathematics confidence" variable and each of the four SATS subscales (Affect, Cognitive competence, Value and Difficulty) of SATS.

Several researchers (Araki & Shultz, 1995; Elmore & Lewis, 1991; Elmore, Lewis, & Bay, 1993; Elmore & Vasu, 1986; Harvey, Plake, & Wise, 1985; Onwuegbuzie, 1995; Roberts & Bilderback, 1980; Schau et al, 1995; Schutz, Drogosz, White, & DiStefano, 1998; Wise, 1985; Woehlke, 1991; Woehlke & Leitner, 1980; Zimmer & Fuller, 1996) have studied the factors which have an impact on students' performance in statistics courses, including attitudes toward statistics. Roberts & Bilderback (1980) developed the Statistics Attitude Survey (SAS). The instrument was designed to be one-dimensional comprising 33 homogeneous items. Since then two other well-known survey instruments regarding attitudes toward statistics have been developed: the Attitudes Toward Statistics Scale (ATS, Wise, 1985) and the Survey of Attitudes Toward Statistics Scale (SATS, Schau et al, 1995). The ATS was designed to measure two attitude components in contrast to the one-dimensional structure of the SAS. The first component measured students' attitudes toward the usefulness of statistics in their field of study. The second component measured students' attitudes toward the statistics courses they were attending. The SATS instrument incorporates 4 subscales which have been designed to measure negative and positive attitudes about statistics. The four subscales are the following: the Affect subscale, the Cognitive Competence subscale, the Value subscale, and the Difficulty subscale. Several studies have been conducted on the gender differences regarding students' performance and attitudes toward statistics. Schram (1996) published a meta-analysis of studies investigating the gender differences on achievement in statistics and reported that the average effect size $d = .08$, was in favor of the female students. Roberts and Saxe (1982) found significant differences when using SAS: the male students had more positive attitudes towards statistics than the female students (pretest, $r = .26$; posttest, $r = .19$). Araki & Shultz (1995) did not report significant gender differences when using the ATS subscale, whereas the aims of the study were to investigate: Undergraduate and postgraduate education students' affect, cognitive competence, value and difficulty toward statistics. Gender differences in the attitudes of undergraduate and postgraduate education students' attitudes toward statistics.

Method

Participants The scale (SATS) was administered to 247 undergraduate ($N = 155$) and postgraduate ($N = 92$) students enrolled in the 4-year Bachelor of Education and the 1-year Graduate Diploma in Education courses in a large Australian University. 13.4% of the undergraduate students were enrolled in a second year mathematics education unit and 49.4% in a fourth year unit. The composition of the final sample was 71.2% female and 15.8% male students (13% missing).

Instrument The SATS questionnaire used in this study consists of 28 items on a seven point Likert scale (1 = strongly disagree, 4 = neither disagree nor agree, 7 = strongly agree). After re-coding the negatively worded items, the highest values in the scale correspond to positive attitudes toward statistics. The questionnaire comprises four subscales: the Affect subscale (6 items), the Cognitive Competence subscale (6 items), the Value subscale (9 items) and the Difficulty subscale (7 items). Analyses Principal Components Analysis (PCA) with a Varimax rotation was conducted and internal consistency reliability estimates were calculated, followed by various box plots, t-tests, correlations and a MANOVA. The SATS internal consistency reliability estimates of this study were consistent with those reported by Schau et al. (1995). The reliability coefficients ranged from .636 to .904. The lowest estimate of Cronbach was obtained for the difficulty subscale, a result consistent with the subscale with the lowest estimates reported in both the Schau et al. (1995) and Cashin & Elmore (2005) studies.

Results and discussion

Schau et al. (1995) used CFA to support a four factor structure of the SATS. In a more recent study Cashin & Elmore (2005) suggested that the SATS might be an instrument with only two domains similar to the two domains of the ATS. In this study the results of PCA suggest that a three-factor solution could offer an alternative to that of the four-factor model. The components reflecting the Affective and Cognitive competence subscales in the three-factor model loaded on a unique factor, which could be perceived as representing a subscale congruent to the ATS Course subscale, as the two subscales could be conceptualised as a measure of students' attitude toward their achievement in a statistics course. Cashin & Elmore (2005) reported that the only significant change in attitudes measured by SATS - before and after the course - was in the scores from the Affect subscale. Affective measures like the Affect subscale of the SATS and self-efficacy confidence measures like the Cognitive Competence subscale of the SATS, are often treated as distinct constructs in educational theory and in research on attitudes toward statistics (Eccles & Wigfield, 1995; Harlow, Burkholder & Morrow, 2002). In this study all correlations among subscales were low except for the correlation between the Cognitive and the Affect subscales, a result confirming the original Schau et al. (1995) study's results. It was found that there were no statistically significant differences between male and female students' attitudes in any of the four SATS subscales. In addition, the results showed no evidence of statistically significant differences between male and female students in the expected statistics course achievement. This last finding is in agreement with the findings of a number of previously conducted studies (Bradley & Wygant, 1998; Waters et al.,

1988; Buck, 1985; Harvey et al, 1985; Schram, 1996; Ware & Chastain, 1991). NOTE: References not included due to word limit but they are available on request.

PAPER PRESENTATION

How teachers, students and experts rate a teaching approach and the connection to student learning

Christine Johannes, Technische Universität München, Germany; Tina Seidel, Technische Universität München, Germany

A commonly used self-report instrument for the assessment of teaching action is the Approaches to Teaching Inventory (ATI, Trigwell & Prosser, 2004, Prosser & Trigwell, 2006, Trigwell, Prosser & Ginns, 2005). Recent doubts about the connection between self-reported approaches and teaching action (Kane, Sandretto & Heath, 2002) raised the question how self-report measures can be validated by the perception of participating students or experts. In our study, we investigated this relationship for the ATI-R. Furthermore we used clarity/coherence and didactical methods as indicators of teaching action and explored their connection to students' learning characteristics such as students' learning strategies and motivation. As a method, a sample of N=17 university teachers from different disciplines and their students filled out a German version of the ATI-R (Trigwell, Prosser & Ginns, 2005) as well as ratings for clarity/coherence and didactical methods after a videotaped session of their teaching. Three experts per teacher rated the corresponding constructs. In addition, students rated their intrinsic and extrinsic motivation as well as deep-level and surface-level learning approaches. The results show that mean student ratings for teacher focus were higher than the corresponding teacher ratings. Compared to teacher ratings, experts were stricter, but both perspectives (teacher, external expert) were moderately intercorrelated. Students' perceptions and expert ratings were systematically correlated with student learning such as learning strategies and motivation. We conclude that teacher self-reports can be applied to compare teachers/ teaching action. In addition, measures such as expert ratings should be used to assess effects on student learning outcomes.

Summary The study explores how self-report measures of teaching action relate to correspondent measurement of participating students and experts. For this question, we focus on university teachers who were questioned and videotaped in one teaching session. The connection of these measures gives insight, how self-report measures of teaching action are related to the actual teaching situation and which restrictions could result from the exclusive assessment of the teacher's perspective. **Theoretical Background** Teachers' teaching approaches are characterized as teaching strategies with associated intentions (Kember, 1997) and seem to have a fundamental influence on learning. For example, Trigwell, Prosser and Waterhouse (1999) reported of more student surface learning approach when teachers describe their teaching approach as teacher-focused. In contrast, if teachers report a more student-oriented teaching approach, students report more deep-level learning. Despite the conceptual closeness of teaching approaches to the actual teaching situation, self-reported teaching action is not necessarily consistent with the concrete teaching action (Seidel, Schwindt, Rimmele, & Prenzel, 2008). To access concrete teaching action, it is necessary to look at the concrete teaching situation rather than a self-report measure (Kane, Sandretto & Heath, 2002), but this has not been done for well-established measurements close to teaching action such as the teaching approach. Above that, self-reports of clarity/coherence and didactical methods, as important features of effective teaching should be checked for connections to teaching action.

Research Questions

In our study, we relate different perceptions of the teaching approach and teaching action by connecting self-report measures to student and expert ratings for a concrete teaching situation. This analysis should shed light on the question, how self-reported teaching approaches relate to the perceived teaching action. Specifically, three research questions are explored: (1) How do self-reported teaching approaches relate to teaching approaches rated by students participating in a teacher's course? (2) How do self-reported teaching approaches relate to expert ratings gained in systematic video observations? (3) Which measures show tighter connections to student's learning strategies and motivation?

Methods & Design

N=17 university teachers (7 women, 10 men, M=28.7 years, SD=5.8) from different disciplines were questioned and videotaped in one teaching session within the winter term 2009/2010. Data collection took place during a qualification program for teaching. Above that, student and video ratings of experts (three ratings per teacher) were collected for this teaching session. Answers were given on a six-point Likert scale. Teachers filled out a German version of the revised Approaches to Teaching Inventory (Trigwell, Prosser & Ginns, 2005; $\alpha=.84$ teacher focus, $\alpha=.88$ student focus) and answered five questions regarding clarity/coherence ($\alpha=.72$) and five items regarding their didactical methods ($\alpha=.75$). These elements were independently rated by the three experts with acceptable interrater reliability

for the scales (.63?r?.84). Also, the students of the videotaped classes (N=338) rated teaching approach, clarity/coherence, didactical methods with equal or higher reliabilities. Above that, students rated their intrinsic motivation ($\alpha=.75$), extrinsic motivation ($\alpha=.72$), deep-level ($\alpha=.71$), and surface-level learning ($\alpha=.84$).

Results

Averaged student ratings of the teacher focus were higher than the corresponding self-reports ($t(16)=-2.58$; $p=.02$). In contrast, no differences between student ratings and corresponding self-reports could be found for student focus ($t(16)=0.51$; $p=.96$), clarity/coherence ($t(16)=1.29$; $p=.21$) and didactical methods ($t(16)=-0.45$; $p=.66$). Compared to expert ratings, teachers rated themselves more student-focused ($t(16)=6.09$, $p<.00$) more clear/coherent ($t(16)=3.00$, $p=.01$) and stated more didactical variety ($t(16)=3.26$; $p=.01$). No differences with respect to teacher focus could be observed ($t(16)=0.66$, $p=.52$). Interestingly, correlations for teacher focus ($r=.58$, $p=.02$) and student focus ($r=.67$, $p=.01$) were moderate. Also ratings of clarity/coherence ($r=.67$, $p=.01$) and didactical methods ($r=.50$, $p=.04$) show moderate intercorrelations. For the student learning approaches and motivation (N=17 sessions), students' perceived student focus connected to their intrinsic motivation ($r=.69$, $p=.02$) and, in tendency, to deep-level learning approach ($r=.43$, $p=.09$). Similarly, a marginal correlation between intrinsic motivation and expert-rating of student focus could be found ($r=.46$, $p=.07$). On the other hand, students' perception of a teacher focus were marginal connected to extrinsic motivation ($r=.45$, $p=.07$). No correlations with teachers' self-reports occurred. For students' perception of teaching action, a correlation between clarity/coherence and intrinsic motivation ($r=.63$, $p<.00$) as well as a deep-level learning approach ($r=.69$, $p<.00$) emerged. Above that, student's rating of didactical methods correlated with intrinsic motivation ($r=.83$, $p<.00$) and deep-level learning ($r=.72$, $p<.00$). In tendency, the expert ratings of didactical methods show similar connections to intrinsic motivation ($r=.45$, $p=.08$) and deep-level learning ($r=.44$, $p=.09$). As for the teaching approaches, no significant correlations with teachers' self-reports occurred.

Discussion

Our study focused on how self-reported teaching approaches and teaching action relate to correspondent measurement by students and experts. The current data indicate that (1) in general, teachers and students see their shared teaching situation quite similar. One exception is a teacher focus, which students rated higher. (2) Comparisons to expert ratings as stricter criterion showed that teachers were positively biased in judging of their own teaching. This effect seems to be a rather general bias: Moderate intercorrelations between expert ratings and self-reports indicate the same observational basis connected with an individual reference of frame in teachers. (3) Despite tight connections between self-reports, student and expert ratings, only students' perceptions and expert rating connect to student characteristics such as learning approaches and motivation. This leads to the conclusion that self-reports of teachers are a suitable indicator to compare teacher's teaching action. Other measures such as expert ratings should be used to make connections between teaching action and student's learning outcome. Video-based expert ratings, moreover, offer multiple possibilities for professional development by being able to directly target at the teaching action at hand. Students' perception of teaching action connects even tighter to their learning, but could be biased with respect to pre-knowledge or interest in the teaching subject matter.

PAPER PRESENTATION

Apprentices at Risk: What Conditions Lead to Dropout in Vocational Education and Training?

Simone Berweger, University of Teacher Education St.Gallen, Switzerland, Switzerland; Patrizia Salzmann, University of Teacher Education St.Gallen, Switzerland, Switzerland; Samuel Krattenmacher, University of Teacher Education St.Gallen, Switzerland, Switzerland; Samuel Schoenenberger, University of Teacher Education St.Gallen, Switzerland, Switzerland

In a longitudinal design we are studying a cohort of 849 apprentices throughout their three-year training. They commenced their vocational training in health care or building construction in 2009. The objective is to identify conditions (characteristics of the individual, the in-company training, the vocational school training and the family of

origin) of successful vocational training. Borrowing from the self-determination theory (Ryan & Deci, 2000) and Krapp's (1998, 1999) person-object theory of interest, we are focusing specifically on motivation variables.

In this paper we compare those who dropped out during the first year ($n=63$, 7.4%) with those who made the transition to the second year ($n=786$, 92.6%) of training. We consider the identification, by vocational schools, of apprentices at risk due to poor academic performance during the probation period. This allows for the comparison of a first group of apprentices that had been correctly identified as being at risk, a second group that could not be identified in advance and a third group of adolescents – classified as a risk group – but who did not drop out. First results show that those who dropped out were less satisfied with their chosen apprenticeship from the beginning and that they had often declared that it did not correspond with what they desired. As expected, they started with weaker intrinsic motivation towards their training and agreed that they enjoyed work less since starting the course.

We are studying a cohort of apprentices ($N=849$), who entered vocational training in health care or building construction in 2009, throughout their three-year training (longitudinal design). The objective of the study is to identify conditions (characteristics of the individual, the in-company training, the vocational school training and the family of origin) of successful vocational training. Borrowing from the self-determination theory (Ryan & Deci, 2000) and Krapp's (1998, 1999) person-object theory of interest, we are focusing specifically on motivation variables. In this paper, apprentices who dropped out of vocational training by the end of their first year are compared with those who successfully managed the transition to second year. Additionally, to get a more differentiated insight, three groups of apprentices will be compared to each other: (1) dropouts who had been identified as being at risk by the vocational schools because of poor academic performance during the initial probation period, (2) dropouts who could not be identified in advance and (3) apprentices who had been classified into the risk group, but who did not drop out. We address the research questions on how these groups of apprentices and their training situation are characterized, what conditions lead to dropout and which factors might be protective. A special focus is set on the impact motivational variables have on dropout. We analyse if and how the groups differ in terms of the compromise they had to make when choosing their vocation and any special support received from their school and their company.

Theoretical background

In Switzerland, more than two out of three adolescents do an apprenticeship during this challenging period of their lives. Mastering the transition from obligatory school to vocational training, attending and completing this formation successfully, and the subsequent entrance into the labour market are important challenges for adolescence. Vocational training facilitates the entry into the labour market and the beginning of one's working career, and is seen as assuring integration into the world of work (OECD, 2000; Ryan, 2001; Bynner & Parsons, 2002; Imdorf, 2007). In general, the acquisition of theoretical knowledge and practical skills relevant to the occupation are important criteria for a successful course of formation. From the point of view of those learners who drop out, the decisive factors are an unfortunate choice of occupation, their relationship to the VET trainer, and aspects of learning at the workplace (Stalder & Schmid, 2006; Schmid, 2000). For many students from schools with basic requirements, the key question is not whether their interests fit the occupation, but (1) whether they can find an apprenticeship at all (Herzog, Neuenschwander & Wannack, 2006) and/or (2) whether they can attain a vocational qualification. Therefore, it seems particularly important to allow for situational interest in aspects of the occupation during training, in order to activate motivational processes, and, in the long run, develop more stable interests relevant to the occupation (see Krapp & Lewalter, 2001). Work motivation theories propose a strong connection between task-related (more intrinsic) motivation and notions of growth and autonomy (e.g. McGregor, 1960; Herzberg, 1972; Hackman & Oldham, 1976), which is very close to the self-determination theory (Ryan & Deci, 2000).

Method

We are collecting data from a cohort of 849 apprentices, that started their apprenticeship in the field of health care or building construction in 2009, as well as from their VET trainers throughout the three-year training (longitudinal design). As dependent variables we are surveying the apprentices' performance, satisfaction with the apprenticeship, intention to pursue the training and complete it. Among the independent factors, of greatest interest are those that foster motivation and are central to approaches such as the self-determination theory (Ryan & Deci, 2000), Krapp's (1998, 1999) person-object-theory of interest, as well as approaches from organizational psychology (e.g. Hackman & Oldham, 1976). Special attention is granted to attributes of the workplace (e.g. job characteristics, mentoring and working atmosphere) that are expected to have a positive influence on psychological states that support intrinsic motivation and satisfaction. Furthermore, attributes of support and learning atmosphere at the vocational school are considered. An additional questionnaire is sent to those apprentices who drop out. The reasons for dropout, the apprentices' situation after the dropout, their prospects, as well as, the experienced support are examined.

First results

In this contribution, we present selected results from the first two sets of data collection (in the middle of the initial probation period, and in the second half of the first year of training). The initial findings indicate that at the time of signing the apprenticeship contract, a majority of adolescents is confident or very confident that they have chosen the right vocation, and also expect to fit in well with the employer. The data show that 63 (7.4%) out of 849 apprentices dropped out during the first year of apprenticeship. This group was already dissatisfied with their chosen vocation at the beginning of the apprenticeship and had often declared that the vocation did not correspond with what they desired. About a quarter of those who dropped out, as well as those who did not, experienced difficult situations in the company during the probation period. As expected, the two groups differed significantly in their intrinsic motivation towards their course, with those who dropped out showing weaker intrinsic motivation. About three quarters of the apprentices agreed or rather agreed that during work, they often experienced feelings of boredom as well as overtaxation, and no difference was found between those who dropped out and those who continued. But the former agreed less that they had enjoyed work since entering the vocational training. This finding reinforces the assumption that intrinsic motivation is important for success with the initial qualification. The current integration of data concerning the identification of apprentices being at risk by the vocational schools is almost complete and will allow for an additional and more discriminating analysis that we expect to give important indications of what conditions lead to dropout and which factors might be protective.

PAPER PRESENTATION

Business Internship Advisors as Protagonists of Workplace Learning

Annette Ostendorf, University of Innsbruck, Austria, Germany; Markus Ammann, University of Innsbruck, Austria

Business internships as a type of experiential learning settings are supposed to foster students' abilities to connect theoretical and practical knowledge, to support their personal and emotional development, and to help them in finding the right career path. There are many hints that they do so but we also have to face that these - from an educational view of perspective highly desirable - outcomes are not guaranteed or in any sense achieved automatically. This may lead us to investigate structures and conditions for high quality in business internships more intensively. In this paper the focus will especially be on the workplace advisors of business internships. This group of 'educators' can be considered as the hidden ones. There is not much transparency on their involvement in workplace learning processes. In the present study we discuss results of a qualitative-empirical case study conducted in summer 2010 in a mid-sized, Austrian company in the public sector. Central issues are expectations, role interpretation and competencies of business internship advisors. We attempt to make a contribution to the development of a quality framework for counselling structures and processes in internships.

Introduction and aims

Business internships as a type of experiential learning settings are supposed to foster students' abilities to connect theoretical and practical knowledge, to support their personal and emotional development, and to help them in finding the right career path. There are many hints that they do so but we also have to face that these - from an educational view of perspective highly desirable - outcomes are not guaranteed or in any sense achieved automatically. This may lead us to investigate structures and conditions for high quality in business internships more intensively. The construct „quality“ in this context should be properly judged in terms of educational aims (as opportunities for personal development and learning) but also in terms of contributions to economic achievement. That attitude depends on the special definition of internships. One attribute of internships is that they are a combination of learning and working. If only one of these processes is exclusively stressed it cannot be called an internship any longer. A second attribute of internships is the existence of a sort of didactic framework. That means that there has to be a minimum of planning concerning learning outputs, work-related aims, processes, advisors and workplace conditions.

Our central issue is to find out quality features for counselling or advising business internships. That includes also a deeper discussion on quality criteria in cooperative educational settings. In this paper the focus will especially be on the workplace advisors of business internships. This group of 'educators' can be considered as the hidden ones. Research on their role, expectations or competencies is still rare in educational literature.

Methodology and methods

In the face of this lack of theories and empirical data a qualitative-empirical case study was conducted in summer 2010 in a mid-sized, Austrian company in the public sector. An interpretative approach seems to meet the research goals best. Business internships are very different depending on the type of business field, the company's size and location, its cultural surroundings, including the educational system etc.. Therefore comparison between different internships is difficult.

The explored firm with about 500 employees offered a total of 48 internships for pupils and students of higher educational institutions in technical fields and administration or service in the year 2009. The company investigated offered internships with a duration from one week to two months. In the classification of Stake (2005: 445) the investigation was designed as an instrumental case study. That means that the special case was investigated mainly to facilitate understanding of the issue and for generalization purposes. The mentioned case study is one component in a broader project on business internships funded by the Tyrolean Science Fund (2009-2010) at the University of Innsbruck.

Besides the document analysis and some effort to sum up the company's background four semi-structured qualitative interviews have been conducted at the firm. Criteria for the selection of the interview partners were on the one hand their direct responsibility for the intern and on the other hand their long-term experience in counselling internships. They have been questioned as experts on their living environment. With these four persons the most relevant protagonists of internship counselling in the focussed company have been covered.

Findings

In this short summarizing abstract we want to note only some special outcomes.

- o When the advisor's commitment to young people is highly valued by the leaders the additional and voluntary work as a advisor is not considered as strong a burden.
- o There is a close nexus between experiences in trainee supervision within the Austrian dual vocational system and their ability to deal with interns. Amazingly they refused an organizational link between the two types of learners within the company.
- o In the eyes of the internship advisors one of the most relevant personal attributes of a advisor should be his identification with the work and the company. That is considered as an indispensable attribute for facilitating interns' participation in the world of work.
- o Very important for the successful work as a advisor is an appreciating and respectful attitude towards the interns.
- o There is no link between schools, teachers and the advisors. Even though there is a strong wish for cooperation nobody cares about an initiative in that direction.
- o Internship advisors don't get any support concerning the design of educational situations.
- o Didactic support in the task arrangements for the interns dedicated by teachers would be seen as very helpful and not as constricting.

Theoretical and educational significance of the research

Business internships are strongly discussed in the Austrian school community in terms of their strengths in combining theoretical and practical settings of education. They are estimated as one powerful tool to improve the weakness of medium and higher vocational schools (outside of the dual system) in offering direct business experiences. In an international view there is also an old tradition and new revival of educational discussion on cooperative education (Howard 2004: 4) to which our research can contribute some aspects.

We found out that there is also a lack of 'sense making' on the positioning and design of business internships between companies and schools. Discussions often focus only on the role of teachers in accompanying internships of their students. Less strong attention is given to the 'other side of teaching' – the advisors. So our paper brings the view of in-company advisors more to the foreground and may open opportunities for the design of high quality cooperation in that field.

PAPER PRESENTATION

Training for transfer. A comprehensive evaluation study

Jan Ulrich Hense, Ludwig-Maximilians-University Munich, Germany; Stephanie Maite Gretsche, Ludwig-Maximilians-University Munich, Germany; Heinz Mandl, Ludwig-Maximilians-University Munich, Germany

The present evaluation study of trainings for Six Sigma, a methodology for organizational quality improvement, aimed to demonstrate how a theory-based multi-method approach comprising context, input, process and outcome analyses will generate valuable insights into the problem of training transfer. Method and results of four sub-studies are presented in detail: content analysis of the training concept, structured observations of training sessions, pre- and post-training surveys, and a transfer survey. Overall, these studies showed that the evaluated trainings already implemented many features to be expected from an effective transfer-oriented learning environment in the view of current learning research. However, it was also possible to identify a number of weaknesses which served as a source for recommendations for improving the trainings' concept and realisation. It is argued that approaches to training evaluation which focus only on outcomes would not be able to provide this kind of formative feedback.

Aims and theoretical background

Transfer of training to the workplace is a major and recurrent concern from educational as well as economical viewpoints. If learners are not able to apply the knowledge and skills they have learned in and between training sessions in their everyday work, valuable resources have been wasted. Drawing on the classical framework of Baldwin and Ford (1988), several possible reasons for the failure of transfer can be identified: Trainee characteristics (e.g. lack of preconditions, previous knowledge or motivation), training design (e.g. wrong choice of contents or learning approach), or work environment (e.g. lack of support or opportunity to apply contents). According to Laker (1990), transfer is not monolithic but has to be conceptualized as a two-dimensional construct. First, in regard to generalisability, transfer can be near, i.e. happen in contexts which are similar to the learning situation, or far, i.e. happen in other contexts which are distinctively different from the learning situation. Secondly, on a temporal dimension, distinct phases of transfer from initiation to maintenance have to be differentiated. From a learning theory viewpoint, it can be argued that there are two major preconditions for transfer of complex learning goals: a learning environment which fosters learners' active involvement with authentic problems (e.g. problem oriented or inquiry based learning), and instructional support, e.g. during self-directed and cooperative learning phases, and, in particular, after the training in the form of coaching at or near the workplace (Stark, Mandl, Gruber & Renkl, 1999). Accordingly, it was expected that for the trainings to be most effective in regard to enabling transfer, trainers are to provide authentic, cooperative and self-directed problem-solving contexts with well dosed direct instruction and guidance to enable learners to actively acquire, process, and exercise new knowledge and skills (e.g. Schmidt et al., 2009).

In many past training evaluations, the focus has been on measuring learners' acceptance and learning outcomes, while the complexities of analysing training transfer have often been neglected in the past. Therefore, in the current study which aimed at evaluating Six Sigma trainings in a corporate setting, a complex multi method evaluation design was applied to analyse training transfer within a comprehensive theory based framework. This framework incorporated context, input, process, and outcome variables to allow for a comprehensive analysis of training transfer.

Context of the study

The evaluation study was conducted in an international industrial gases and engineering company. The subject of the evaluation is the training for Six Sigma, a systematic, data-driven approach to quality improvement with the goal to achieve error free processes. The training concept comprises four training weeks with a 4-6 week interval in between each week, during which the participants work on their own authentic Six Sigma projects while receiving coaching by an experienced "Master Black Belt". The contents of the individual training weeks ideally run parallel to the progress of the participants' project work carried out in between the training weeks.

Research questions

The research questions addressed the following aspects in regard to the transfer-oriented theoretical model: (1) training concept, (2) training implementation, (3) participants' preconditions, (4) training outcomes, (5) transfer conditions at the workplace, and (6) actual transfer of learning contents.

Methodology

A multi-method approach comprising four studies was chosen. These used content analyses of training manuals to examine the training concept (question 1), structured participant observations of training sessions to study implementation (question 2), pre- and post-training surveys (questions 3-5), and transfer surveys and interviews (question 6).

Findings

The analysis of the trainer manuals (question 1) suggested that the training concept provided a mix of diverse teaching and learning methods, which basically conformed to central criteria for transfer-oriented learning environments (e.g. work-place related exercise, case studies). The observation of training sessions (question 2) revealed that the training was implemented mostly in accord with the trainer manuals. Accordingly, the training implementation applied

important elements of a transfer-oriented methodology (e.g. learners were actively engaged in individual (14% of overall training time) or group work (33%) while receiving support by the trainers). The pre-post-test surveys revealed that important preconditions favourable for transfer were met (question 3) (e.g. participant motivation; authentic, problem-oriented projects from participants' own workplace). It also demonstrated satisfactory training outcomes (question 4) (e.g. gains in knowledge and skills) and for most participants transfer conditions were favourable in particular in regard coaching at the workplace (question 5). Finally, the transfer study (question 6) illustrated that learners did actually apply not all, but a substantial percentage of the learning contents.

Theoretical and Educational Significance

Based on the empirical results, several recommendations for further improvements of the training concept and realisation were made at the context, input, and process levels. Among these were providing better transfer conditions at the workplace by guaranteeing line managers' support (context), making sure that participants' own projects which they bring to the training were actually suited for realisation within the training duration (input), and decreasing the percentage of lectures, interactive lectures and the usage of presentation slides during training sessions (process). The theory-based, multi-method approach demonstrates that for understanding and optimizing the transfer of training under real world conditions, a comprehensive perspective, comprising context, input, process, and outcome analyses, needs to be applied.

PAPER PRESENTATION

The Juice Factory; designing authentic learning in vocational education.

Loek FM Nieuwenhuis, IVA, university of Tilburg, Netherlands; Marjan Kat, IVA, university of Tilburg, Netherlands; Marijke Van Vijfeijken, IVA, university of Tilburg, Netherlands

In this paper the introduction of the Juice Factory is analysed. The Juice Factory is a simulated production line for training occupational and professional competencies. Based on curriculum theory (Van den Akker, 2003) and design principles for authentic learning environments (Zitter, 2010), teachers from Dutch colleges for vocational/professional education and training are interviewed on their instructional theories and practices. The teachers lack a theory of professional development, so they are not well equipped to use the Juice Factory as an instructional tool for preparing their students for the transition from school to work.

Workplace learning is seen essential in Dutch Vocational Education (VET), for developing occupational competences. Apprenticeships are seen as a strong system for school to work transitions (Mýller & Shavit, 1998; OECD, 2009). However, the effectiveness of workplace learning can be questioned for (early) instruction goals. Nijhof and Nieuwenhuis (2008) make clear that for developing occupational, theoretical knowledge the workplace is not effective, and for training skills other learning environments may be more effective. Billett (2004) argues that workers learn a lot in the workplace, but not always the right things: due to economic constraints the workplace is filled with short-cuts and wicked routines, which are bad learning examples for novices and apprentices. Dehnbostel (2001) state that off the job learning "bays" are effective for skill training, because production stress can be decreased, so opportunities emerge for instruction and rehearsal. Workplace learning should be sequenced in a vocational curriculum, in which a variety of practical learning environments are deliberately scheduled (Van Merriënboer a.o., 2004).

VET colleges and training companies are looking for alternative learning environments combining the attractiveness of realistic work environments and the effectiveness of simulated work environments. Zitter (2010) developed an analytical tool for designing authentic learning environments, based on two dimensions: 1) simulation versus authenticity and 2) acquisition versus participation. The latter dimension is based on the two metaphors for learning, developed by Sfard (1998): in the first metaphor, learning is targeted at the acquisition of knowledge and skills, whereas in the second metaphor learning is targeted at becoming a member of a community (cf. Wenger, 1998).

Simulated practice is favourable for acquisitional goals (skill development and knowledge acquisition), whereas realistic practice is enhancing socialisation processes (legitimate peripheral participation, becoming a member of the working community; Lave and Wenger, 1991).

In the paper a case study is presented on the design and use of the "Juice Factory" in a Dutch VET college. The Juice Factory is a complete and running production line for bottled juice, which is run by students from several higher and intermediate vocational and professional courses (business administration; process technology; mechanical/electronic engineering; sales and retail). Work masters from a neighbour factory and teachers from several colleges are responsible for supervision and coaching and for the delivery of in-company classes. On small scale, the Juice Factory is delivering juice to external clients, so a realistic production process is created. The case study focuses on the teachers of these courses: we were interested in the instructional theories and practices used in course delivery before and after implementation of the Juice Factory. In the case study we reconstruct the implementation process of the Juice Factory, and we interviewed teachers, students and managers of 8 courses (from different colleges involved and on different levels of educational attainments). Besides the analytical model of Zitter, we used the curriculum development theory of Van den Akker (2003) as an agenda for the interviews. Van den Akker discerns 1) the curriculum as designed by developers; 2) the curriculum as used by teachers; and 3) the curriculum as learned by the students. In the paper we will present the design principles used by the VET-teachers of these courses. Although the factory has been operational for three years, teachers hesitate to incorporate the Juice Factory into their teaching and instruction. They do not see the Juice Factory as an innovative educational tool; they use the Juice factory as a regular training company, which is out of their reach. They lack a theory of professional development, so they are not well equipped to use the Juice Factory as an instructional tool for preparing their students for the transition from school to work.

PAPER PRESENTATION

Unraveling characteristics of powerful learning environments for self-regulation in mathematics

Erik De Corte, University of Leuven, Belgium; Fien Depaepe, University of Leuven, Belgium; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

There is today a broad consensus among researchers in mathematics education that the ultimate goal of mathematics education consists in students' acquisition of adaptive competence, i.e. the ability to apply meaningfully learned knowledge and skills flexibly and creatively in a variety of situations. Research has shown that self-regulation constitutes an important component of adaptive competence in mathematics, and is highly correlated with academic achievement. But there is also evidence that students do not become self-regulated learners spontaneously. Taking all this into account the challenging question is: What kind of learning environments needs to be designed in view of fostering in students the acquisition of good self-regulation skills as part of becoming competent in mathematics? This paper will review the available research relating to this important issue, starting thereby from the early studies in the 1980s and resulting in the identification of research-based major characteristics of effective learning environments.

Theoretical background and objective

There is broad consensus that the ultimate goal of mathematics education consists in students' acquisition of adaptive competence, i.e. the ability to apply meaningfully learned knowledge and skills flexibly and creatively in divers contexts. Research shows that self-regulation skills constitute an important component of adaptive competence in

mathematics and are highly correlated with achievement (De Corte & Verschaffel, 2006). However, there is evidence that students do not become self-regulated learners spontaneously. Taking this into account a challenging question is: What kind of learning environments needs to be designed and implemented for fostering in students the acquisition of good self-regulation skills as part of becoming competent in mathematics? This paper reviews the relevant research relating to this issue.

Data sources and results

Early studies in the 1980s investigated the impact of modeling, guided practice, and corrective feedback on primary school students' acquisition of self-regulation skills during mathematics instruction. They showed that using models during teaching can enhance students' self-regulation and achievement (Schunk, 1998). However, these studies were limited to teaching discrete computational skills instead of focusing on the effects of self-regulation on complex activities, especially problem solving. Furthermore, they mostly addressed discrete aspects of self-regulation (e.g., goal setting). Moreover, the interventions were short. De Corte, Verschaffel, and Op 't Eynde (2000) reviewed design experiments involving more extended and more comprehensive interventions focused on problem solving. These studies yielded also promising results that, moreover, converge well with respect to the crucial self-regulatory aspects as well as the instructional models underlying the interventions. Significant self-regulatory activities were: strategic behavior aiming at constructing an appropriate problem representation, and developing a solution plan. Important characteristics of the interventions included: (1) using a variety of teaching methods and learning activities; (2) creating an innovative classroom culture based on social norms that stimulate self-regulated learning. Building on that previous work a considerable series of new intervention studies were carried out over the past decade. We will selectively summarize this research based mainly on two meta-analyses (Dignath, Buettner, & Langfeldt, 2008; Dignath & Býttner, 2008) that cover studies in different subject-matter domains, among them a substantial number in mathematics. In the meta-analysis by Dignath et al. (2008) 17 studies pertain to mathematics at the primary school and report 47 effect sizes. The interventions included teaching of metacognitive strategies (e.g., planning, reflecting) besides cognitive strategies (e.g., heuristics). The results show that the interventions had a positive effect (mean effect size 1.00) on students' performance in mathematics but also on their motivation (1.04) and strategy use (0.77). Interestingly, in the second meta-analysis by Dignath and Býttner (2008) involving 28 studies on mathematics in primary and secondary school (reporting 132 effect sizes) the effect of self-regulation training on performance for secondary students was much smaller (0.23); for primary school the results were in line with the previous meta-analysis (0.96). Overall these meta-analyses show that self-regulated mathematics learning can be fostered in primary and in secondary school students. More recent studies by Mevarech and Amrany (2008), Perels, Dignath, & Schmitz (2009), and Kistner et al. (2010) yielded additional positive results. The important question is then: Which aspects of an intervention make it powerful for enhancing students' self-regulation skills and mathematics achievement? The findings from the meta-analyses and the most recent studies corroborate and complement the characteristics of the effective learning environments identified in the success stories mentioned above, namely interventions should (1) train in an integrated way self-regulation skills using a variety of teaching methods; (2) pay explicit attention to the usefulness and benefits of strategies; (3) create opportunities for practicing strategies and provide feedback about strategy use; and (4) install an innovative classroom culture that stimulates self-regulated learning, especially reflection. Implications for educational practice and directions for continued research This review documents not only that self-regulation has a significant impact on students' mathematics learning, but also that self-regulation of mathematics learning can be fostered by instructional guidance, already in primary school. The most obvious implication is that teaching of self-regulation skills should be appropriately implemented in mathematics classrooms, starting in elementary school. However, this represents a major challenge. Indeed, observation studies have shown that teachers spend little instruction time to strategy teaching (Depaepe, De Corte, & Verschaffel, 2007; Hamman, Berthelot, Saia, & Crowley, 2000). Therefore, a first condition for the large-scale implementation of teaching self-regulation is that policy-makers and school leaders stimulate the design and adoption of novel learning environments that focus on it. Furthermore, curricula, educational materials such as textbooks, and assessment instruments need to be revised accordingly. Whereas all this is necessary, it is not sufficient. Research shows that introducing textbooks based on a new perspective on learning and teaching does not easily and certainly not automatically result in a high-fidelity and sustained implementation of the innovative ideas. Indeed, teachers interpret – often unconsciously – the new ideas through their prior knowledge, beliefs, and experiences (see e.g., Depaepe et al., 2007; Depaepe, De Corte, & Verschaffel, in press). Therefore, an indispensable condition for success lies in the training of teachers, who should be intensively immersed in learning environments that embody the self-regulated learning approach they are expected to implement in their classroom practice. But this involves an appeal for further research focused on how learning environments that aim at improving students' self-regulation competence can successfully and sustainably be implemented in classrooms. As argued by Dignath and Býttner (2008), today scarce information is available about supporting teachers how to do so. Finally, although theoretical models emphasize the importance of motivational components in self-regulation of mathematics learning, until now interventions in the available studies focused almost exclusively on cognition and metacognition (Dignath et al., 2008; Dignath & Býttner, 2008). Lip-service should be

replaced by conducting research aiming at designing learning environments that pursue intentionally at developing students' motivational self-regulatory skills (e.g., keeping up one's motivation to solve a problem), their motivational meta-knowledge (e.g., becoming aware of one's fear of failure when confronted with a complex mathematical problem) and their motivational beliefs (e.g., positive self-efficacy beliefs).

PAPER PRESENTATION

Investigating strategies to develop self-regulated learning in young science students

Julie Moote, University of Edinburgh, United Kingdom; Joanne Williams, University of Edinburgh, United Kingdom; John Sproule, University of Edinburgh, United Kingdom

Self-regulated learning (SRL) is at the forefront of educational research today (Martin & McLellan, 2008). The optional Creativity in Science and Technology (CREST) Award scheme, a completely student-run science project supported by the Science, Engineering and Technology Network, is currently being implemented in schools throughout the United Kingdom. The central aim of this research was to explore the effectiveness of CREST as a strategy to develop SRL and related motivational constructs including self-efficacy, assessment anxiety, and intrinsic motivation. The study followed a quasi-experimental design and involved a 'control' group (N=34) and a 'CREST' group (N=38) of students between the ages of 11 and 12 from a school in Edinburgh, UK. The Motivated Strategies for Learning Questionnaire (MSLQ, Pintrich & DeGroot, 1990), the Modified Five Component Scale for Self-regulation (FCSSR, Maclellan & Soden, 2006), and the Science Motivation Questionnaire (SMQ, Glynn, Taasobshirazi, & Brickman, 2009) were administered to students before and after the CREST programme.

Significant differences were found between CREST and control groups in pre to posttest performance on the MSLQ (test anxiety); the FCSSR (goal setting, strategy implementation, strategy monitoring, and overall SRL); and the SMQ (intrinsic motivation and personal relevance, self-efficacy and assessment anxiety, self-determination and career motivation). While the MSLQ is widely used to assess SRL interventions, it was found to be less sensitive in identifying intervention effects in the present study. In addition, as part of a larger intervention study, this research supports the curricular potential of the CREST programme for enhancing both SRL and science education.

Theoretical and Educational Significance of Research

Internationally, there is increasing interest in focusing educational initiatives toward developing effective, responsible learners. In the classroom context, responsibility involves perception of control and self-regulation. Self-regulated learning (SRL) is at the forefront of educational research today (Martin & McLellan, 2008). SRL is reflective learning that involves monitoring, regulating, and controlling cognition, behaviour, and motivation (Kaplan, Lichtinger, & Gorodetsky, 2009; Martin & McLellan, 2008).

While the concept of SRL is well developed in the literature regarding post-secondary students and adults, the picture of SRL in young students transitioning into adolescence remains unclear (Lewis, 2001). Understanding and developing SRL at a young age may help reduce the stress and frustration currently seen at the university level for all parties involved. In addition, the physical, mental, and educational changes experienced during adolescence highlight the importance of building the self-regulation literature in this age group (Cleary & Chen, 2009; Wigfield & Eccles, 2002). Current publications have stressed the need for self-regulation research to be context-specific (Kaplan et al., 2009). The present study focuses on SRL in science. Policy makers have documented concerns regarding the recent decline in engagement in school science and the decreasing number of students pursuing postsecondary study in science (Archer, Dewitt, Osborne, Dillon, Willis, & Wong, 2010). This is further supported by empirical findings which suggest that student interest in science is most threatened between the ages of 10 and 14, highlighting the need for further investigation in the development of SRL in this age group (Archer et al., 2010).

While researchers are not in agreement on definitions and conceptions SRL, there seems to be agreement as to how to improve SRL, shown through the trends in SRL interventions documented in the literature (Gaskill & Hoy, 2002). However, in practice, one of the major barriers to the uptake of SRL development programmes is the fact that the majority are run outside of classroom teaching time. The optional Creativity in Science and Technology (CREST) Award programme, a completely student-run science project supported by the Science, Engineering and Technology Network, is a SRL intervention currently being implemented in schools throughout the United Kingdom. The research presented here is a systematic evaluation of the impact of the CREST award scheme on SRL and science education.

Aims

The central aim of this research was to explore the effectiveness of CREST as a strategy to develop SRL in young science students. In addition, the impact of SRL on related motivational constructs including self-efficacy, assessment

anxiety, and intrinsic motivation were also assessed. In addition, this project aims to provide insight into the most effective way to administer the programme in schools throughout the UK. Method

The study followed a quasi-experimental design and involved a 'control' group (N=34) and a 'CREST' group (N=38) of students between the ages of 11 and 12 from one independent school in Edinburgh. The SRL questionnaire was administered prior to the intervention and after its completion. This study utilised three measures of SRL; the Motivated Strategies for Learning Questionnaire (MSLQ, Pintrich & DeGroot, 1990), the Modified Five Component Scale for Self-regulation (FCSSR, Maclellan & Soden, 2006), and the Science Motivation Questionnaire (SMQ, Glynn, Taasoobshirazi, & Brickman, 2009). Teachers' assessments of student SRL were also collected. This study is part of a larger intervention involving a number of schools across Scotland, UK.

Analysis

In order to verify that the two groups are matched at outset, t-tests were performed comparing CREST and control group on all pretest measures (Chularut & DeBacker, 2004). Following the methods of Chularut & Debacker (2004), split-plot analyses of variance were performed on each of the dependent variables with repeated measures of time (pretest and posttest) and with CREST as the independent variable. Main effects and three-way interactions were also tested (Chularut & DeBacker, 2004).

Findings

Findings showed an overall difference in the ability of the SRL measures to identify intervention effects. While the MSLQ identified a significant interaction effect for test anxiety ($F(1,70) = 5.12$, $p = 0.068$), no other group or interaction effects were found. However, the FCSSR identified differences between the CREST and control groups in terms of their pre to posttest change for goal setting ($F(1,72) = 5.21$, $p = 0.068$), strategy implementation ($F(1,71) = 5.19$, $p = 0.068$), strategy monitoring ($F(1,72) = 4.01$, $p = 0.053$) and the total SRL score ($F(1,71) = 8.17$, $p = 0.103$). The SMQ similarly found pre to posttest differences between the CREST and control group for intrinsic motivation and personal relevance ($F(1,70) = 4.93$, $p = 0.066$), self-efficacy and assessment anxiety ($F(1,65) = 10.01$, $p = 0.133$), self-determination ($F(1,72) = 6.20$, $p = 0.079$), and career motivation ($F(1,71) = 5.52$, $p = 0.072$).

Conclusions

Using an inter-disciplinary approach drawing from education, educational psychology, and science education, this research has potential to be published in a variety of peer-reviewed journals. The results of the present study found significant differences between CREST and control groups in pre to posttest performance on a range of constructs relating to SRL including self-efficacy, assessment anxiety, and intrinsic motivation. While the MSLQ is widely used to assess SRL interventions, in the present study it was less sensitive in identifying intervention effects. This study, as part of a larger intervention study, supports the curricular potential of the CREST programme for enhancing both SRL and science education.

PAPER PRESENTATION

A Design-Based Approach with Vocational Teachers to Promote Self-Regulated Learning

Helen Jossberger, University of Regensburg, Germany; Saskia Brand-Gruwel, Open University, Netherlands; Els Boshuizen, Open University, Netherlands; Margje van de Wiel, Maastricht University, Netherlands

In this design-based research study, we joined in with vocational teachers and investigated how we can diminish obstacles and optimise students' self-regulated learning in pre-vocational secondary education by better understanding the connection between teaching and learning in workplace simulations. The study consisted of two design circles: design of learning tasks and design of teacher feedback. First, authentic and challenging learning tasks were designed, which included a clear goal, a planning, visible assessment and performance criteria, and a reflection. Second, teachers were instructed to give feedback on process and self-regulation level to reduce the discrepancy between current understanding and performance of students and promote their self-regulated learning. Method triangulation was used for gathering data, including observations, logbooks of teachers, and questionnaires for students. This practice oriented approach, in which teachers were actively involved, revealed that changing learning tasks only is not sufficient to promote self-regulated learning. Only if teachers assess students' processes and performance thoroughly and give feedback on process and self-regulation level, a gain in students' self-regulation can be achieved.

Innovations in vocational education are important to meet the demands of the business community and to improve educational quality constantly. A great number of vocational schools has implemented workplace simulations (WPS), but this innovative implementation requires pedagogical content knowledge that is lagging behind. Little is known

about the way students learn in such learning environments, which instruction method is most suitable for teachers and learners, and how the learning environment can contribute to optimal learning. This lack of knowledge bears the risk that the innovation is doomed to fail before the pedagogical knowledge can be developed. Innovations in education directly influence the teacher, the student, and the learning environment. Therefore, it also seems self-evident that innovations will especially succeed, when they take into account the needs and wishes of teachers and students. In this study, we focus on the design of learning tasks and direct feedback from the teacher in order to improve students' self-regulated learning in WPS. Authentic learning tasks are the starting point in WPS to trigger students' interest, get them engaged in the learning process, and stimulate self-regulated learning. The tasks should have a clear goal that is specific and challenging, so that it focuses students' attention. During task performance supportive information should be available for students, because it can help them to integrate theoretical and practical knowledge. Performance and assessment criteria that are clearly stated can make the learning process more visible and learning needs become more transparent which should enable optimal learning (e.g., Kicken et al., 2008). Feedback has been identified to be the most powerful influence on learning and achievement and can help learners to learn to self-regulate their learning (Hattie & Timperley, 2007). Feedback aims to close the gap between the current level of performance and the desired level that needs to be reached. In order to reduce this discrepancy, three questions need to be addressed by effective feedback, including "Where am I going?" (What are the goals?), "How am I going?" (What progress is being made toward the goal?), and "Where to next?" (What activities need to be undertaken to make better progress?) (Hattie & Timperley, 2007). The three questions work together and have the power to trigger learners to initiate further actions. According to Hattie and Timperley, the effectiveness of feedback depends on its focus. Deep processing and mastery of tasks are especially promoted by feedback on process and self-regulation level, because this feedback is related to learning. In this design-based research study, we joined in with vocational teachers and investigated how we can diminish obstacles and optimise students' self-regulated learning in pre-vocational secondary education by better understanding the connection between teaching and learning. The central research questions are: 1) What changes need to be made in the learning tasks to promote self-regulated learning of students? and 2) To what extent can teachers promote students' self-regulated learning by providing direct feedback on process and self-regulation level?

Method

On the basis of integrated cycles of design and analysis, we systematically tested, evaluated, and improved the educational practice with regard to 1) the learning tasks and 2) teachers' feedback. Three teachers and 66 students participated. First, changes were made in the preparatory and practical part of a learning task. A clear task goal and learning goals were formulated, so that students immediately see what the task is about and what is expected from them. In the practical task three changes were made. We added a work planning, assessment criteria, and a reflection. Second, teachers were informed about giving and receiving feedback. The aim of feedback was explained and examples were provided to illustrate the different levels of feedback and their effects. Teachers were advised to give feedback on process and self-regulation level and to stimulate learners to explicate how it is going. Three questions were provided as support: 1) What are the learning goals of the student? 2) What is the progress in relation to the goals? and 3) How can you stimulate the progress? Method triangulation was used for gathering data. Process data (including design and evaluation sessions with teachers, short teacher evaluations after a WPS lesson, recordings of teachers' feedback, and observations) and outcome data (including a student questionnaire, students' task completions) were collected. The processes of designing and revising as well as teachers' feedback were recorded and documented carefully.

Some Results and Conclusions

The results with regard to the learning tasks revealed that the new structure was clear for teachers and students. According to teachers, students asked less questions and worked more independently. The goal setting and assessment criteria made the task and the requirements transparent and became the starting point for the evaluation. Planning ahead was difficult for students and they often did not use the planning during the practical task. The results regarding the feedback revealed that teachers started to take more time to trigger students' critical thinking by asking open questions about their processes. This interaction elicited students' reflection, which otherwise remained superficial. Task completions of students show that their self-regulation concerning planning, evaluating, and reflecting improved with the help of the teacher. Concluding, it is important that WPS turn into a place, in which learning tasks are carefully designed to stimulate self-regulation and providing feedback on process and self-regulation level becomes a daily practice in the interaction between teacher and student. The learning tasks were the starting point in promoting self-regulation and feedback helped students to become more actively involved in the learning process. The provided support raised teachers' consciousness of self-regulated processes and requirements for self-regulation, which helped them to realise the theoretical ambitions of self-regulation and independent working in WPS better. However, promoting self-regulation requires a lot of time and consistency.

PAPER PRESENTATION

Relations between specific and global domains of self-concept. New tests of James' models

L. Francesca SCALAS, University of Cagliari, Italy; Herb Marsh, University of Oxford, United Kingdom

In this research, we investigate two crucial models about self-esteem determination dating back to James (1890): the Actual-Ideal discrepancy model–AID and the Importance-Weighted Average model–IWA. Although intuitively appealing, the models have weak support from rigorous empirical research. Thus, we use a stronger methodological approach to better evaluate AID and IWA models applied to a range of self-concept domains (physical self-concept, academic self-concept, spiritual self-concept) and subdomains (appearance self-concept, math self-concept, verbal self-concept) in young adolescents of two different countries (study 1: 402 adolescents from the United Kingdom; study 2: 250 adolescents from Italy). Support for the AID and IWA models was generally weak; the only exception was for spiritual self-concept. Overall, general components of self-concept are more determined by actual accomplishments than ideal standards. Moreover, the contribution of specific areas of self-concept to self-esteem did not vary systematically with the importance placed on each specific component of self-concept. Finally, results from a MonteCarlo study provide an explanation to the elusive nature of the models. Only advanced methodologies and big samples can detect the critical effects. These outcomes are relevant to self-concept theory and research, but also to the development of self-concept enhancement programmes that should be focused mainly on actual accomplishments.

Background and aims

Our research investigates how effects of multidimensional, specific components of self on global self-esteem depend on framing factors such as ideal standards and the importance of specific components. Two mechanisms dating back to James (1890) have been hypothesized to affect global self-esteem: 1) the discrepancy between the perception of actual self and ideal standards in specific domains (Actual-Ideal discrepancy model–AID), 2) and the interaction between the actual perception and the importance that particular components of self have for an individual (Importance-Weighted Average model–IWA).

Since rigorous empirical research has provided weak support for both models (e.g., Farmer, Jarvis, Berent, Corbett, 2001; Marsh, 1986, 1993, 2008; McDaniel & Grice, 2008), we use a stronger methodological approach based on latent variables and multiple items (Scalas & Marsh, 2008) to better evaluate AID and IWA. The principal aim of the study is to extend the models to a range of various self-concept domains (physical self-concept, academic self-concept, spiritual self-concept) and subdomains (appearance self-concept, math self-concept, verbal self-concept) in young adolescents of two different countries (United Kingdom, Italy). Specifically, appearance and physical self-concept have been considered in order to favor comparability with the previous studies (Lindwall, Asci, Palmeira, Fox, Hagger, accepted paper; Scalas & Marsh, 2008). The academic selves have been examined since this is an area quite important for self-worth during adolescence. The spiritual self-concept has been used since this is a domain that can be very important for some people but not important at all for others. Therefore, this might be a critical domain to test in particular the IWA model.

Methodology

We conducted 3 studies. Study 1 was designed to extend and generalize the multiple-item methodology for both the AID and IWA models to various self-concept domains (physical, academic, spiritual) and subdomains (appearance, math, verbal) from different perspectives (actual, ideal, importance). A sample of 402 adolescents (age range: 13-15) from the UK anonymously completed an electronic version of the questionnaire. Items of the questionnaire were based on the Self-Description Questionnaire (Marsh, 1992) and the Rosenberg scale of self-esteem (Rosenberg, 1965). Study 2 was designed to generalize results from study 1 over country (UK; Italy). A group of 250 adolescents of the same age completed a paper and pencil version of the questionnaire. Special attention was given to the physical area, since previous research supported the AID model for the relation between appearance, physical self-concept and self-esteem in Italian adolescents and young adults (Scalas & Marsh, 2008).

Study 3 was a MonteCarlo study and it was added subsequently to explore some power issues connected to results associated to the physical appearance domain. Indeed, as noted by Muthen and Muthen (2002) "a sample may be

large enough for unbiased parameter estimates, unbiased standard errors, and good coverage, but it may not be large enough to detect an important effect in the model" (p.600).

Results

AID and IWA models for different domains (physical self-concept, academic self-concept) and self-domains (appearance, math, verbal self-concept) were not supported in studies 1 and 2. Moreover, these poor results generalized over countries (UK; Italy). The only exception was related to the spiritual self-concept. In both samples, for this domain, AID assumptions of a positive effect of actual self on self-esteem (UK: .32, t-value = 4.12; Italy: .26, t-value = 2.59) and of a negative effect of ideals on self-esteem (UK: -.24, t-value = -3.04; Italy: -.22, t-value = -2.15) were supported. Also in relation to the IWA model, a significant and positive interaction between actual self and its importance was found only for the spiritual self-concept in the UK sample (.16; $t=2.55$).

A special interest of study 2 was on results from the physical area. Although, the estimates were not significant, in both the UK and Italian samples, the confidence intervals (CI) for ideal appearance betas on physical self-concept (UK, CI: from -.164 to .012; Italy, CI: from -.215 to .045) included the value found by Scalas & Marsh (2008) in their study (-.11).. This pattern suggests that a power issue might have prevented results from being significant.

Therefore in study 3, we performed a MonteCarlo study for power purposes (Muthen & Muthen, 2002). Results suggest that a sample of at least 800 cases is needed to provide sufficient power (.80) to detect a significant effect from ideal appearance to physical self-concept (assuming that the population value is -.11).

Discussion and conclusion

Support for the AID and IWA models was generally weak; the only exception was for spiritual self-concept. Overall, general components of self-concept are more determined by actual accomplishments than ideal standards. Moreover, the contribution of specific areas of self-concept to self-esteem did not vary systematically with the importance placed on each specific component of self-concept.

The weak support for AID and IWA models generalized reasonably over country (UK, Italy).

A special focus of this research was on physical area. We have found that for the majority of the people the contribution of ideal appearance is low; thus only with big samples it will the result be statistically significant as confirmed by our MonteCarlo study. This outcome is particularly relevant since it enlightens the elusive nature of the AID-model in the literature. Indeed studies in this are typically considered samples of few hundreds of subjects.

In summary, results provide an explanation to the elusive nature of both AID and IWA models. Only advanced methodologies and big samples can detect the critical effects. These outcomes are relevant to self-concept theory and research, but also to the development of self-concept enhancement programmes that should be focused mainly on actual accomplishments.

PAPER PRESENTATION

Listening and audio-visual comprehension in L2 - Empirical evidence for the two constructs?

Raphaela Porsch, Westfaelische Wilhelms-Universitaet Muenster, Germany; Ruediger Grotjahn, University of Bochum, Germany; Bernd Tesch, Humboldt-University of Berlin, Germany

According to the "National Educational Standards for the First Foreign Language" enacted by the Standing Conference of the Ministers of Education and Cultural Affairs of the Federal States in Germany (KMK, 2003, 2004) listening comprehension and audio-visual comprehension in the first foreign language (in Germany: English or French) are competencies that need to be acquired until the end of lower secondary education. However, the Standards and the Common European Framework of Reference (Council of Europe, 2001) - on which the Standards are based - have not provided two separate construct descriptions for developing tasks for teaching and testing the understanding of audio and audio-visual material. The study to be presented aims at answering the question of whether one can differentiate empirically between these constructs by assessing German ninth-graders ($N = 156$) by means of an experimental design with either a listening or an audio-visual comprehension test in French as a foreign language using the same items. Results show that if the pictures of the authentic videos in French provide help, learners are significantly better in the audio-visual condition. In addition, the challenges posed for defining a construct of audio-visual comprehension in a foreign language are explored, and a discussion about consequences for further research along with recommendations for teacher training is provided.

Introduction

According to the "National Educational Standards for the First Foreign Language" enacted by the Standing Conference of the Ministers of Education and Cultural Affairs of the Federal States in Germany (KMK, 2003) listening comprehension and audio-visual comprehension in the first foreign language are competencies that need to be acquired until the end of lower secondary education. However, the Standards and the Common European Framework of Reference (CEF; Council of Europe, 2001) on which the standards are based have not provided separate construct descriptions for developing tasks for teaching and testing the understanding of audio and audio-visual material. Much research in processing text and pictures has been undertaken by media psychologists. Paivio (1986) introduced the theory of dual coding stating that information is processed and stored by two interconnected systems: one verbal and one visual. Picking up this idea, Baddeley (1992, 2006, 2007), Mayer (2001) and Schnotz (2005), for example, have developed models that describe the cognitive processes of text and picture comprehension and studied factors that facilitate or hinder learning from texts and pictures. Results from empirical work in the context of foreign language learning with the focus of processing audio-visual information is summarized by Wagner (2008) stating that there are no clear results whether texts combined with pictures support learning. Some studies have found that the additional visual input increases learning (see, e.g., Gruba, 1993, 1997, 1999; Brett, 1997, 2001; Coniam, 2001; Ginther, 2001, 2002), others could not confirm this (see, e.g., Parry & Meredith, 1984; Chung, 1994; Sueyoshi & Hardison, 2005). Most studies have been conducted with participants speaking English as a second language focusing on the question of what type or combination of input improves learning. Recently, especially in the context of computer and web based testing, standardized foreign language tests have used audio-visual material (see, e.g., Ockey, 2007; Wagner, 2008) but mostly static images (e.g. TOEFL iBT).

Research Aims

The study was carried out to investigate whether one can differentiate empirically between the constructs of listening and audio-visual comprehension in a foreign language. Accordingly, the research question was: Do foreign language learners of French show higher scores in a standardized listening comprehension test if additional visual aids are offered? Understanding an audio text and related items can be described as a result of an interaction between text and task features and the recipient's competence. Determinants of listening comprehension difficulty have been widely researched (see, e.g., Brown, 1995; Freedle & Kostin, 1999; Grotjahn, 2000; Buck, 2001). Therefore, three task-specific hypotheses were formulated whether the visual input produces significant enhancement of performance or not.

Method

156 ninth-graders learning French as a foreign language at higher secondary schools ("Gymnasien") in Germany in 2009 took part in the study. Randomly, the complete learning groups/classes were assigned to two groups: 1 = audio-visual comprehension (AV; N = 68) and 2 = listening comprehension (LC; N = 88). The following instruments were applied: (1) Pretest: Students of both groups received the same listening comprehension test in French. (2) Testing in two conditions: Group 2 as the control group listened to audio texts (sound), group 1 as the experimental group watched video sequences (sound and pictures). In both conditions students had to answer the same items and listened to the same audio texts.

Results

First, it was tested whether both groups did not differ significantly in their French listening comprehension abilities, answering the question "Is the assignment of the students done randomly?" The total score of group 1 (AV) in the listening comprehension test was only slightly lower than that of group 2 (LC). However, the difference was not statistically significant. Second, all items for each task were considered (sum score on the basis of ten dichotomously scored items). Students from group 1 (AV) had, on average, significantly higher scores than those receiving an aural input only. The effect size was large ($d = .40$). Beforehand, the videos have been analyzed whether the visual information provides help for understanding the items while listening to the audio texts. The hypotheses – regarding the support of the pictures – are related to one item per task/video. Thus, in a third step, the mean scores of these items in each group were compared using one-factor ANOVA. As predicted for two items, students performed significantly better with pictures providing visual aid ($F[1, 156] = 8.908, p = .003$; $F[1, 156] = 12.426, p = .001$). In both cases the effect was highly significant and large ($d = .49$ and $.57$). Finally, the scores of all other items of each task were examined assuming that the pictures do not provide an additional aid in understanding the information given by the audio texts. With two exceptions the results were confirmed. They can be explained by the difficulty of the language and the condition that additional pictures were presented, which contextualize the information and thus may facilitate understanding.

Conclusion

The results clearly suggest that one can differentiate between listening and audio-visual comprehension when testing German students learning French as their first foreign language. Consequently, in order to develop adequate test and teaching materials, one needs to establish a construct definition for both competencies. This presents quite a challenge as the ongoing international discussion shows (see, e.g., Gruba, 1997, 2006; Buck, 2001; Choi, Kim & Boo, 2003; Wagner, 2007, 2008). The question is "How can one differentiate between foreign language competence and media competence when testing L2-learners with audio-visual material? Furthermore, future studies should examine in detail the factors determining the difficulty of understanding video material. The study to be presented used authentic texts based on the descriptors of the CEF. This makes it difficult to draw general conclusions but is in line with modern foreign language teaching principles demanding the use of authentic texts in the foreign language classroom (see, e.g., Higuchi, 1998; Murdoch, 1999; Mishan, 2005).

PAPER PRESENTATION

Differences in Reported Foreign Language Learner Strategy Use Across Educational Levels

Katerina Vlckova, Masaryk University, Czech Republic; Marie Daskocilova, Masaryk University, Czech Republic

Learning strategies constitute an important concept in the theory of foreign language acquisition. The use of foreign language learning strategies and its contexts were investigated at the end of primary education, lower secondary education, and higher secondary comprehensive education (according to ISCED 97) in the Czech Republic. Adopted Strategy Inventory for Language Learning – SILL (Oxford 1990) was applied in a cross-sectional research which focused on how the reported use of strategies differs and what specific characteristics of the three groups of learners were. The research concentrated on both direct (memory, cognitive and compensatory) and indirect (metacognitive, affective and social) strategies and also examined variables potentially influencing strategy use as well as variables influenced by strategy use. The differences in strategy use among the groups were significant in many aspects. The relation between strategy use and the variables that influence strategy choice and use (gender, strategy instruction etc.) or variables that are influenced by the strategy use (achievement) seems to be predominantly stable across the groups.

Learning strategies present a crucial concept of many disciplines; since the 1960s, they have been gaining an important place in the theory of first and second language acquisition. Nowadays, learning strategy is a concept that captures a wide range of linguistic behaviours. Strategies are defined as sets of "conscious thoughts and actions that learner takes to achieve a learning goal" (Chamot 2004), or as operations to acquire, retain, retrieve or perform (Rigney 1978). The concept is connected with self-regulation, metacognition, learning and cognitive styles. Strategies are most often classified according to psychological functions – cognitive, metacognitive, socio-affective (O'Malley, Chamot 1990), or 4 language skills (Cohen, Weaver 2006). Strategy choice and use is influenced by different variables (gender, experience, educational level, proficiency, age, motivation, language aptitude). Strategy use influences variables such as school grade, knowledge or development of language skills which are the focus of our research based on Oxford's language learning strategy classification (1990) and adapted, enlarged inventory SILL (Oxford 1990). Strategies are divided into direct (memory, cognitive, compensatory) and indirect (metacognitive, affective, social) ones. The research questions are: Do pupils at 3 levels of comprehensive education in the Czech Republic differ in their perceived strategy use? Do the variables affecting the strategy use and variables influenced by strategy use differ at the 3 levels?

Methods

Research sample (non-random sampling) comprised 1482 pupils of 5th grade at 56 elementary schools (i.e. at the end of primary level), 2384 pupils of 9th grade at 54 elementary schools (i.e. at the end of compulsory education) and 1038 students of the one before last year at 22 upper secondary schools – grammar schools (i.e. 12th grade/near the end of comprehensive education). The strategy inventory for the 5th grade pupils consisted of 28 items with a 3-point frequency scale ($\alpha = 0.74$). The inventory for 9th ($\alpha = 0.90$) and 12th ($\alpha = 0.796$) grade used 5-point scale for 67 items. In the 5th grade, knowledge tests of English ($\alpha = 0.81$) and German ($\alpha = 0.78$) were used. Students were asked to report their strategy use in a preferred foreign language which was mostly English.

Results

In the 5th grade, not all the strategies in the inventory for the 9th and 12th grade were investigated because of the cognitive limits of younger learners. Therefore some comparisons were only conducted with the 9th and 12th grade pupils and an average use of strategies on all educational levels was calculated on 18 strategies. Pupils in the 5th grade used strategies ($x = 3.28$, $SD = 0.63$ at the adapted 5-point scale) significantly more often than students in the 12th grade ($x = 3.01$, $SD = 0.45$). The lowest strategy use was revealed in the 9th grade ($x = 2.81$, $SD = 0.51$). Cognitive, compensatory, metacognitive and social strategies were used in the 12th grade more than in the 9th. Affective

strategies were used more in the 9th grade. No significant differences were found in memory strategies, they were generally scarcely used. The order of use of the six strategy groups was the same at the 9th and 12th grades (compensatory – cognitive – metacognitive – social strategies). In the 9th grade, memory strategies were the least used group, while in the 12th grade those were affective strategies.

Cognitively more demanding memory strategies (association, contextualisation, phonetic representations) were used more in the 12th grade than in the 9th. Grouping, mind maps and physical response were used in the 9th grade more than in the 12th. In the 5th grade, students used more mechanical techniques such as cards. Practising phonetics and orthography was more frequently used in lower grades. Practising in natural settings was used in the 12th grade more than in the 5th or 9th grades. Pupils of the 5th grade reported less co-operation with their schoolmates.

Age, gender, self-efficacy, perceived language aptitude, instruction (both informing about strategies, and practising) played a consistent role in the strategy use at all educational levels. Number of learned languages only affected strategy use in the 9th and 12th grades (the 5th grade pupils only learned 1 language at schools). The differences between the types of acquired languages were only found in the 5th grade where learners of English used strategies more than those of German. Girls used strategies significantly more at all three educational levels. The 5th grade pupils answered more often that they knew how to learn than the 9th and 12th grade pupils. The perceived language aptitude was the smallest in the 9th grade (maybe because of early selection for academic schools in the 6th grade). Younger pupils were more often told how to learn. Learner training was most often conducted by teachers in the 9th grade. There was a significant but weak connection found between the school grade as well as perceived knowledge and strategy use in the 9th and 12th grades. Cognitive strategies were relatively strongly correlated with the school grade in foreign language. In the 5th grade the score in the knowledge test was not correlated with strategy use.

Discussion

Pupils at all education levels were using learning strategies in a way. Children at the primary level use simpler strategies than pupils at higher levels. Many results seemed to reflect demographic composition of the groups. Compensatory strategies seemed to have a specific role in the school learning, they were used when pupils didn't know something therefore these were not expected by teachers to be used in the classrooms. Affective strategies were used when pupils experienced stress mostly when they were not "efficient" language learners, in the 9th grade more often than in the 5th or 12th grades.

At all levels, two thirds of pupils stated they didn't know or only partly knew how to learn foreign language, around one third of pupils thought they didn't have language aptitude. Nevertheless, two thirds of pupils have never or scarcely had strategy instruction. We might assume that there is a gap between pupils/ needs and instructional opportunities, and pupils should be taught how to learn foreign language at all educational levels.

This paper was funded by Czech Ministry of Education, Youth and Sports – project LC06046 Centre of Advanced Research in School Education.

PAPER PRESENTATION

Enhancing Chinese Character Learning of Non-Chinese Speakers using the learning Theory of Variation

Wai Ming CHEUNG, University of Hong Kong, Hong Kong; Wing Yee W.Y. WONG, The University of Hong Kong, Hong Kong

Purpose: Emerging interest in China in western countries has led to a corresponding surge in the study of Chinese. Due to the huge number of Chinese characters and words, it is impossible for learners, regardless of their native languages, to master the language by rote memorization. The acquisition and processing of the Chinese language has therefore become a popular area of study for non-Chinese speakers. This study investigates the possibility of using "Variation Theory" in learning Chinese character for non-Chinese speaking (NCS) students in Hong Kong and its effectiveness. Methodology: Fifty-two Grade 7 South Asian girls aged 12 and 2 teachers from a girl's college in Hong Kong were recruited to join the empirical study for one year. Teachers taught students Chinese characters and Chinese Language using pedagogy developed from Variation Theory. Pretest and posttest were administered at the beginning and end of school year to assess students' learning. Result: After a year of study using the new approach, the post-test scores of participants have shown significant improvement compared with the pre-test. The effect size of improvement in total score is 1.47, showing that students' general improvement has achieved a standard of extremely high level. Significance: This study shed light on Chinese character learning for NCS learners all over the world. Participants showing success of learning Chinese character using Variation Theory will be anticipated to transfer this knowledge of character to their future learning of Chinese reading and writing.

The current trend of globalization has enabled high mobility of people with ease from country to country for various purposes. Emerging interest in China from the western world has led to a corresponding surge in the study of Chinese. Due to the huge number of Chinese characters and words, it is impossible for learners, regardless of their native language, to master the language by rote memorization. The acquisition and processing of the Chinese language has therefore become an area of interest for non-Chinese speakers. Approximately 5% of the population in Hong Kong comes from countries of ethnic minority (EM). The EM students come from diverse cultural and language backgrounds. Effective strategies in learning Chinese as second language thus deserve more attention. NCS students always find learning Chinese difficult as their own languages usually belong to the alphabetic language system, whilst Chinese is an ideographic language. The Variation Theory (Marton, Runesson & Tsui, 2004; Runesson & Marton, 2002) has been proved to be a powerful tool in enhancing the Chinese learning for first language learners (Marton, Tse & Cheung, in press). We explore how the Variation Theory can be put into practice to inform teachers in handling the teaching of Chinese characters for NCS students. This study also investigates its effectiveness on student learning. A total of 52 Grade 7 South Asian girls and 2 teachers from a girls' college in Hong Kong were recruited and joined the empirical study in the academic year 2009-10. We chose to implement this study at a girls' school because researchers have reported that traditional family values downplay the importance of second language acquisition and creates linguistic barriers particularly for female South-Asian immigrants (Cumming & Gill, 1991). Students mainly came from Pakistan, India, the Philippines, Nepal, and Indonesia. Six modules of Chinese characters learning were developed based on Variation Theory and the Comprehensive and Integrative Perceptual Approach (Tse, Marton, Ki and Loh, 2007). Teachers taught students Chinese characters and Chinese Language by simultaneous discernment of the shape, sound and meaning of the characters (Chan & Nunes, 2001; Marton, 2006). Tzeng et al.'s study (1986) indicated that Chinese characters are processed as symbols that carry structures possessing different levels of graphic complexity. Target character is shown on the blackboard (structure), with teacher pronouncing the word (sound) and presenting picture (meaning) simultaneously. Teachers would systematically use variation and invariance to help students identify the components of the characters. Variation patterns such as separation and fusion were used in lessons to facilitate acquisition of target characters with the same component. Six meaningful texts were developed in accordance to the features and needs of EM students so as to foster association between Chinese learning and students' funds of knowledge. Target characters were embedded in the texts that could help establish the whole-part relation that meaning is revealed as a whole to NCS students. The Word Test was modified from test developed by Tse, Marton, Ki and Loh (2007). It consisted of six sections and took 60 minutes to complete. The assessments included: Identify the common component of the words: This section assessed whether students could discern the same component of the five characters given; Writing down words related to the pictures: This section assessed the number of words the students were able to write down from memory; Identify characters with correct pictures: In this section students were asked to choose the picture that represented character given in each question; Identify characters with correct structure: This section assessed the students' ability to discern the differences in similar characters and choose the only correct word; Matching correct characters with sounds: This section assessed students' sensitivity to the pronunciation of characters. Students listened to the teacher read aloud the correct answer then picked out the correct pronunciation from five options. Writing: In this section students have to write 100 words with reference to four related pictures given. Pretest and posttest were administrated at the beginning and end of school year to assess students' learning. To see whether the class performed significantly better in the post-test, we conducted a paired-sample t-test. Data analysis on comparison between pretest and posttest result showed positive changes in all six sections. The positive t values in paired-sample t-test were all significant (See Table 1 in the Appendix). The mean of total score has increased from 50.99 to 74.95 with an effect size of 1.47 (n=52). According to Cohen (1977), the extremely high effect size of 1.47 indicated that students' improvement was of high standard. Hong Kong teachers tend to use the traditional way of teaching Chinese to teach NCS students, students learnt characters and vocabulary separated from context, copied the structural pattern and repeated until they could memorize the structure of the characters. However second language learners could not start from the characters solely but from a context which makes the learning meaningful to them. The positive findings indicated a change from traditional Chinese curriculum to a new approach in teaching Chinese as second language necessary. Improvement of Chinese character learning voiced out the significance of using the Theory of Variation in teaching Chinese as second language. Further development on learning Chinese as second language beyond characters using the theory deserves more research efforts in the future. In addition, to equip NCS female learners with competence in the immigrant city, effective educational intervention to improve language acquisition of NCS students and thus their academic achievement is of paramount importance to the students and their family.

PAPER PRESENTATION

Vocabulary learning from reading: Examining interactions between task and learner-related variables

Xiaoli Wu, Katholieke Universiteit Leuven, Belgium; Jan Elen, Katholieke Universiteit Leuven, Belgium

In the field of second and foreign language learning, how various task characteristics affect language learning has been the focus of many recent studies. Much of this research has examined the relationships between task complexity, task sequence and task performance without fully taking into account learner-related variables. The present study aimed to assess task complexity and sequence in relation to the learner-related variables drawn from the social-cognitive perspective of self-regulated learning, i.e. self-efficacy beliefs and frequency of learning strategy use as they were applied to two versions of vocabulary learning from reading tasks. The tasks designed for the present study were based on the componential framework for second language task design. With tasks and task sequence counterbalanced, 146 first-year university students (mean age = 18.59 years) were randomly assigned to one of the four groups. Results revealed a significant effect of task complexity on frequency of learning strategy use; a significant effect of task sequence on vocabulary learning self-efficacy belief, frequency of learning strategy use and task performance; and a significant interaction effect of sequence with task complexity. Findings are discussed in terms of complex interactions between task and learner factors.

In the field of second and foreign language learning, how various task characteristics affect language learning has been the focus of many studies (Skehan, 2001; Robinson, 2001; 2005). In these studies, task complexity is seen as an important construct to both second language acquisition researchers and language teachers. Although relationships between task complexity, task sequence and task performance have been examined (Robinson, 2001; 2005), previous works did not fully take into account the interactions between task complexity and learner-related variables. Given the importance assigned to learners' task interpretations in current instructional design research (Lowyck, Elen & Clarebout, 2004) and the strong predictive power of learner-related variables, e.g. self-efficacy belief, in relation to academic outcome (Pajares, 2002) in mainstream educational psychology research, it is important to better understand the interactions between task and learners' perceptions of designed tasks, and how their perceptions affect learning behaviours and performance. In the present study, we examined task complexity and sequence in relation to the major constructs drawn from the social-cognitive perspective of self-regulated learning, i.e. self-efficacy beliefs and learning strategy use, as they were applied to English vocabulary learning from reading tasks.

Research questions The following questions are addressed in the present study. First, what effect does the designed task at different levels of complexity have on learners' perceived self-efficacy, learning strategy use and task performance? Second, we are also interested to know if there is a main effect of task sequence and any interaction effect of task complexity and task sequence on learners' perceived self-efficacy, learners' use of learning strategies and task performance.

Research method

Participants The sample consisted of 146 first-year university students (137 females and 9 males, mean age = 18.59 years) from a Belgian university. The students were native-born Belgians who had Dutch as their first language. They volunteered to participate in the study and were awarded extra course credit for their participation. **Tasks** The tasks designed for the present study are based on the componential framework for second language task design (Robinson, 2005). In terms of the elements of complexity listed by Robinson, the vocabulary learning task was manipulated along the dimension of +/- single task demand. Two texts describing the profile of two modern artists were chosen for the experiment. Two versions of the tasks (i.e. with/without the provision of a gloss) were created with each text. Therefore, altogether four tasks were used, i.e. two simple tasks, which includes Text 1 + gloss and Text 2 + gloss; two complex tasks, which includes Text 1 - gloss and Text 2 - gloss.

Design and procedures

The experiment used a repeated measures design. The counterbalanced design included four task sequences, i.e. Task simple to Task complex; Task simple to Task simple; Task complex to Task simple; and Task complex to Task complex. Participants were randomly assigned to four groups, and executed two vocabulary learning tasks that were presented separately during two experimental sessions. At the beginning of each session, participants received a booklet with experimental task materials and a self-efficacy scale ($\alpha = .86$). After completing the task, participants were asked to fill in a vocabulary learning strategy questionnaire ($\alpha = .73$). A vocabulary test was administered after the task booklet had been handed in.

Results A 2×2 MANOVA with text as a within-subject variable and task complexity as a between-subject variable showed a significant effect of task complexity (Wilks's Lambda = .89, $F(4, 275) = 8.16$, $p F(1, 275) = 31.83$, p To examine the effect of sequence in more detail, the factor task order was entered into MANOVA. Results showed significant univariate effects for task order on vocabulary learning self-efficacy ($F(1, 275) = 3.80$, $p F(1, 275) = 4.43$, $p F(1, 275) = 21.79$, $p F(1, 275) = 6.08$, $p F(1, 275) = 5.25$, p **Discussions and conclusions** Regarding the first research question, a significant negative effect of task complexity was only found for learning strategy use. Our results do not support the claim from previous works on task complexity (Robinson, 2001; 2005). Differences in the

cognitively defined complexity of tasks were not reflected in learners' perceptions of task and their learning outcomes. Regarding the second research question, our results show that the order in which tasks were performed had a significant effect on students' learning results. What is even more interesting here is the interaction effect of task complexity with task order. These results seem to indicate that learners' perceptions of task evolve along the learning process. What is, from a designer's point of view, an important task complexity dimension may not be perceived by learners as such at the very outset of learning. However, learners' perceptions and judgements develop gradually, and they can get more calibrated with the designer's intention along the process. It means that, in practice, the accuracy of learner task perceptions and efficacy judgements can be trained by manipulating task complexity and task sequence. In the context of our objective to further our understanding of the effectiveness of instructional tasks for language learning, we believe more studies are needed to further explore and validate the complex interactions between task factors and learner-related factors.

PAPER PRESENTATION

In what ways are spelling difficulties related to text quality?

Asa Wengelin, Lund University, Sweden; Victoria Johansson, Lund University, Sweden; Roger Johansson, Lund University, Sweden

In this paper we explore how spelling difficulties, as measured in a standardized test, spelling errors in written texts and spelling revisions during the production process are related to each other, and to text quality in writer with reading and writing difficulties. Spelling test data and text production data were collected from both 15-year-olds and university students. The writing processes were analysed for spelling errors, revisions and temporal distributions. Qualitative analyses of the spelling errors and the revisions are currently being carried out. Not surprisingly the 15-year-olds produced texts with lower quality and more spelling errors than the university students. More interesting was that the quantitative results of the spelling test and the percentage of spelling errors in the text did not correlate at all. In addition, whereas the spelling test predicted text quality, this was not the case for the percentage of spelling errors in the texts. Preliminary results of the qualitative analysis of the spelling errors further indicate that the participants produce different types of spelling errors in the test situation and during text production. Concerning the process data a weak negative correlation between percentage of reading time and spelling errors and a weak positive correlation between reading and text quality was found. The differences between the results of the spelling test and the spelling errors in the texts indicate that in order to get as complete a picture as possible of children's spelling difficulties they need to use both spelling tests and free writing.

Writing by children and adults with reading and writing difficulties is typically associated with spelling problems. In addition their texts frequently receive lower quality ratings than the texts of writers without reading and writing difficulties. The explanation usually given for this is that poor lower-level writing skills of the writers with reading and writing difficulties limit cognitive resources for higher-level production processes such as planning and reviewing (e.g. McCutchen 1994). However, the relations between spelling difficulties, higher level processes and the mechanisms behind these relations are not clear. Moreover, spelling difficulties is an ambiguous concept. To a certain extent they are represented by spelling errors made by the writer. However, during the text production process a writer may have encountered more spelling difficulties than the errors found in the finally edited texts. The questions of this presentation are: How are spelling difficulties, as measured in a standardized test, spelling errors in written texts and spelling revisions during the production process related to each other, and how are these measures related to text quality?

Two groups of writers with reading and writing difficulties – thirteen 15-year-olds and ten university students – were recruited by means of a screening process involving a spelling test and a word decoding test. Data from two control groups were also collected. Each participant produced an expository text elicited by means of a video clip showing different scenes from a school setting, such as cheating, bullying and theft, all chosen to inspire discussion (Berman & Verhoeven 2002). All text production was recorded by means of keystroke logging (ScriptLog) and eye tracking (SMI iView X Hed). Finally all writers were interviewed about their attitudes towards writing. The text products were analysed for spelling and text quality as well as for text length, lexical diversity and syntactic complexity, but only the spelling errors and the text quality will be reported here. The writing processes were analysed for revisions and temporal distributions. The revisions are currently being categorized. In addition, two types of qualitative analyses of the spelling errors are also being performed at the moment: (a) surface analyses categorizing errors into insertions, omissions, substitutions and transpositions, and (b) a linguistic analysis categorizing errors as phonological, morphological or lexical and as either phonologically acceptable or unacceptable.

As expected the two groups with reading and writing difficulties produced shorter texts with more spelling errors and less quality than the control groups. In addition, they made more pauses and more revisions. Since the control groups produced very few spelling errors and this paper focus on spelling difficulties only data from the two groups with reading and writing difficulties will be further reported. Not surprisingly the 15-year-olds produced texts with lower quality and more spelling errors than the university students. However, the individual variation was quite large. More interesting was that the quantitative results of the spelling test and the percentage of spelling errors in the text did not correlate at all. Moreover, whereas the spelling test predicted text quality, this was not the case for the percentage of spelling errors in the texts. Preliminary results of the qualitative analysis of the spelling errors further indicate that the participants produce different types of spelling errors in the test situation and during text production. These results agree with for example Wengelin (2002). Concerning the process data a weak negative correlation between percentage of reading time and spelling errors and a weak positive correlation between reading and text quality was found. Neither percentage of spelling errors, nor text quality correlated with number of revisions. However, another picture may emerge once the revisions have been categorized.

Despite the case that the number of spelling errors in the finally edited texts did not correlate with text quality, the result that the spelling test predicted text quality indicate that spelling difficulties is indeed can indeed influence text quality. One possibility is that poor results of a spelling test are due to general processing difficulty. Another possible explanation is that only certain types of spelling errors influence the judgements of the raters. We will have a clearer picture of that after the categorization of the errors. A third possibility is that the writers put a lot of effort into strategies for correcting and avoiding spelling errors. This explanation is supported to a certain extent by the weak correlation between reading and number of spelling errors. It could possible also be supported by the interviews in which the participants state that they find spelling to be the most difficult part of spelling. This would also explain the different types of spelling errors in the test and the texts. The differences between the results of the spelling test and the spelling errors in the texts indicate that in order to get as complete a picture as possible of children's spelling difficulties they need to use both spelling tests and free writing. Moreover, the more detailed analysis of errors and revisions will contribute towards both our theoretical and practical knowledge about writing difficulties.

PAPER PRESENTATION

Teaching Struggling Writers Argumentative Writing: An Intervention Study

Carmen Gelati, University of Milano Bicocca, Italy; Lerida Cisotto, University of Padova, Italy; Pietro Boscolo, Università di Padova, Italy

Writing an argumentative text is a very demanding task for young students because many cognitive processes are implied (Coirier & Golder, 1993). Children of primary and middle school often write unpersuasive argumentative texts (Applebee, Langer, Mullis, Latham, & Gentile, 1994). Writing argumentative essay is difficult in particular for struggling writers that, compared with their peers, have more troubles to simultaneously carry out several cognitive processes (Bereiter & Scardamalia, 1987). Usually these difficulties have also motivational consequences, particularly in primary school where children's will to express and communicate ideas and feelings in written form may be restricted by their concern to avoid mistakes in written texts and poor teacher evaluation. This study was aimed at analysing the effects on struggling writers in grades 5 and 7 of an instructional intervention focusing on argumentative writing. Primary and middle school struggling writers were randomly assigned to the experimental and control conditions. In the experimental group six 90-minute workshops were realized. Activities of writing and analysis/revision of argumentative texts were proposed to children.

Analyses of covariance revealed that the intervention proved to be successful in improving the ability to write argumentative text. In fact, after the intervention, experimental group children wrote better, longer, and more complete argumentative texts than control group children. Independently of the intervention, middle school students wrote longer texts than elementary school children, and girls better than boys. The second objective regarded the motivational aspects. No difference emerged for the liking of writing and for the self-perception of competence.

Writing an argumentative text is a demanding task for young students. This activity, in fact, involves many cognitive processes such as combining arguments together, refuting, generalizing, considering other points of view and opposing arguments (Coirier & Golder, 1993), as well as, of course, planning, translation, and revising (Hayes & Flower, 1980). The researchers found that the ability to write an elaborated argumentative text develops with age: at 7-8 years a position is stated and it is supported by one argument; progressively, the argumentative structure becomes more complex thanks to the addition of other supporting arguments, and, by age 13-14, of counterarguments (Brassard, 1990; Golder & Coirier, 1994; Schnewly, 1988). However, as Applebee and collaborators showed (Applebee, Langer, Mullis, Latham, & Gentile, 1994), the argumentative writing of most students

is often unpersuasive: many students of 4th and 8th grades write undeveloped or minimally developed responses for presenting their opinion, few reasons without support, and rarely they consider different points of view. Writing argumentative text is difficult in particular for struggling writers that, compared with their peers, have more troubles to simultaneously carry out several cognitive processes (Bereiter & Scardamalia, 1987). In general, struggling writers do little spontaneous planning, tend to use knowledge telling (Bereiter & Scardamalia, 1987), have limited knowledge of the structure of genres, revise superficially, and have limited metacognitive awareness. These difficulties usually have motivational consequences, particularly in primary school, where children's will to express ideas in written form may be restricted by their concern to avoid mistakes and poor teacher evaluation. The intervention studies have privileged the cognitive component of writing, while the motivational component has been given less importance. Recently, several scholars have considered the motivational aspects of writing (Boscolo & Gelati, 2007, 2008; Bruning & Horn, 2000; Hidi & Boscolo, 2006, 2007; Pajares & Valiante, 2006), in particular the relationship between interest in writing, on the one hand, and self-perceptions of writing competence, on the other. The present study analyzed the effects on struggling writers in grades 5 and 7 of an instructional intervention focusing on argumentative writing. The intervention was planned and conducted with a dual objective. The first was to improve students' ability to organize and write argumentative texts. The second objective was to modify students' attitude to writing, thanks to a collaborative writing environment, in which struggling students were not concerned with teacher evaluation.

Method

Preliminary phase Three hundred and sixty-one students participated in the study: 186 5th graders (M = 82, F = 104) and 175 7th graders (M = 88, F = 87). The classes were randomly assigned to the experimental condition. Since the intervention was focused on struggling writers only, we selected students with writing difficulties by evaluating on a 5-point scale a text written by the students before the intervention. The language skills teachers were also asked to rate students' writing ability on a 5-point scale. Students rating below the 33rd percentile in written text and in teacher evaluation were considered to be struggling writers.

Participants There were 74 struggling writers in the experimental group - 38 5th graders (M = 21, F = 17) and 36 7th graders (M = 21, F = 15) – and 65 struggling writers in the control group - 34 5th graders (M = 14, F = 20) and 31 7th graders (M = 18, F = 13). Measures before the intervention1. Children were asked to write an argumentative text.2. Writing self-efficacy questionnaire: 10 items on a 10-point scale. 3. Liking of writing questionnaire: 10 items on a 4-point scale. The interventionSix 90-minute workshops. Basic principles:a) Close connection between reading and writing by analysing exemplar texts for enriching repertory of ideas and lexicon, and identifying the elements of the argumentative text (Toulmin, 1958).b) Writing workshops for making students more aware of planning and revising processes, using "cognitive tools" such as notes, maps etc. c) Alternation of individual, collective, and group work.Activities for improving the ability to take a position, justify a thesis, support it, analyze other points of view and opposing arguments were realized.Measures after the intervention1. Children were asked to write an argumentative text.2. Writing self-efficacy questionnaire.Liking of writing questionnaire.

Data analysisLength: number of T-units. Text quality: holistic score on a 5-point scale.Text structure: the structural level of each text was analysed using Toulmin's model (1958).ResultsArgumentative text. A MANCOVA revealed that, after the intervention, experimental group children wrote better texts than control group children, $F(1, 114) = 4.43$, $p = .05$. Moreover, they wrote argumentative texts with a more complex structure: both 5th and 7th graders reported more reasons to support their thesis and many 7th graders used also counterarguments. Independently of the intervention, girls outperformed boys, writing texts with higher quality, $F(1, 114) = 8.52$, $p = .01$. Middle school students wrote longer texts than primary school children, $F(1, 114) = 59.33$, $p < .001$. Writing Self-Efficacy. From an ANCOVA no significant difference emerged between the experimental and control groups.Liking of writing. From an ANCOVA no significant difference emerged between the experimental and control groups.

Discussion

This study was carried out with two objectives. The first was to improve students' ability to organize and write argumentative texts. The intervention proved to be successful in improving the ability to write argumentative text. In fact, after the intervention, experimental group children wrote better, longer, and more complete argumentative texts than control group children. Independently of the intervention, middle school students wrote longer texts than elementary school children, and girls better than boys. The second objective regarded the motivational aspects. No difference emerged for the liking of writing and for the self-perception of competence. The result may depend on the difficulty for struggling writers of modifying their attitude to writing - which have developed over years of unsuccessful writing experiences - with a relatively short intervention. This is a problem which should be explored in greater depth in future studies on writing difficulty.

PAPER PRESENTATION

Cognitive benefits of expressive writing

David Galbraith, Staffordshire University, United Kingdom; Norma Sherratt, Staffordshire University, United Kingdom

Previous research has suggested that expressive writing can have beneficial effects on cognitive functioning and subjective well being. In the present study, we tested whether this is mediated by increases in working memory (WM) capacity, and whether this varies as a function of self-monitoring and individual differences in emotional expressivity. We also examined whether it is specific to verbal WM, or whether it also occurs for non-verbal measures of WM capacity. 84 undergraduates completed measures of self-monitoring and emotional expressivity. They were then randomly assigned to either an expressive writing condition - in which they wrote about past traumatic events - or a control condition - in which they wrote descriptively about the events of the day - on three separate days over a two week period. Measures of verbal and spatial WM capacity, and of general health, were taken immediately before the first writing session, and two weeks after the final writing session. Results showed that expressive writing led to an increase in verbal WM capacity but not in spatial WM capacity. These effects were moderated by individual differences in emotional expressivity: individuals who habitually express their positive and negative emotions in their everyday lives showed smaller effects, while individuals who typically mask their emotions in their everyday interactions showed stronger effects. These results suggest that expressive writing may be a valuable tool for improving academic performance at university, and provide an important argument for including expressive writing as well as functional writing within the school curriculum.

Research by Pennebaker and others (e.g. Pennebaker, 1997; Frattaroli, 2006) has suggested that expressive writing about past traumatic events can lead to beneficial effects on health and cognitive functioning. Klein and Boals (2001) suggested that expressive writing leads to a reduction of intrusive thoughts, and that this should lead to a freeing of working memory resources. This was supported in an empirical study suggesting that expressive writing leads to an increase in working memory capacity after writing. In the present study, we aimed to replicate this effect, and to investigate whether it varied as a function of self-monitoring and individual differences in emotional expressivity. We also examined whether it is specific to verbal working memory, or whether it also occurs for non-verbal measures of working memory capacity. All participants were asked to complete an emotional expressivity questionnaire (Gross and John, 1998), measuring five facets of emotional expressivity: Expressive Confidence, Positive Expressivity, Negative Expressivity, Impulse Intensity, and Masking. They were also asked to complete a Self-monitoring scale (Snyder and Gangestad, 1986). 84 low and high self-monitors (categorised using a median split of scores on the self-monitoring scale) were then randomly assigned to either an expressive writing condition or to a control condition. In the expressive writing condition, participants wrote about a past traumatic event for 20 minutes on 3 separate occasions spread over a two-week period. In the control condition, participants wrote descriptively, on the same occasions, about the events of the day. Before writing, all participants completed the operation span test of working memory capacity (Unsworth, Heitz, Schrock and Engle, 2005) and the General Health Questionnaire (GHQ). Two weeks after the final writing session, they completed the same measures again, and also a non-verbal test of working memory capacity (symmetry span). The results showed a significant effect of expressive writing on operation span scores, with writers in the expressive writing condition, but not the control condition, showing increases in working memory capacity. This replicates Klein and Boals' findings. By contrast, there were no differences in symmetry span as a function of writing condition. This suggests that the effect of expressive writing is specific to the verbal component of working memory, and is compatible with the assumption that the effect is related to the reduction of intrusive thoughts, which are assumed to be verbal in form. Individual differences in emotional expressivity affected the size of this effect: individuals who habitually express their positive and negative emotions in their everyday lives showed significantly smaller effects of expressive writing, while individuals who typically mask their emotions in their everyday interactions showed significantly stronger effects of expressive writing. Although effects on health were in the same direction, they were not statistically significant, possibly because of a lack of statistical power. Working memory capacity is strongly associated with tests of cognitive ability and with performance on a wide range of tasks involving higher level mental processes. The present results strongly support the use of expressive writing in educational contexts. Pennebaker and his colleagues have found that, when new undergraduates are asked to write about their anxieties about coming to university, they subsequently achieve better grades in their academic work than students assigned to a control condition. Less directly, these results also imply that intrusive thoughts have a chronic influence on working memory capacity. The results provide an important argument in favour of a less instrumental writing curriculum, one in which pupils learn how to make meaning out of their personal experience. In future research we plan to investigate whether creative writing has similar effects on cognitive functioning and subjective wellbeing.

PAPER PRESENTATION

Aspects of Hungarian undergraduates' writing skills

Zsuzsanna Balazsne Nagy, University of Szeged, Hungary; Tamas Barassevich, Graduate School of Educational Sciences, University of Szeged, Hungary

This study focused on prospective Hungarian teachers' writing skills development. The research questions included (1) the text quality and communicative value of students' writing; (2) the application of critical thinking and argumentation strategies involved in the writing process; and (3) the mapping of the influence of self-concept as a background variable. The process of writing, as described in the classic cognitive models is a metacognitively triggered, complex self-regulatory activity. Hence, the approach of process writing places the emphasis on the goal setting and regulation of the communication process, as well as on the social environment of the task (Rijlaarsdam and Bergh, 2006). The sample consisted of BA students from a Hungarian university, attending a preparatory preparatory course for teacher training. The analysis presented is based on a total number of 49 respondents. In order to assess the development and quality of their writing skills, participants had to complete three realistic tasks, (a) write a job application letter, (b) evaluate two texts and formulate their advice and (c) do the Hungarian adaptation of the Ennis-Weir test of critical thinking. (n=35 completing all three tasks). The results indicate that the undergraduates in the sample are rather egocentric thinkers and communicators. The findings provide information for the development of curricular and methodological interventions.

This study raises issues regarding prospective teachers' writing skills development. The research questions were formulated in a Hungarian context and aimed at (1) the text quality and communicative value of students' writing; (2) the application of critical thinking and argumentation strategies involved in the writing process; (3) the mapping of the influence of self-concept as a background variable.

Theoretical background

The process of writing, as described in the classic cognitive models is a metacognitively triggered, complex self-regulatory activity. Hence, the approach of process writing places the emphasis of the goal setting and regulation of the communication process, as well as on the social environment of the task (Rijlaarsdam and Bergh, 2006). The means of development is then found in teaching strategies to students, enhancing their metacognition (Jenks, 2003). According to Reimer (2001), those who master the elements of the process will become more successful writers.

The Hungarian National Core Curriculum requires the secondary school leavers to have the skills of a successful communicator in writing as well, to be able argue in writing in a sophisticated manner, to think critically about their subject matter and to be conscious writers, yet previous research revealed that this is not a target attained in the secondary school leaving population. However, we know little about the well-achieving population that enters higher education with the prospect of becoming teachers themselves. At the same time, if they enter this profession, they will have to facilitate their students' development in their mother tongue skills.

Methods

The sample consisted of BA students from a Hungarian university, attending an introductory preparatory course of education, which is a preparatory course for teacher training. The number of full responses in study 1 was 39, in study 2 it was 47. A total of 35 students participated in both studies. In spite of the small size of the sample, it reflects gender ratios among students in teacher training, with women (21) outnumbering men (14), and also a wide variety of majors were represented from arts to sciences.

In order to assess the development and quality of their writing skills, participants had to complete three realistic tasks. They were asked (a) to produce a job application letter, and (b) to evaluate two such texts and formulate their

advice to the authors of these two letters. The resulting texts were analysed with regard to conceptual, linguistic and coding aspects. The standards of evaluating the responses to task (a) were based on the 1990 IEA study of written composition. Subjects were also administered (c) the Hungarian adaptation of the Ennis-Weir test of critical thinking, which required them to write a letter to the editor of a local newspaper in response of a public letter. The texts were analysed with regard to characteristics of critical thinking and argumentative strategies. The genre-specific communicative features of tasks (a) and (c) were identified and analysed.

Results

Average text quality was found, while critical thinking and the communicational features of the texts were poor. However, students performed rather well when evaluating the sample texts. Measures of text quality for tasks (a) were rated on 6 point scales for six analytical and one holistic score. All of these correlated significantly with each other ($r=.181$, $p<.05$ – $r=.785$, $p<.01$), however, none had a significant correlation with performance on the critical thinking task (c). The content analysis showed that the texts contained mostly writer-centered information and betrayed a neglect of the awareness of the participants' positions in the given situation.

As regards judging others written communication, Kendall's test of concordance reflected very high level of agreement (.920 – 1.000) with the expert's rating in the case of the first letter of task (b), which was a poor text, yet the index is much lower (.500 - .929) in case of the second sample letter, a text with several good qualities to it. In giving advice to the writer of the evaluated texts, students had rather diverse performances (.13 – 1.00). They were most inclined to give a list of the mistakes the writer made without offering the means of possible development.

The critical thinking achievements were poor (6.54, $sd=5.45$) in the Ennis-Weir essay test. Subjects tended to use fictional data or their beliefs about social justice as counterarguments for the false syllogisms of the test, and they were not sensitive to the mistakes made in the original argumentation. In responding to the task, students failed to connect their text to the original arguments or to do so consistently. Also, only one fourth gave a proper introduction to the text. The existence of introduction here seems to be an indicator of audience awareness, with significant correlations ($r=.388$, $p<.05$) with the total critical thinking score and indicator of the quality of advice offered ($r=.381$, $p<.05$) in task (b).

General, verbal, and emotional self-concept as well as problem solving had strong, significant correlations with relevant aspects of the texts (r values around $\pm .35-.45$).

Discussion

The above results conformed to those of previous studies among Hungarian secondary students. The results above indicate that even well-achieving university students are egocentric communicators in writing. Yet, given the viewpoints, and given the role of detached evaluators, they are able to spot mistakes, which knowledge they do not transfer to text production.. The findings provide information for the development of curricular and methodological intervention.

PAPER PRESENTATION

Multidimensionality of Reading Comprehension Variables: Topics in Theory and Methodology

Jonna Kulikowich, Penn State, United States; Danielle McNamara, The University of Memphis, United States;
Art Graesser, The University of Memphis, United States; Patricia A. Alexander, University of Maryland, United States

The topic of multidimensionality is an important one in both learning theory and psychometric theory. Many variables in reading comprehension research are theoretically multidimensional. Further, scores for these variables are likely best studied assuming more than one dimension or trait establishes how best to study their reliability and validity. In this presentation, intentionality to read in an academic domain and text complexity are studied as two important reading comprehension variables that differ in how they must be studied psychometrically given their multidimensional characteristics. Implications for both reading comprehension and psychometric theory as well as for quantitative methodology are discussed. Recommendations are provided given applications of Item Response Theory, multilevel modeling, and Structural Equation Modeling in the study of these important reading comprehension variables.

The ability to comprehend complex texts nested within a variety of media (e.g., Internet, newspapers, or textbooks) is important in today's world for students to learn and communicate in a globally networked society (Wiley, Goldman, Graesser, Sanchez, Ash, & Hemmerich, 2009). In this theoretical presentation, the multidimensionality of variables is examined as well as theoretical components and methodological frameworks required to study reading comprehension. Two variables included in the discussion are the intentionality to read in an academic domain (e.g.,

Kulikowich & Alexander, in press; McCrudden, Magliano, & Schraw, 2010) and text complexity (e.g., Graesser & McNamara, 2010; McNamara, Graesser, & Louwerse, in press). With regard to reading comprehension, each variable needs to be grounded theoretically, with reasonably reliable and valid operational definitions. This requires some complexity and uniqueness to the variables associated with different comprehension levels. A one-size-fits all quantitative framework may not offer the opportunity to make advances in the fields of cognitive and educational psychology and to introduce what Marsh and Hau (2007) refer to as methodological-substantive synergies. A methodological-substantive synergy occurs when each theoretical and methodological viewpoint reinforces each other well beyond what each can do alone.

To work toward methodological-substantive synergies, variables must be understood given their complex and unique characteristics, and variables can differ in many ways. Variables can differ with respect to whether they are latent (e.g., Borsboom, 2005) versus directly measured. Latent constructs have values that vary randomly in a statistical sense and are assumed to cause responses or behaviors given what readers know or how they process information. Intentionality to read in an academic domain is a latent random variable that refers to a mental state, but it is also important to consider observed behaviors or responses (selections of texts to solve problems, use of references to support a claim) that result from these intentions. By comparison, text complexity, which can be measured using computer programming tools such as Coh-Metrix (Graesser & McNamara, 2010 ; McNamara et al. in press), is arguably a manifest, multidimensional variable because it can be defined using indices in computational linguistics that belong to texts as the units of analysis. The text characteristics are directly observable and are most often measured using ratio scales such as the frequencies of modifiers, nouns, and verbs included in the text. Whereas latent traits are often studied using statistical techniques such as exploratory and confirmatory factor analysis, text complexity defined by indices in computational linguistics is often analyzed using principal component analysis techniques. Intentionality to read to learn also includes several latent elements that involve goal-setting, planning, execution of plans, and evaluation of plans that operate within a processing network. This network includes temporal and recursive properties as goals can change, plans can be modified or abandoned altogether relative to one's initial intentional set. By comparison, text complexity as measured by Coh-Metrix indices may also have several components or dimensions; however, these multiple dimensions serve to summarize the computational linguistic variables rather than define how they are inter-related in a network that attempts to describe how readers process information. Multidimensional variables may also differ given how best they are studied statistically in relation to other variables. This difference is essential in knowing how to specify and test complex statistical frameworks to address empirical research questions. Contextual variables, such as those of classroom or school settings, may alter the dimensionality of any theoretically-defined multidimensional variable. Students may be assigned to read or select to read texts that vary in complexity, for example, and this relation between students and texts may change given: a) classroom or school setting; b) by reading offline versus online; or, c) with reference to state, national, or international standards given the assessment of comprehension. In this 20-minute presentation, the need to study multidimensionality of variables theoretically and methodologically is introduced. Brief definitions of intentionality to read to learn in an academic domain and text complexity are provided with review as to how these variables have been assessed in the literature. The presentation closes with demonstrations of how IRT, HLM, and SEM models can be specified differentially given the theoretical premises associated with each multidimensional variable.

PAPER PRESENTATION

SimScientists: Using Simulations to Assess Complex Science Learning

Edys Quellmalz, WestEd, United States; Barbara Buckley, WestEd, United States; Matt Silbergitt, WestEd, United States

The SimScientists research and development program at WestEd combines a model-based learning approach with evidence-centered design into a powerful framework for transforming science assessment. This paper describes a large-scale field test of simulation-based assessments for two middle school topics in three states with 55 teachers and 5500 students. Findings document the feasibility, utility, and technical quality of science simulations for formative, curriculum-embedded assessment and summative, end-of-unit benchmark assessment. SimScientists projects contribute to the research base on the design and validation of the next generation of innovative assessments and their articulation throughout levels of an educational assessment system.

Aims

This paper presents research funded by the U.S. National Science Foundation and the U.S. Department of Education on the feasibility, utility, and technical quality of science simulations designed as formative, curriculum-embedded assessments and as summative, end-of-unit benchmark assessments. The SimScientists program at WestEd seeks to provide evidence that simulation-based assessments can gather and document evidence of students' understanding of connected science knowledge and extended inquiry not often or well measured in the U.S. by conventional tests (See simscienists.org). Curriculum-embedded assessments provide feedback and coaching to advance the learning. Unit benchmark assessments test proficiency and report it for teaching and accountability purposes.

In addition, these assessments are envisioned as components of multilevel, balanced state science assessment systems. The assessments test U.S. national science standards at the middle school level (grades 6-8) for life science (e.g., ecosystems), physical science (e.g., climate), and physical science (atoms and molecules).

Methods

The SimScientists research and development program combines a model-based learning approach with evidence-centered design into a powerful framework for transforming science assessment and learning (Buckley, in preparation; Mislevy et al, 2003). The SimScientists projects proceed through phases of design, expert review, programming, small scale feasibility testing, and classroom testing. The design process involves analyses of learning research, national science standards, and curriculum materials to specify grade-appropriate system components, interactions, and emergent behavior. For example, ecosystem components consist of organisms in the roles of consumers, producers, and decomposers. Interactions involve transfer of energy and matter through the ecosystem, represented in food webs. Emergent system behaviors involve population levels of organisms and changes in them due to varying conditions. Inquiry practices, as specified in the 2009 NAEP Science Framework, include designing, conducting, interpreting, and evaluating. Simulation shells specify the representations of science phenomena to be modeled by the simulation environment. Model-based progressions proceed from observations of organisms, inferences of interactions, and predictions, observations, and explanations of varying population levels. The paper will present examples of the assessment design documents.

In 2010, the U.S. Department of Education funded a large-scale pilot of simulation-based assessments for two middle school topics to investigate the feasibility, utility, and technical quality of the simulation-based formative and summative assessments. Fifty-five teachers, 5,500 students, in 28 districts in three states participated. Data included expert reviews of the alignments of the assessments with national science standards, quality of the science, items, and tasks, cognitive labs in which students think aloud as they respond to the assessments, classroom observations, teacher surveys and interviews, and psychometric analyses. An external evaluation of the project was conducted by UCLA's Center for Research, Evaluation of Students and Standards (CRESST). A Design Panel of representatives of six state departments of education science assessment directors reviewed the pilot test findings and a policy brief summarizing the pilot test and offering alternative models for integrating science simulations into state science assessment systems.

Findings

The paper will summarize qualitative and quantitative data from the pilot test in the three states and the recommendations in the Policy Brief for using science simulations in a balanced state science assessment system. Feasibility and utility were indicated by evidence that the students were engaged in the simulation-based assessments and that the teachers found the reports of student progress useful for understanding student learning and for adjusting instruction. Across the 28 school districts and 55 classrooms, teachers were able to implement the simulation-based assessments in computer labs. Psychometric analyses of the benchmark assessment data indicated

that they were reliable and valid. The Policy Brief describes alternative models for using benchmark data in balanced multilevel state science assessment systems.

Theoretical and Educational Significance. A growing body of research shows model-based reasoning to be a signature practice of the sciences, as scientists create insights and understandings of nature through conceptual, physical, and computational modeling. Further, cognitive research shows that learners who internalize schemas of complex system organization – structure, functions, and emergent behaviors – can transfer this heuristic understanding across systems. Simulations can represent dynamic science systems "in action", making visible the causal, temporal, and spatial phenomena that are invisible and making models available for extended, active investigations of authentic problems. A technical infrastructure that captures and analyzes students' actions and answers can yield cognitively rich evidence of learning in reports for teachers and school systems and can also provide feedback and customized, graduated coaching. The multiple physical and symbolic representations in simulations can also reduce language demands.

In large-scale assessments, the area of science is leading the way in exploring complex, multi-faceted problem types and assessment approaches. The 2006 Programme of International Student Assessment (PISA) pilot tested a Computer-based Assessment of Science specifically to test knowledge and inquiry processes not assessed in the paper-based test booklets. Topics included the functions of a nuclear reactor and genetic breeding of plants. The 2009 National Assessment Educational Progress (NAEP) for Science administered Interactive Computer Tasks (ICT) to test students' inquiry practices. The 2014 NAEP for Technology and Engineering Literacy will be entirely computer delivered and will administer interactive, scenario-based tasks (See www.naeptech2014.org). States such as Minnesota have online science tests with simulated laboratory experiments or investigations of phenomena such as weather or the solar system. The SimScientists projects described in this paper contribute to the research base on the design, development, and validation of the next generation of innovative assessments and their articulation throughout the levels of an educational assessment system.

PAPER PRESENTATION

Reliability and validity analyses of a test to assess learning strategy knowledge

Katharina Maag Merki, University of Zurich, Switzerland; Yves Karlen, University of Zurich, Switzerland; Erich Ramseier, PHBern – University of Teacher Education, Switzerland

The competence of self-regulated learning is considered to be important for student learning. Yet, analyses of the impact of self-regulated learning show that this is only partially true. Methodological problems in the measurement of self-regulated learning have been discussed in the literature as one possible explanation. A recently introduced approach focuses on developing tests to measure knowledge of learning strategies (e.g. Schlagmýller & Schneider, 2007). Up to now, such tests have only been applied in reading, mathematics, and natural science experiments. However, testing procedures capable of measuring learning strategy knowledge for tackling complex and difficult assignments or projects at school are still lacking. This paper aims to study the reliability and validity of such a test that was developed in a Swiss longitudinal study. Additionally, we used a standardized questionnaire to measure habitual cognitive and metacognitive learning strategies as well as motivational self-regulation. Reliability and validity analyses taking into account the multilevel structure of the data indicate satisfactory goodness-of-fit of the instruments. The analyses show that knowledge of learning strategies is especially crucial in mathematics, but less so in German and in-depth subjects since in these subjects motivational regulation is more important than knowledge of learning strategies. In conclusion, we discuss the implications for future research.

PAPER PRESENTATION

The Mechanism of Washback (test impact) - Revisited

Satomi Mizutani, University of Auckland, New Zealand

The current study investigated the mechanism of the phenomenon known as washback in the context of the national assessment for senior students at secondary schools in New Zealand. Washback refers to the impact that assessment has on teaching and learning in the field of language testing. There have been a few attempts to describe how assessment influences teaching and learning in the field. However, such models failed to articulate exactly how the mechanism of washback works. Washback was previously thought to be unpredictable because of mixed results of educational reform through assessment change. The current study specifically looked at the role of beliefs held by teachers and students, and their contextual factors (e.g., subject and the socio-economic status of school) in the process of washback. The results suggested that at least part of the mechanism of washback could be predicted as the research demonstrated patterns of the ways certain washback effects were brought about by certain types of contextual factors and beliefs. Based on the findings, a new model of washback was proposed, describing how intended positive washback effects are promoted or hindered by certain contextual factors and beliefs held by teachers and students. It is argued that this washback model can help us further understand the mechanism of washback and can potentially help promote intended positive washback while minimising undesirable negative washback.

The current study investigated the mechanism of test impact on teaching and learning in the New Zealand context. High-stakes assessment has often been used not only as a measurement of educational achievement, but also as a strategy to bring about desired teaching and learning as part of educational reform around the world (Linn, 1992; Petrie, 1987). New Zealand is not an exception. In 2002, the government introduced the National Certificate of Educational Achievement (NCEA), a new standards-based assessment where students' performance is evaluated against pre-described criteria (Donnelly, 2000), in an attempt to motivate students of all abilities to strive for higher levels of achievement by emphasising self-comparison and providing them with a clear focus on the standards to achieve (Fancy, 2001).

However, such education assessment reform efforts including the recent case in New Zealand have led to mixed results (e.g., Alison, 2005; NZQA, 2006). It is argued that this may be a reflection that the mechanism of test impact is complex and the link between assessment and desired outcome has not been well understood. Chapman and Snyder (2000) argued that policy makers who advocated educational reform through assessment change failed to see that explicit catalysts were required between the testing strategies they used and the outcomes they hoped to see. Chapman and Snyder (2000) stressed that policy makers were responsible for clarifying and elaborating the link between testing and improved teaching and learning. They also suggested that success in educational reforms could not be guaranteed because it was not the test itself that influenced teachers' behaviour, but rather it was teachers' beliefs about the test that influenced their behaviour. Fullan (2001) also suggested that beliefs would play an important role in promoting desired test impact. Therefore, it can be argued that for a successful educational reform, one of the embedded assumptions is belief change.

The concept of assessment influencing teaching and learning is often referred to as washback in the field of language testing. As was the case in the field of education, studies in the field of language testing have found mixed results of efforts to bring about desired washback (e.g., Alderson & Wall, 1993; Andrews, Fullilove & Wong, 2002; Cheng, 1997, 1998; Watanabe, 1996). There have been a few attempts to create washback models which illustrate how assessment influences teaching and learning in the field (e.g., Alderson & Wall, 1993; Bailey, 1996; Shih, 2007). Such models indicated that many factors such as subject, school setting, personal background of teachers and students as well as beliefs held by them influenced the nature of washback. However, the models failed to articulate exactly how washback effects were mediated by such factors. Thus, the research question was as follows: What is the role of contextual factors and beliefs in the mechanism of washback?

The current study involved teachers and students of four subjects at secondary schools: Japanese, French, History, and Mathematics in order to compare foreign language subjects and non-foreign language subjects. Data were collected through questionnaires. The questionnaires were designed to tap into the nature of washback of NCEA and beliefs held by teachers and students. The questionnaires also collected information on the following contextual factors: subject, socio-economic status of the area where schools were located, gender, the length of teaching career (teachers only), expected achievement level (students only).

Questionnaires were sent to schools throughout New Zealand and a total of 161 teachers and 845 students responded. The data from the participants were then analysed with the use of a series of exploratory maximum likelihood factor analyses to identify the underlying structure of the items for both teacher and student

questionnaires. In order to investigate how washback effects of NCEA and beliefs held by teachers and students varied depending on contextual factors, a series of multivariate analyses of variance (MANOVAs) were conducted. Where there was a statistically significant difference, a post hoc Scheffe test was carried out to identify where the difference lay. Effect sizes were calculated in order to indicate the magnitude of differences. Multiple regressions were also carried out to explore how certain types of beliefs held by teachers and students contributed to various types of washback effects of NCEA.

The results suggested that contextual factors and beliefs played a role in bringing about certain types of washback. For example, where subject was a factor, whether it was a verbal (i.e., Japanese, French, or History) or numeric (i.e., Mathematics) subject made a difference in the way teachers and students interpret washback of the assessment on student motivation and on variability of marking practice. While socio-economic status was rarely a factor for teachers which influenced washback of NCEA and their beliefs, it was often a factor for students, indicating a clear difference between lower and higher socio-economic status. The results also indicated that gender, the length of teaching career, and students' expected achievement level played only a small part in mediating the impact of NCEA and beliefs held by teachers and/or students.

This study also clearly demonstrated a link between washback effects and beliefs held by teachers and students. The results suggested that positive washback was mediated by positive beliefs and negative washback was mediated by negative beliefs. The study also indicated that positive beliefs had another function, which is to mitigate negative washback. This highlighted the important role of positive beliefs in bringing about desired positive washback.

To my knowledge, the current study is the first empirical study which demonstrated exactly how washback effects were mediated by beliefs and contextual factors. A model is proposed to describe the mechanism of washback, showing how washback could be mediated directly and indirectly by contextual factors and beliefs. The links established between teachers' and students' beliefs, their contextual factors, and washback in the proposed model are arguably useful to increase understanding of the mechanism of washback of an assessment on teaching and learning. By clarifying the link between assessment and desired outcomes, the model can potentially help promote intended positive washback while minimising undesirable negative washback.

PAPER PRESENTATION

Silencing socialization of religious Girls in Israel

Zehavit Gross, Bar-Ilan University, Israel

The aim of this paper is to analyze the silencing processes in the socialization of religious girls brought up in a transitional society between traditionalism and modernity. Using qualitative in-depth interviews, 20 girls (5 Jewish, 5 Muslim, 5 Christian-Arab and 5 Bedouin) aged 18-25, were examined. The findings show that silencing is embedded in the ideal school graduate. The girls are situated in an ambiguous dichotomic world where they are expected to be confident, proud of their religion and ethnic origin, yet submissive and silenced religious women who repress their "thick desires" (Fine, 1988; Fine & McClelland, 2007). Though the ideal model of school socialization is the silenced modest woman, their voice is enlisted for collective and political religious purposes in the public sphere. This is especially apparent among Muslim girls and is echoed in the discourse of Jewish, Christian and Bedouin girls. The Muslim girls perceive the veil, which represents Islam and Allah, as a means to enter the public sphere. For all the girls, literacy and education allow them to "bargain with the patriarchy" (Kandiyoti, 1988) and to enter the public sphere as equals.. The discourse reflects school priorities and policy. Arab girls view literacy and knowledge as a key to their future; among the Jewish girls, this issue is less prominent. While the discourse of Arab Christians and Jewish girls was more individualistic in nature, the discourse of the Muslims and Bedouin girls was more collective in nature. Whereas the discourse of Muslim and Bedouin girls was feministic discourse of rights, the discourse of Arab Christians and Jews was more a feministic discourse of identity (see also Gross, 2006).

Introduction

The aim of this paper is to analyze the silencing processes in the socialization of religious girls brought up in a transitional society between traditionalism and modernity. Van Manen (1990) distinguishes between three categories of silence: literal, epistemological and ontological. Literal, namely, the space between the words that can be awkward or poetic, chilling or rebellious; epistemological, namely, tacit information – knowing without being able to articulate what we know; the ontological approach is the "silence of being" that instills a sense of inspiration into life. To these categories, Clair (1998) added a fourth category dealing with the ideological perspective, namely "the silencing of marginalized groups of people".

In Israel

The feminist revolution is connected to literacy. The more access women have to knowledge the more empowered they are. In his power/knowledge theory, Foucault (1980) explained that knowledge generates power and that there is a high correlation between them. This is not true of women in Israel. Religious schools for Arab and Jewish Girls
In the case of both Arab and Jewish women in Israel, religious schools constrain the woman's sphere of activity to the domestic environment.

Data Collection

Using qualitative in-depth interviews, 20 girls (5 Jewish, 5 Muslim, 5 Christian-Arab and 5 Bedouin) aged 17-25, were asked about the silencing they had experienced in school.

Analytical Method

The interviews were analyzed according to the constant comparative method (Strauss, 1987).

Findings

The voice of the woman is considered impure Among all the Arab girls, not only is a loud voice forbidden but loud laughter is forbidden also. While they said that laughing aloud was a terrible thing that school fought against, this was not mentioned at all by the Jewish girls. All the Arab girls said that a loud laugh was considered a misdemeanor.

Sanctions

The school silencing process was accompanied by a specific system of sanctions. silencing through shouting was the main sanction used by all the schools. Christian and Jewish girls emphasized that their silencing socialization was rooted in endless preaching. The Muslim system more frequently sent letters to the parents. The Bedouin and Muslim system sent the girls home as a punishment Only Jews used lowering the grades as a silencing weapon which was extremely effective. All used public humiliation but only the Muslims ignored the girls, and this psychological threat was extremely effective.

The most prominent feature among the Jewish and Muslim girls was the ideological silence.

The prominent words among the Bedouins and Christians were 'respect' and 'honor'.

The power of silence

Women are socially constructed. They are socialized in a male dominated culture. De Beauvoir talks about the ironic interplay between presence and absence.

All the girls said that the most important tenet and instruction in education was not to talk with the boys. This was especially apparent in Christian schooling.

The silencing power of the discussions

Silencing was perceived by all the participants as an integral part of religious education. In retrospect, the graduates talked about the religious leadership as a controlling and coercive body because they represented the religious hegemony had the power to control. The girls felt that their future was in the hands of the religious leadership that had a castrating and silencing power.

Discussion

This paper attempted to analyze the silencing processes in the socialization of religious girls brought up in a transitional society between traditionalism and modernity. The findings show that silencing is embedded in the ideal school graduate. The girls are situated in an ambiguous dichotomic world where they are expected to be confident, proud of their religion and ethnic origin, yet submissive and silenced religious women who repress their "thick desires" (Fine, 1988; Fine & McClelland, 2007). Though the ideal model of school socialization is the silenced modest woman, their voice is enlisted for collective and political religious purposes in the public sphere. This is especially apparent among Muslim girls and is echoed in the discourse of Jewish, Christian and Bedouin girls. Knowledge acquisition is viewed as the key to their future progress and religious strengthening, but more prominently among Arab girls than among Jewish girls. While Arab girls indicate that the most important goal of their school was academic achievement, the religious Jewish girls claim that the most important goal of their school was education to values. The discourse reflects school priorities and policy. Arab girls view literacy and knowledge as a key to their future; among the Jewish girls, this issue is less prominent. While the discourse of Arab Christians and Jewish girls was more individualistic in nature, the discourse of the Muslims and Bedouin girls was more collective in nature. Whereas the discourse of Muslim and Bedouin girls was feminist discourse of rights, the discourse of Arab Christians and Jews was

more a feministic discourse of identity (see also Gross, 2006). The research findings attest to a quiet feminist revolution that is occurring among religious Arab and Jewish girls in Israel, through modern knowledge acquisition and traditional religious strengthening.

The Muslim and Christian woman are trained to be autonomous and assertive, yet they are encouraged to be silent – to speak quietly, which they are socialized to believe is a sign that they are more religious and more feminine. This too is a relatively small price to pay for the security, stability and presumed respect this promises them. School uses a wide range of sanctions for social control purposes. Young religious girls in Israel are brought up in the religious education system (both Jewish and Arab) to be invisible and voiceless. This is justified by religious reasoning as they are told if you are voiceless and invisible you are considered more modest, more feminine and more religious. This has to be abolished because this is exactly what fosters and nourishes discrimination, which is meant to strengthen and continue the hegemony of patriarchy and male chauvinism. However in Israel a velvet revolution is occurring in Israel among religious Jewish and Arab Christian, Muslim, and Bedouin girls who are exposed to higher education and literacy and target themselves to bargain with male chauvinism and patriarchy through silencing, using silencing as a tool for resistance and emancipation. The interviewees indicate that men interpret female delicacy and voicelessness as a weakness and thus abuse and manipulate women. In order to combat this, education should draw a line between how to equip the girls with assertiveness to resist victimization and yet preserve the beauty of this delicacy which is a gift that God bestowed on the world to improve and humanize it.

PAPER PRESENTATION

Extrinsic and Intrinsic Values among adolescents in Israel

Zehavit Gross, Bar-Ilan University, Israel

The aim of this research is to investigate which values are considered more important to Arab and Jewish students (N=586) in state schools in Israel and how these choices differ by nationality, gender and religion. The questionnaire used in this research (Zieberts & Kay, 2005) consisted of eight value scales in two groups. The first group included the extrinsic values and consisted of three scales: modernity, attractiveness and. These scales represent concepts that are described as trendy and are aggressively portrayed in advertising. The second group of intrinsic values consisted of five scales. Three represent civil values: family orientation, professional orientation, and self-management. The findings show that whereas Jews endorse more auto-centric intrinsic values, the Arab students endorse nomo-centric extrinsic values. However, differences in gender and religiosity are apparent. As a minority group that belongs to a traditional society that strives to adapt to neo-liberal Israeli society, Arab students endorse the extrinsic values, which are functional and have the potential to help them to achieve, succeed and survive. The results of the research corroborate literature findings that show that people are not born with values but are educated to values. People are not born extrinsic or intrinsic; they become one or the other in a process of socialization, mediated by intervention programs and the environment in which they live.

The goal of this research was to examine which values are considered most important by students attending Arab and Jewish schools in Israel. While Jewish education in Israel views value education as a core part of its curriculum and is in fact anchored in the State Education Law, Arab schools in Israel, for various reasons that are described here, educate solely for achievements but not for values. Therefore, it is worth asking whether differences will be found in the emphasis given to values, between students of Arab schools and their peers attending Jewish schools. We will analyze the central definitions dealing with value education, describe its status in the Jewish and Arab school systems in Israel, and finally present our findings and attempt to explain them in view of the special context in which they occur. Value education

A value is defined as the belief that one type of conduct or state of existence is preferable to others (Rokeach, 1976). Klages (1988) distinguishes between auto-centric values represent a modern approach, whereas the nomo-centric values represent a more traditional approach.

The intrinsic or extrinsic dimension of a value

In his book *Protagoras*, Plato distinguished between intrinsic values – those that the individual is interested in because of their self-value, and extrinsic values, in which the individual is interested in order to achieve another goal.

Value education in Israel

In Israel, value education is perceived as a basis of the education system; the goal of education is teaching as well as educating for values.

Value Education in Israel's Arab population

The Arab citizens of Israel are a minority group. Minority groups are generally typified by a stronger orientation to achievement, to assist in the goal of survival. And indeed, Arab schools in Israel focus specifically on educating toward achievements, more than on educating for values (Abu abasa, 2001).

The Study

The goal of the study was to identify the variables that influence the personal values of Arab and Jewish high school students in Israel, and which values they perceive as admirable and preferable.

Population

The population included 586 twelfth graders in Jewish (N=293) (Female N= 191 (65.2%), Male N= 102 34.8%) and Arab (N=293) (Female N= 191 (65.2%), Male N= 102 34.8%) high schools in Israel.

Two groups of values were examined: extrinsic (that deal with external considerations, which are means to achieve something else) and intrinsic (values that represent ends in themselves). These values were examined according to three variables: ethnic affiliation (Arab/Jewish), gender, and degree of religiosity (secular, traditional or religious).

The research tools

The questionnaire used in this research (Zieberts & Kay, 2005) consisted of eight value scales in two groups (extrinsic and intrinsic).

The results

A MANOVA analysis was performed on the values by ethnic affiliation (Jewish/Arab), gender, and degree of religiosity (secular, traditional, orthodox). In the variance analysis performed for each parameter separately, significant differences were found between Arabs and Jews for all the values examined. In the intrinsic values, the Jewish students scored higher, and in the extrinsic values, the Arab students scored higher.

Significant differences on all values were also found for levels of religiosity. Furthermore, a significant interaction was found between ethnic affiliation and gender. In the three levels of religiosity, the values of attractiveness, modernity and authenticity were more important for the Arab students than the Jewish ones. Among religious students, the differences between Arab and Jewish students are larger and more prominent than for the two other groups.

Discussion

The variables of gender, religiosity, and ethnic affiliation have an impact on the way in which students endorse certain values over others. However, to base this analysis only on these variables may lead to stereotypes and prejudice as, according to current literature (Bar-Tal, 2003) preference is principally influenced by the context and character of the educational framework where the socialization process occurs de facto. The results of the research show that the Jewish students who studied in an education system where value education is widely applied are characterized by intrinsic values. The Arab students who studied in a framework that focuses on education toward achievements and does not engage in value education, were characterized as having extrinsic values. It transpires that the context in which the process of socialization for values takes place has a far-reaching effect. Bronfenbrenner's (1979) ecological theory maintains that the surroundings where individuals live exercises an influence on their psychological development. Socialization is aimed at enabling the individual to adapt to the environment where s/he lives and functions, and at the same time to change the environment and impact on it, in order to meet his/her needs. According to Vygotsky's ([1934] 1978) socio-cultural theory, socialization for values takes place by a process of intersubjectivity, in which the teacher and student begin a discussion with different conceptualizations and can ultimately reach a shared understanding. This is made possible by a process of adjustment to the perspective of the other, and scaffolding that involves the social support given by the adult in any learning process.

Shannon (2000) maintains that the social context has a far-reaching impact on the shaping of intrinsic or extrinsic motivation. "The social context can influence the goals adopted in a given situation, and can also create a more enduring climate that results in internalization of values ... which includes values as to what is interesting and worth pursuing" (p. 451).

The technological changes and the modernization process that Arab society has undergone in Israel since 1948 have been intensive and rapid. Arab society could not absorb such sweeping changes and did not manage to internalize them. Therefore it principally experienced them in the extrinsic stratum,

The results of the research corroborate literature findings that show that people are not born with values but are educated to values (Oser, 1999 Tirri 2007). People are not born extrinsic or intrinsic; they become one or the other in a process of socialization, mediated by intervention programs and the environment in which they live. Implications

The results of the research corroborate that the value world of students is the outcome of the social climate in which they were raised. In the neoliberal world where study achievements are perceived as the main issue, it is important to allocate defined time in the curriculum for value education. When this does not happen, the graduates of that sort of education will focused on extrinsic goals alone. Educational intrinsic values are likely to provide a significant source for developing students who are human beings – not just knowledgeable robots.

PAPER PRESENTATION

Students' negotiations of moral issues related to socially constructed family patterns

Catherine Dimitriadou, University of Western Macedonia, Greece

The changes that occur in the structure of nuclear families give rise to a reconsideration of the student's normative conceptual view of traditional family patterns. Educational approaches to these representations should focus on moral aspects with regard to the essential children's needs, as they are clarified in the Children's Rights. On the occasion of Brecht's *The Caucasian Chalk Circle* teaching in Literature, twelve-year-old students from a Greek primary school classroom were engaged in a six-month participatory research study in order to address moral issues deriving from the tug of love between the natural and the foster mother of a child. The project included the approach contained within five further literary texts on the same topic, which created opportunities for a flexible learning environment open to discussions, narratives and activities focused on relevant moral dilemmas. The application of a pre- and a post- questionnaire revealed a change in the students' beliefs and attitudes concerning the concept of 'belonging' to a genetic family and the stigmatization of adoption. Moreover, the entries written in the teacher's diary testified to students' discourses on moral versus normative values justification on the subject. According to the results, students' engagement in critical responses to real life situations reflected in Literature help them to negotiate difficult moral dilemmas and to adopt ethical priorities which depart from stereotypical representations of family social construction.

AIM

The current changes characterising the New Age have a justifiable impact on the traditional family patterns, thus creating scepticism on the social circumstances under which children are supposed to be brought up in the future. Moral dilemmas (Kohlberg, 1985) concerning children's abandonment or adoption can be introduced in the school curriculum and provide a field for discourses on moral versus normative values justification (Oser, 1996; Mihalakopoulos, 2007) pertaining to family social constructions. In this respect, our study aims to help students elaborate, interpret and change their beliefs about ethical priorities corresponding to the social construction of a family, thus forming their own meaningful criteria for the concept of motherhood and linking them to the essential needs of a child (Wegar, 2000).

RESEARCH QUESTIONS

The following research questions were posed:

- How do students perceive the concept of 'belonging' in a child – mother relationship?
- What are the students' views on the social norms concerning adoption?
- To what degree can Literary based instruction change students' representations of family patterns regarding moral aspects of motherhood?

CONTEXT

The study was conducted in an urban state primary school in Thessaloniki, Greece, with a multicultural student population from mainly low socio-economic classes. It concerned the application of a project in Literary and took place from October 2007 to March 2008. Bertold Brecht's *The Caucasian Chalk Circle* and five further literary texts posing dilemmas and raising ethical questions on the concepts of motherhood and family were used as 'vehicles' for the consideration of moral aspects concerning family patterns. Having adopted a constructive perspective, the study was built on the assumption that students' engagement in Literary based moral problem solving situations of the nature described above could possibly cause changes in their conceptual representations of nuclear families.

PARTICIPANTS

The sample consisted of twenty 12-year-old students, 8 boys and 12 girls, attending the 6th form in a primary school. It is worth noting that none of these children came from an adoptive or one-parent family.

DATA & DATA COLLECTING METHOD

The data were collected from multiple sources: a) the students' responses to a questionnaire they were given in the beginning and at the end of the project, b) the texts and the pictorial material students produced during the project, and c) the notes the students' teacher kept in her journal. The students were initially exposed to a moral dilemma

arising from the Brechtian text. A second story (The Lost Doll) provided material for the compilation of a pre- and a post-questionnaire as tools for data collection on students' responses to an equivalent dilemma: 'Which of the two girls is actually the owner of the doll?'. Four more stories on the same topic raised discourses and reactions: Solomon's Story of the Two Women, The Girl with the Two Mothers, A Home for Five, and Xoot. The students were involved in text writing, discussions, open ended stories, role play and picture depictions. This data highlighted and supported the information provided in the teacher's diary. The students also created comics, notebook covers with symbolic pictures and a poster, which they exhibited at school after the end of the project.

THEORETICAL FOUNDATION

The study had a broad theoretical grounding on Socio-psychology, Pedagogy and Literary Theory, since the project unfolded on the basis of different ontological and epistemological points of departure, complementary to each other. Participatory research methods (Hughes & Seymour-Rolls, 2000) and flexible child-centred procedures were applied drawn on the theory of Social Constructivism (Hua Liu & Mattheus, 2005), thus providing liberating, empowering and educative learning opportunities.

FINDINGS

Comparison of the data between the two questionnaires revealed a change in the students' responses to the same dilemma (pre-questionnaire: 'The doll belongs to Lolita'; post-questionnaire: 'The doll belongs to Paca'). This shift testifies an impact of the project on the students' beliefs and the forming of conceptual representations about family structures which subvert stereotypical patterns. More precisely, the students defined their own criteria for a mother's love and care for her child; they renounced abandonment of a child and approved of adoption as an action of morality; they criticised the ethical codes which give priority to the concept of 'belonging' to a mother instead of essential mother care; and they disagreed and argued about individual rights and responsibilities, as well as on the optimal responsive styles for a child's happiness and social competence. Their latter perceptions were construed following an open discussion held between the students and a lady who had been brought up by a foster mother and who had been invited to the classroom especially for the purpose of this exercise.

The students concluded that adoption is another way that families are created: that a child can be safe and happy even if it is not related to its mother by blood; and that alternative solutions can be found to claims on the ownership of an adopted child on the basis of moral versus social conventional considerations.

SCIENTIFIC ORIGINALITY & CONTRIBUTION

The study appears to set a methodological framework for teaching approaches concerning both aspects of the double assignment of school: the achievement of content knowledge and the negotiation of moral aspects. With regard to teacher training, it underpins the value of teachers' knowledge creation on how to communicate difficult moral issues to the classroom, setting a scene of empathy out of collaborative research strategies (Dimitriadou & Solachidou, 2010). With regard to individual learners and teachers, it indicates how a constructive perspective of teaching arising from Literary texts can help students to think critically while addressing difficult moral dilemmas usually confronted in real life situations; and furthermore, how this perspective can influence students' stereotypical beliefs within a climate of assertiveness and responsive behaviour.

PAPER PRESENTATION

Does religious learning through physical activity lead to a better ability to empathize with actors?

Ulrich Riegel, Chair of Religious Education, Germany

Does learning through physical activity increase the students' ability to empathize with actors of a story? This hypothesis is backed up by neurophysiological theory as well as by empirical evidence from outside the field of religious education. Within this field, the didactic approach of "performative" religious education combines mere knowledge about religion with the experience of religion. In this setting, physical activity becomes a basic method of learning. However, the performative approach has not as yet been subjected to empirical evaluation. Does learning through physical activity make a difference in religious education, especially with regard to increasing the ability to empathize? The ELLRU-Project analysed this question in a quasi-experimental design. In 2008, 624 4th-graders (age: 9.16 years; denomination: 81% Protestant, 8% Roman Catholic, 11% without religious affiliation) in 31 Bavarian classrooms were introduced to a learning module about Moses and one about Martin Luther, half of them being taught using physical methods, half of them using methods based only on the children's imaginations. A pre-test and a post-test after each module checked the effects on the ability to empathize with the main actors of teaching units; another test at the end of the school year checked the sustainability of this ability. The analysis using a dichotomous Rasch model does not show an overall effect on the students' ability to empathize. Learning through physical activity can, however, prove to be an asset in some circumstances as an analysis of differential item-functioning shows.

Does learning through physical activity increase the students' ability to empathize with actors of a story? This hypothesis is backed up by neurophysiological theory as well as by empirical evidence from outside the field of religious education. Within this field, the didactic approach of "performative" religious education combines mere knowledge about religion with the experience of religion. For instance, "performative" religious education invites the students to take part in a prayer and discusses relevant individual experiences afterwards. Or, the pupils express with their body possible feelings of Martin Luther living as monk before discovering the love of God. In this "performative" setting, physical activity becomes a basic method of learning.

However, the performative approach has not as yet been subjected to empirical evaluation. Does learning through physical activity make a difference in religious education? The ELLRU-Project analyzed this question in a quasi-experimental design. In 2008, 624 4th-graders (age: 9.16 years; denomination: 81% Protestant, 8% Roman Catholic, 11% without religious affiliation) in 31 Bavarian classrooms were introduced to a learning module about Moses and one about Martin Luther, half of them being taught using physical methods, half of them using methods based only on the children's imaginations. A pre-test and a post-test after each module checked the effects of teaching units; another test at the end of the school year checked the sustainability of these effects.

In the EARLI-paper we will concentrate on the ability to empathize with the persons being portrayed in the two teaching units. Therefore the students filled in seven multiple-choice-questions regarding the feeling of Moses or Luther in distinct situations. Each of these situations had been elaborated in the teaching units explicitly. In a first step, the answers will be analyzed by using a dichotomous Rasch model. This analysis does not show an overall effect on the students' ability to empathize. Students who have elaborated the Moses-topic or the Luther-topic respectively by physical methods are not generally better in reproducing correct feelings than students who had elaborated both topics by imagination only. In a second step we analyzed the answers by differential item functioning. This analysis identifies three didactical settings showing significant differences. In two settings physical learning is better than imaginative one, in one setting imaginative learning is better than physical one.

Going into details, the two didactical constellations of the physical teaching unit, which do better than the imaginative counterpart, are characterized by a smooth atmosphere. The students deal with their own feelings and body movements, having time to explore them without being distracted by social interaction. In both settings learning through physical activity does lead to a better reproduction of correct feelings. In the physical teaching unit, which did worse than the imaginative counterpart, the students have been busy with a symbolic role play. They had to perform complex body movements, joined by a lot of social interaction. Obviously learning through physical activity is a powerful mean of religious education, when the student is able to center on himself and has the time to explore the internal effects of physical motions and sensations. Then learning through physical activity is increasing the ability to empathize with other persons.

This exploration of physical learning as a way of enhancing the learned effects of religious and spiritual content fits well with the common theme being explored in this SIG 19 symposium which concerns the extent to which religious and spiritual education can be utilized for broader educational purposes and, in turn, how wider educational experiences can facilitate effective education in and around religious and spiritual knowledge.

PAPER PRESENTATION

Effective Use of Multiple Representations by Novices in Learning Chemistry

David Corradi, Katholieke Universiteit Leuven, Belgium; Jan Elen, Katholieke Universiteit Leuven, Belgium; Geraldine Clarebout, Katholieke Universiteit Leuven, Belgium

Theories on learning with multiple external representations (MER) claim that novices in science have difficulties using MER (e.g., Ainsworth, 2006). Nevertheless such MER are argued to be essential to understand scientific concepts. In contrast, some research does find that novices can use specific combinations of representations for learning (e.g., Carney & Levin, 2002). In this study we investigate the effect of MER on novices' learning gains in chemistry. Undergraduates (n=67) participated in a pre-post randomized experiment. Participants read texts, that were – depending on the condition – accompanied with symbols and/or pictures. Result found no significant differences in learning gains. Combining symbols and/or submicroscopic representations with text does not help novices learning with MER.

Aims

Understanding scientific concepts entails the ability to recognize and switch between multiple external representations (MER) of that concept (e.g., Rappaport & Ashkenazi, 2008). We focus here on texts, symbols (both descriptive representations) and submicroscopic representations (depictive representations). Symbolic

representations are part of the systematic language of chemistry that communicates for example the composition of matter. Submicroscopic representations provide information at the level of invisible and untouchable particles (Johnstone, 2006).

Comparisons between novice students and more knowledgeable students show that novices tend to have difficulties understanding and translating between MER (e.g., Seufert, 2003). If learning with MER is to be successful, research concludes, prior knowledge of the domain and its representations is required (Ainsworth, 2006). However, other research found successful use of MER with novices. The main difference was that text was the main representation and other descriptive and depictive representations (illustrations) had a supportive function (e.g., Levie & Lentz, 1982).

We want to know whether combining symbolic and submicroscopic representations with texts of chemistry increases the level of conceptual understanding for novices (i.e., chemical literacy; Schwartz, Ben-zvi & Hofstein, 2006). Adding representations to texts has a positive effect for novices on learning because it supports memory, guides attention, organizes information and structures learning behavior (e.g., Carney & Levin, 2002). Additionally, combining descriptive and depictive representations benefits learning since both are processed differently. Depictions interact with the picture's internal perception and the prior knowledge of the subject matter. A description's surface structure is first mentally represented. Its semantic content then generates a propositional representation. That representation is formed into a mental model (Schotz & Bannert, 2003).

Therefore we think that learner's chemical literacy increases significantly more when learning with texts, symbols and submicroscopic representations compared to when learning with only texts or with text and either a symbolic or a submicroscopic representation.

Methods

Participants

Participants were sixty seven undergraduates. 7% were male. Mean age was 18.61 (sd= 0.91).

Design

In a pre-post randomized experiment, participants were distributed over four groups. Group 1 (n=16) received texts about basic chemical concepts. Group 2 (n=17) received symbolic, group 3 (n=17) submicroscopic representations and group 4 (n=17) got both symbolic and submicroscopic representations about each concept (always with text; representations: Lagasse, 2007).

Instruments and procedure

Pre and post-tests were chemical literacy tests. One instrument in each test assessed recognition of chemical concepts (nominal literacy; self-report) and the second one the ability to correctly describe concepts (functional literacy; open questions) (Schwartz, Ben-Zvi, & Hofstein, 2006). The nominal literacy pre-test had Cronbach $\alpha = .89$; post-test: $\alpha = .91$. Coders scored the functional literacy test. Inter-rater agreement (kappa) scores for all tests were between .60 and .90. Coders compromised on the scores they did not agree on. Pre and post-test lasted 10 minutes each. The intervention was the assignment to read five texts (206 words average) on a computer. Only one representation was shown at the time and actions were logged. We used an ANOVA to measure difference in learning gains (posttest minus pretest results).

Results

Pre-test ANOVA did not find a difference between the conditions, $F(3,63) = 0.069$, $p > .05$, partial $\eta^2 = 0.003$ (i.e., successful randomization). Our hypothesis was that the condition with three representations per concept would have more learning gains compared to the other groups. Table 1 shows a higher mean for group 4. The ANOVA reveals no significant differences between the four conditions, $F(3, 63) = 0.949$, $p = .42$, partial $\eta^2 = .043$. Hence, our hypothesis that MER help learning is falsified. There is also no evidence that using MER negatively affects learning.

Discussion

That we found no significant difference between the groups can mean two things. First, combining text with other representations does not help novices more than when text is given without representations. Participants had low prior knowledge and this may have limited them in using the representations (Ainsworth, 2006). Second, even though some state that MER may cause negative learning gains (e.g., Schnotz & Bannert, 2003), using text combined with other representations does not lead to negative learning gains here. Based on these results we assume that representations had either a decorative function for learners (i.e., redundant) (Winn, 1993) or were ill conceived.

The value of these results is that it has shed light on an ambiguity of the literature concerning novice learning with MER. Conceptual understanding did not increase more than just with text. Hence, combining text with other representations does not seem to help novices make connections between them.

PAPER PRESENTATION

Comparing learning outcomes across different instructional approaches in preschool science education

Mirjam Steffensky, IPN, Germany; Eva-Maria Lankes, TU Muenchen, Germany; Claus Carstensen, University of Bamberg, Germany

Science learning in preschool aims at imparting usable everyday knowledge in the sense of scientific literacy. The main focus is often on hands-on activities which are not always sufficient for a deeper understanding of science. Therefore learning opportunities are helpful in which learners are cognitively engaged. This paper presents results from a research project which compares learning outcomes across different instructional approaches in preschool science instruction. Central issues are, 1. which effect has the direct support of children to relate concepts and everyday situations and, 2. which effect have hands-on activities on the understanding of science in preschool children.

In an experimental study with a total of four experimental groups, we studied the effects of (1) doing experimental activities (N=45), (2) the explicit supporting of children to relate everyday situations with scientific concepts (N=42), and (3) the combination of both (N=42) on preschoolers' scientific understanding. Group 4 (with none of the named factors) served as a control group on time on task effect (N=64). A further group served as a baseline group (N=64). The intervention was based on three instruction units. In a pre-, post- and follow-up-test we used structured interviews for assessment.

Results were modeled with a Rasch-type model. All five groups show an increase in the abilities. In the post test results controlling for pretest results and general cognitive abilities, only the third Group (combination of experimental activities and everyday situations) shows significantly higher results than the baseline group.

Recent studies show that preschool children are able to develop scientific knowledge in different content areas (Samarapungavan, Mantzicopoulos & Patrick, 2008). However, little is known about the support of science learning at preschool age. This paper presents results from SNAKE a research project which compares learning outcomes across different instructional approaches in preschool science instruction. In the presentation the assessment, the instructional approaches and the effects of the different approaches on learning outcomes will be reported.

Science learning in preschool aims at imparting usable everyday knowledge in the sense of scientific literacy (Gelman & Brenneman, 2004). This includes, for example, the ability of children to describe and predict what happens in a specific everyday situation in their own words and actual terms. However, in Germany as in many other countries, science instruction in kindergarten occurs only sporadically. The main focus is usually on hands-on activities that entertain and amaze children. However, research shows that hands-on activities are not sufficient for a deeper

understanding of science (Butts, Hofman & Anderson, 1994). For a deeper understanding learning opportunities are helpful in which learners are cognitively engaged and reflective thinking processes are fostered. Moreover, to foster a generalized knowledge students should be given the possibility of observing, recognizing and relating concepts in and to different (everyday) contexts, so that they are able to recognize patterns and relate pieces of information (Harlen, 1998).

Against this background central issues in the project described here are, 1. which effect has the direct support of children to relate concepts and everyday situations and, 2. which effect have hands-on activities on the understanding of science in preschool children. The conceptual contents of the instructional approaches were "melting and freezing", "evaporation and condensation" and "solving".

Method

In an experimental study with a total of four experimental groups, we studied the effects of (1) doing experimental activities (N=45), (2) the explicit supporting of children to relate everyday situations with scientific concepts (N=42), and (3) the combination of both (N=42) on preschoolers' scientific understanding. Group 4 (with none of the named factors) served as a control group on time on task effect (N=64). A further group received no intervention at all and served as a baseline group (N=64). General cognitive abilities of the students were tested and the children were distributed accordingly among the five groups.

The intervention was based on three instruction units (each for one content) which were preceded by a pretest and followed by a posttest shortly after the end of instruction as well as a follow-up test four months after the instruction had taken place.

For assessment we used the SNAKE-test, which was individually presented as a structured interview. The test consist of 29 items for each measurement point; 10 of those were anchor items whereas the others varied over the measurement points (WLE-Reliabilities are .75 (pre-test) and .80 (post-test)). The items were scored as 0, 1 and 2 for wrong answers, partly correct answers or correct answers respectively.

Description of the experimental variation

For the conception of the different instructional approaches we firstly defined for each content the relevant terms, like melting, warm /hot, cold, solid, liquid, and relevant concepts like "melting is the change from (solid) ice to (liquid) water" and "the speed of the melting process is influenced by the surrounding temperature". We then choose experimental activities in the three content areas and everyday situations in which they relevant concepts are observable.

In the first experimental group the children carried out hands-on activities. Afterwards the observations, results and conclusions were discussed and compared with other experimental activities; however, explicit references to everyday situations were not given and induced. In the second group the teacher talked (using supporting materials) with the children about situations in which the conceptual contents can be experienced. Activities such as watching a water boiler at work were performed. A combination of both (hands-on activities and everyday situations) activities was performed with the third group. In the fourth group we read picture books to the children, in which we incorporated the relevant terms and concepts.

Results

Results of the assessment were modeled with a Rasch-type model (a modified Partial credit model). All five groups show an increase in the abilities, on average by $d=0.58$ standard deviations. The baseline group increases by $d=0.49$ standard deviations, so solely the experience of test taking led to conceptual advances.

Differences in achievement gains between the four groups were analyzed in comparison to the baseline group controlling for general cognitive abilities using a covariance analysis design. For example, in the post test results controlling for pretest results and general cognitive abilities, only the third Group (combination of experimental activities and everyday situations) shows significantly higher results than the baseline group (p

Discussion

The major concern of this study was to contribute to the question of how to support preschool students' conceptual understanding of science topics. Our results show that only the combination of hands-on activities and the support of relating concepts to everyday situations leads to significantly higher achievement compared with a baseline group without any treatment. In typical science learning environments in kindergarten, hands-on activities are often not

combined with reflecting everyday situations, which means that the potential of learning possibilities is not used to its full extent.

PAPER PRESENTATION

Is science a belief?: Classrooms, controversy and contradictions

Berry Billingsley, University of Reading, United Kingdom; Keith Taber, University of Cambridge, UK, United Kingdom;

Fran Riga, Cambridge University, United Kingdom; Helen Newdick, University of Reading, United Kingdom

In this study we look at the messages that teachers present to pupils about the status and nature of scientific and religious ideas in the context of discussions about science and religion. Drawing on interviews with science and RE teachers from four English secondary schools, we notice that the culture in secondary schools is such that teachers of science and RE have little insight into the teaching that takes place in the other classroom. We suggest that this lack of joined up teaching has several unwelcome repercussions. One is that it reduces opportunities to make conceptual links where these might be helpful; secondly it means that teachers are sometimes answering questions that seem designed to challenge without the reassurance of knowing what a specialist from the other area would say. In our analysis, we report on the concerns that teachers raised in relation to the teaching of topics that are common to science and religion. We also highlight points where the terminology and explanatory frameworks used by science and RE teachers seem poorly matched and in places, conflicting.

Background

Science and religion are each about many things but when considering the relationships between them, the focus is frequently on what each say is 'true' and on whether those 'truths' can or should be compared. When discussing the relationships between science and religion, two precepts are commonly argued to be important. One is that science provides a relatively stringent and trustworthy method of discovering and testing knowledge (McComas, Clough, & Almazroa, 2002). The word relatively is important as there is no suggestion that science is a path to certainty. The second is less consensual but is widely held and is that science and religion are primarily concerned with different 'realms' (Poole, 2007). This means that when science and religion address similar questions, the explanations they produce may or may not be competing. In the secondary school context in England, science and religious education are generally taught by subject specialists in separate classrooms, each following a subject-specific scheme of work. While the curriculum guidance for RE makes many references to science, the curriculum guidance for science makes no overt references to religion. The expectation is that in the RE classroom pupils examine the nature of science alongside the nature of religion and so identify where ideas from science and religion do and do not compete (QCA, 2004). During this reflection, pupils are expected to consider the two precepts described previously (QCA, 2004). There are reasons to suggest that the compartmentalised nature of secondary school education in England potentially impedes teaching about these precepts.

Research questions

In this project we are interested in the terminology and conceptual links used by RE and science teachers when discussing beliefs, ideas and evidence. The aim is to assemble a picture of how this area is presented to pupils in the two classrooms to test the coherence of the bigger picture.

Methodology

This study reports on research in four diverse schools in different geographic areas of England. In each of these schools, one science and one religious education teacher were interviewed, after selection by the Head teacher. Contemporaneously, a convenience sample of three students from Year 9 were also interviewed. This paper primarily discusses the interviews with teachers. Interviews followed a semi-structured interview format (Patton, 2002). With participants' consent, they were recorded and transcribed. Participants' names were changed during the transcription process. Teachers were asked about their own ideas about the relationships between science and religion; they were also asked questions relating to their teaching with regards to the nature of science, the nature of religion and the relationships between them.

Two methods of analysis were used. Through content analysis, sections of the interview were selected in which teachers discussed any or all of the following terms: beliefs, facts, ideas, truth, claims, evidence, reasons. This enabled us to discuss and compare teachers' approaches and uses of terminology. In a parallel analysis process, descriptive narratives were produced for each teacher, describing their perceptions of the theme of science and religion in relation to their teaching (its relevance and importance) and their self-perceptions when teaching on the theme (their confidence, enthusiasm, experience and expertise.)

Findings

As might be expected, the RE teachers in our sample were generally better prepared to teach on this theme than the science teachers, in that, for example, they were able to describe conceptual models that enabled comparisons of ideas drawn from science and religion. Only one of the four science teachers had a ready conceptual model for this purpose. Having said this and on the basis of the teachers' comments, the theme of science-and-religion was presented or discussed in all the teachers' classrooms, prompted either by questions from pupils or because it was introduced by the teacher. The need to have a secure understanding of science and the nature of science emerged as an issue at several levels. For science teachers a point of tension was a perception that religion does not have a valid way to test and support claims. This tension was heightened by a tendency to see religion as methodologically in conflict with a scientific perspective. For RE teachers, tension arose where there was a self-perception of a lack of science subject knowledge on questions of Origins. The most striking finding was the lack of common ground and collaboration between the subject areas on the teaching of this theme, such that terminology and explanatory frameworks were disjointed and in places, conflicting.

PAPER PRESENTATION

Cognitive and Motivational Determinants of Science Achievement

Nele Nicole Kampa, Humboldt University Berlin, Germany

Despite the conceptual and operational fuzziness of terms such as competence, ability, achievement, aptitude or skill, they are prevalent and prominent in educational research. In order to dismantle the concept of science achievement and to determine the underlying constructs we examine the effect of cognitive aspects such as general cognitive ability and reading ability and also affective aspects such as motivation and self-concept on science achievement. A large sample of 6.084 ninth-graders worked – in a multi-matrix design – on a total of 998 items measuring science achievement. The used items were developed in the process of establishing national performance scales in sciences in Germany. According to didactical considerations two constructs were separated in the process of item construction: a) gaining knowledge in sciences and b) usage of domain-specific knowledge. Participants also completed a nonverbal cognitive ability test, two C-tests assessing reading ability, and newly developed scales assessing motivation and self-concept in sciences. We report to what extent science achievement covary across both constructs and within three different school subjects in Germany – Biology, Chemistry, and Physics. Main focus is to decompose the didactically motivated constructs by regressing on well-established cognitive and motivational constructs. Implications for curricular development in science and assessment of science achievement will be discussed.

Background

The concept of competence has become prominent in educational research throughout the last decades. In various competence fields, studies have investigated the relationship between cognitive and affective aspects influencing competence. Research tackling both cognitive and affective aspects of science competence is rare. There is varying evidence of relationship between competence (in science) and the cognitive aspects intelligence, reading and domain-specific knowledge as well as the affective aspects motivation and self-concept. Therefore, we seek to shed light on the dimensionalities of science and its association between cognitive aspects - prior knowledge, general cognitive ability and reading - and affective aspects - motivation and self-concept.

In the literature, intelligence is considered as one of the strongest predictors for inter-individual differences in school performance and knowledge acquisition processes (Weinert & Helmke 1997b). However, there is much debate concerning the relationship between intelligence and competence. Studies show that the relationship between intelligence and competence vary according to the nature of the science test (e.g.: $r_{\text{corr}} = .36$, (Klos et al. 2008), $r_{\text{corr}} = .24$ when controlling for prior knowledge, (Schroeders et al., in press)).

Another major predictor in the literature associated with competence is reading skills. In the PISA-studies, competence in science and reading are highly correlated ($r_{\text{corr}} = .80$ in 2000 and $.84$ in 2006). Klos et al. (2008) only found a moderate correlation of $r_{\text{corr}} = .26$ in their study focusing on Chemistry, using the verbal KFT as a proxy for reading ability.

Many authors agree that prior knowledge is a major determinant of competence (e.g. Brunner 2006). Schroeders et al. (in press) found that domain-specific knowledge highly correlates with their comprehension of science tasks ($r_{\text{corr}} = .78$). Klos et al. (2008) report the even higher correlations for 12th graders ($r_{\text{corr}} = .85$).

The academic self-concept is based on the academic success and a comparison to the average of a social group (Marsh 2001); but it can also influence school performance (Antunes et al. 2004). Another affective aspect that is highly associated with school performance outcomes is motivation (Jyoti & Devi 2008). Motivation here is conceptualized as an individual's energy and drive to achieve to their potential and the behaviors that follows from this energy and drive (Martin 2007).

The described findings regarding the relation of the cognitive and affective aspects of competence in science result in the following research questions:

1. How are the cognitive aspects intelligence, reading and domain-specific knowledge related to competence in Science and its sub-dimensions concept and process knowledge?
2. How are the affective aspects motivation and self-concept related to competence in Science and its sub-dimensions concept and process knowledge?

Methods

The Institute for Educational Quality Improvement (IQB), Germany tested 506 concept knowledge items and 492 process knowledge items in autumn, 2009 in 159 schools in eight states of Germany. We used a Multi-Matrix-Design for the construction of the test. We operationalized the construct of general cognitive ability with the 30 items of the non-verbal KFT for the ninth and tenth grade. Also tested were items, which addressed students' prior knowledge, creating an instrument of prior knowledge. We used two C-tests to examine reading ability. Of the 6084 ninth-graders, 49,1% were female. We stratified the sample between the three main tracks in the German school system: general secondary, technical general secondary, and university bound secondary education. All students answered the questionnaire, consisting of a 10-item motivation and a 12-item self-concept scale.

We scaled the items on all constructs applying multi-dimensional Rasch-modeling with the software ConQuest (2.0). In later calculations, we apply Structural Equation Models to shed light on the various dimensions of science competence with affective and cognitive aspects.

First Results

Initial results reveal that science competence is multi-dimensional (see Table One).. Of the six models calculated model six proves to fit the data best. This model has four dimensions with one content dimension and three process dimensions for Biology, Chemistry, and Physics.

The dimensions in model six prove to be highly correlated with one other (r_{corr} between $.73$ and $.86$). Based on this analysis of dimensionality, we use these dimension of science competence and examine their association with affective and cognitive aspects through Structural Equation Modeling.

Discussion and further research

The first results indicate that science consist of one content and three process dimensions. We hypothesize that these four dimensions will be highly associated with both cognitive and affective processes – especially with regards to the various process dimensions. This study has several implications for learning and teaching as well as curricula development.

PAPER PRESENTATION

An Organizational Model for School Achievement

Anita Woolfolk Hoy, The Ohio State University, United States; Wayne Hoy, The Ohio State University, United States

Most discussions of teaching and learning in schools focus on the teachers and students. This inquiry, however, examines the school context and how it can facilitate student learning, achievement, and performance. In the past ten years two lines of research have emerged that are promising. Bryk and Schneider (2002) in a 10-year longitudinal study of urban school schools found that relational trust was a key factor in explaining academic achievement. At the same time, Hoy and his colleagues (Hoy, Tarter, & Woolfolk Hoy, 2006) found three school properties that are consistently related to school achievement: collective efficacy, collective trust, and academic emphasis. Academic optimism is an overarching construct to unite efficacy, trust, and academic press. We synthesize the body of work on school properties—relational trust and academic optimism—that facilitate student achievement by developing a theoretical (path) model that explains how school organization can influence teaching and learning in schools. The proposed model harnesses and synthesizes more than two decades of research in a heuristic way that will provide both researchers and reformers with an important agenda for years to come.

Most discussions of teaching and learning in schools focus on the teachers and students. This inquiry, however, will examine the school context and how it can facilitate student learning, achievement, and performance.

Aim: The objective of this paper is to review the research and synthesize the body of work on school properties that facilitate student achievement by developing a theoretical (path) model that explains how school organization can influence teaching and learning in schools.

Method: Because this analysis is primarily theoretical, our method is to review and synthesize the empirical and theoretical research on school characteristics that are related to student achievement after controlling for the socioeconomic (SES) conditions of the school student body. Our work in this area is one of the first attempts to develop such a model, but is supported by other researchers who have grappled with the same problem (Bryk & Schneider, 2002; Hoy, Tarter, & Woolfolk Hoy, 2006). The literature that is most relevant for our purposes is the theoretical and empirical work on the organizational constructs of collective efficacy, collective trust, academic emphasis, and academic optimism.

Findings: Since the Coleman report (1966) in the United States, researchers, educators, and policy makers have searched for school-level properties that are positively related to school achievement. The quest has been difficult because the negative power of low socioeconomic factors simply overwhelms most school properties by either dampening or eliminating their positive effects. Although a general pessimism gave way to cautious optimism with the work of Edmonds (1979), who found schools that apparently succeeded in spite of low SES, subsequent quantitative research on effective schools was not as encouraging as the initial promise.

In the past ten years, however, two lines of research have emerged that are promising. Bryk and Schneider (2002) in a 10-year longitudinal study of urban school schools found that relational trust was a key factor in explaining academic achievement in math and reading, even controlling for teacher background, student demographics, and other school contextual factors. They argue that such trust is only indirectly related to achievement, but the trust enables a set of organizational conditions that fosters achievement: teacher sense of responsibility and self efficacy, outreach to parents, professional learning community, and high expectations and standards.

At the same time, Hoy and his colleagues (Forsyth, Adams, & Hoy, 2012; Goddard, Hoy, & Woolfolk, 2004; Hoy, Tarter, & Woolfolk Hoy, 2006; Kirby & DiPaola, 2009; McGuigan & Hoy, 2006; Smith, & Hoy, 2007) found three school properties, that are consistently related to school achievement, even controlling for SES and other demographic characteristics: collective efficacy, collective trust, and academic emphasis. Optimism is an overarching construct to unite efficacy, trust, and academic press because each concept contains a sense of the possible; in fact, the three concepts form a latent construct called academic optimism (Hoy, Tarter, & Woolfolk Hoy, 2006), which is remarkably similar to the organizational conditions that Bryk and Schneider (2002) conclude produced higher student achievement.

What has been missing in both of the formulations, however, was an explanation of how these conditions produced higher student achievement. We address the question by building a model in which goal theory, motivation, and cooperation are key elements in the explanatory framework (See Figure 1--in Appendix).

Theoretical and Educational Significance: The proposed model harnesses and synthesizes more than two decades of research in a heuristic way that will provide both researchers and reformers with an important agenda for years to come.

PAPER PRESENTATION

Educational Attainment, Primary school, Reading

Louise Tracey, University of York, United Kingdom; Bette Chambers, University of York, United Kingdom; Pam Hanley, University of York, United Kingdom; Louise Elliott, University of York, United Kingdom

Success for All is a comprehensive literacy programme aimed at improving the literacy of those children most disadvantaged in our society. Evaluations in the US have found significantly positive effects on pupil achievement. This paper presents the findings of a large-scale longitudinal national evaluation of the Success for All programme in England. Using a quasi-experimental design 40 schools were recruited to the study and children entering Reception classes were pretested on measures of vocabulary, and letter and word identification. Children were re-tested at the end of Reception and, again, at the end of Year 1 using additional reading measures. Initial hierarchical linear model results showed statistically significant first-year school-level effects. Preliminary analysis of the second-year data also suggests positive impacts for pupils in the experimental schools. The project ties together two central themes of educational research and policy today: the scale up, or replication of school-based interventions, and the development of high-quality evidence of their causal effects. The outcomes have established that large-scale quasi-experiments involving replicated school-based interventions are both possible and desirable in the UK and can help establish a bank of research-proven programmes for children who live in deprived areas.

Educational outcomes for those children living in low-income households are often not as favourable as for those from other backgrounds. Such differences can be detected early in a child's school career, in particular through gaps in literacy attainment (Burroughs-Lange & Douetil, 2007; DfES, 2005). Under the National Literacy Strategy the literacy of disadvantaged children improved between 1997 and 2000, but since then it has remained static. With new policies providing primary schools with greater freedom to choose among different approaches to teaching reading, scientific evaluations are needed to enable educators to choose programmes and practices that have the potential to significantly reduce reading gaps. Success for All is a programme which has shown promising results in the US where it

began in 1987. The programme is a combination of research-proven practices in beginning reading instruction implemented primarily in deprived communities. It involves systematic instruction in phonemic awareness and phonics as well as vocabulary and comprehension and has been positively evaluated in more than 40 experimental-control comparisons in the US (cf: Borman, Slavin, Cheung, Chamberlain, Madden & Chambers, 2007). Success for All was introduced into British schools in 1997 and, adapted to the UK context, is designed to ensure children have solid decoding skills by the end of Key Stage 1. Studies involving small numbers of schools in England have found positive effects on Key Stage 1 and Key Stage 2 assessments (Hopkins, Youngman, Harris & Wordsworth, 1999; Slavin, Wordsworth & Jones-Hill, 2005). This paper presents findings from a large-scale quasi-experimental study that is evaluating the effects of the Success for All programme on the reading achievement of children in the UK. This presentation will report on the findings from the first two years of the study (Reception and Year 1).

This matched study initially recruited 20 Success for All schools and 20 control schools. Control schools followed their usual literacy instruction. Schools were in underprivileged urban communities throughout England and were matched on demographics and prior national test scores. Children entering Reception classes in September 2008 were individually pre-tested on the British Picture Vocabulary Scale (Dunn, Dunn & NFER-Nelson, 1997) and the Woodcock Reading Mastery Letter Identification and Word Identification Scales (Woodcock, 1987). They were post-tested at the end of Reception and again at the end of Year 1. Testers were independent testers, mostly undergraduate university students trained to administer the measures using standard procedures, who were blind to the condition of the schools. End of Reception and Year 1 measures included the Woodcock Reading Mastery Word Identification and Word Attack Scales (Woodcock, 1987). At the end of Year 1, the York Assessment of Reading for Comprehension (YARC) was added (Snowling, Stothard, Clarke, Bowyer-Crane, Harrington, Truelove, Nation & Hulme, 2009). This measures pupils reading accuracy, fluency and comprehension.

The first year results (end of Reception year) were analysed using a hierarchical linear model (HLM) with the school as the unit of analysis (Raudenbush & Bryk, 2002). Pre-tests were used as covariates. This showed that the Success for All condition produced statistically significant first-year school-level effects on the three measures for Reception students, controlling for the BPVS pre-test. The coefficient for school mean reading achievement indicated that the effect of Success for All on the Letter Identification post-test was equal to an individual-level effect size of +0.25 (p < .05). The pattern of treatment effects appears to be consistent with previous studies, the Success for All programme theory and more general research and theory on the development of young children's emergent literacy skills. As a large, longitudinal study, the results of this evaluation, now in its third year, have strong external validity and relevance for policy and practice. The project ties together two central themes of educational research and policy today: the scale-up, or replication of school-based interventions, and the development of high-quality evidence of their causal effects. The outcomes have established that large-scale quasi-experiments involving replicated school-based interventions are both possible and desirable in the UK and can help identify research-proven programmes for children who live in deprived areas.

PAPER PRESENTATION

Frequency and types of feedback interventions during classroom interaction in secondary education

Lia Voerman, Utrecht University, Netherlands; Paulien Meijer, Utrecht University, Netherlands; Fred Korthagen, VU University, Netherlands; P. Robert-Jan Simons, Utrecht University, Netherlands

During the last decades, several major review studies have been published to unravel which feedback interventions actually enhance learning. In this study, we firstly analyzed the types of feedback interventions that emerge from these review studies as being helpful for student learning. Second, we examined whether and to what amount teachers in secondary education use these types of feedback. Results show that in most cases, the teachers did not use these types of feedback interventions. The results did not differ for school type, grade level, school subject, gender, age or experience. We conclude that teachers do not automatically know how to provide effective feedback and also do not seem to learn this through mere experience. In order to improve teachers' feedback skills, in pre-service and in-service teacher education more attention should be paid to effective feedback interventions.

Introduction

Feedback is generally seen as an important tool for enhancing learning (Kluger & DeNisi, 1996; Black & William, 1998; Hattie & Timperley, 2007; Shute, 2008). Hattie (1999) showed that some types of feedback are more influential for promoting learning than others. We regard feedback as information from the teacher about the performance or understanding of the student, aimed at improving learning and/or retain or enhance motivation (Hattie & Timperley 2007; Shute 2008).

Our main research question is: Which of the feedback types that have been shown to enhance learning, are actually used by teachers in their interaction with students? We focus on feedback that is orally provided for by the teacher in a classroom setting.

Theoretical framework: features of feedback interventions that enhance learning

Our study is based mainly on three major and influential review articles that have drawn conclusions about the features of feedback that enhances learning (Kluger & DeNisi, 1996; Hattie & Timperley, 2007; Shute, 2008).

The frequency of feedback interventions appears very influential in student learning (Hattie, 2009). According to Hattie (1999), the incidence of feedback in a classroom is at best only measurable in seconds per day. Pauli (2010) found that a large part of teacher statements (46%) does not have any feedback components. Instead, she found that teachers often ask new questions or explain further, without explicitly reviewing the answers or statements of the students. If feedback occurred, it was in most cases non-specific ("yes", "that's right").

Shute (2008) stated that feedback should preferably be specific and goal-related, and presented in manageable units. Non-specific feedback may cause students to view the feedback as useless. On the other hand, feedback that is too elaborated may cause a cognitive overload or may direct the attention from the receiver away from the task (Kluger & DeNisi, 1996; Hattie & Timperley, 2007).

Another distinction is made between positive and negative feedback (Bracksick, 2001). Positive feedback shows support, encouragement or appreciation, negative feedback shows disapproval, or even sarcasm (Losada, 1999). Baumeister et al. (2001) showed that negative feedback has a greater impact on memory and self-esteem than positive feedback. This might lead to the conclusion that to overcome the impact of negative feedback, experiences of positive feedback need to outnumber experiences of negative feedback. A study by Losada and Heaphy (2004) on positive and negative feedback showed that a ratio of at least 3:1 is linked with broader behavioral repertoires and more optimal functioning.

Combining these features of feedback interventions, we can discriminate between four types of feedback interventions, namely non-specific positive and non-specific negative feedback interventions, and specific positive and negative feedback interventions.

Design

We videotaped lessons from 78 teachers working in eight different schools for secondary education in the Netherlands. Schools ranged from very traditional to very innovative in their way of teaching. We selected ten minutes per teacher during classroom interaction and made an analysis using five categories: non-specific positive and negative feedback, specific positive and negative feedback and "other interventions", for example questions or brief instructions. Cohen's Kappa was used to determine inter-rater reliability. The paper describes the scheme of categories we developed in this study in greater detail, and contains examples of the feedback categories provided by the teachers in this study.

In addition, we collected background information regarding school type, grade level, school subject, gender, age and experience. This information was used to examine whether teachers' feedback interventions might be in part explained by these background variables. MANOVA's and ANOVA's were used to establish statistical relations.

Results

Regarding our research question, we found that specific positive feedback as well as specific negative feedback was seldom given by the teachers. Less than 20% of all teacher interventions was a feedback intervention. The feedback interventions that research has shown to be effective, formed only 6% of all the teacher interventions. About 56% of the teachers did not show a 3:1 ratio of positive and negative feedback. Frequency, types of feedback and the positive-negative ratio did not differ for school type, school subject, grade level or gender. Even more fascinating and quite unexpected is that neither frequency nor feedback type differed for age and experience. It seems that teachers do not learn to provide the effective types of feedback in the appropriate ratio through aging or experience.

These results suggest that the quality of the feedback teachers provide should be improved. This might be done by teaching them how to provide more specific (including goal-related) feedback as frequently as possible, in an appropriate ratio. Hence, teacher education and programmes for teacher professional development should focus more on how to provide feedback that research has shown to be effective.

PAPER PRESENTATION

Dropout in Secondary Education: A Multilevel Discrete-time Hazard Model, Accounting for School Change

Carl Lamote, K.U.Leuven, Belgium; Jan Van Damme, K.U.Leuven, Belgium; Wim Van Den Noortgate, K.U.Leuven, Belgium

The present study addresses the effect of student background variables and school-level variables on dropout in secondary education in Flanders, Belgium. This study is based on data from the LOSO-project, a longitudinal study in Flemish secondary education. We conducted a multilevel discrete-time hazard analyses, where we incorporate a multiple-membership on the school-level. These models extend the methodological approach of studying dropout, by taking into account the mobility of students. We compare these models with more traditional approaches in studying dropout. Initial results indicate a significant variation between schools and between grades, on the proportion of dropouts. Dropout can be (partially) explained by grade retention, age, gender, socio-economic status of the student and the average SES of the school. Discrete-time hazard models, with a multiple membership structure, give better fit-values compared to more traditional approaches.

Objectives

The present study addresses the effect of student background variables and school-level variables on dropout in secondary education in Flanders, Belgium. These variables are integrated in a multilevel discrete-time hazard model (DTHM) with multiple-membership structure. Bearing in mind often cited arguments and critiques on dropout research, we propose some methodological recommendations by applying a survival model with multiple membership, and compare this model with more traditional approaches.

Theoretical framework

During the past decades, numerous student background variables were considered in search of an explanation for dropout. In this study, we will consider the most widely investigated variables: grade retention, socio-economic status

(SES) of the student, gender and (prior) achievement. Especially the strong relation with grade retention in primary and secondary school received a lot of attention (e.g. Alexander, Entwisle, & Horsey, 1997). In their review, Jimerson, Anderson, and Whipple (2002) pointed at the strong predictive power of (early) grade retention on dropout. SES, especially the educational level of (one of) the parents and their income, remains an important contributor to success in school. Even when controlling for other individual background variables, students with a low SES have a higher dropout probability, compared to students with a high(er) SES (Alexander, Entwisle, & Kabbani, 2001). Another often investigated demographic variable in dropout research is gender, where boys tend to have higher odds of leaving school early (Marks, 2007). Besides grade retention and the (socio)demographic variables, low-achievers are often at higher risk for dropout. Alexander et al. (2001) concluded that low achievement in first grade, was one of the major predictors of dropping out. Only a few studies integrated school characteristics in a multilevel model. Studies who did take into account the school level, showed an effect of socioeconomic composition of the school on dropout rates. Rumberger and Thomas (2000) concluded that low-SES schools had 60% higher dropout rates than an average SES school. Taking into account this summary of the research literature, we consider the following research questions: - Does a model, which takes into account the longitudinal and multiple-membership structure, give a better fit to the data compared to more traditional models? - Which grades are more hazardous for dropout in secondary education, taking into account the background characteristics of students? - In line with past research, we expect the highest risk to dropout for male students, which are retained in grade, with low SES and low achievement scores.

Method

To answer these questions, we opt for a discrete-time multilevel hazard analysis, where we incorporate a multiple-membership on the school-level. This multiple-membership structure, combined with a hazard analysis, is the strength of our model for several reasons. First, as Singer and Willett (2003) mentioned, DTHM makes use of censoring instead of treating graduating students as missing. Second, DTHM solves the problem of tied observations, which is common in educational research. Third, since not every student remains in the same school, and our data has a longitudinal character, it would be incorrect to account for school effects based on the first school attended. Therefore, we incorporate a multiple membership where students are members of more than one higher level unit (school) by assigning weights to every school attended, proportional to the time spent in a specific school (see e.g. Goldstein, 2003; Leckie, 2009). These discrete-time hazard models were estimated with logistic regression techniques, with the MCMC-algorithm in MLwiN, accounting for the multiple membership (Rasbash, Steele, Browne, & Goldstein, 2009). We compare these multiple membership models with 'traditional' DTHM's by comparing the DIC-values (Spiegelhalter, Best, Carlin, & Linde, 2002).

Data Sources The data were drawn from the Flemish 'LOSO'-project (i.e. the Dutch acronym for Longitudinal Research Project in Secondary Education) (Van Damme et al., 1997). This longitudinal research project started in 1990 and followed a cohort of 6411 students through secondary education. In this study, we selected a subsample of 5334 students in 55 secondary schools, who started in 1990 in the first year of secondary education. For every student, we collected data on grade retention, gender, age, school trajectory and the moment of dropout. Grade retention is implemented as a time-varying variable. Furthermore, the SES variable was constructed from information on educational level, occupational level, income and cultural capital of both parents. At the start of grade 7, achievement tests for math and (Dutch) language were administered. Math achievement, language achievement and an intelligence score are combined into one variable: 'initial cognitive level'. School compositional variables are equal to the school means of the SES-variable and cognitive level variable. Results Male students who started secondary education older and were retained in grade during secondary education, have the highest risk of dropout. These results are in line with the conclusions of Alexander et al. (2001) and Bowers (2010). At the school-level, the average socio-economic composition has a significant effect on dropout; schools with a low socio-economic composition tend to have higher dropout rates, compared to schools with a higher socio-economic composition. The discrete-time hazard model provides information on more or less hazardous years in secondary education. Our results indicate a significant variation between schools on the proportion of dropouts. These results also indicate some differences between grades, with a low risk of dropout in grade 7 and 8. Starting from grade 9, the risk of dropout increased, with grade 11 as the most hazardous year. When we take into account the multiple membership structure, our models show a better fit to the data, favoring multiple membership models instead of models based on the first school. Importance The main contribution of this study is to extend (the methodological approach for) dropout research, making use of a DTHM, with a multiple membership structure. Our model takes into account the different schools attended, and focuses on the longitudinal character of the dropout decision. Our results indicate an effect of the socio-economic composition of the school and an effect of several student-level variables. These findings stress the importance of a longitudinal, multilevel approach when studying dropout and provide evidence for the negative impact of grade retention on dropout.

PAPER PRESENTATION

Effects of increased SRL opportunities on students' motivation and metacognition

Emmy Vrieling, IJsselgroep, Netherlands; Theo Bastiaens, Open University, Netherlands; Sjef Stijnen, Open University, Netherlands

This intervention study focused on the relationships between primary student teachers' (STs) self-regulated learning (SRL) opportunities and their motivation for learning and use of metacognitive learning strategies. A mixed methods pre- and post-test design was used in an authentic primary teacher education class setting. The participants were 11 teacher educators (TEs) and 257 first- and second-year STs of 5 different institutes. During one semester, TEs and STs were monitored by questionnaires measuring SRL opportunities offered by the program. Questionnaires were also administered monitoring STs motivation for learning and use of metacognitive learning strategies. During data collection, TEs participated in a training course and tutorial conversations aimed at increasing STs SRL opportunities in the educational pre-service program. At the end of the research period, all TEs and a sample of STs were interviewed. All instruments and materials used were specifically developed for this study. Results indicated that STs use of metacognitive skills increased significantly in a learning environment with increased SRL opportunities. Although STs motivation for learning correlated significantly with SRL opportunities, there was no significant increase of STs motivation for learning during the research period. Also, significant correlations were found between the metacognitive and motivational constructs measured.

Aims

The present study searched for relationships between primary STs SRL opportunities and their motivation for learning and use of metacognitive skills. The research questions central to the study were: Does STs use of metacognitive learning strategies change in a learning environment with increased SRL opportunities? Does STs motivation for learning change in a learning environment with increased SRL opportunities? What relationship exists between STs motivation for learning and use of metacognitive learning strategies in a learning environment with increased SRL opportunities?

Methodology

From January 2010 until June 2010, the exploration of the effects of STs increased SRL opportunities on STs use of metacognitive learning strategies and motivation for learning was conducted with 11 TEs and 257 first- and second-year STs in 5 primary teacher education institutes in the Netherlands. The research was conducted in educational theory courses containing lectures, lessons and moments of guidance.

In a former study (Vrieling et al, 2010), two instruments were developed: (1) the 'SRL Opportunities Questionnaire' (SRLOQ) that enables TEs to measure the degree of SRL opportunities they provide to STs, and (2) the 'Motivation and Metacognition Questionnaire' (MMQ) that measures the level of STs use of metacognitive learning strategies as well as their motivation for learning.

In order to answer the research questions of the study, intervention research was conducted using a mixed methods one-group pre- and post-test design (O1 X O2 X O3). The degree of STs SRL opportunities was measured with the SRLOQ. STs use of metacognitive learning strategies and their motivation for learning were measured by the MMQ. TEs and STs were qualitatively tracked by depth interviews (TEs) and retrospective interviews (STs).

The pre-test (filling in both questionnaires) was performed at the end of the third lesson. At that time, TEs and STs were expected to be unaware of the increased SRL opportunities that would be applied in the intervention-period. By monitoring both TEs and STs on self-regulated learning opportunities (SRLOQ) rather than TEs alone, the statements of TEs and STs could be compared to obtain better interpretable data. After the pre-test, two kinds of treatments were carried out with TEs aimed at increasing STs SRL opportunities: (1) a training course (after lesson 3) and (2) individual tutorial conversations (after lesson 4). The tutorial conversations were based on the analysis of the pre-test. At the end of the sixth lesson, both questionnaires (SRLOQ and MMQ) were administered again (intermediate-test).

Based on the analysis of the intermediate-test, tutorial conversations were carried out again (after lesson 6) aimed at a further increase of STs SRL opportunities. At the end of the last lesson, the post-test (filling in both questionnaires) was conducted. Within a week after the post-test, all TEs were interviewed in depth and a sample of STs was interviewed retrospectively.

Theoretical importance

The use of metacognitive learning strategies is a quality of SRL that is stressed in constructivist views of learning (Zimmerman and Schunk, 2001). Such active and self-regulated strategy use is found to be positively related to achievement (e.g. Pintrich & De Groot, 1990).

Several researchers demonstrate that (meta) cognitive strategy use mediates the relationship between motivation on the one hand and achievement on the other (e.g. Eccles & Wigfield, 2002). At any particular time, students have a level of motivation that they experience and that influences their choice, effort and persistence regarding a particular activity (Wolters, 2003).

In order to transform this motivational drive into academic achievement, students have to use metacognitive skills. In this way, they become aware of and monitor their progress towards their goals, monitor their learning and comprehension, in order to make any adaptive changes in their learning. So, it is important to include metacognitive processes in research concerning motivation and successful learning (Zimmerman & Moylan, 2008).

Empirical importance

The present study shows the relationships between primary STs SRL opportunities and STs use of metacognitive learning strategies and their motivation for learning, both important constructs for STs successful learning.

Findings

Correlation analyses, regression analyses and independent-Samples T-tests indicated that STs use of metacognitive skills increased significantly in a learning environment with increased SRL opportunities. This indicates that TEs can influence STs use of metacognitive learning strategies in one semester. In addition, a major need was identified for more explicit metacognitive strategy instruction in primary teacher education.

STs motivation for learning was also enhanced in a learning environment with increased SRL opportunities. However, with exception of the motivational expectancy part, this relationship was not shown to be significant. STs indicated to appreciate the increased SRL opportunities in the educational program, but also stressed the importance of TEs providing an adequate knowledge base to avoid uncertainty.

The relationship between STs use of metacognitive skills and their motivation for learning was shown to be significant in the present study.

In conclusion, this study revealed that the degree of SRL opportunities provided in a pre-service learning program is strongly related to primary STs use of metacognitive skills and also enhances their motivation for learning, both important constructs for STs academic career.

PAPER PRESENTATION

Self-Regulated Learning of Texts Presented on Screen With and Without Time Constraints

Rakefet Ackerman, Technion--Israel Institute of Technology, Israel

People tend to attribute their reluctance to study lengthy texts on screen to technology-related factors. However, Ackerman and Goldsmith (in press) proposed that screen inferiority is rooted not in such factors, but rather, in less effective metacognitive regulation of screen learning relative to paper learning. In support of this proposal, they found screen inferiority only under free study time regulation, but equivalent test scores for screen and paper learning under fixed and insufficient study time. The present study examined an alternative explanation for these results, suggesting that when screen learners knew they would be working under time constraints, they perceived this study environment to be challenging and took compensatory actions, recruiting cognitive resources that enabled them to

overcome technology-related barriers to learning. In the present study, undergraduate students (N=96) studied texts on screen or on paper. Time condition was manipulated within participant and included free regulation, a fixed and insufficient study time, and interrupted study where study was unexpectedly stopped after the same insufficient study time. The alternative explanation was rejected: No difference was found between fixed and interrupted study on screen, suggesting that no compensatory action was taken when the time constraint was known in advance. Further, as more control over study was given, screen learners exhibited reduced study efficiency and less accurate metacognitive monitoring relative to paper learners. The findings reinforce the conclusion that metacognitive regulation of text learning on screen is less effective than on paper.

Learning from textual material is one of the most important skills in the modern society. In computerized environments, however, people are reluctant to study lengthy texts and often attribute their preference for print to discomfort associated with the screen display medium (Spencer, 2006). Ackerman and Goldsmith (in press) compared screen and paper learning in an attempt to differentiate technology-related and study regulation factors. They found lower performance for screen than for paper learning only under free study-time regulation condition (FreeRC), with equivalent performance under fixed and insufficient study-time condition (FixedTC). At the end of each study period, but before taking the multiple-choice test, the participants provided a metacognitive Prediction of Performance (POP). Surprisingly, in view of participants' overall reluctance to study on screen, comparing the POPs to the participants' test scores revealed a consistently larger upward calibration bias (overconfidence) for the screen learners compared with the paper learners. An upwardly biased POP is expected to produce misguided study regulation decisions, such as whether to invest more study time, restudy difficult material, apply learning strategies, or seek help (Aleven & Koedinger, 2000; Winne, 2004). Ackerman and Goldsmith concluded that technology-related factors are not the main source for study difference, but metacognitive factors. The present study examines an alternative explanation for Ackerman and Goldsmith's (in press) results. People have flexibility in the allocation of cognitive resources depending on their motivation (Pintrich, 2003). It is possible that under FixedTC, screen learners—but not the paper learners—perceived their study environment to be challenging, and recruited cognitive resources that allowed them to engage in qualitatively improved processing (Csikszentmihalyi, 1996) relative to the FreeRC. This could have helped these participants to overcome technology-related barriers and perform at the levels achieved by paper learners. If this interpretation is correct, it means that the screen participants showed improved metacognitive regulation under FixedTC, in contrast to the interpretation suggested by Ackerman and Goldsmith (in press). To examine this possibility, the present study employed the same materials (5 texts, 1000-1200 words each) and a similar procedure to that of Ackerman and Goldsmith (in press) with two key differences. First, the time conditions, FixedTC (7 min.) and FreeRC, were manipulated within participants. Second, an interrupted study condition (InterruptedSC) was added. Under this condition, the participants began studying a text under FreeRC instructions, and were interrupted after the insufficient time allotted learning under FixedTC. Immediately after studying each text, the participants provided POP and got tested. If improved study regulation was responsible for the performance achieved by screen learners under FixedTC, those participants who knew in advance that they would have limited study time should perform better than those whose study was interrupted. The participants were 96 undergraduate students. The measures were study time under FreeRC, test score, and POP. Calibration bias is the difference between mean POP and mean test score reflecting over- or underconfidence. Study efficiency is derived from test scores divided by invested study time reflecting knowledge gain rate. Study time under FreeRC (8.8 min.) was indeed longer than the FixedTC with no significant difference between the screen and paper learning. Figure 1 presents the test scores and POPs for screen and paper learners under the three time conditions. The present study's main question was whether screen learners benefited from planning ahead when studying under known time constraints. No difference was found between the InterruptedSC and the FixedTC conditions on screen. This finding is important in rejecting the alternative explanation for Ackerman and Goldsmith's (in press) findings. Only paper participants succeeded in improving their test scores under FixedTC, leading to a significant difference between the media. The equivalence of all measures between the paper and screen groups under the InterruptedSC reinforces the conclusion that technology-related factors are not the main source for screen inferiority, because these factors should have been as relevant in this condition as in the others. The results suggest that for screen learners, metacognitive monitoring accuracy (calibration) and study efficiency both fell as the learner's control increased. Their ability to plan effectively seems to have enabled the paper learners to achieve higher test scores without investing redundant time. We can conclude that study regulation is an important factor in explaining learning differences between screen and paper.

To summarize, numerous studies have questioned the effectiveness of computerized environments for learning, and pointed to a variety of features that may contribute to limiting their value (Sancho, 2009). The present study reinforces the intriguing proposal that screen inferiority is rooted primarily in psychological factors, rather than aspects of technology per se. This understanding is of critical importance, because it is clear that the integration of computers in study environments is already a fact. The current findings shift our attention away from technology, and

invite educational practitioners to consider ways to enhance metacognitive monitoring and study regulation in computerized environments.

PAPER PRESENTATION

Think peer! The potential of reciprocal peer tutoring in promoting students' metacognition

Liesje De Backer, Ghent University, Belgium; Hilde Van Keer, Ghent University, Belgium; Martin Valcke, Ghent University, Belgium

It is widely recognized that metacognition is an important mediator for successful and high-level learning, especially in higher education. Nevertheless, few higher education programs succeed in effectively preparing students for metacognitive self-regulation. The present study explores the potential of reciprocal peer tutoring (RPT) to promote both university students' metacognitive knowledge and their metacognitive regulation skills. The study was conducted in a naturalistic higher education setting, involving 67 students tutoring each other during a complete semester. A multi-method pretest-posttest design was used combining a self-report questionnaire (assessing students' metacognitive knowledge and their perceived metacognitive skilfulness) with the analysis of think-aloud protocols (revealing student's actual use of metacognitive strategies). Results indicate that RPT has no significant impact on students' metacognitive knowledge nor on their perception of metacognitive skilfulness. In contrast, RPT significantly influences students' actual metacognitive regulation. After the intervention, students demonstrate significantly more frequent and a more varied use of metacognitive regulation skills and strategies, especially during the orientation, monitoring, and evaluation phase. Furthermore, results point at an increase in more profound and higher-quality strategy use after participation in the tutoring programme.

Theoretical framework

Since high quality learning requires metacognition, its promotion is assumed to be a worthwhile objective in current education (Meijer, Veenman, & van Hout-Wolters, 2006). In line with Brown (1987) we conceptualise metacognition as being comprised of metacognitive knowledge and metacognitive regulation. Metacognitive knowledge refers to learners' understanding about the way they process information when performing academic tasks. Metacognitive regulation involves a set of self-regulatory skills that are used by learners to orchestrate their learning. Brown (1987) distinguishes orientation, planning, monitoring, and evaluation as the major regulation skills. Especially in higher education, learners' metacognitive awareness and skilfulness are crucial for academic success (Cornford, 2002). However, few students possess sufficient metacognitive competence to self-regulate their learning adequately (Maclellan & Soden, 2006). The present study makes an important contribution to both theory and practice by exploring the promotion of university students' metacognition from the theoretical perspective of metacognition as a socio-cognitive construct (Volet, Vauras, & Salonen, 2009). According to this view, metacognition has a social dimension by nature and can best be stimulated through social interactions, in which metacognitive strategies can be modelled and internalised. More specifically, we examine the potential influence of reciprocal peer tutoring (RPT), as a particular type of collaborative learning. The following research questions are put forward: What is the impact of RPT on higher education students' (1) metacognitive knowledge; (2) perceived metacognitive regulation; and (3) actual metacognitive regulation?

Method

Participants and setting

Sixty-seven students Educational Sciences participated. Students were randomly assigned to twelve small and stable tutoring groups (5-7 students). The face-to-face RPT-program was a formal component of students' curriculum and consisted of nine weekly sessions (each taking 90 minutes).

Intervention

The RPT-program was same-age and reciprocal, for literature shows that especially tutors gain numerous academic, affective, and metacognitive insights (Falchikov, 2001). Since the tutor role is exchanged among participants in RPT, all students got equal opportunities to gain from the tutoring environment. During the sessions, students worked on authentic assignments, demanding high levels of cognitive processing. The entire RPT-program was designed taking into account research-based guidelines promoting effective tutoring (Topping, 2005). We structured peer interactions by developing a tutor curriculum script for each session (King, 1998). Furthermore, all students participated in a compulsory preliminary training in generic tutoring skills and received ongoing support in interim feedback and reflection sessions (Falchikov, 2001).

Design and instruments.

A multi-method pretest-posttest design was used, combining off-line self-reports with concurrent think-aloud protocol-analysis. All students completed the 'Metacognitive Awareness Inventory' (MAI) (Schraw & Dennison, 1994) before and after the RPT-intervention. The subscale 'knowledge of cognition' assessed students' metacognitive knowledge. Cronbach's α was .78 (pretest) and .81 (posttest). The subscale 'regulation of cognition' measured students' self-reported use of metacognitive skills. Cronbach's α was .90 (pretest) and .89 (posttest). Additionally, students individually performed a think-aloud task (Meijer et al., 2006). By analysing the verbal protocols, students' actual metacognitive skills underlying performance could be identified. Based on the literature, a coding scheme was developed. The scheme represents a hierarchical model of metacognitive regulation, in which orienting (task analysis, content orientation, structuring task instructions), planning (planning in advance, interim planning), monitoring (monitoring of strategy use, comprehension monitoring, monitoring of progress), and evaluating (product and process evaluation) are situated as the main categories.

Data analysis

Pretest and posttest scores on the MAI were compared by means of paired-samples t-tests. Two trained coders independently double coded 23% of the think-aloud protocols. Cohens' kappa ($\kappa=.80$) indicated high interrater reliability. After coding, the occurrence of metacognitive skills at pretest and posttest was compared quantitatively by means of paired-samples t-tests.

Results

Results of the paired-samples t-tests on students' self-reported metacognitive knowledge and regulation reveal no significant difference between pretest and posttest scores (respectively $t = -1.25$, $df = 58$, $p = .215$ and $t = -0.65$, $df = 58$, $p = .515$). However, results of the think-aloud protocol analysis on students' actual metacognitive regulation show differing outcomes. First, students orientate themselves significantly more on task execution after the RPT-intervention, by paying significantly more attention to task-analysis ($t = -14.76$, $df = 58$, $p = 2.55$), structuring task instructions ($t = -3.02$, $df = 58$, $p = 0.75$), and orientating themselves on the content of the task ($t = -7.81$, $df = 58$, $p = 1.52$). Second, students are significantly more active in monitoring both their comprehension ($t = -9.88$, $df = 58$, $p = 1.72$) and their progress ($t = -8.78$, $df = 58$, $p = 1.67$). A significant effect on students' monitoring of strategy use could not be distinguished ($t = -1.64$, $df = 58$, $p = .106$). Third, students engage significantly more in metacognitively evaluation of both learning outcomes ($t = -12.15$, $df = 58$, $p = .001$, $d = 2.46$) and their problem solving process ($t = -5.00$, $df = 58$, $p = 0.92$). In contrast, RPT did not yield a significant effect on students' metacognitive planning ($t = -2.14$, $df = 58$, $p = .063$). In sum, after the RPT-intervention, students apply metacognitive skills more frequently and show a more varied use of specific metacognitive strategies, particularly when orientating, monitoring, and evaluating. Results of the more detailed analyses on specific metacognitive strategies will be presented at the conference.

PAPER PRESENTATION

The relationship between metacognition, intelligence and text-learning performance.

Seda Sarac, yildiz technical university, Turkey; Alev Onder, Marmara University, Turkey; Sema Karakelle, Istanbul University, Turkey

Metacognition and intelligence are both important predictors of learning outcomes. However, the nature of the relationship between these two constructs has not been clarified, yet. Considering inconsistent results from several studies, we wanted to test the hypothesis that whether these discrepancies are due to issues related to measuring metacognition. If this is the case, we expected that different metacognitive measures would lead to different relational patterns among metacognition, intelligence and learning performance. For testing our hypothesis, we used three measures for assessing metacognition namely, accuracy ratings, think aloud protocols and a self report questionnaire. The Raven's Standard Progressive Matrices was used for assessing intelligence. The participants were fifth grade elementary students (N= 91, 47 girls, 44 boys, Mage = 10.04 years, age range: 9-11 years). The results of the study indicated that intelligence do not correlate significantly neither with the scores from the self-report questionnaire nor with the scores from think aloud protocols. On the other hand, there is a significant correlation between accuracy ratings and intelligence scores. The results, also, showed that the scores from the self-report questionnaire do not contribute to students' text-learning performance. Accuracy ratings, together with intelligence predict text-learning performance and both predictors have their own unique contribution. The scores from the think aloud protocols, together with intelligence contribute to text-learning performance but think aloud protocols do not have predictive value independent of intelligence. In conclusion, the findings of the study showed that when we use different metacognitive measures, we get different results.

Metacognition and intelligence are both important predictors of learning outcomes. However, the nature of the relationship between these two constructs has not been clarified, yet. Current conceptions of intelligence strongly support the relationship between metacognition and intelligence (e.g., Binet & Simon, 1916; Naglieri & Das, 1997; Sternberg, 2003, 2005), but several studies has revealed inconsistent results. Some researchers have reported significant positive correlations between metacognition and intelligence (e.g., Schneider, Körkel & Weinert, 1987; Swanson, 1990, 1992; Alexander & Schwanenflugel, 1994). On the other hand, some studies have revealed that there is no substantial correlation between the two (e.g., Allon, Gutkin & Bruning, 1994; Coutinho, 2006; Yalçın & Karakas, 2008). Also, there are studies showing negative significant correlation between metacognition and intelligence (e.g., Dresel & Haugwitz, 2005). Veenman and colleagues, also, focused on the relationship between metacognition and intelligence but extended their research to the relation of both variables with learning performance (e.g., Veenman, Elshout ve Meijer, 1997; Veenman & Verheij, 2003; Veenman & Beishuizen, 2004; Veenman, Kok ve Böste, 2005; Veenman & Spaans, 2005; Van der Stel & Veenman, 2008). The researchers introduced three models for explaining the relationship between metacognition and intelligence as predictors of learning performance. The mixed model suggests that metacognition and intelligence are related but metacognition has a surplus value on top of intelligence for the prediction of learning. According to the intelligence model, metacognition cannot predict learning independent of intelligence as metacognition is a manifestation of intelligence. The independency model suggests that the two variables are entirely independent predictors of learning. Considering these inconsistent results from several studies, we wanted to test the hypothesis that whether these discrepancies are due to issues related to measuring metacognition. If this is the case, we expected that different metacognitive measures would lead to different relational patterns among metacognition, intelligence and learning performance. Results from several other studies using multiple metacognitive measures discredits the measures that are frequently used in metacognitive research and compels researchers to scrutinize what these measures are really measuring (e.g. Desoete, 2008; Cromley & Azevedo, 2006; Saraç & Karakelle, 2010). For testing our hypothesis, we designed a multi-method study, to investigate the relationship between metacognition and intelligence as predictors of learning performance. We used three measures for assessing metacognition namely, accuracy ratings, think aloud protocols and a self report questionnaire. The participants were presented a text-learning task. They were requested to think aloud while they were studying the text. After the participants finished studying the text, they were asked to rate how well they think they understood the text on a rating scale. Their learning performance was assessed by a post-test consisting of 15 multiple choice questions (a=.77). The Raven's Standard Progressive Matrices was used for assessing intelligence. The

participants were fifth grade elementary students (N= 91, 47 girls, 44 boys, Mage = 10.04 years, age range: 9-11 years). The results of the study indicated that intelligence do not correlate significantly neither with the scores from the self-report questionnaire nor with the scores from think aloud protocols. On the other hand, there is a significant correlation between accuracy ratings and intelligence scores. The results, also, showed that the scores from the self-report questionnaire do not contribute to students' text-learning performance. Accuracy ratings, together with intelligence predict text-learning performance and both predictors have their own unique contribution. This result corroborates the mixed model. The scores from the think aloud protocols, together with intelligence contribute to text-learning performance but think aloud protocols do not have predictive value independent of intelligence. This result confirms the intelligence model. This study confirmed the importance of using multiple metacognitive measures in metacognitive research as previously recommended by Veenman (2005) and Winne and Perry (2000). In conclusion, the findings of the study showed that when we use different metacognitive measures, we get different results in terms of the relationship among metacognition, intelligence and learning performance. This finding leads us to think about what we are really measuring. Are the measures that researchers frequently use in metacognitive research are valid means of assessing metacognition? Are these methods measuring different metacognitive constructs?

PAPER PRESENTATION

Teachers' vs. student language learning beliefs

Martin Herles, WU Vienna, Austria; Ruth Trinder, WU Wien, Austria

The English programme at WU Wien is characterised by a strong focus on content, particularly terminology, which poses a considerable challenge for teachers and students without business background. Additionally, a number of administrative and logistical constraints impact on the learning environment: class size, heterogeneity of groups, testing parameters, reduction in contact hours, etc. This gives rise to the question of how local conditions/contexts interact with more global influences to affect teachers' and students' perceptions of the learning situation, their motivations and their actions.

Students' notions of what constitutes good and useful English for their future careers and their beliefs as to how languages are best learnt and taught were identified in an earlier qualitative survey. Emerging themes included views on formal teaching activities and informal learning, the importance of interaction and pronunciation, accuracy versus fluency, attitudes towards content and language integrated teaching, and preferred learning strategies.

Building on that, the present talk adds the teachers' perspective, identifying differences and similarities to students' cognitions. We investigated how the interplay of local learning context and global developments determines the expectations of all players involved, and whether there is a mismatch between students' and teachers' perceptions, frequently claimed to negatively affect achievement and satisfaction. Results indicate that in many areas, learners' and teachers' beliefs diverge to a lesser degree than expected, and conflicts mainly arise from the pressure exerted by top-down and contextual constraints. We will further discuss students' and teachers' coping strategies, as well as insightful beliefs and approaches of successful students.

Learner attributes and cognitions are increasingly seen as critical factors determining approaches, behaviours and choice of strategies, and thus, by extension, ultimate attainment. In the field of foreign language learning, learners' conceptions about what the process of language learning entails include ideas about the nature and difficulty of the language to be studied, about the role of personal attributes such as aptitude or extroversion, and about the effectiveness of certain teaching approaches and learning strategies. The effects of beliefs on learner actions (or refusal of action) is well documented in the literature (e.g. Mori 1999, William and Burden 1997) and can be disconcertingly direct. Learners may refuse or invest little effort in learning activities if they conflict with their views of how languages should be taught, and what appropriate roles for teachers/learners are. Mismatch between beliefs and the prevailing teaching approach has been found to cause disillusionment and demotivation or even lead to discontinuation of study (Brown 2009, Stracke 2007).

It is the potential conflict between the beliefs of students, teachers, and the institutional teaching environment which was the focus of an empirical study we conducted at WU Vienna. The interest in the field of learner beliefs has been unabated since Horwitz's pioneering study in 1981. Similarly, there have been abundant studies looking at how teacher beliefs on various aspects of language teaching translate into classroom action; yet only few researchers have attempted to present a more global picture of how teachers' and students' conceptions of language learning compare against the background of a given teaching context.

The present study aims to redress this issue, investigating whether there is friction or alignment between students' and teachers' notions of effective language learning and teaching, to what extent these ideals are realized in the

teaching environment in question, and how teachers and students deal with mismatches between their expectations and reality. A qualitative approach (interviews and mini-essays) was used to answer the following research questions: What are students' and teachers' beliefs concerning the nature of language learning, the usefulness of the target language, and the role of individual learner attributes? How do students' and teachers' notions of effective teaching and learning practices compare? To what extent are these practices facilitated by the WU programme? How do they correspond to students' aims and motivations? How do students and teachers deal with mismatches between their beliefs and the actual learning situation?

Entwistle (1991) argues that any investigation of student learning must take account of the complex net of environmental factors shaping the reality of studying at a higher education institution. In line with this exhortation, we identified local and global influences on institutional practices and explored how these external factors affect belief systems. Contextual factors shaping the learning context range from global to national and local. Global developments include a shift from EFL (English as a foreign language) to ELF (English as a lingua franca), the predominance of English in international business, and the ubiquity of the web and social media - all of which may alter students' perceptions of the role and importance of 'correct' English as well as their motivations and opportunities for learning in and out-of-class. Developments that impact on the situation of Austrian universities have taken place on the European level (i.e. Bologna process) and the national level (i.e. open university access, budget cuts). Effectively, the latter two factors have meant reductions in contact hours and, consequently, oversubscribed classes and highly unfavourable student-teacher ratios. The strongest local influence is departmental policy, dictating pronounced emphasis on content and terminology and standardized testing. These conditions interact to produce heavy constraints on what is actually feasible in terms of instructional approaches and testing, and may lead to teaching situations that are at odds with teachers' as well as students' aims, motivations and expectations.

The empirical study presented here builds on an earlier survey of student beliefs conducted by the authors. Emerging themes included views on formal teaching activities and informal learning, the importance of interaction and pronunciation, accuracy versus fluency, attitudes towards content and language integrated teaching, awareness of English as a lingua franca, and preferred learning strategies. Building on that, the present talk adds the teachers' perspective, identifying differences and similarities to students' perceptions. We interviewed the entire departmental teaching staff (n=28) to get an insight into the ramifications of context and beliefs from the faculty's perspective; this was compared and contrasted with advanced students' views (n=80) established in the survey mentioned above. Results indicated that in many relevant areas, students' notions are broadly in agreement with the teacher perspective. There are just a few aspects where teachers' and learners' opinions diverge, such as the role of aptitude and the usefulness of explicit error correction. What clearly transpired was that the main conflict students and teachers experience is due to top-down pressure and contextual constraints, and, sometimes, an overreliance on teacher-transmitted knowledge.

The study uncovered how academic institutions may fall short of fulfilling students' (and teachers') needs, and, furthermore, how students' studying orientations may be dysfunctional in a given context. One step towards alleviating the present situation would be to key into students' meta-cognitive knowledge and explicitly address curricular goals and constraints, as well as to discuss limiting beliefs & underused strategies; in short, to point students in the direction of autonomy and independent learning.

PAPER PRESENTATION

Optimism, self-concept and school achievement: relations and educational consequences

Helena Bilimoria, Instituto Piaget - Gaia, Portugal

The aim of our study is to verify the relations between optimism, self-concept and school achievement.

Optimism is associated with low levels of anxiety (Ruthig et al., 2004; Stoecker, 1999). Regarding academic success, there is some inconsistency in research results.

We applied to 36 7th grade students (17 boys and 19 girls; mean age - 12 years old), the "scale of optimism" (Barros, 1998), a 5 options likert scale, with 4 dimensions (future perspectives, hope, future projects and general optimism) and the Portuguese version of the Piers-Harris Self-Concept Scale for Children (Veiga, 2006), a dichotomous scale with 6 dimensions (behavior, anxiety, popularity, intellectual and school status, physical appearance and satisfaction). The school results were also obtained in the end of the first school period (December).

The results point to significant correlations between anxiety and some optimism dimensions. Significant correlations between future projects and intellectual status, as well as with satisfaction.

General optimism was found to be associated with most of all self-concept dimensions.

Regarding school achievement, no significant correlations were found with optimism.

A multiple regression analysis revealed that intellectual status explains 38,6% of school achievement variance ($R^2 = .386$, $b = .62$, $t = 4,623$, $p = .000$). We suggest in future research, the use of a domain-specific measure of optimism (e.g. academic optimism) and recommend further investigation with causal models to verify the associations and mediation effects of anxiety, intellectual and school status, optimism and school results

Optimism as a general disposition to expect positive events and positive outcomes for personal, present and future experiences (Barros, 2004; Koizumi, 1992; Solberg et al., 2006; Toor, 2009) is associated with physical and psychological well-being (Fontaine & Seal, 1997; Scheier & Carver, 1985, 1992; Scheier, Carver & Bridges, 2002). It's associated with low levels of anxiety, namely in academic settings (text anxiety) (Ruthig et al., 2004; Stoecker, 1999). Regarding academic success, there is some inconsistency in research results. Some enlighten the relation between optimism and school achievement (Brown & Marshall, 2002; koizumi, 1992; Schulman, 1995); others, on the contrary, refer the high levels of optimism as detrimental to school achievement (Haynes et al., 2006; Ruthig et al., 2004; Satterfield et al, 1997). Some studies link indirectly optimism to school achievement through the relation between optimism and anxiety (Ruthig et al., 2004).

The aim of our study is to verify the relations between optimism, self-concept and school achievement.

To do so, we applied to 36 7th grade students of a Portuguese school near Oporto (17 boys and 19 girls; mean age - 12 years old), the Portuguese "scale of optimism" (Barros, 1998), a 5 options likert scale, with 4 dimensions (future perspectives, hope, future projects and general optimism). This scale is based on LOT scale (Life Orientation Test (Scheier & Carver, 1985). We also applied the Portuguese version of the Piers-Harris Self-Concept Scale for Children (Veiga, 2006), a dichotomous scale with 6 dimensions (behavior, anxiety, popularity, intellectual and school status, physical appearance and satisfaction). The school results were also obtained in the end of the first school period (December).

The results point to significant correlations between anxiety and future perspectives ($r(36) = 0,488$, $p = .003$), future projects ($r(36) = .357$, p

Also significant correlations were found between the future projects and intellectual and school status ($r(36) = .384$, p

We also detected that general optimism seems to be associated with satisfaction ($r(36) = .388$, locus of control (Barros et al. 1993) and less anxiety, characteristics that can contribute to feel more satisfied with oneself. Also, optimistic persons are more sociable (Barros, 2004) what can explain the correlation with popularity (being more sociable can explain popularity, but being popular can explain being optimistic in general).

Regarding school achievement, no significant correlations were found between school results (mean score and grades in each discipline) and the dimensions of optimism. This can be explained taking into consideration the high mean levels for the dimensions of optimism (around 4,0 each). These high means point to a situation of "unrealistic optimism": some students may be overly optimistic. These students might withdraw from the academic context to protect themselves from negative effects of failure (Robins & Beer, 2001), or fail to have a backup plan to respond to unpredicted outcomes (Ruthig et al., 2004). These behaviors can explain the absence of a correlation between optimism and school achievement.

In our study, however, we didn't prove the deleterious effects of higher levels of optimism on the school results, presented in other studies (Haynes et al., 2006; Ruthig et al., 2004; Satterfield et al., 1997). In future researches, we consider important to use a domain-specific measure of optimism (e.g. academic optimism), once it has been proved to be more related to academic achievement than the general optimism measures (Toor, 2009).

A multiple regression analysis with stepwise method, revealed that only intellectual status explains school achievement (as a mean score of grades): 38,6% of the variance is explained by intellectual and school status ($R^2 = .386$, $b = .62$, $t = 4,623$, $p = .000$). The effect of the school and intellectual status on school achievement has been largely proved (Marsh, 1990, 2003; Marsh and Yeung, 1997; Shavelson & Bolus, 1982).

This investigation contributed to understand the central role of self-concept, namely, intellectual and school status, regarding the school achievement. It also enlightened the role of anxiety. Indirectly, it also contributed to the reflection and debate about teachers' ideal attitudes and pedagogical practices in order to promote academic access and success for all students.

Given the relations found between the self-concept dimensions (anxiety and intellectual and school status) and optimism dimensions (general optimism and future projects) we suggest further investigations, with causal models to verify the associations and mediation effects of anxiety, intellectual and school status, optimism and school results

PAPER PRESENTATION

Teacher Epistemic Beliefs and their articulation to broader personal beliefs. An Empirical Exploratio

Cecilia Mornata, University of Geneva, Switzerland; Etienne Bourgeois, University of Geneva, Switzerland

The study presented in this paper is part of a broader research project aiming at three objectives: 1) to explore the various dimensions and functions of high school teachers' cognitions and beliefs about learning and knowing; 2) their antecedents as related to both the teachers' biographies and current work environment; and 3) the process through which these cognitions are gradually constructed over the teachers' career. The study concerns the first part of this project. Being able to characterize teacher epistemic beliefs in their content and to see how they are articulated to the person's broader system of personal beliefs and values is therefore a necessary preliminary step to further examination of their antecedent and consequences. Preliminary results are presented and discussed here.

Aims

The study presented in this paper is part of a broader research project aiming at three objectives: 1) to explore the various dimensions and functions of high school teachers' cognitions and beliefs about learning and knowing; 2) their antecedents as related to both the teachers' biographies and current work environment; and 3) the process through which these cognitions are gradually constructed over the teachers' career. The study presented here concerns the first part of this project.

Teachers' epistemic cognition deserves careful attention, in particular to the extent that they appear to play a crucial function in structuring and orienting actual teaching practices (Maggioni & Parkinson 2008; Brickhouse, 1990; Hashweh, 1996) and in influencing student beliefs about knowledge and learning (Maggioni, Riconoscente & Alexander, 2006; King & Kitchener, 2004; Louca, Elby, Hammer & Kagey, 2004; Rading, 2002). It can also be hypothesized that they may have some specific particularities in their content given the specificity of the teaching profession (teaching is an activity about learning and knowing) (Lyons, 1990). This particular profession may be likely to attract people with certain beliefs and cognitions about learning and knowing and engagement in this profession is in turn likely to shape these beliefs over time (Wandsworth, 2007). Being able to characterize teacher epistemic beliefs in their content and to see how they are articulated to the person's broader system of personal beliefs and values is therefore a necessary preliminary step to further examination of their antecedent and consequences.

The literature on this issue is quite rich but also somewhat disparate, borrowing from both sociology and psychology of teaching and education. A review of this literature led us to select 4 major dimensions (Hofer & Pintrich, 1997; Schommer, 1990; Hofer, 2004; Hammer & Elby, 2002; Charlot, 1997, 2003, 2006; Charlot, Bautier & Rochex, 2000; Dweck, 1999):

- Epistemic beliefs *stricto sensu*, i.e., cognitions about what learning and knowing are, how they function and can be characterized as processes, their sources and aims or functions
- Personal beliefs about the world as potential source of Learning and knowledge: society at large
- Personal beliefs about significant others, such as one's family, colleagues, students or any person acknowledged as mentors: one's local environment (family and school)

- Personal beliefs about oneself, as a teacher, parent and student: one's own experience as a teacher or as a parent

In this approach, the focus is primarily on the functions that knowing and learning fulfill in the teachers' personal and professional life: how they are invested and valued in relation to teachers' personal goals? We were primarily interested in examining the articulation of epistemic beliefs to other personal beliefs and values (about oneself, others and the world) and not only the content of the epistemic beliefs in the narrow sense.

Method

Data collection

The study was based on individual semi-structured interviews conducted with the whole teaching staff of a small public high school in Geneva, Switzerland, addressing teenagers aged 12 to 15 years. 19 teachers in total were interviewed, ranging from 30 to 61 year-old, including 7 males and 12 females. Each teacher was interviewed twice on his or her workplace except for one, who was interviewed at home.

In the first interview teachers were presented a set of pictures and asked to choose the one representing the most and the one representing the least – knowledge » in their eyes. They were subsequently asked to justify and comment their choice with a view to elicit what learning and knowing meant to them.

The second interview took place three months later (in order to avoid any priming effect of the first one). Respondents were given a task in four steps that was meant to have teachers think and speak as freely as possible about the most significant learning experience in four life areas (personal, professional, schooling and continuing education).

Data analysis

Interviews were transcribed verbatim and analyzed through a classical content analysis method (using ³N*Vivo software) in reference to analytical categories derived from the four theoretical dimensions initially selected. However, other categories emerged in the course of the analysis, which were incorporated into the initial category framework.

Preliminary results

The content analysis of the teachers' epistemic beliefs and cognition led to identifying three main profiles.

1. Teachers for whom epistemic beliefs appear to be invested as a central component of their personal and professional self-concept
 - a. They define themselves and the world through the subject-matters they teach and knowledge they have invested
 - b. What they teach is associated with strong emotions
 - c. Their beliefs about knowing and Learning cannot be dissociated from their other personal beliefs
2. Teachers for whom knowing and learning are instrumental means of achieving specific personal goals (such as having a job or better understand an particular activity considered as important to the person)
 - a. Knowing and learning appear to be clearly subordinated to personal goals
 - b. Knowing and learning are not valued for their own sake, but only as means to achieve overarching personal goals
3. Teachers for whom knowing and learning are seen primarily as means of personal development
 - a. They are invested as means to become a "better person"
 - b. They are valued for their own sake, as crucial avenues to personal growth

Theoretical and educational significance

This part of the study allowed for a clarification of "epistemic beliefs" as the core construct of our broader research project. In particular, it shows the extent to which are deeply embedded in a broader beliefs and values system and cannot therefore be looked at as isolated from the latter. It also shows that epistemic beliefs are "functional", not only in the area of teaching practices but also in the person's approach to life in general.

PAPER PRESENTATION

Warm Achievement in Science: Interplay of Epistemic Beliefs, Motivational Beliefs, and Knowledge

Lucia Mason, University of Padova, Italy; Pietro Boscolo, Università di Padova, Italy; Caterina Tornatora, University of Padova, Italy

This study examined the role of students' knowledge and "warm" characteristics to explain achievement differences in the domain of science. To extend current research, we were interested in testing a comprehensive model that

includes simultaneous interactions between domain-specific epistemic beliefs, achievement goals, knowledge, self-concept, and self-efficacy. Participants were 193 high school students in grade 11. Structural equation modeling was performed to test the hypothesized relations among the observed variables. Starting from a baseline model, variables and paths were removed on the basis of statistical reasoning and theoretical aspects. A revised model provided a good fit for the results obtained. This model indicated that science epistemic beliefs were directly related positively to mastery-approach. In turn, mastery-approach was positively related to knowledge in science. Epistemic beliefs were also directly related to knowledge, which had a direct effect on achievement in science. Mastery-approach was also positively related to self-concept and self-efficacy. Finally, both self-concept and self-efficacy had a direct effect on achievement.

The study is of educational significance, especially for science teachers, as it indicates the complex and delicate interplay of individual characteristics that underlies academic achievement in science, starting from the role of domain-specific epistemic beliefs.

Theoretical Framework and Aim

Since Pintrich, Marx, and Boyle (1993) classic article, who called for "hot" conceptual change, not only cognitive factors but also affective and motivational variables have been taken into account by scholars interested in science learning, which often implies revision of inaccurate conceptions (Sinatra, 2005). Besides knowledge, in this study we examined several "warm" constructs as possible resources for achievement in science: epistemic beliefs, achievement goals, self-concept, and self-efficacy.

Epistemic beliefs, that is, representations about the nature of knowledge and the process of knowing (Hofer & Pintrich, 1997) have been proved to be associated not only with learning scientific concepts (Strömsö, Bråten, & Samuelstuen, 2008; Mason, Gava, & Boldrin, 2008; Sandoval, 2005; Sinatra, Southerland, McConaughy, & Demastes, 2003; Stathopoulou & Vosniadou, 2007) but also with overall academic achievement (Hofer, 2000; Schommer, 1993; Schommer-Aikins, Duell, & Rutter, 2005). Only more availing beliefs in knowledge as complex, evolving, and personally constructed act as resources for academic performance. Much empirical evidence has also documented that academic achievement is influenced by achievement goals. Mastery (focus on improving one's competence) and performance-approach (focus on demonstrating competence), and performance-avoidance goals (focus on avoiding lack of competence) in particular, have been studied in relation to achievement (Harackiewicz, Barron, & Elliot, 1998; Midgley, 2002; Pintrich, 2000). According to normative models of achievement goals, mastery goals are associated with deep learning, adaptive self-regulatory behavior, and positive affect. Performance goals are related instead to superficial learning, low self-regulation, and negative affect (Maehr & Zusho, 2009; Smiley & Dweck, 1994; Pintrich, 2000; Urdan, 1997). Scholars however, have questioned whether performance goals are truly maladaptive (Barron & Harackiewicz, 2001; Harackiewicz, Barron, Pintrich, Elliot, & Thrash, 2002). Studies in the science domain have shown their effects to be insignificant (Linnenbrink & Pintrich, 2002), or even positive in certain cases (Qian & Pan, 2002). In contrast, deleterious consequences are related to performance-avoidance goals (Elliott, McGregor, & Gable, 1999). In addition, the positive role of self-efficacy, that is, future-oriented self-perception of one's abilities to learn or perform at a designated level, has been documented in science (Chen & Pajares, 2010; Pajares, Britner, & Valiante, 2000). Furthermore, self-concept in a domain, that is, past-oriented self-perception of one's capability (Marsh, 1990) is not only positively related to self-efficacy but also to achievement (Schunk & Pajares, 2005). Interestingly, a relationship between epistemic beliefs, achievement goals, and learning strategies has emerged (Bråten & Strömsö, 2004; Buhel & Alexander, 2005, 2009; DeBacker & Crowson, 2006; Muis & Franco, 2009). It has also been indicated that mastery-approach is associated with more availing beliefs in complex, evolving, and personally constructed knowledge (Bråten & Strömsö, 2004; DeBacker & Crowson, 2006). Given that a multiplicity of factors, besides knowledge, play a role in academic achievement, an open question concerns how these factors interact simultaneously and what direct and mediated effects they produce on achievement. The following research question guided the study: for the science domain, what are the associations of domain-specific epistemic beliefs, achievement goals, self-concept, self-efficacy, and knowledge with achievement in high school? Based on Muis' (2007) model, we hypothesized that epistemic beliefs about science would be positively related to mastery-approach and negatively related to performance-avoidance goals. We also expected that both mastery and performance approach goals would be positively related to knowledge in science, while performance-avoidance goals would be negatively related. We also hypothesized that knowledge would have a direct effect on achievement in science as well as indirect effect through self-concept and self-efficacy. Mastery and performance goals would also be positively related to self-concept and self-efficacy, whereas performance-avoidance goals would be negatively related to both. Finally, both self-concept and self-efficacy would have a direct effect on achievement.

Method

Participants were 193 high school students in grade 11 (mean age= 16.4; 94 girls). Through self-report questionnaires the following measures were collected: science epistemic beliefs (Conley, Pintrich, Vekiri, & Harrison's, 2004), science achievement goals (Middleton & Midgley, 1997), science self-concept (Marsh, 1990), and science self-efficacy (Pintrich, Smith, Garcia, & McKeachie, 1991). All instruments had good reliability coefficients. Questions taken from PISA were used to assess domain knowledge at the beginning of grade 11. Achievement in science was measured through the end-of-term grade collected in numerical form as the teachers marked it. Structural equation modeling was performed to test the hypothesized relations among the observed variables using the LISREL 8.7 (Jöreskog & Sörbom, 1998). Assessment of fit was based on several indices. We considered the NNFI (Non-Normed Fit Index) and the CFI (Comparative Fit Index), which perform well with small and large samples. The Root Mean Square Error of Approximation (RMSEA) was also used. This is an absolute fit index assessing approximation of parameter estimates to true parameters in the population.

Results

First, scores for all scales were examined for normality (Kline, 1998). All scales were well within the ranges suggested for skewness and kurtosis. Structural equation modeling was then performed to answer both research questions. Starting from a baseline model, variables and paths were removed on the basis of statistical reasoning and theoretical aspects. A revised model provided a good fit for the results obtained, $\chi^2(6, N=193) = 4.06$, $p=0.67$, NNFI=1.01, CFI=1.00, and RMSEA= 0.0. This model indicated that science epistemic beliefs were directly related positively to mastery-approach. In turn, mastery-approach was positively related to knowledge in science. Epistemic beliefs were also directly related to knowledge, which had a direct effect on achievement in science. Mastery-approach was also positively related to self-concept and self-efficacy. Finally, both self-concept and self-efficacy had a direct effect on achievement (Figure 1).

Scientific and Educational Significance

The study has scientific significance in that it sought to advance theoretical specifications of the relationships between domain-specific epistemic beliefs, achievement goals, knowledge, and self-beliefs by testing their simultaneous interaction influencing achievement in science. The study is also of educational significance, especially for science teachers, as it indicates the complex and delicate interplay of individual characteristics that underlies academic achievement in science, starting from the role of domain-specific epistemic beliefs.

PAPER PRESENTATION

Activating and sharing prior knowledge before reading an expository text

Christian Tarchi, University of Florence, Italy

Although the process of learning from text has been widely studied, students still encounter difficulties, especially when engaged with expository texts. Literature on this issue has often underlined the importance of reader's prior knowledge, inference-making skill, and metacognition. This contribution had a twofold aim: 1) verifying the efficacy of a model of intervention on reading comprehension based on the activation and sharing of prior knowledge; 2) verifying the impact of this model on several reading comprehension components. The participants to this study were 213 7th and 8th graders. The sample was divided into three groups: two experimental groups (one working with the prior knowledge model, the other one with the reciprocal teaching approach) and a control group. In the two experimental samples, students worked collaboratively in small groups for 1 hour on four different texts, each belonging to a specific domain: history, geography, science, and a newspaper article. The prior knowledge activation group outperformed the control group in reading comprehension and semantic inferences, and outperformed the reciprocal teaching group in metacognition and free recall. On the other side, the reciprocal teaching group was more effective in asking questions about the topics tackled in the texts. From an educational perspective, this study helps to explore the interaction among reader's characteristics, text properties, and instructional environment.

Aims

The main aim of the present contribution was to assess the efficacy of a training for fostering reading comprehension based on the activation and sharing of prior knowledge among readers. Theoretical background

Almost every day students from primary to high school are engaged with expository texts. Text comprehension represents one of the most important aspects in learning, given the role it plays in the processes of acquisition, sharing, and construction of knowledge. According to the data of the PISA project, only a minority of students (8.6%) were proficient at the highest reading level (OECD, 2007). Students encounter difficulties especially when reading and learning from expository texts (Dymock, 2005). The factors that influence the process of "learning from text" have been the central interest of many educational psychologists over the past decades, who focused on the cognitive processes and mental structures underpinning this activity, as well as the textual properties that contribute to successful reading (Hailikari, Nevgi & Lindblom-Ylaenne, 2007). Research on reading comprehension has often

underlined the importance of reader's prior knowledge (Dochy, Segers, & Buehl, 1999; Ozuru, Dempsey & McNamara, 2009; Shapiro, 2004). Prior knowledge is considered a multidimensional construct (Alexander & Jetton, 2010). In a previous study (Author, 2010) a model of prior knowledge based on the contributions of Alexander & Jetton (2000), Dochy (1994), Hailikari et al. (2007), and Samuelsten & Braten (2005) has been tested, and results showed the importance of addressing both categories of topic knowledge, meanings and facts, in order to foster students' inference-making skills and the construction of a mental model of the text. On the other hand, many studies have widely demonstrated the importance of inferences (Oakhill & Cain, 2007; Rapp van den Broek, McMaster, Kendeou & Espin, 2007) and metacognition (Veenman & Beishuizen, 2004) for reading comprehension. Prior knowledge generally makes the largest total contributions to comprehension, but this variable has both, a direct effect and an indirect effect mediated by metacognition and inference, on reading comprehension (Cromley & Azevedo, 2007). Research question and Hypothesis

Despite the role played by prior knowledge in accordance with inference-making skills and metacognition has been widely demonstrated, there is a lack of studies assessing the efficacy of training addressing this pattern of components in order to foster reading comprehension. Therefore this contribution had a twofold aim: 1) verifying the efficacy of a model of intervention on reading comprehension based on the activation and sharing of prior knowledge; 2) verifying the impact of this model on several reading comprehension components. Methodology

Participants. The participants to this study were 213 students attending grade 7 and grade 8 of three schools placed in Florence, Italy (Age: 12.85 \pm .79).

Materials and measures

Four texts have been used for the two experimental groups' trainings, each belonging to a specific domain: history, geography, science, and a newspaper article. Two kinds of assessments have been utilized, one as a measure of change, the other one as a measure of process. In the former, a set of reading comprehension components has been assessed before and after the trainings, in order to compare the differences between the pre-assessment and the post-assessment (reading comprehension, inference-making skills, metacognition, topic interest, and free recall). In the latter, at the end of each training session the students were assessed on the level of depth of their comprehension of the text just read (literal and inferential comprehension, conceptual-map, and problem-solving questions).

Procedure

The sample was divided in three groups: one following the approach based on the activation and sharing of prior knowledge, one following the reciprocal teaching approach (Palincsar & Brown, 1984), and one following traditional didactic. In the two experimental samples, students worked collaboratively in small groups for 1 hour.

Findings

In order to assess the differences in the three groups between pre-test and post-test, a series of repeated measures MANOVAs have been conducted through general linear models. The within-subjects factor was time (2 levels), that is pre-test and post-test assessments, and the between-subjects factor was group (3 levels): prior knowledge activation group, reciprocal teaching group, and control group. The prior knowledge activation group outperformed the control group in reading comprehension and semantic inferences, and outperformed the reciprocal teaching group in metacognition and free recall. On the other side, the reciprocal teaching group was more effective in asking questions about the topics tackled in the texts.

In order to explore more the process through which the two trainings implemented exert their effect, data have been analyzed through a series of one-way analyses of the variance (ANOVA). The prior knowledge group outperformed the reciprocal teaching group on the history, geography, and science text, whereas no differences were found regarding the newspaper article.

Theoretical and educational significance

This study has both, a theoretical and educational significance. From a theoretical perspective, it helps to explore the interaction among reader's characteristics (reading comprehension components), text properties (different disciplinary-content texts), and instructional environment (focus on prior knowledge or on strategies), which is considered to be the determinant of the processes readers apply during comprehension (Rapp et al., 2007). From an educational perspective, this study assessed the efficacy of a training that can be easily implemented by teachers in their classroom, without the need of expensive resources. The study explores also the efficacy on single reading comprehension components, so that it can be used also to tackle difficulties in both, reading comprehension as a whole process or single processes, such as inference-making or metacognition. Finally, this study refers to a vast literature on prior knowledge and reading comprehension, therefore the training can be potentially implemented in

accordance with the available assessment tools (i.e. tests for inference-making skills, or assessment of prior knowledge).

PAPER PRESENTATION

The relationship between collaborative learning activities and individual learning

Inge Molenaar, University of Amsterdam, Netherlands; Carla Van Boxtel, University of Amsterdam, Netherlands; Peter Sleegers, University of Amsterdam, Netherlands; Ming Ming Chiu, University of Buffalo, United States

This study examines how different learning activities contribute to knowledge acquisition during collaborative learning. We analyzed cognitive, metacognitive, relational, procedural and off task behaviors of students. We analyzed the relationship between individual learning behaviors and other group members' behaviors and their contributions to knowledge acquisition. We found that students own cognitive and metacognitive behaviors during collaboration contribute to domain and metacognitive knowledge. Additionally, other group members' social regulation positively influences the development of domain knowledge and students own off task behavior negatively influences metacognitive knowledge.

Aim

The underlying assumption of constructivist learning theories is that the nature of learning activities influences learning achievement (Duffy & Jonassen, 1992). The assumption has been extended to collaborative learning settings (Janssen, Erkens, Kirschner, & Kanselaar). However studies addressing on the relation between collaborative learning activities and knowledge acquisition focused on the effects of one particular learning activity, such as elaboration (Van Boxtel, 2004; Van Drie & Van Boxtel, 2004), metacognition (Azevedo & Cromley, 2004; Molenaar, Van Boxtel, & Sleegers, In press) or off task behavior (Chiu, 2004). This provides an isolated view of the contributions of these learning activities. Cognitive activities, metacognitive activities and social regulation independently contribute to effective collaboration and consequently influence group performance and students knowledge acquisition. However, we lack a complete overview of the learning activities that contribute to individual knowledge acquisition during collaborative learning (Jansen et al., 2010). Additionally, both the individual student's constructive involvement and the contributions of other group members are emphasized as important factors influencing individual learning in collaborative settings (Chi, 2009; Webb, 2009). Nevertheless, little is known about the relation between one's own learning behaviors and other group members' behaviors and individual knowledge acquisition. The "active, constructive, interactive framework" formulates the hypothesis that students own activities are more constructive than listening to other students activities. Therefore individual activities are expected to be more influential for knowledge acquisition (Chi, 2010). The purpose of our study is to examine all learning activities during collaborative learning and determine the relationship between individual behaviors, other group member behaviors and individual knowledge acquisition.

Methodology

We describe the learning activities of 54 students (aged 10-12) collaborating face-to-face in triads while working in an electronic learning environment. We analyzed the discourse to determine the learning behaviors of the students. The total dataset of discourse turns entails 108 hours and 51.339 utterances. As learning achievements we measured students' domain and metacognitive knowledge. We present a mixed method study, with a statistical component and a qualitative component. We performed a multi-level regression analysis to examine how students engaging in specific behaviors, and experiencing other group members' behaviors acquire knowledge. The findings of these analysis are elaborated on with qualitative examples, which will not be discussed in this abstract.

Findings

Our first goal was to understand which learning activities small groups' engage in during collaborative learning. Students in our study engaged in content related activities such as cognitive activities (27%) discussing the task content and metacognitive activities (20%) regulating the cognitive activities. Additionally, student performed relational oriented activities such as social regulation (21%) of their collaboration, procedural regulation (12%) of the learning environment and off task activities (11%). Our second aim was to determine the effects of individual students behaviors and other group members behaviors on students knowledge acquisition. Relative to their group's total turns, students who perform proportionately more cognitive and metacognitive behaviors scored higher on the domain knowledge test. Moreover, students whose group members performed proportionately more social regulation behaviors scored higher on the domain knowledge test. Students who performed proportionately more cognitive behaviors and metacognitive behaviors scored higher on the metacognitive knowledge test. In contrast, students performing proportionately more off task behavior scored lower on the metacognitive knowledge test.

Theoretical and education significance

On a theoretical level, this shows that different learning activities contribute to the knowledge acquisition of students and therefore it is important to study all learning activities opposed to isolating only one particular activity. Additionally, these findings are in line with the hypothesis of "the active, constructive, interactive framework", indeed students own behaviors on the content space (cognitive and metacognitive activities) are most influential for knowledge acquisition. Additionally, domain knowledge is also influenced by the social regulation of other group members. Thus students' own social regulation does not influence their own knowledge acquisition, but it does support other group members to gain more domain knowledge. This indicates that during collaboration not only contributions on the content space (cognitive and metacognitive behaviors) are important, but also contributions on the relational space (social regulation) play an significant role in contributing to domain knowledge acquisition. On a practical level, the results can help us to create instructional designs which engage students in those activities most beneficial for learning achievements. This study suggest that instructional designs might enhance individual group members domain knowledge by engaging all group members in cognitive and metacognitive activities and helping group members to uphold social regulation of one another. Additionally, instructional designs could enhance individual group members metacognitive knowledge, by engaging all group members in cognitive and metacognitive behavior and reducing their off task behavior.

PAPER PRESENTATION

Self and social regulation of learning during collaborative activities in the classroom

Valeska Grau, Pontificia Universidad Catolica deChile, Chile

It has been widely recognised that in order to explain processes of self-regulated learning, consideration of the social regulatory aspects should not be left behind especially when we try to explain the quality and effectiveness of collaborative learning processes. This present paper presents the finding of two subsequent observational studies attempting to integrate the self and social aspects of regulation in learning contexts through an integrative model of analysis applied to collaborative learning activities in primary school. The findings of study 1 suggest interesting associations between individual self-regulated learning and social regulation within the collaborative activities, while the findings of study 2 focus on the conditions of the emergence of shared regulation episodes described in study 1, and shed light on the individual behaviours triggering episodes of productive mutual regulation. The two studies represent a contribution to the study of different levels of regulation in relation to learning processes in primary school.

Introduction

Nowadays, the inclusion of the social dimension in the traditional self-regulation of learning models have had two directions: on one side, the socio-cognitive models conceive the social as influencing self-regulatory processes and, on the other side, the sociocultural models define regulatory processes as intrinsically social. It has been argued that in order to give a more complete account of the regulation processes occurring during collaborative learning, there must be an explicit consideration of self and social aspects of regulation, and the avoidance of reductionism to the individual or the collectives to which they belong. (Akkerman et al, 2007; Hadwin, 2007; Iiskala et al, 2004; Volet, Vauras & Salonen, 2009). Following the conceptualization of self, co-regulation, and shared regulation described by

Iiskala et al (2004), and the concept of co-regulation defined by Volet et al (2009) the current paper presents two studies attempting to integrate the self and social aspects of regulation in learning contexts through an integration of analysis models applied to collaborative learning activities in primary school.

Thus, the research questions are basically, How can we integrate individual and social levels in the analysis of collaborative learning activities in primary school? In which ways these two levels are related? How can the episodes of social regulation be described and which dimensions are related to their emergence? The relevance of the studies relates to 3 issues: the attempt to develop a framework of analysis integrating self and social aspects of regulation; the advance on the description of shared regulation episodes and the conditions of emergence; and the contribution to the study of children working together and regulating each other during the first years of schooling, who are relatively under-represented in studies of self-regulated learning as much as collaborative group-work.

Methodology and findings

Study 1 is part of a broader exploratory study which aimed to collect evidence of self-regulated learning skills and conceptual development in authentic classrooms. It consisted of a multiple case study of 8 children followed up during one academic semester, belonging to the third grade of primary school. Thus four cases per classroom were systematically observed in different school situations regarding the teaching and learning of scientific concepts in order to obtain 'thick' data of each case. Data collection and analysis presented in this paper are related to the video data of 5 sessions of collaborative learning spread throughout the semester (March to July). In terms of data analysis, a coding scheme of individual evidence of self, co-, and shared regulation was developed, together with a discourse analysis in order to qualify individual utterances and interactive episodes of shared regulation, respectively. Considering the results obtained through the rates of self-regulated behaviours using the coding scheme, there was a significant increase in the rates of self-regulated behaviour –adding all the individual contributions- between session 1 and 5 in the two groups observed. However, there were significant differences in the percentages of rates of shared regulation between the two groups. Also, the rates of shared regulation were significantly correlated to the students' talk about relevant knowledge needed to solve the task. These differences were even more accentuated when the analysis of interactional episodes was carried out. The students belonging to the class showing more individual utterances directed to shared-regulation also had far more episodes of shared regulation. Study 2 has a similar design, but it aimed to answer some questions posed by study 1. Specifically, it addressed the issues related to the contexts of emergence of episodes of shared regulation during group work and sought to improve the analysis framework. It consisted of the follow up of 4 groups of students working together (16 children), belonging to 2 parallel classes over 7 months (between 3rd and 4th grade of primary school) during sessions of collaborative group-work. 5 sessions were videotaped (around once a month), with a focus on individual and social processes of regulation. The main differences with study 1 were, in terms of data collection, the consideration of a longer period of time, more participants, the inclusion of interviews with the children directly after the collaborative session and a feedback to teachers after each videotaped session -with the objective of planning activities to improve the quality of the collaborative activity. In terms of analysis, the coding system and the discourse analysis were refined, considering the elements suggested by study 1, and the analysis of interviews. The findings of study 2 are still preliminary. Up to now, it shed light on the characterization of emergence of episodes of shared regulation, and the way in which individual participants perceive the group situations. These preliminary findings are pointing to two main features of individual behaviour as playing an important role on triggering episodes of shared regulation: (1) The ability to make an argument and articulate thinking processes and (2) The capacity of emotional openness to discuss, negotiate and evaluate student's own thinking with others. There is still some analysis to be done to confirm these initial results.

Also, this study is enabling us to carry out an improved temporal analysis on the history of interactions within a group, and look at how this temporal dimension plays a role in the group development of regulatory processes. These studies attempted to conceptualise individual and social aspects of regulation within regular primary school children, carrying out collaborative activities in natural contexts. Also, they have involved an innovative methodology of data analysis, allowing the consideration of individual and group cognition, in the search of integration between both levels of analysis. Finally, they represent a contribution to the study of effective collaborative learning interactions during the first years of schooling.

PAPER PRESENTATION

Knowing how to collaborate: Collaborating to know with Web 2.0 tools

Dorothy Faulkner, Open University, United Kingdom; Denise Whitelock, Open University, United Kingdom; Rebecca Ferguson, Open University, United Kingdom; Kieron Sheehy, The Open University, United Kingdom

This paper reports an exploratory study that draws on sociocultural accounts of learning to frame an investigation of 10 – 11 year-olds' experience of using of Web 2.0 tools to support informal, self-directed learning activities at home and out-of school contexts. Focus group interviews and visual elicitation methods were used to support informed dialogues with 10-11 year-olds about their use the Internet and Web 2.0 applications. Fourteen children from a UK primary school's robotics and with computer clubs participated in the study. Children were interviewed in small groups of three or four and were also invited to produce visual representations of the ICT hardware, software and Internet applications they used at home. Preliminary analyses of the drawings and interview transcripts revealed that these participants routinely engage in both face-to-face and on-line learning activities with friends and that they use a variety of instant messaging and mobile technologies to share and exchange knowledge and expertise about gaming and the Internet, the usefulness of different search engines and information and retail sites. The data also reveal that although these children enjoy an extended, global network of family and friends, the learning potential afforded by Web 2.0 tools is hampered by inefficient information search and knowledge-sharing strategies. The paper will draw on the theoretical and analytical framework of activity theory to explain these findings.

Collaborative Web 2.0 tools, (social networking sites, blogs, wikis, video- and music-sharing sites), offer many potential benefits to learners and can facilitate information sharing, knowledge creation and on-line collaboration in both formal and informal learning contexts. Selwyn, Potter and Cranmer, (2009) report that for 7-11 year-old children, creative and collaborative uses of Web 2.0 applications are not prevalent either at home or at school and there is little evidence for the 'transformatory and empowering influence on children's learning' often claimed for these tools by educational technology commentators, (p. 292). Although this study demonstrated little difference between home and school, a considerable body of evidence has demonstrated that for children, these two sites represent distinct cultural settings or 'activity systems'. As the motivation and purposes of children's ICT-related activity is likely be different in each setting (Kerawalla & Crook, 2002), it is claimed their experiences of learning, and the mental resources and higher order thinking skills they are willing to expend on educational activities will depend in part on how they perceive the activity system and sociocultural context in which this activity is located (Lim, 2002). The study reported in this paper is exploratory in nature and draws on sociocultural accounts of learning. These emphasize the need for detailed investigation of, 'the whole configuration of events, activities, contents and interpersonal processes taking place in the context that ICT is used', (Lim, 2002, p.411). The study investigated 10 – 11 year-olds' experience of using of Web 2.0 tools to support informal, self-directed learning activities at home and out-of school contexts. The research question was, 'How do young learners make use of the collaborative tools available online to support informal learning?' The aims were to identify the tools used by 10-11 year-olds to support their learning outside school; to examine their knowledge and understanding of the ways in which they learn of, about and with these tools; and to investigate how young learners perceived the constraints and affordances of these tools. As outlined above, there is little evidence that the affordances of Web 2.0 tools for collaborative learning and knowledge sharing are employed effectively in formal educational contexts. Nevertheless, Hermans et al. (2008) maintain that the Web offers an enabling learning-environment. The rapid increase in the availability and sophistication of computer-mediated communication applications and social media means that the online, collaborative tools available to learners today are radically different compared with a decade ago. Tools are no longer primarily text-based: they offer multimodal communication opportunities with simultaneous images, sounds and speech (Jewitt & Kress, 2003). In informal educational settings, (e.g. computer clubs), these are taken up enthusiastically by children, who report that they both support and motivate learning (e.g. Maloney, Peppler, Kafai, et al., 2008). By contrast, the slow educational uptake of these media may reflect the fact that adoption of Web 2.0 creates a number of practitioner tensions, which exist as significant challenges to innovation (Crook, et al., 2008). The high levels of informal learning identified by some previous studies of collaborative Web 2.0 tool use, suggests that finding out how Web 2.0 applications are used successfully can offer guidance on ways to resolve these tensions so that these tools can be deployed successfully in formal learning contexts (Clough, 2009). To date, however, the majority of studies have focused on adult learners and secondary school students. The experience of younger learners has been somewhat neglected. Also, (with notable exceptions, e.g. Kerawalla & Crook, 2002), recent studies have used written questionnaires to interrogate younger learners' understanding of learning in relation to their use of these applications in school and at home, (e.g. Selwyn et

al., 2009, Murphy & Beggs, 2003). Even with open-ended questions, however, this may not be a sensitive-enough method. Written answers to questions are unlikely to be sufficiently comprehensive to reveal all of the ways that younger learners use Web 2.0 tools and is unlikely to reveal their meta-knowledge and understanding of the affordances of these tools. Consequently, our study used focus group interviews and visual elicitation methods to support informed dialogues with 10-11 year-olds about their use the Internet and Web 2.0 applications. A semi-structured interview format allowed the researcher to offer flexible responses to emerging themes in the conversation. Offering drawing materials provided a means for children to use various forms of visual representation to support their verbal descriptions. Interviews were carried out at a local primary school with members of a Year Six robotics club, and with organizers and members of a computer club. Fourteen children, (ten boys and four girls) were interviewed in small groups of three or four and all children were invited to produce visual representations of the ICT hardware, software and Internet applications they used at home. Preliminary analyses of the drawings and interview transcripts has revealed that the 10-11 year-olds in our study routinely engage in both face-to-face and on-line collaborative, learning activities around computers with friends and that they use a variety of instant messaging and mobile technologies to share and exchange knowledge and expertise about gaming and Internet searching techniques and to discuss the usefulness of different search engines and information sites. These children discuss and evaluate the usefulness of Internet book and music stores and appear to be discerning and discriminating consumers. They offered interesting evaluations of the reliability of information sources, (e.g. Wikipedia, the BBC, You Tube) and revealed good awareness of the potential risks of participating in social networking sites such as Facebook. The data also reveal that although these children report on-line engagement with an extended, global network of family and friends, the learning potential afforded by Web 2.0 tools is hampered by inefficient information search and knowledge-sharing strategies. More detailed analysis will draw on the theoretical and analytical framework of activity theory to organize themes that are beginning to emerge from the data concerning children's use of Web 2.0 tools to mediate simultaneous activity in overlapping activity systems; their collaborative division of labour during in knowledge building activities and their understanding of rules and strategies that enable or restrict these activities. The findings suggest that if an (adult) objective of these informal learning activities is the development of higher order thinking and communication skills, (Cole & Engeström, 1993), then there is a need for sensitive scaffolding by more knowledgeable adults and peers that can enable children to realize the full social-learning potential of Web 2.0 tools.

PAPER PRESENTATION

Training English Skills among Finnish Dysfluent Readers

Piia Bjorn, University of Jyväskylä, Finland; Paavo Leppanen, University of Jyväskylä, Finland

Responding to intervention (FastForWord) of English language was examined among Finnish speaking students. The fifth-grade students identified as having reading problems were randomly assigned to a training group and a training control group. The training group (n = 14) received a 50-minute computer program-based instruction daily for a 10-week period. Students in the comparison condition (training control group, n = 11) received the school's regular instructional program. The third group (typically reading control group) consisted of fourteen normally advanced students. The students' skills in English and Finnish languages were examined in pre-test, post-test and follow-up measures containing a battery of psychometric, phonological and language comprehension tests. This presentation will discuss the findings concerning the English language skills. The findings showed modest improvement in rapid naming skills among the training group students suggesting that the program is useful in training basic language elements. Educational implications of the results are discussed.

Introduction

Children who learn English as a second language struggle with acquisition of grammar, phonology, and semantics. Auditory perception and phonological awareness are essential skills in processing language (Gaab et al., 2007). It remains unclear, whether problems in these skills are a result of poor speech-sound perception or problems in sound representations in the brain. Further, the problems in the speech-sound perception might also be interrelated with more comprehensive deficits in the auditory system itself (Hämäläinen et al., 2008). The FastForWord program we used in the intervention, is based on a theory assuming that developmental language deficits are driven or caused by difficulties in perceiving rapid changes in sensory stimulus stream within speech (Tallal, 1996). However, not all the dysfluent readers have problems in auditory processing (See, Hämäläinen et al., 2008; Pennala et al., 2010). A common trend has been that intervention research targeted to language problems uses Internet and very "high-tech" computer programs (For example, see Goswami, 2005; Lyytinen et al., 2007). One of these kinds of Internet-based programs is the FastForWord-program family (www.scilearn.com). There is some previous literature available reporting research conducted within similar conditions compared to the present study (see, Friel-Patti et al., 2001). Aims In this presentation, our aim is to discuss the results of FastForWord computer intervention among Finnish fifth-grade dysfluent readers reported as having problems in English (secondary language, learned at school) in comparison to typically reading class mates and a training control group. Methods Participants The name of our project "EngLexia"

comprises of the first part 'Eng' referring to English language and the latter part 'Lexia' referring to reading. Using reading fluency tests and teacher assessments we formed three groups: training group (n = 13), training control group (dysfluent readers, n = 11) with the school's regular instructional program only and typically reading control group, also only attending to regular school program (normal readers, n = 14).

Procedure

The pre-measurements took place in February 2007. End-measurements after training phase were administered in May 2007. Finally, the follow-up measurements took place in December 2007. The participants' auditory skills (CTOPP and TAPS), English language comprehension (WLPB-P), rapid naming (CTOPP) and items measuring phonemic awareness (CTOPP) of English language were tested. InterventionFastForWord Language -program was developed on the basis of research conducted by Professor Paula Tallal (Tallal et al., 1996). The program includes items which, for example, train discrimination and order judgment of non-speech auditory items presented at different frequencies, word-level comprehension, grammar and finally sentence-level comprehension. The program was administered via classroom computers with headphones (50 minutes daily for 10 weeks).

Analysis

This presentation discusses the results of pairwise post hoc tests (Tukey's HSD) for group comparisons at each measurement timepoint. Results The results presented here are examples. In the actual presentation we will discuss all the measured areas of English language comparing the three groups. In English language pre-measurements, we found no statistically significant differences in any of the measured skills between the dysfluent reader groups and the typically reading group, suggesting that the English language tests were equally difficult for all the groups at the baseline.

At the end-measurement tests right after the training period, a difference in rapid naming errors was found between the training group and typical readers (mean difference = 0.82, p rapid naming time (mean difference = 2.42, p In follow-up measurements after six months, the training group participants had now gained in rapid naming errors (mean difference = 0.37, p = 0.67) –the difference was no longer statistically significant. In addition, although the difference in rapid naming time was still statistically significant (mean difference = 1.83, p English reading comprehension (mean difference = 0.93, p

Theoretical and Educational significance

Our research project showed that computer-assisted games work as motivating extras from both the teachers' and students' perspectives. Our results concerning second language learning were only modest suggesting that in the future it would be useful to develop ways to combine computer-assisted learning and actual teacher - student interaction.

PAPER PRESENTATION

Inclusive education: A Portuguese study about attitudes and concerns

Joel Santos, Lisbon University, Portugal; Margarida Cesar, Lisbon University, Education Institute, Portugal

The 21st century mainstream schools are characterised as cultural diverse spaces/times (Céêsar, 2009). In Portugal, we observe a growing diversity among students that attend mainstream schools (Céêsar & Santos, 2006) offering opportunities to develop broader inclusive educational settings (Ainscow, 1999; Céêsar & Ainscow, 2006). The

construction of more inclusive educational settings is intimately related with the educational agents' sentiments, attitudes and concerns towards inclusive education (IE) (Forlin, Loreman, Sharma, & Earle, 2007; Loreman, Earle, Sharma, & Forlin, 2007). It is crucial to study changes promoted by teacher education on the educational agents' sentiments, attitudes and concerns towards IE (Forlin et al., 2007; Loreman et al., 2007). This research is from a broader research project *Educação Inclusiva e Processos de Formação*. Its main goal is to study the sentiments, attitudes and concerns presented by teachers and other educational agents, before and after attending pre- and in-service teacher education curricular units regarding IE. We developed a long panel survey (Cohen & Morrison, 2001). The participants (N=289) included teachers and other educational agents from all over Portugal. To collect data we used: (1) documents; and (2) the SACIE scale – Sentiments, Attitudes & Concerns about Inclusive Education – by Loreman, Earle, Sharma, and Forlin (2006). This scale was answered in two moments: at the beginning and at the end of the selected curricular units. When confronting data from these two moments we observe a slightly increasing number of answers that indicate more inclusive sentiments and attitudes along with a high level of concerns towards IE.

In the last decades the Portuguese society has become increasingly multicultural (Céêsar, 2009). These changes fostered diversity within students who attend the Portuguese mainstream schools (Céêsar & Santos, 2006). Although students have become more diverse, from the 1.2 million mainstream students around 95 thousand still face exclusion by failing school or experiencing early school dropouts (INE, 2009). We conceive IE as a mediation tool for developing a quality education for all, within a specific culture, space and time (Céêsar & Santos, 2006; Daniels, 2001; Vygotsky, 1934/1962), in which all voices are celebrated as valuable resources for all (Armstrong, Armstrong, & Barton, 2000; Bakhtin, 1929/1981; Céêsar, 2009). In Portugal, the graduate and post-graduate teacher education curricula changed. They started including curricular units addressing IE and/or special educational needs (SEN) (Santos, 2008; Santos & Céêsar, in press). Although these changes promoted the construction of more inclusive settings, we still observe non-inclusive practices in Portuguese mainstream schools (Rodrigues, 2003). Authors stress the relations between the construction of (more) inclusive educational settings in mainstream schools and the sentiments, attitudes and concerns of the educational agents towards IE, and how these may be fostered through teacher education (Forlin et al., 2007; Loreman et al., 2007). Furthermore, teacher education must be consistent with the educational agents' zone of proximal development (ZPD) (Vygotsky, 1934/1962) in order to promote more desirable impacts on the educational agents' sentiments, attitudes and concerns towards IE. Thus it is essential to study the changes after pre- and in-service teacher education on the sentiments, attitudes and concerns of the educational agents (Forlin et al., 2007; Loreman et al., 2007). This study is part of a broader research project *Educação Inclusiva e Processos de Formação*. Its main goal was to study the sentiments, attitudes and concerns presented by educational agents in Portugal.

The problem that originated this research was the existence of non-inclusive sentiments, attitudes and concerns from the teachers and educational agents who develop their practices in mainstream schools (Santos, 2008). We considered these research questions: (1) What sentiments, attitudes and concerns about inclusive education do the teachers and other educational agents present before attending some teacher education units related to inclusive education?; (2) What sentiments, attitudes and concerns do the teachers and other educational agents present after attending some teacher education units related to inclusive education?; and (3) What are the changes between these two moments?

We carried out this research using a design based in a long panel survey (Cohen & Morrison, 2001). The participants include teachers and other educational agents (N=289), like educational psychologists, physical rehabilitation professionals and special education teachers. They attended higher education professional courses with curricular units related to IE. Since the participation was in a volunteer basis, some institutions did not accept to participate. To collect data we used: (1) documents; and (2) the SACIE scale – Sentiments, Attitudes & Concerns about Inclusive Education – by Loreman, Earle, Sharma, and Forlin (2006). This scale was answered in two moments: at the beginning and at the end of the selected curricular units. The selection of the curricular units was conducted through a document analysis in which we identified the intention to explore contents related with IE and/or to SEN.

Data analysis showed a high level of concern towards students categorised as presenting SEN along with a substantial number of educational agents that indicated inclusive comfort sentiments and attitudes towards IE. When confronting data from the before and after the curricular units regarding IE and/or SEN, there is a slightly increasing number of individuals that indicated more inclusive comfort sentiments, attitudes and concerns. For instance, more of these educational agents indicated comfort when around a student categorised as presenting SEN, also agreeing with the presence of aggressive students in mainstream classes. We also observe a slightly decreasing number of teachers and educational agents that indicated concerns towards an increase in stress when in the presence of a student categorised as presenting SEN in a mainstream classroom. A possible interpretation is that the curricular units only

lasted three/four months and sentiments, attitudes and concerns change processes need more time to become visible.

PAPER PRESENTATION

Index of Commitment toward Inclusive Communities

Marina Santi, University of Padua, Italy; Elisabetta Ghedin, Padua University, Italy

The benefits and the advantages of full-inclusion are recognized in the scientific and cultural communities at international level (UN Convention on the right of persons with disabilities, 2006, UNESCO). To this aim some instruments are created to sustain the process of inclusion such as that created by the CSIE (Booth and Ainscow, Index for inclusion in schools). In the Italian context the need and the importance to enlarge the attendance of all children are recognized and regulated by Italian law but the authentic process from insertion through integration to inclusion is very complex, long and difficult.

Starting from the "Index for inclusion" (Booth et al., 2000, 2006) the aim of this study is to create an "Index of Commitment toward inclusive communities", that can be used by the schools in a double way:

- to recognize specific educational political and cultural actions toward inclusive education in which schools are committed to, and which could be observed, implemented and evaluated.
- to provide a tool of self-evaluation, accountability and a repository of good practices for organizations and staff.

The implications of these findings are considerable because the study provides results directly derived from a favorable context as Italy (the unique context of full-inclusion of children with disabilities in mainstream schools) and from the modification and application of indicators accredited and recognized at international level (Index for Inclusion in Italy). The main results of this study is the creation of a "mixed tool" in which top-down principles are related with bottom-up good practices implemented in the schools in order to create an inclusive communities repertoire.

Summary:

In the first step of the research a definition of inclusion is elaborated and provided. based on the concept of belonging relationship. Transposing this definition in the field of social inclusion, this relationship is considered as a complex

sense of (well)-being which implies: feeling respected, valued for who you are; feeling a level of supportive energy and commitment from others so that you can do your best work (Santi & Ghedin). Many authors (Sen, 1999; Nussbaum, 2007, Terzi, 2005, Unterhalter 2009, Saito, 2003) establish strong connections between philosophical aspects of inclusion with the processes of inclusive education, and link inclusion to core-dialectics as equality/inequality, justice/discrimination, inclusion/exclusion and core-concepts as dignity, human development and freedom. In our Italian context several authors (Canevaro, 2007; Caldin, 2004; Ghedin, 2009; Pavone, 2010, lanes, 2005) wrote about the process of inclusion of the persons with disabilities in school, considering historical evolution from "inserimento", to "integrazione", towards inclusion. Also the international organizations recognize the right/need of inclusion of disabled in many documents as Salamanca Statement (UNESCO, 1994), the Convention on the Right of Persons with Disabilities (UN, 2006), the International Classification of Functioning (ICF; WHO, 2001), and the Index(es) for Inclusion (Booth & Ainscow, 2002, 2006).

State of the art

The concept and practices of school integration are a unique part of the Italian social and cultural context and historical development (Armstrong, 2009). In the Italian context the children with special educational needs and disabilities are integrated in mainstream schools because the Italian legislation (L. 181/71, L. 517/77, 104/92) recognized the importance of inclusion for the activity and participation dimensions of the child and the importance of the environmental factors for the determination of a disability. The notion of inclusion does not set boundaries around particular kinds of disability or learning difficulty, but instead focuses on the ability of the school itself to accommodate a diversity of needs (Booth et al., 2000, Kalambouka et al 2005, Demeris et al. 2007).

Our study starts by analyzing the two Index(es) for inclusion in schools and in early years and childcare edited by CSIE (2002, 2006), considered as a way of improving settings (Schools/Communities) by:

- a) Offering supportive process of self-review and development
- b) Building collaborative relationships and improvements
- c) Encouraging a view of learning in which children and young people are actively involved.

Purposes

The purpose of our study is to move from a descriptive aim, that of the Index(es) for inclusion, to a pre-scriptive aim, that of our index of commitment toward inclusion.

To this aim we create an "Index of Commitment toward inclusive communities" that can be used in particular by the schools both to:

- recognize specific educational political and cultural actions toward inclusive education in which schools are committed to, and which could be observed, implemented and evaluated;
- provide a tool of self-evaluation, accountability and a repository of good practices for organizations and staff .

Hypotheses

The accessibility of mainstream school by all children (disabled and not) is a right and an opportunity for learning and citizenship. To this aim instruments are created such as the Indexes of inclusion by the CSIE. In the Italian context the integration of students with disabilities in school are guaranteed by the law, but the authentic process from insertion towards inclusion is very complex, long and difficult.

An "Index of Commitment toward inclusive communities" allows the schools:

to recognise their strengths and weaknesses toward the implementation of inclusive education as a dynamic process realizable through a set of responsible and shared actions, providing explicit declinations into praxis and producing evaluable and "externalised" changes in schools activities and politics.

Methods

In order to create an "Index of Commitment toward inclusive communities" we have started from the two existing "Index for inclusion" considering the three dimensions (creating inclusive cultures, producing inclusive policies, evolving inclusive practices), and the connected indicators and the detailed questions.

Focus-group with schools' staff representatives (Headmasters, Representatives of Territorial Centre for Integration, teachers for disabled students, mainstream teachers, students, disabled students...) was carried out in order to explore the coherence and consistency of the index of commitment and its efficacy of grasping different school practices.

A first part of the study is already concluded: the modification of the Index for inclusion into the Index of Commitment to inclusive communities, with the selection of 35 commitments and 5 questions for each commitment that represent the feedback for the schools' work toward inclusion.

The second part of the study involved a representative group of the schools (primary and secondary schools) of the Veneto Region spread over all the different provinces, in collaboration with the Veneto Regional Instructional Office with the aim of bringing out the commitment of the schools toward inclusion.

Results and Discussion

The data implementation is still in progress and will be presented and discussed in the paper, with the main educational implications of the results. Data collected will be analysed with SPSS with the aim to accredit and certificate the schools committed to the process of inclusion. The main results of this study is the creation of a "mixed tool" in which top-down principles are related with bottom-up good practices implemented in the schools in order to create a useful inclusive communities repertoire.

Findings

The implications for these findings are considerable because:

- 1) the study provides results directly derived from the application of indicators of the Index for Inclusion in Italy, the unique context of full-inclusion of children with disabilities in mainstream schools.
- 2) it is interesting to use a Commitment version of Index in which the corresponding
 - actions/doings for inclusion
 - features/beings for inclusionare expressed/externalized and became recognisable, sharable, and available among different institutions and so evaluable, also by families and students.

Future directions

- . To provide an on-line form of the tool for school accountability
- . To create a good practices repository/self/reciprocal-trainingpedia
- . To realize the participation of children/ parents' commitments considering the inclusive paradigm.

PAPER PRESENTATION

Raising levels of achievement for pupils with Moderate Learning Difficulties

Annamari Ylonen, University of Exeter, United Kingdom; Brahm Norwich, University of Exeter, United Kingdom

While pupils with moderate learning difficulties (MLD) represent the largest proportion of those identified as having special educational needs, they have tended to be neglected as a focus for educational initiatives. The Raising Levels of Achievement project aims to improve the learning experiences and opportunities of pupils with MLD to enhance their educational achievements and broader well-being in schools. This will be done through a programme of professional development using Lesson Study methodology, a high profile international method of in-school professional development. The project has a multitude of different aims and objectives – all of which cannot be considered here. This proposal focuses on one specific element of the evaluation of the project, namely the outcomes for participating pupils (especially MLD pupils), teachers, classes and schools at a half-way point of the two-year long project. More specifically, this evaluation focuses on examining how and why changes took place following the introduction of the Lesson Study methodology and the impact of these changes on individuals and schools concerned.

Aims

At the heart of this project lies the aim of raising the status of MLD as an important area of educational research and a field for development. Pupils identified with MLD come disproportionately from families who experience socio-economic disadvantage compared to other areas of SEN, such as autism and speech and language impairment. There is a notable lack of well established advocacy or voluntary groups dedicated to the interests of these pupils. Another difficulty arises from the fact that the MLD category is a contested one. Moderate learning difficulties was a term introduced in the Warnock Report 1978, but there is prevailing uncertainty as to which pupils are designated as having MLD. The debate about the MLD category highlights the question about whether these pupils are just the lowest of the lower attaining pupils or whether they have an intellectual disability (Norwich and Kelly 2005). This historic uncertainty about the position of pupils with MLD as being between those with severe intellectual disabilities and 'normal' pupils who are lower attaining is also relevant to understanding the educational neglect of these pupils. It is important to note that MLD pupils – regardless of the problems and debates over categorisation – tend to be notable educational underachievers, as Desforges (2006) concluded in his review of achievement of pupils with MLD at Key Stage 3 and 4. DCSF statistics show, for instance, that while 68% of those doing GCSE achieved 5+ A*-C grades in 2007, only 17% with SEN at School Action Plus and 9% with Statements achieved this level (DCSF 2007). Though these figures relate to all identified as having SEN at these levels, given that MLD represents a quarter of these pupils, these

statistics give some indication of levels of secondary school attainments. The Raising Levels of Achievement project, which began in the autumn of 2010, aims to improve the learning experiences and opportunities of pupils with MLD to enhance their educational achievements and broader well-being in schools. This will be done through a programme of professional development using Lesson Study methodology, a high profile international method of in-school professional development originating from Japan. In short, the Lesson Study methodology provides opportunities to examine lessons in a detailed way, which enables planning for wider learning aims (DCSF 2009). The evaluation of the project will be ongoing during the two-year period of the project and it will focus on two domains: outcome evaluation and process evaluation. The paper proposal discussed here focuses on outcome evaluation at a half-way point of the project as outlined below. The aims of the evaluation of the project considered here relate to three separate, but interlinked areas: The impact of the Lesson Study on the learning and learning dispositions of pupils with MLD in the project schools. The enhanced professional development of participating teachers. The enhanced curriculum and pedagogic development in the participating schools. In addition, the evaluation aims to examine the usefulness of the MLD category in secondary schools. The research question is whether there are any differences between participating pupils identified as having MLD, those who are below average and with other kinds of learning difficulties in terms of attainments, cognitive abilities, attitudes to learning and self concept.

Methodology

At phase 1 of the evaluation there are a mixture of 20 secondary and special schools from two urban authorities (Plymouth and Bristol) and two rural areas (Somerset and Devon). The secondary schools have been selected to reflect a range of provision for MLD. The special schools have a high proportion of pupils with MLD, but may not be designated as MLD special schools. 20 teachers from the participating schools are trained in Lesson Study design and will continually review their own classroom practice in order to help them to develop learning experiences. They will be also trained in research methods to support this work – data gathered by teachers constitutes an important element of the project evaluation. In each secondary school there are two classes where the Lesson Study method is used. Within these classes the sample of pupils include two pupils identified with MLD, one with specific learning difficulties (e.g. dyslexia), one low attaining pupil and one average attaining pupil. Within the special schools the sample consists only of pupils designated as having MLD with some having other kinds of associated difficulties. . Testing and assessment of these case pupils (pre and post intervention) focus on examining academic, cognitive and self-concept issues and will utilise the British Ability Scales (BAS), Myself-as-a-learner Scale (MALS), Resiliency Scales, and pupil attitude to school measures. In addition, teacher attainment assessment will be utilised. These measures are relevant to the question of the usefulness, or otherwise, of the MLD category as well as elucidate outcomes of the Lesson Study method. Data used in the evaluation come from a variety of different sources and consist of data collected directly by evaluation staff by using both quantitative and qualitative methods (e.g. test, surveys, interviews and observations), and data collected by teachers in the development work (e.g. interview and observation data, video recordings and field notes).

Findings

The paper reports learning characteristics and achievements of participating pupils with MLD and other pupils in the participating Lesson Study classes and the wider impact of Lesson Study on teachers and schools. The pupil level assessment highlights findings about the usefulness of the MLD category while teacher/class/school level analysis highlights the impact of the Lesson Study method on teacher professionalism, class cohesion and the school as an effective learning environment. Issues of inclusion (and exclusion), school-wide ethos and pupil-pupil/ teacher-pupil relationships are also brought to attention. The paper contributes to developing theoretical knowledge and awareness of MLD as a SEN category, how to develop specific pedagogies addressing the needs of this thus far largely neglected group of children in educational research, and how to increase teacher professionalism and efficacy in this area.

PAPER PRESENTATION

Comparison of a direct and combined training in cognitive learning strategies

Silja-Susann Taxis, Ulm University, Germany; Tina Seufert, Ulm University, Germany

Cognitive learning strategies are effective support for learners dealing with complex learning material. In our study we analyzed the effects of direct and combined training in learning strategies (containing text reading, task solving and reciprocal teaching) on strategy use and learning performance. Furthermore, interaction effects between partners' cognitive abilities in reciprocal teaching were investigated. Students in grade 5 received either a direct or combined training or remained untrained. Results indicate an advantage of direct over combined training in text reading and problem solving on strategy use and learning performance. Both training groups outperformed the control group in reciprocal teaching and students with higher cognitive abilities showed better learning results when learning with low ability than with high ability students.

Introduction and Theoretical Background

When learning, learners need specific strategies for understanding texts or solving complex tasks or problems. Besides these specific strategies, there are general strategies like reciprocal teaching, where students share their ideas to understand a text or solve a problem together. When these interactions are unscripted, high ability learners take on the teacher's role, while low ability learners take on the role of a learner (Wiegmann, Dansereau & Patterson, 1992). Specific as well as general strategies can have a positive impact on learning outcomes and can be fostered directly or indirectly (e.g. Artelt, 2006). In a direct training strategies are delivered explicitly, whereas in an indirect training strategies are an implicit part of the learning environment. Both types of training can be combined with indirect learning opportunities after an explicit instruction. In our study we analyzed the effects of direct and combined training on learning performance and strategy use. We predicted advantages of the combined over the direct training because of the increased number of learning opportunities. Moreover, concerning reciprocal teaching, we investigated interaction effects between the cognitive abilities of both partners on learning performance. One could assume role conflicts when learners with comparable cognitive abilities are learning together, which may lead to lower performances than in groups of learners with different cognitive abilities.

Method

We compared three groups of 5th grade Gymnasium students: one training group received only a direct training in learning strategies (N=54), the second one received a combined training over three months (N=58) and the third group served as an untrained control group (N=51). The learning strategy training consisted of three cognitive strategies: a text reading strategy, a problem solving strategy and a strategy for reciprocal teaching (Palinscar & Brown, 1984). The learning strategy training was implemented in class by teachers. After the direct instruction of the strategies the students received cards for lessons and homework where the three strategies were described stepwise. Cognitive ability was assessed by a cognitive ability test (Heller & Perleth, 2000). Students were classified by median split into four groups: students with low or high cognitive abilities learned with partners with either low or high cognitive abilities. After the end of the combined training, we assessed strategy use on a behavioural level and analyzed if students conducted the steps of the strategy cards while working with texts and complex tasks. To assess the effect of the text reading strategy and reciprocal teaching on performance, students had to answer questions pertaining to the texts; the effect of the problem solving strategy was measured by complex mathematical problems.

Results

With respect to strategy use, an ANOVA for effects of the text reading strategy found a main effect for training ($F(2, 162) = 28,88, p < .001, \eta^2 = .27$). Both training groups used more text reading strategies than the control group (control group vs. direct training: $MD = -.49, SE = .07, p = .001, MD = -.20, SE = .06, p = .001, MD = .29, SE = .06, p = .001, MD = 6,48, SE = 3,41, p = .03$). An ANOVA for strategy use while solving a task found a main effect for training ($F(2, 160) = 6,09, p < .001, \eta^2 = .07$). The directly trained students used more strategies than the control group ($MD = -.16, SE = .07, p = .02$) and the combined training group ($MD = 0.23, SE = .07, p = .001, MD = .17, SE = .10, p = .04$) and the control group ($MD = -.24, SE = .10, p = .02$). Concerning reciprocal teaching, an ANOVA with the factor treatment and the factor for the interaction effect between the cognitive abilities of both partners on learning performance found a main effect for training ($F(2, 163) = 13,59, p < .001, \eta^2 = .15$): both training groups outperformed the control group (control group vs. direct training: $MD = -19,55, SE = 4,04, p = .001, MD = -16,48, SE = 3,90, p = .001, F(3, 163) = 5,47, p < .001, \eta^2 = .10$). Students with higher cognitive abilities learning with students with lower cognitive abilities showed better learning results than those learning with students with higher cognitive abilities ($MD = 8,38, SE = 4,65, p = .04$).

Summary and Discussion

We analyzed the difference between direct and combined learning strategy training on strategy use and learning performance. For all three strategies we didn't find the assumed advantage of a combined training over a direct training on the level of strategy use and learning performance. One explanation might be that we measured the effects after different time periods: while students of the direct training have been tested on short-term effects directly after the training, the combined group was only tested after a longer period. Hence, positive short-term effects might have declined during this time, which might be due to interference effects with existing strategies, or due

to the reduced intensity of the training. Reciprocal teaching led to better learning performance. Partly, we also found an interaction effect of learners' cognitive abilities. Students with higher cognitive abilities showed better learning results when learning with low ability students than with high ability students. With an inferior partner they can follow the classical role arrangement and profit from taking over the active role.

PAPER PRESENTATION

The development of high school students' interest in philosophy: A longitudinal study

Pietro Boscolo, Universita di Padova, Italy; Paolo Piccinin, university of Padova, Italy

The study was aimed at analysing the development of 11th graders' interest in philosophy, a discipline novel to them, which was taught according to two different methods: dialogue-based and text-based. The first method is based on the teacher's exposition of a topic and students' participation through questions and discussion. In the second method, the teacher starts with the reading of a philosophical passage, from which students are guided to get information about a problem and related concepts. The study, lasting for a school year, was conducted with 101 11th-graders from 4 classes of a Scientific Lycaenum (M = 58, F = 43). Two classes (N = 51, M = 29, F = 22) were casually assigned to the dialogue-based teaching procedure, and two (N = 50, M = 29, F = 21) to the text-based teaching procedure. The philosophy syllabus was divided into 5 main topics (from pre-Sophists to Aristoteles) and students' interest and learning were assessed after each topic.

Results showed that interest was higher in the dialogue-based group, whereas the text-based group students were more cognitively involved. Regarding the relationships between interest in a topic and learning, in the most interesting topic students scored better in all questions, and significantly higher in questions requiring deeper elaboration of knowledge.

In recent years, several studies have analysed the nature of interest, mainly in the light of the distinction between situational and individual interest (e.g., Hidi, 1990; Hoffman et. al., 1998; 2006; Renninger et al., 1992; Schiefele, 1991). Situational interest is elicited by the attractive or novel features of an object/event, whereas individual interest is a long-standing orientation towards an object. The relationships between the two types of interest have been conceptualized in Hidi and Renninger's (2006) four-phase model of interest development. According to the model, situational interest includes two phases: triggered and maintained, whereas individual interest includes emerging and well developed interest.

The study was aimed at analysing the effects of the teaching method on the development of 11th graders' interest in philosophy, a new discipline to them. The study was based on two main assumptions. The first assumption was that, although interest is often considered a unique variable, it includes several components, which may emerge in different ways in its development. For instance, being interested in a philosophical topic implies to perceive the relevance of a theory, and/or to feel cognitively stimulated by philosophical argumentation (e.g., Boscolo et al., in press; Schraw, Bruning, & Svoboda, 1995; Schraw & Lehman, 2001). The second assumption was that the teaching method influences the development of interest in a complex subject. In the study, two methods were compared, differing in the role of analysis of philosophical texts (Bowery & Beaty, 1999; Sadler, 2004). The dialogue-based method starts from the teacher's exposition of a topic and the related basic concepts. Analysis and interpretation of a philosophical text follows, does not precede, the exposition of topics. During the exposition, the teacher re-constructs an author's ideas and stimulates and facilitates students' participation in the lesson through questions and discussion. In the text-based method, the teacher starts with the reading of a philosophical passage, from which students are guided to get information about a problem and related concepts. During the lesson, the teacher helps students clarify concepts, integrate information, and focus on the context, ideas and new words emerging from reading.

The study, lasting for 1 school year, addressed the following questions:

1. does teaching philosophy through students' questions and classroom discussion contribute to students' interest in the subject more than a method based on philosophical text analysis?
2. do the two methods have different effects on the development of students' ideas of philosophy and its utility?
3. does an interesting topic influence learning more positively than an uninteresting one?

Method

Participants

The study was conducted with 101 11th-graders from 4 classes of a Scientific Lycaem. (M = 58, F = 43). Two classes (N = 51, M = 29, F = 22) were casually assigned to the text-based teaching condition, and two (N = 50, M = 29, F = 21) to the dialogue-based condition. The students had not previously studied philosophy. The teacher of philosophy was the same in the four classes.

Measures and procedure.

1. Initially, all students were administered questionnaire 1 regarding their ideas and expectations about the contents of philosophy, usefulness for young people's education, interestingness, and main sources of study difficulties. The philosophy syllabus was divided into 5 topics: 1. Pre-sophist philosophy, 2. Sophists and Socrates, 3. physis and nomos (nature and law), Plato, Aristoteles.

After presentation and study of each topic, that is 5 times, questionnaire 2 was administered, including questions on global interest in a specific topic and sources of difficulty; open-ended questions on the most and least interesting parts of the topic. Moreover, 24 questions (4-point rating from "False for me" to "True for me") regarded the following aspects of interest in philosophy:

Liking (e.g. "I like philosophy because it poses basic questions")

Relevance of themes/topics ("While studying philosophy, I realize that the basic questions of our life are always the same")

Situational interest ("The teacher's lively presentation of philosophers and their theories makes the philosophy class enjoyable")

Cognitive involvement ("I feel stimulated by the study of philosophy to think by myself, not only through the teacher's or book's words").

Questionnaire 2 also included questions aimed at assessing the comprehension of the specific topic.

Lastly, at the end of the year, all students were administered questionnaire 3, including some questions of questionnaire 1 (definition of philosophy, perceived usefulness for young people's education). Moreover, students were asked to indicate the most and least interesting topic, and reply to open-ended questions regarding these topics. These questions regarded different levels of knowledge elaboration.

Results

All students' interest scores increased from topic 1 to 3 (from pre-sophists philosophy to physis and nomos), and decreased with topic 4 and 5. Regarding the development of interest, a multivariate analysis of variance, with group as a between-subject factor and time (5 administrations) and components (4) as within-subject variables, showed that the dialogue-based group students scored higher than the text-based group in the Liking, Situational interest and Relevance components, but lower in Cognitive involvement ($F(2, 367) = 12,57$, $p2=.11$). Regarding the relationship between interest and learning, the most interesting topic was always related to better scores in the learning questions requiring deeper elaboration of knowledge ($F(2, 92) = 23,24$, $p2=.17$). Lastly, regarding students' ideas on philosophy, a log-linear analysis showed a higher frequency of more advanced definitions at the end of the year, regardless of the teaching method ($z = 2.745$, p

Discussion

The development of participants' interest in philosophy partially confirmed the developmental trend from triggered to maintained interest. The text-based teaching method fostered students' cognitive involvement, but they preferred a less cognitively demanding method, based on dialogue. The role of interest in fostering learning, underlined in recent literature, was confirmed. The study is relevant from the instructional and theoretical points of view, because it gave the opportunity to analyze the development of interest in a discipline in the classroom context, and to test the Hidi and Renninger's (2006) model.

PAPER PRESENTATION

Better thin harmony than thick dispute? On different ways to communicate scientific controversies

Dorothe Kienhues, Institute of Psychology, Germany; Rainer Bromme, Universitat Muenster, Germany

To be active members of our knowledge society, people not only need to possess basic scientific knowledge but also, and in particular, an understanding of the sciences, their potentials and limitations. Although scientific uncertainties and controversies routinely come along with the process of establishing knowledge, laypeople usually expect sound orientational knowledge. This paper focuses on laypeople's cognitive processing of scientific controversies. We assume that laypeople may struggle with finding a good explanation for scientific controversies, especially when the conflict displayed is emotionally charged, because then the conflict might appear to be interpersonal but not inherent to the topic. We presented a newspaper article on two experts discussing the benefits and harms of a fictional anesthetic. In a first study, psychology students ($N = 40$) were randomly assigned to two different versions of this newspaper article: a neutral version or an emotionally charged version. Dependent variables were change in epistemic beliefs, confidence in the two experts, whether participants would recommend the anesthetic, their own decision certainty and the assumed certainty of experts. Results reveal an equal change in epistemic beliefs for both groups, and only minor differences in the other variables. We assumed that effects might be stronger in a sample less experienced in dealing with controversies than psychology students. We conducted a second (ongoing) study where less experienced participants ($N = 60$) dealt with the same materials, and we added measures on several potential covariates. We will derive implications for laypeople's understanding of scientific controversies

In western culture, we live in a knowledge society. On the one hand, we have easy access to all kinds of information (e.g. via the Internet, independent newspapers or magazines). On the other hand, knowledge and facts play a dominant role in many everyday decisions, e.g. whether to stick with nuclear energy, what kind of medical treatment to select. In consequence, to be active members of the knowledge society, people not only need to possess basic scientific knowledge but also an understanding of the sciences, their potentials and limitations. A normal feature of scientific knowledge is its uncertainty and preliminaryity. Although scientific controversies are everyday routine in empirical sciences and come along with the process of establishing knowledge, laypeople usually expect sound orientational knowledge. This paper focuses on laypeople's cognitive processing of scientific controversies. Scientific controversies are – in an epistemological sense – argumentative approaches towards the best conclusion. They are based on the cognitive content of the conflict, and the conflict is inherent to the topic. That means the conflict is not predominately made up by the opponents, e.g. because they are at strife with one another or dislike each other. Such emotional "side effects" of conflict can occur, but are not the dominant explanation for scientific controversies. We assume that laypeople, who do not expect scientific controversies, may struggle with finding a good explanation for scientific controversies, especially when the conflict displayed is emotionally charged: Then the conflict might appear to be interpersonal but not inherent to the topic. For our studies, we made up a newspaper article on a scientific controversy. The article was about two experts discussing the benefits and harms of the fictional anesthetic "madofol". The newspaper article differed with regard to the affectivity and asperity included. In one version of the article, the discussion of the experts was displayed as neutral and fair (neutral condition). In the other condition, the discussion of the two experts was emotionally charged (emotional condition). In this version, the experts were much more excited and verbally attacked each other. The two versions of the article were identical with regard to the factual information they contained. In a first study, participants ($N = 40$, predominately psychology students) were equally assigned to the research conditions. We administered an instrument (CAEB) measuring two dimensions of epistemic beliefs about medicine (texture and variability of knowledge) a few days before participants read the newspaper article. After participants read the newspaper article, we again administered the CAEB. Participants also filled in several questions regarding their confidence in each of the two experts, whether they would recommend the application of madofol, the estimated certainty in this decision, and the estimated certainty of experts making the same decision. An ANOVA revealed a significant difference between pre- and post-instructional measurements for both factors of the CAEB (texture: $F(1,38) = 17.07$, $p = .00$, $\eta^2 p^3 = .31$; variability: $F(1,38) = 26.56$, $p = .00$, $\eta^2 p^3 = .41$). The interaction between the pre-post comparison and the between-subject variable condition failed to attain significance for both factors (texture: $F(1,38) = 1.90$, ns; variability: $F(1,38) = .29$, ns). In line with other studies on confronting participants with the complex and conflicting nature of science, dealing with conflicting information lead to more advanced beliefs. The emotionality of the information dealt with did not have specific influence on the change. With regard to the confidence in the two experts, we checked whether the two groups differ in the estimation of each of the two experts and also in how far they differentiate between the experts. Results reveal that the two groups did not differ in their confidence in expert A, $t(38) = -.89$, ns, and in expert B, $t(38) = .00$, ns. Furthermore, we tested in how far participants differentiated between the two experts, indicating a significant difference for the estimation of the experts, $F(1,38) = 9.38$, $p = .00$, $\eta^2 p^3 = .20$, but no significant interaction between estimations and the between-subject variable condition, $F(1,38) = .35$, ns. An inspection of the means suggested that the groups indicated a greater confidence in the expert who argued against the anesthetic. We tested for differences in the decision on whether they would recommend the application of madofol. In the neutral condition, five participants said yes, six said no and nine didn't know. In the emotional condition, eleven participants said yes, five said no and four didn't know. However, the two groups did not differ significantly, $\chi^2(2, N = 40) = 4.24$, ns. In addition, participants

did not differ significantly in their own decision certainty, $t(38) = -.49$, ns, and in the assumed certainty of experts making the decision, $t(38) = .63$, ns. Participants differentiated between their own certainty and the certainty of experts, $F(1,38) = 3.89$, $p = .06$, $\eta^2 p^3 = .09$. The interaction between the pre-post comparison and the between-subject variable condition failed to attain significance, $F(1,38) = .66$, ns. However, the results for the two conditions suggested different amounts of differentiation depending on the kind of article dealt with. In order to clarify the results further, paired t tests were conducted, revealing that only the participants of the neutral condition considered experts to be more certain in their decision than themselves, $t(19) = -2.35$; $p = .03$; $d = -2.82$, while participants in the emotional condition did not differentiate between experts and themselves. $t(19) = -.72$; $p = ns$. We assume that some of the effects might be stronger in a sample less experienced in dealing with controversies than psychology students. Therefore, we conducted a second study ($N = 60$) with less experienced participants. We added instruments on participants' prior attitude and their perceived relevance of the topic, as these might be determining factors of how people deal with scientific controversies. We will also report on these data and compare the results found in the two studies. We will discuss implications of our studies for laypeople's understanding of scientific controversies in modern societies. Suggestions for communicating scientific controversies will be highlighted in the full paper.

PAPER PRESENTATION

The impact of standard-based teaching on students' performances in English as a foreign language

Jenny Frenzel, Humboldt University Berlin, Germany; Jessica Andrade, Humboldt University Berlin, Germany

Based on data of the first German national assessment in English as a foreign language, this contribution investigates the impact of standard-based teaching practices on students' performances in listening and reading comprehension. We analysed 684 teachers' responses concerning the frequency of initiated activities in class in a multi-level-model in regards to 23,934 students' performances in listening and reading comprehension on a standard-based English test. Although students' performances for listening and reading highly correlate ($r = .87$), we analyse data separately due to didactical reasons.

First, descriptive results for listening comprehension show a rare use of standard-based listening activities during class for all German school tracks. Nevertheless, further results from multi-level analysis show a significant impact of listening activities on students' performance controlling for students' sex and self-concept. The impact still holds when controlling for teachers' age, sex and regional differentiation. We hypothesize that the results for reading comprehension also support these findings. Furthermore, we expect an impact of about more than a standard deviation. The results will be discussed with respect to further implementation of competence-orientation in teaching and curricular development.

Changes in the German education system have shifted toward teaching which focuses on the development on students' individual competencies. The reform asks teachers to initiate processes of competence development in classroom activities to reach the defined Educational Standards (NES) in English as a foreign language.

The NES are based on the Common European Framework of Reference for Languages (CEF, 2001) and include reading and listening comprehension in the area of communication skills. Because reading and listening are receptive activities, the CEF focuses on active language use in authentic situations, such as activities listening to public announcements, to media and listening as a member of a live audience (CEF, 2001, p. 65). The tasks for national assessments is grounded in the CEF and NES objectives, which is why care is taken to utilize authentic audio materials. The classroom offers the possibility of language acquisition through language development activities in listening and reading as well as writing. Bernaus and Gardner (2008) analysed the relationship between several classroom activities and achievements in English. With regard to perceived use of traditional and innovative strategies, they found no significant correlation between the perceived strategy use of either type and level of English achievement (Bernaus and Gardner, 2008, 393). They conclude that teachers use rather traditional than innovative strategies and that students are more aware of the traditional strategies.

Since standards-based testing focuses on reading and listening comprehension in Germany, we developed the following research:

- 1) Do reading and listening activities in the classroom as reported by students differ from teachers' suggestions towards competence orientation?
- 2) How do reading and listening activities affect students' outcome when controlling for age, sex, self-concept and regional differences?
- 3) Do competence-oriented classroom activities have an impact on student outcomes?

We hypothesize that teachers and students have different perceptions about classroom practices. Teachers will respond with more socially desired answers than students.

We also hypothesize that initiated standard-based listening activities during class have a positive association with students' listening outcome.

Sample:

The first national assessment took part in 2009 in the domain of English as a foreign language. Nationwide, 23,934 ninth-graders were tested in the domains of listening and reading comprehension. Students answered a questionnaire about classroom practices and background information. 684 English-teachers answered a questionnaire about their teaching, qualifications, and perceptions of the Educational Standards.

Method:

We scaled the standard-based reading test consists of 237 items and the listening test of 213 items using IRT-modeling, controlling for several background-characteristics. We compared teachers' and students' questionnaire data, which in part consists of six items on reading activities in class as well as six items on listening activities, inquiring about the frequencies of standard-based activities within the last six months using a scale from 1 (never) to five (each lesson). We calculated students' standardized differential value and compared with teachers' suggestion for that class using Kendall's tau.

For the second research question, because of the nested data, we constructed a series of multi-level-models using HLM (Raudenbush & Bryk, 2002). We scaled the six listening activity-items by means to a common variable called "listening activities". Analysed with random-intercept models, polynomial variables on level 1 are were group-centered and grand-centered on level 2.

Results:

Listening and reading performance data is highly and significantly correlated ($r = .87$).

The descriptive analyses divided into two school-tracks and reported by students show a small mean for the listening activities within the last six months (see Table 1).

For the reading activities, the frequencies are increased. The mean for the 15 items ranges from 2.24 to 3.16 for Gymnasium and from 2.41 to 3.12 for the other schools, which means a frequency of two to five times in the last six months.

When comparing the two perceptions within the same class (teacher perception versus students' statements), Kendall's tau ranges from $\tau = .10$ to $\tau = .74$ (mean = .48).

Regarding the second question, we constructed a series of multi-level-models to investigate the impact of standard-based teaching practices on students' outcome controlling for sex and the self-concept of students. The Intra-class-correlation (ICC) ($\rho = .55$) on level 1 shows an explained variance of students' outcome in listening comprehension of 55 percent. Model 3 shows an impact of standard-based listening activities on students' listening outcome. This effect remains when taking in account the eastern/western differences.

By calculating the same model for reading comprehension, we predict a strong, positive magnitude, based on the fact that teachers reported a higher frequency of reading activities than listening activities.

Discussion

Even preliminary results show that competence-oriented activities have a positive impact in students' outcomes. Despite this, teachers and students both report a small frequency of usage during class. This analysis has major implications for classroom practices. Teachers, who plan their lessons with authentic activities focusing on competence orientation, can help their students towards higher learning outcomes. One limitation of this analysis is that the questionnaire only addressed certain activities in receptive domains. Further research should focus on all domains of English as well as a wider breadth of activities.

PAPER PRESENTATION

Integrating Self-regulation Procedures in the Reciprocal Teaching of Reading Strategies.

Nina Schuenemann, Justus Liebig University Giessen, Germany; Vanessa Seuring, Justus-Liebig-Universität Giessen, Germany; Nadine Spoerer, University of Potsdam, Germany; Joachim Brunstein, Justus-Liebig-University, Germany

In this classroom intervention study, we examined incremental effects of integrating methods of self-regulated learning in the reciprocal teaching of reading strategies on 5th graders' text comprehension skills. For this purpose, we contrasted students who were taught reciprocal teaching strategies in tandem with self-regulation procedures (RT+SRL) with (a) students in a traditional reciprocal teaching condition (RT) and (b) students in a no-treatment control condition. In a clustered randomized trial, fifteen intact classes (N = 323 students) were randomly assigned to conditions. The treatment phase comprised 7 weeks and was delivered by trained teaching assistants in natural classroom settings.

Measures of reading comprehension, reading fluency, and self-efficacy were administered at three occasions: pretest, posttest, and maintenance.

At posttest, students in both treatment conditions outperformed students in the control condition on a standardized test of reading comprehension. Students in the two treatment conditions did not differ at posttest but at maintenance, favouring the combined RT+SRL program over the traditional reciprocal teaching program. In addition, at maintenance, RT+SRL students read more fluently and reached higher reading self-efficacy scores than students in the two comparison conditions.

These findings suggest that the integration of self-regulation procedures in the reciprocal teaching of reading strategies produces beneficial and lasting effects on students' literacy skills and personal sense of reading competence.

Reciprocal teaching (RT) is an instructional procedure in which small groups of students learn to improve their reading comprehension through the use of the four reading strategies clarifying, summarizing, questioning and predicting (Palincsar & Brown, 1984). In the last 20 years, many studies have been conducted to test the effectiveness of RT (Rosenshine & Meister, 1994). Although there is clear evidence that RT promotes reading comprehension, a number of difficulties with implementing and practicing RT in a whole-class setting have been reported. As Hacker and Tenen (2002) pointed out, teachers modify the practice of the four strategies in several ways to adopt RT to the classroom situation. These modifications often led to deficits in or loss of the three key elements of RT, strategy use, meaningful dialogues within the groups and scaffolded instruction. According to current models of self-regulation, metacognitive monitoring will produce effective regulation, and this in turn will improve students' learning processes (Thiede, Anderson, & Theriault, 2003). The awareness and use of self-regulation strategies can enhance students' reading comprehension. However, until today only a few studies investigated the effect of self-regulation procedures on reading comprehension (Paris, Cross, & Lipson, 1984).

Aims

In order to close this knowledge gap, we trained students to become self-regulated readers who acquire and use self-regulatory knowledge and skills that enhance their reading performance. The aim of this study was to examine the effects of a potentially more classroom-appropriate intervention in which the students' use of RT is facilitated by incorporating specific self-regulation procedures into the training.

For this purpose, we contrasted students who were taught reciprocal teaching strategies in tandem with self-regulation procedures (RT + SRL) with (a) students in a traditional reciprocal teaching condition (RT) and (b) students in a no-treatment control condition. In the RT condition we integrated methods of direct instruction with cognitive modeling and phases of independent group work to help students acquire the reading strategies. In the RT+SRL condition students were trained equally but we taught RT in tandem with self-regulation procedures (setting process and outcome goals, self-monitoring, self-recording, self-evaluation).

We predicted that, compared to traditional RT and a no-treatment control condition, RT+SRL would be more effective in fostering the reading comprehension, reading fluency and self-efficacy in the short and medium term.

Methods

The sample consisted of 323 students of 15 fifth-grade classes from four different German comprehensive schools. In a clustered randomized trial, fifteen intact classes were randomly assigned to conditions. Six classes were assigned to each RT and RT+SRL and three classes acted as no-treatment control condition.

Strategy instruction in both training conditions was delivered in 14 lessons (7 weeks) by trained teaching assistants. Measures of reading comprehension and reading fluency were assessed at pretest, posttest (directly after training) and maintenance (8 weeks after the end of the treatment) with standardized German reading comprehension and fluency tests (Auer, Gruber, Mayringer & Wimmer, 2005; Souvignier, Trenk-Hinterberger, Adam-Schwebe & Gold,

2008). Self-efficacy was assessed with six items following the model of Wigfield's and Guthrie's (1997) MRQ. The items used a four-point Likert scale and showed a satisfying reliability ($\alpha > .80$).

The data collected in this study was analyzed with a nested analysis of covariance approach. Using classroom as the unit of analysis, we conducted a fully specified mixed-model ANCOVA with student nested within classroom and with classroom nested within treatment condition. When no classroom-within-treatment effects were found, classrooms within a treatment were combined and the individual student became the unit of analysis, thereby providing greater statistical power for the detection of treatment effects.

Results

Regarding all measures no classroom-within-treatment effects were found at posttest and maintenance ($p > .25$). Therefore we analyzed our data on the student level.

An analyses of covariance with condition as between-subject factor and pretest scores as covariate showed a significant main effect for condition at posttest, $F(2, 300) = 4.090$, $p = .03$, and maintenance, $F(2, 299) = 4.198$, p

Students reading fluency scores did not differ at posttest, $F(2, 288) = 1.828$. At maintenance there was a significant main effect for the between-subject factor condition, $F(2, 288) = 15.673$, p

Self-efficacy measures at posttest failed showing a significant main effect for training condition, $F(2, 268) = 2.704$, $p = .06$, but post-hoc tests revealed a significant difference between RT+SRL and the no-treatment control condition.

At maintenance a significant main effect for condition was found, $F(2, 285) = 4.833$, p

Educational significance of this research

The results of our study indicate that traditional RT and RT+SRL can be effectively implemented in regular classrooms. Furthermore we were able to show a significant gain of reading comprehension for students in the RT+SRL condition. These students benefited most from the intervention, while RT students showed no or only small improvements in contrast to a no-treatment control condition. These results lead to the conclusion that including self-regulation procedures in the training leads to higher self efficacy and more fluent reading in the medium term and better reading comprehension in the short and medium term.

Future research is needed to preserve the best possible results directly after the training. To gather more information on possible improvements in the training itself we could reanalyze the data and investigate possible mediators like self-efficacy that could determine the success of the RT+SRL condition.

PAPER PRESENTATION

Parental engagement and home support on betterment of adolescents' reading literacy in Macao

Kwok Cheung CHEUNG, University of Macau, Macau; Pou Seong SIT, University of Macau, Macau; Soi Kei MAK, University of Macau, Macau

Macao, special administrative of China, participated in PISA 2009 reading literacy study. Through the use of the parents' responses in the parent questionnaire and the 15-year-old students' responses to the test booklets, the present study sought to examine the effects of parental engagement and home support variables on reading literacy performance. Through the use of structural equation modeling (SEM) and hierarchical linear modeling (HLM) to analyze the interrelationships amongst parents' engagement and support of child's reading literacy variables, provision of home reading resources for child's use, and reading literacy performance, it was found that the direct/independent effects of the parents' engagement and support of child's reading literacy variables on reading literacy performance was negligible, and their joint indirect effect was weak but practically substantial, essentially mediated by provision of home reading resources for child's use. This finding has taken into account the effects of economic, social and cultural status of the home and gender of student. In the light of these findings, recommendations are put forward for Macao parents and schools to develop better home literacy environments for the betterment of adolescents' reading literacy in Macao.

Reading literacy is a fundamental competence cherished worldwide and nourished early in childhood (Anderson, Hiebert, Scott, & Wilkinson, 1985). Unless resources and environments are available from the earliest stage, a child is unlikely to read well or love to read (Gates, 2002). Because reading acquisition is not a natural process, without appropriate parental guidance and support, our literate society will have youngsters and adults who are illiterate (Lyon, 1998). Research shows that certain kinds of parental engagement and home activities do make a difference to

young children's reading literacy development (Finn, 1998). However, some parents' engagement and home reading activities are more effective than others, suggesting that family literacy is needed for family members working together to promote mutual literacy development (Smith, 1991). Teachers and parents can partner to create conducive environments to support children's reading acquisition at home and in the classroom (Finn, 1998; Marion, 2000; Darling, 2005).

Throughout childhood, there are changing roles for parents in motivating their children to learn to read, and after that to read to learn (Klauda, 2009). For the unmotivated or uneducated parents, promoting their adolescent children's reading motivation and activities is a daunting formidable task and this is especially the case when dealing with struggling readers (Baker, 2003). In addition, unmotivated/ uneducated parents are less likely to create developmentally appropriate environments for their adolescent children to read to learn. The present study examines the effects of parental engagement and home support, as well as provision of home reading resources, on the enhancement of reading literacy for 15-year-old students in Macao.

In 2009, around six thousand 15-year-old students (3036 males and 2960 females) from a total of 45 secondary schools were sampled for the PISA 2009 reading literacy study. The two-stage sampling, involving all Macao schools in the first stage, followed by all eligible students in the second stage necessitates data analyses to take into consideration the nested structure of the sample design. In the parent questionnaire there were questions pertaining to parental engagement and support in home and reading activities, namely: (1) parents' reading activities when their child attended the first year of primary school (e.g. read books, write letters or words); (2) motivational attributes of parents' own reading engagement (e.g. reading is one of their favorite hobbies); (3) parents' current home and reading activities with children (e.g. discuss how well the child is doing at school); (4) provision of reading resources for child's use at home (e.g. Internet connection, chat online, books of the child's own).

Scaling of these responses using factor analyses and item response theory (IRT) resulted in the composition of the four conceptually and empirically clear constructs to interrelate with reading literacy performance: (1) parents' support of child's reading literacy at beginning of primary education (PRESUPP: 9 items); (2) motivational attributes of parents' own reading engagement (MOTREAD: 4 items); (3) parents' current support of child's reading literacy (CURSUPP: 6 items); (4) provision of reading resources at home for child's use (READRES: 6 items). In the present study parents' engagement and support of child's reading literacy was manifested in terms of: PRESUPP, MOTREAD and CURSUPP. Utilizing these constructs, the following three research questions may be answered:

1. What is the frequency distribution of variables pertaining to parental engagement and support in home and reading activities?
2. What is the interrelationship amongst parents' engagement and support of child's reading literacy, provision of home reading resources for child's use, and reading literacy performance?
3. To what extent the effect of parents' engagement and support of child's reading literacy on reading literacy performance is mediated by provision of home reading resources for child's use, after accounting for the effects of economic, social and cultural status of the home and gender of student?

For research question 1, frequency distribution of parents' responses to questions pertaining to their engagement and support of home and reading activities were carried out. For research question 2, Pearson correlations of the constructs delineated were calculated. Structural Equation Modeling (SEM) was applied to test the hypothesis that provision of home reading resources was a mediating variable channeling the joint effects of parents' engagement and support of child's reading literacy on the enhancement of reading literacy performance. For research question 3, Hierarchical Linear Modeling (HLM) was applied to examine the independent mediating effect of provision of home reading resources for child's use on reading literacy performance, after accounting for the effect of parents' engagement and support of child's reading literacy, economic, social and cultural status of the home and gender of student.

In Macao, upon entering primary schools, parents should have engaged with their children on emergent reading activities, and the common ones understandably are reading storybooks, and writing letters or words with the children together. The first finding of the present study is that this kind of early parental engagement has not been associated to any appreciable degree with enhanced reading literacy performance some ten years later when children reached aged 15.

The second finding is that although research in other parts of the world often shows that when children grow older parents' motivated, and continued support is of utmost importance for children's reading literacy development. Regrettably, in Macao, for those parents with positive motivational attributes, the direct independent effect of their

support on their children's reading literacy development is not statistically significant, and in fact is practically negligible.

The third finding is that although the effect of parents' current support for students' reading literacy development may not be as productive as it should be, the role of home reading resource provision which mediates the effects of parental engagement and home support in the enhancement of students' reading literacy performance is not only statistically significant but also practically substantial in magnitude of influence.

With these findings, the authors propose a number of recommendations to revitalize parental engagement and home support for the betterment of adolescents' reading literacy in Macao. Successful experiences of other educational systems, such as Korea, Hong Kong and New Zealand are consulted (Pressley, Billman & Perry, 2007).

PAPER PRESENTATION

Teachers' knowledge of reading

Henk Van den Hurk, Utrecht University of Applied Sciences, Netherlands; Wim Van de Grift, Groningen University, Netherlands; Thonia Houtveen, University of Applied Sciences, Netherlands

Teachers' professional knowledge of reading is of major importance in designing the effective reading instruction needed to improve student learning. In contrast to other content areas such as mathematics and science, surprisingly little is known about what teachers need to know about reading in order to teach it. At present, research has yielded only a few tests of teachers' knowledge of reading with adequate psychometric characteristics. In the Netherlands there are no such tests at all. In this paper we present a questionnaire for measuring teacher knowledge of reading building on Lee Shulmans concept of pedagogical content knowledge.

Background:

In our ideas on test development for measuring teachers' professional knowledge we highly build upon Lee Shulman's concept of Pedagogical Content Knowledge (1986, 1987). In the last decades this PCK-concept was extended and further developed by several other scholars (e.g. Grossman, 1990; Thames & Phelps, 2008; Sherin, 1996; Van Driel, 2008). In contrast to the quantity of research on teachers' Pedagogical Content Knowledge in for instance science (for a review see: Abell, 2007) and mathematics (see further: Baumert et. al. 2010), strikingly less research has been done in the field of reading (Lyon & Weiser, 2009). At present, research has yielded only a few tests of teacher knowledge on reading with adequate psychometric characteristics. In the Netherlands there are no such tests at all. Therefore we had to start out with the construction of a test for measuring teachers' professional knowledge on teaching reading.

Aims:

Our study focuses on the relationships between 'teachers' professional knowledge on teaching reading', 'the quality of reading instruction these teachers are supplying' and 'student outcomes on reading'. In our presentation we would like to elaborate on the first part of our study in which we developed a test for measuring teachers' professional knowledge on teaching reading.

Method:

We started the process of test development with writing an item pool on three major domains: 'phonemic awareness', 'phonics' and 'reading fluency'. These domains were selected because they represent a range of important content in the elementary reading curriculum.

Content Validity

In order to check the content validity of the test, we presented these items to a panel of 30 reading experts. We wanted to find out whether these experts agreed on the importance to include these items in a test about teacher's knowledge of reading. The expert consultation resulted in a test of 45 items, 15 items on each topic area.

In spring 2010 the test was presented to a group of 217 teachers. In the psychometric analyses we sought to answer the question whether it is possible to develop a reliable measure of teacher knowledge on the afore mentioned domains.

Reliability: Classical test theory

First of all we studied the reliability of the test in terms of classical test theory. After removal of four test items the coefficient KR-20 on the whole test was .71. The four items removed were equally divided over the three domains. One removed item originated from the domain of 'phonemic awareness', another item originated from the domain of 'phonics' and two items were removed from the domain of 'reading fluency'.

Reliability: Item-response theory

Item-response theory puts more stringent demands on reliability. For fulfilling the demands of the dichotomous Rasch model all items should have parallel item characteristic curves and the whole set of test items should be unidimensional.

We tested the parallelity of the item characteristic curves of the original 45 items with the Anderson test in which the item parameters of a high-scoring and a low-scoring group were compared. After removal of 7 items the chi square satisfied the demands ($\chi^2 = 36.77$; $df = 37$; $p = .480$). Three of the removed items were the same as the items that had to be removed to fulfill the demands of classical test theory and four other items did not have parallel item characteristic curves. One removed item originated from the domain of 'phonemic awareness', four removed items originated from the domain of 'phonics' and two items were removed from the domain of 'reading fluency'.

By using the Anderson test on the 38 remaining items we tested whether the unidimensionality of the scale was violated by gender, age, years of experience in teaching, grade, and level of education. The results were fully satisfying on gender, age and years of experience (male and female teachers ($\chi^2 = 38.71$; $df = 37$; $p = .392$); younger (age 40) teachers ($\chi^2 = 29.29$; $df = 37$; $p = .813$); less (10 years) experienced teachers ($\chi^2 = 30.57$; $df = 37$; $p = .763$)). From these results we concluded that the unidimensionality of the scale was not violated by gender, age and years of experience of teachers.

The results on grade, and on level of education were satisfying in a more moderate degree (teachers working in kindergarten and grade 1 and teachers working in grade 2 to 5 ($\chi^2 = 70.70$; $df = 37$; $p = .001$); teachers and teacher-assistants ($\chi^2 = 69.86$; $df = 37$; $p = .001$). More research is needed to explore why the unidimensionality test had such humble results on grade. The knowledge base for teaching lower grades might be different from the knowledge base needed for teaching higher grades. If so, it probably is more suitable to work with another knowledge test about reading for teachers working in grades 2 to 5. The same line of reasoning (differences in knowledge about reading) might be valid for the small unidimensionality problems found comparing teachers with teacher-assistants.

Results:

The mean score on the questionnaire was 1.47 ($sd = .80$) on a scale ranging from -5 to +5, indicating an acceptable knowledge level of the participating teachers. On the basis of these findings we are able to differentiate less-knowledgeable from more-knowledgeable teachers.

Educational and theoretical significance:

Theorists assume that teachers' professional knowledge of reading is of major importance in designing the effective reading instruction needed to improve student learning. In this study we hypothesize that students of more knowledgeable teachers will make greater reading progress. In order to study this relationship we first constructed a test about teachers' professional knowledge of reading. Next in our research we will combine these outcomes with the results of teacher observations and teacher questionnaires on the quality of delivered instructions. In the last stage of our research we will compare outcomes of these analyses with students reading achievement.

PAPER PRESENTATION

Does reading development over summer vacation depend on family background and reading motivation?

Ellen Schaffner, University of Potsdam, Germany; Ulrich Schiefele, University of Potsdam, Germany; Anne Kruger, University of Potsdam, Germany

Past research has demonstrated effects of family background and reading motivation on reading achievement. We expect these effects to be especially pronounced during summer vacation, when school cannot compensate for less stimulating out-of-school environments (cf. Alexander, Entwistle, & Olson, 2001). Thus, the major objective of the present study was to investigate the effects of family background and reading motivation on reading development over six weeks of summer vacation. Participants were 235 third-grade students whose reading achievement (word, sentence, and text comprehension) was assessed shortly before and after summer vacation. Before summer vacation, reading motivation, reading frequency, and family background (cultural communication, cultural activities) were also assessed. Partial correlations (controlling for gender) revealed that intrinsic reading motivation, reading frequency, and family background were significantly associated with reading achievement, and that these correlations were higher after summer vacation than before. Structural equation analyses with latent variables will be applied to investigate, if the development of reading achievement over summer vacation depends on students' and family background reading engagement. These analyses are still in progress.

There is ample evidence that family background and reading motivation both play influential roles in the development of reading achievement. For example, it has been shown that socioeconomic status and cultural resources of a family

are significantly related to children's reading skills (van Steensel, 2006). Research on reading motivation suggests that intrinsic and extrinsic components have to be distinguished. Intrinsic reading motivation aims at the fulfillment of interests or feelings of enjoyment while reading. Extrinsic reading motivation, in contrast, has been characterized by the purpose to obtain positive consequences of the reading activity (e.g., better grades or social recognition). In prior studies, intrinsic reading motivation proved to be positively related with children's reading frequency and reading achievement, whereas extrinsic reading motivation seemed to be less conducive to foster reading development (cf. Wang & Guthrie, 2004).

Both family background and intrinsic reading motivation presumably affect reading skills mainly during out-of-school time (e.g., in summer vacation; cf. Alexander, Entwistle, & Olson, 2001). As a consequence, students with highly supportive families and high intrinsic reading motivation should exhibit a more favourable reading development over summer vacation than students of less supportive families or with lower intrinsic reading motivation. The present study intends to investigate these assumptions. Participants were 235 third-grade students who were tested twice, before and after summer vacation. On the average, they were nine years old ($SD = .58$). Approximately the same number of boys and girls participated in the study.

Shortly before summer vacation, the students were given a questionnaire regarding their intrinsic reading motivation (e.g., "I read, because reading helps me to learn more about my interests"; $\alpha = .77$, $n = 217$), extrinsic reading motivation (e.g., "I read, because I want to be a better reader than my classmates"; $\alpha = .75$, $n = 211$), reading frequency (e.g., "How many books did you read during the last twelve months?"; $\alpha = .71$, $n = 224$), cultural communication in the family (e.g., "Did your parents ever talk to you about books and authors?"; $\alpha = .66$, $n = 223$), and cultural activities in the family (e.g., "Did you ever go to a museum or exhibition with your parents?"; $\alpha = .61$, $n = 222$). In addition, students were administered a standardized reading test (ELFE 1-6; cf. Lenhard & Schneider, 2006) on word comprehension ($\alpha = .92$, $n = 227$), sentence comprehension ($\alpha = .84$, $n = 229$), and text comprehension ($\alpha = .75$, $n = 229$). After six weeks of summer vacation, we assessed students' word comprehension, sentence comprehension, and text comprehension again by means of parallel test forms. EM-estimates of missing values were computed by NORM 2.03 (Schafer, 1999). The percentage of missing data per variable did not exceed 10%. Six students with missing data on gender had to be excluded, because EM-estimates should not be computed for binary variables.

Mean comparisons for paired samples were conducted to test the difference between reading achievement measured before and after summer vacation. Because three separate analyses were performed (for word, sentence, and text comprehension), we reduced the level of significance to $\alpha = .017$ (Bonferroni adjustment). Results revealed that students' word and text comprehension on the average did not change across summer vacation. However, text comprehension improved significantly (before vacation: $M = 4.9$, $SD = 2.2$; after vacation: $M = 5.9$, $SD = 2.5$; $t [227 \text{ df}] = -8.7$, p

To investigate the relations between our predictor variables (family background, reading motivation/reading frequency) and reading achievement, partial correlations were computed (controlling for gender). Results revealed that, with the exception of extrinsic reading motivation, all predictor variables were significantly associated with at least one measure of reading achievement (see Table 1). The highest partial correlations were observed between sentence comprehension (after vacation) and intrinsic reading motivation ($r = .40$, $df = 225$, p after vacation) than with reading achievement before vacation. This seems to support the assumption that family background and intrinsic reading motivation exert a stronger impact during vacation than school time.

To investigate the effects of family background on reading development over summer vacation, structural equation modelling will be applied (these analyses are still in progress). Two latent variable models will be tested (see Figure 1) to investigate, if the cultural capital of a family (indicated by cultural communication and cultural activities) and a student's reading engagement (indicated by intrinsic reading motivation and reading frequency) contributes to the prediction of reading development over summer vacation.

PAPER PRESENTATION

Computer-supported writing activities for bridging the gap between learning locations in VET system

Elena Boldrini, Swiss Federal Institute for Vocational Education and Training, Switzerland; Alberto Cattaneo, Swiss Federal Institute for Vocational Education and Training, Switzerland; Elisa Motta, Swiss Federal Institute for Vocational Education and Training, Switzerland; Christoph Arn, Swiss Federal Institute for Vocational Education and Training, Switzerland; Carmela Aprea, Swiss Federal Institute for Vocational Education and Training, Germany

Do computer supported collaborative writing activities help to better connect the different learning locations in the context of the dual-track school/work based Vocational Education and Training Swiss programmes? This is the underlying question of a study conducted with commercial employee apprentices in the framework of a wider Swiss national project founded by the Federal Office for Professional Education and Technologies (OPET) and named Dual-T. More specifically the research question investigates whether giving apprentices the opportunity to collaboratively write about the professional experiences they encounter at the workplace is beneficial in fostering reflective thinking, professional identity and the linking between general procedures and real professional situations.

The Swiss VET system as an instance of the so called 'dual systems' foresees different learning locations, being established mostly on an alternation between the work-based and the school-based segments. However, apprentices do not only experience workplace situations that differ among companies, but often even perceive a gap among the different learning contexts (e.g. Eteläpelto, 2008). We assume that technologies can help to bridge this gap mainly by serving as tools to capture authentic professional situations experienced at the workplace, and consequently to exploit them at school[1]. The hypothesis is that collaborative writing on these experiences can be a useful means in this respect, as well as for encouraging confrontation, and comparison dynamics among the apprentices. More specifically, our research is focused on the design and evaluation of Computer Supported Collaborative Learning activities. Adopting a writing-to-learn perspective (e.g. Flower & Hayes, 1980) we hypothesize that describing professional experiences lived on the job and commenting the peers' ones can 1. have a direct influence on apprentices' capacity to describe and understand professional procedures, 2. foster – by inserting scaffolding questions – their reflective attitude and consequently 3. effect – through confrontation with peers' practices – their self-efficacy and particularly reinforce their professional identity. To explore these hypotheses, we conducted a study with 186 first and second year commercial employee apprentices in Ticino, Switzerland. More specifically, the study involved three intact classes as the treatment group (n=46) and other 140 apprentices as control group.

With the treatment group, we implemented three peer-tutoring and peer-commenting activities using blogs and wikis. In these activities the learning tasks were focussed on the detailed description of a procedure experienced at the workplace. Each activity was structured in three parts: 1. each apprentice developed the starting text; 2. had to comment and revise the text written by a peer; 3. refined his/her starting text, taking into account the peer's contributions. To assess the learning outcomes we considered the Process Unit (PU)[2], using a. the official overall rates of its descriptive part, and b. the quality of the texts produced by apprentices. This latter was evaluated on the reflective capacity on professional practice, using the 5Rs model (Bain et al., 2002). Additionally, we submitted a pre-post questionnaire which – among others – intended to detect apprentices' perceived self-efficacy (Bandura, 2006), reflective attitude (Kember et al., 2000) and professional identity (Heinemann & Rauner, 2008). Concerning the PU overall rates, no significant differences emerged between the two conditions. However, the experimental group has significantly higher rates in the test items concerning their capacity to link the experience described and the "general" underlined procedure they know in an abstract form (i.e. as a flowchart), both for 2nd year classes ($t(96)=2.146$; $p=.034$) and the 1st year one (Mann-Whitney U test: $z=-2.29$; $p=.022$). Concerning reflective attitude, we have an overall significant difference ($t(97)=2.17$; $p=.032$) between the control and the experimental conditions, favouring the latter ($M_{exp}=3.54$; $SD=.74$ versus $M_{contr}=3.2$; $SD=.83$). Besides, the experimental group agrees on the fact that "describing professional experiences makes one reflect" significantly more than the control group ($t(97)=2.23$; $p=.028$). Concerning self-efficacy, we found a significant pre-post decrease for the control group ($t(39)=2.17$; $p=.036$) and a stable perception for the experimental group. Focusing on self-efficacy at school, interesting differences appear comparing the pre-post difference of the 1st year experimental class and the control group ($MD(I-J)=7.16$; $SDE=3.27$; $p=.032$ for the overall subscale; $MD(I-J)=13.35$; $SDE=5.02$; $p=.010$ for specific commercial employees subjects). Concerning professional identity, the post test measure is significantly higher ($t(52)=-2.17$; $p=.035$) in the experimental condition ($M=21.96$; $SD=2.92$) than in the control group ($M=20.05$; $SD=2.73$). Furthermore, the data indicate a significant pre-post decrease for the control group ($t(39)=-2.99$; $p=.005$). Although not being completely consistent with respect to the overall PU rates, the results of the study all in all give promising hints concerning the efficacy of the presented approach. However, in order to further substantiate our conclusions, the data from the questionnaires have to be combined with the qualitative analyses of the textual productions, which are currently in progress and will be available for the Congress. Moreover, additional formative evaluations indicate that teachers and apprentices were satisfied with the proposed learning activities. Thus, we decided to re-implement them in the current school-year. This will give us not only the chance to approve the procedural measures but also to further clarify the theoretical model.

This paper deals with a project jointly conducted by the SFIVET and Geneva teams.[2] The PU is a report that each apprentice must produce every year of the apprenticeship and which includes – among other things – the detailed description of a professional procedure applied at the workplace. The PU is part of the final exam which provides the Federal VET Certificate.

PAPER PRESENTATION

Capturing Workplace Situations to be Exploited at School

Alberto Cattaneo, Swiss Federal Institute for Vocational Education and Training, Switzerland; Elisa Motta, Swiss Federal Institute for Vocational Education and Training, Switzerland; Carmela Aprea, Swiss Federal Institute for Vocational Education and Training, Germany

Learning is a contextually and socio-culturally shaped process and is conditioned by the learner's engagement and the affordances he/she finds on site (Billett, 2001). This is particularly true for Vocational Education and Training (VET), where apprentices experience multiple learning contexts and have to connect them into a whole. Using technology as means to capture professional situations lived at the workplace in order to exploit them at school as learning material - maybe hypermedially enriched by the teacher - could help in designing effective learning activities at school. On this subject, a preliminary study conducted with three classes of car mechanics apprentices in Switzerland is presented here to exemplify this assumption. Measures include apprentices' learning outcomes (in terms of declarative knowledge) and both apprentices' and (school) teachers' perceived ease of use and usefulness of the captured materials. Preliminary results indicate very positive tendencies, even if more sophisticated designs have to be tested.

In Switzerland, roughly two-thirds (65%) of the young people coming out of lower-secondary school enrol in an upper secondary level vocational education and training (VET) programme. These VET programmes are mostly based on a "dual" system which alternates the work-based and the school-based segments. A third training segment – known as "intercompany courses" or "industry courses" – is also added to complete the model. Concretely, this means that apprentices spend between 3 to 4 days – depending on the profession – in a company and the rest of the week at school. This structural characteristic can be a very interesting opportunity, but at the same time a source of problems: by splitting opportunities for learning over at least two main locations (i.e. workplace and school) the dual-track VET system imposes an important condition to promote learning, namely that of being able to aggregate information and experiences gathered in two different contexts into a coherent body of knowledge.

Since this aggregation task is neither obvious nor self-making, we need to foster it through a specific learning environment design, able to exploit the effects that the context has on the learners' motivation (Volet & Järvelä, 2001). The study presented here starts from the assumption that mobile technologies can constitute an effective means on which to design learning activities able to properly connect the two mentioned contexts. Considering that 1. apprentices are generally more motivated to learn in the context of the company than at school, and 2. that the workplace-segment influences learning but is in turn conditioned by the apprentices' personal engagement and the affordances that it offers him/her (Billett, 2001), we suppose that the design of the learning activities should be based on the exploitation of what apprentices experience at the workplace. In this respect, technologies can be used to capture real professional situation to be used at school. Given these premises, the underlying research questions can be summarized as follows: a) Are mobile technologies a feasible means to capture professional situation at the workplace? b) Do apprentices and teachers accept these technologies? c) Which effects can the "captured materials"

have on learning? The present study[1] involves three intact vocational school classes (n=60) of car mechanics apprentices from Ticino, Switzerland. The apprentices from one of these classes were allowed by their supervisors to wear a headband camera while working, so that they could video-record significant situations experienced at the workplace. The material collected was then handed over to the teachers, who selected interesting pieces of the videos and edited them in three- to five-minutes-long clips. Five videos have been developed and subsequently used in four different sessions, in three different ways, corresponding to three different treatment groups: in one class (EXP-RAW), the teacher just showed the raw videos at the end of the lesson. In a second class (EXP-PLUS) videos were hypermedially enriched with additional learning materials, considering principles coming from the Cognitive Theory of Multimedia Learning (Mayer, 2005), and have been used during the lesson. Apprentices of this class also had at their disposal the enriched videos on a moodle platform to prepare themselves to the learning tests. A third class (CON) was involved as a control group. After each of the four mentioned sessions, a learning test was submitted. Additionally, at the end of the school year, a final learning test on all the contents was submitted to assess the mid-term effects on retention.

In parallel, we submitted two questionnaires, based on technology acceptance models (e.g. Venkatesh et al., 2003), to measure apprentices' and teachers' perceived usefulness of the materials produced, as well as their quality and richness. Preliminary results show that the EXP-PLUS group got significantly higher learning outcomes than the CON group and the EXP-RAW group in four of the five post tests: Session-1, $F(2;53)=26.00$ $p < .05$, Session-4, $F(2;47)=7.20$, $p < .05$. The EXP-PLUS class perceived a higher – even if not significant – degree of usefulness of this kind of learning material for the school ($M=5.74$ - on a 7-points Likert scale - $SD=1.33$; $p > .05$) than the control group ($M=5.37$; $SD=1.36$). The EXP-RAW class, when showed the enriched one, perceived – as imagined, not as really experienced – a higher potential usefulness of the tool both for the school and the "garage life" ($M(\text{EXP-RAW})=6.39$ $SD=0.69$) than the other classes ($F(2;50)=5.36$; $p < .05$).

Concerning the quality and richness of the materials produced, mechanics' teachers (n=15) were positive, both for the technical quality ($M=4.33$, $DS=1.59$) and above all for the potential to be used at school ($M=5.7$, $DS=0.68$). The teachers gave significantly higher ratings for the didactical potential (Mann-Whitney Test $p=.01$) of enriched videos compared to the raw ones. Teachers recognize the potential of the "captured materials", especially if they are enriched with additional information. Even more interestingly, it seems that the use of this approach has positive effects on declarative knowledge acquisition. The present study was an attempt to go beyond the consideration of the motivational effects on learning and to integrate the cognitive and practical sides of learning. The solution presented here seems to be promising, but surely needs additional deepening and refinements: for example, 1. the "teacher" effect should be better controlled in a new study. 2. Cognitive Load measures should be included; 3. a special focus on the integration of the learning activities in larger learning units and in the curriculum is needed.

PAPER PRESENTATION

Technology and Gender Equity Among Secondary School Students in Ghana

Kwaku Frederick Sarfo, University of Education, Winneba, Ghana

This study explored the attitudes of male and female students in Ghana towards ICT. The results show that students' attitudes towards technology do not differ in terms of gender. Furthermore, the results indicate that the locality (rural or urban areas) of the male and female students does not influence their attitudes towards technology. However, according to the results female students from urban areas have more positive attitudes towards technology than female students from rural areas.

Technological literacy and integration of information and communication technology (ICT) in education have received a great attention worldwide. This is because ability to use ICT to achieve one's means, is critical to economic, social, cultural, and educational life. Harvey (1983) envisages that the effectiveness of the use of computers in education may

be an important factor in determining which countries will succeed in the future. Following this idea, many governments have carried out policies involving investment in education, investment in infrastructure, creation of favourable institutions, and fostering new institutional innovations to promote ICT literacy programmes and integration of ICT in education (Quibria et al, 2003).

In Ghana many educational practitioners, policy-makers including the government, and other agencies accept that computer technology is the bedrock of quality socio-economic activities and quality education, particularly quality teaching and learning (President's Committee on Review of Education in Ghana, 2002; ICT4AD, 2003; World Bank, 2007). In this regard, a significant portion of the country's budget is invested in the planning and implementation of ICT policies for quality education and socio-economic development of the nation. In 2004, the Parliament passed into law Ghana's ICT for Accelerated Development (ICT4AD) policy. The policy indicates the vision of Ghana in relation to ICT in the knowledge and technological age. It addresses the exploitation and deployment of ICT to promote the economy – financial system, agriculture, civic, culture, import, export, democracy, legal, education, and others – of Ghana. This policy is at various stages of implementation. For instance, in 2009, ICT courses were introduced in all basic and second cycle schools in rural and urban areas of Ghana. This initiative by the government, as stipulated in ICT4AD policy, is to ensure that students have ICT skills before coming out of each level of education.

Even though ICT awareness and competencies are increasingly important, there are some barriers that can handicap the success of ICT literacy programmes and the integration of ICT in education for the nations' development (Cunningham 2007). Among other factors, researchers (e.g., Shade, 2002) often describe women's attitudes towards technology as problematic. Research findings from science, technology, engineering and math (STEM) provide theoretical grounding for the study of gender and ICT. In other words, research findings from STEM perspective identified emotional, cultural, and structural barriers which girls and women face in achieving technological equity. Studies on women's attitudes towards technologies in developed countries indicate that women's negative experiences with technologies have several consequences including limited participation in the information economy as well as limited participation in courses related to technology (Cunningham, 2007). In Ghana, generally, both national and education policies pay attention to gender balance. However, specifically, from the perspective of planning and implementation of ICT policies (ICT literacy programmes as well as integration of ICT in education) in Ghana, little or no attention has been paid to research on gender differences with technologies. This state of affair is in line with the assertion of Benzie (1995), confirmed by Albrini (2006) that in developing countries, national programmes have not been so successful to implement ICT into educational systems because they were not supported with educational research.

The present study is aimed at investigating the attitudes of male and female students (from rural and urban areas in Ghana) towards 1) ICT policy (ICT4AD) in Ghana, 2) learning to acquire ICT skills, and 3) using ICT to facilitate teaching and learning. Furthermore, the study is intended to explore the effect of the locality (rural and urban areas) of the male and female students on their attitudes towards technologies. An evidence-based understanding of girls and boys (in the rural and urban areas in Ghana) attitudes towards technology will help contribute to decisions of successful planning and implementation of gender equity ICT literacy programmes and gender equity policies for integrating ICT into education. In addition, effective and efficient management and administration of ICT; investment in infrastructural support; and in-service training of teachers will also benefit from evidence of girls and boys (from rural and urban areas in Ghana) attitudes towards technology

To answer the research questions, 307 participants comprising 157 males (60 from rural areas and 97 from urban areas) and 150 females (70 from rural areas and 80 from urban areas) were randomly selected from 3 rural and 3 urban senior high schools in Ghana. Their average age is 18.3 with SD of 1.4. Three kinds of five points Likert-type scale questionnaire, ranging from strongly agree to strongly disagree, were constructed to measure the participants' attitudes towards: ICT4AD policy in Ghana, 2) learning to acquire ICT skills and) using ICT to promote teaching and learning; Cronbach alphas were .77, .72, and .70 respectively. The questionnaire was administered to the students in their normal classrooms. The participants were instructed to do independent work and they were supervised by the researchers. They were allowed to use 25 minutes to answer the questions.

Univariate analysis and t test were employed to analyse the data. The results of the analyses indicate that secondary school students' attitudes towards: 1) ICT4AD policy in Ghana, 2) learning to acquire ICT skills, and 3) using ICT to facilitate teaching and learning do not differ in terms of gender. Furthermore, the results indicate that the locality (rural or urban areas) of the male and female students does not influence their attitudes towards technology. However, according to the results the female students from urban areas have more positive attitudes towards technology than female students from rural areas. Interestingly, there is no significant difference between the attitudes of males from rural areas and the attitudes of males from urban areas towards technology. The outcome of

the study can be used in the designing and implementation of gender sensitive ICT policies and gender sensitive innovative educational programmes in the rural and urban areas in Ghana.

PAPER PRESENTATION

Equity and access issues in the educational use of learning management systems (LMS) in a globally networked society

Ramon Garrote Jurado, University of Borås, Sweden; Michael Christie, Stockholm University, Sweden

In this paper the authors present research findings from a comparative case study involving the pedagogical use of learning management systems (LMS) at the university level. Two engineering programs are compared, one based at the University College, Borås, Sweden (hereafter UB) and the other at the Instituto Superior Politécnico Joséé Antonio Echeverría, Havana, Cuba (hereafter ISPJAE). At UB twenty two engineering lecturers were surveyed concerning their use of LMS. At ISPJAE fifteen lecturers were given a course on LMS, provided with tools to use it, and subsequently interviewed about the extent to which they had employed it in their courses. The aim of the case study was threefold. Firstly to compare the lecturers' knowledge and understanding of the pedagogical advantages of using LMS in face-to-face, blended and online learning. Secondly to determine the extent to which an LMS was used and evaluate the pedagogical value of such use. Thirdly to investigate the administrative, technological and pedagogical barriers involved in using an LMS.

As the title of the paper suggests the purpose in comparing such disparate groups was to investigate if there were differences in terms of equity and access issues in the use of LMS in higher education. Another aim was to use the case study to better understand some of the assumptions underlying the concept 'education for a globally networked society'.

The paper used case study as its research method and data was gathered by means of surveys, interviews and the analysis of course evaluations. The method was embedded in an action research process. Results from an earlier cycle of the research process have been used to inform and help the participants in their use of LMS. The extent to which this has resulted in a more efficacious use of LMS is still being monitored and the project is now engaged in a third cycle of research. The theoretical basis for the research is Habermas' communicative action theory (Habermas, 1989). This paper makes a theoretical and educational contribution by using the empirical case to illustrate differences in access to an uncensored Internet and the barriers that lecturers from different political, social and economic systems encounter when seeking to use LMS as a pedagogical tool in Higher Education.

The results from the case study indicate that because lecturers at UB were regular users of the Internet they had a more sophisticated knowledge and understanding of the pedagogical potential of LMS. In Cuba lecturers have to ask permission and book time to use the Internet. For economical reasons only 50% of the Cuban participants had a computer at home and none of them had internet access. During brainstorming sessions however it was clear that many of these lecturers had innovative ideas about the use of LMS. Our second aim concerned the use of LMS at both sites. LMS was available to both sets of teachers. The teachers at UB used the 'content' tools available in the LMS in 60% of their courses. They employed the system to create a course structure, publish document files, link to pages on the internet and allow students to download information. Only 21% of their courses made regular use of tools that allowed students to submit assignments online and receive feedback about their results. The use of communicative tools such as chat, asynchronous discussions, email within the system, announcements and calendar varied from 13% to 20% in the courses. At ISPJAE the LMS freeware Moodle was available on the faculty's server for intranet use but none of the teachers had used it prior to March 2010. In that month the first author gave a course on the pedagogical use of LMS and in June 2010 conducted a follow up meeting with the participants. Eight presented their progress and detailed ways in which they used both content and communicative tools Seven could not be present at the presentations but were surveyed later and indicated that they mainly used the content tools available in the LMS. Participants from both UB and ISPJAE perceived that the LMS provided the means to better organise their courses and enable students to obtain course material. Downloading material was much easier for Swedish than Cuban students because the latter have to queue to gain computer access. The teachers were uncertain about the overall pedagogical value of LMS use and this needs further research. In terms of the administrative, technological and pedagogical barriers to LMS use the case study clearly reveals differences between UB and ISPJAE participants. Lack of time was the most common barrier at UB whereas lack of computer hardware, software and bandwidth were restraining factors in Cuba. At UB the lack of time also meant that lecturers were not so willing to change their pedagogical practice unless they could be convinced that using an LMS was both pedagogical and time efficient.

The theoretical and educational significance of this paper is that it provides an actual case that illustrates access and equity issues in education for a globally networked society. Just under 500 million users come from countries that

control Internet content for ideological reasons. In the case of Cuba access itself is controlled. Can we talk about a global network when 1.5 billion people have no electricity (Gronewold, 2009), no digital infrastructure and no public or personal resources to buy computers, mobile devices and bandwidth? Can we talk about a networked society when its 2 billion users come from different countries with very different social, cultural, political and economic systems?

PAPER PRESENTATION

The Relationships Among Personality Traits and Video Game Preferences in Undergraduate Learners

John Quick, Arizona State University, United States; Robert Atkinson, Arizona State University, United States; Wilhelmina Savenye, Arizona State University, United States; Lijia Lin, Arizona State University, United States

Very little research has been conducted on how personality impacts learner perception and use of video games. This study aims to identify the relationships among undergraduate learners' personality traits and their video game preferences. As of this writing, 164 undergraduate students have completed an online survey representing these aspects. A preliminary factor analysis has identified six categories that explain how and why players engage in gaming activities. A preliminary cluster analysis has identified three major categories of learners based on their game preferences and personality traits: avid gamers, casual gamers, and non-gamers. EARLI attendees will be introduced to the relationships between personality traits and gaming, which are believed to have meaningful implications for the design, use, and research of game-based educational technologies.

Introduction

Personality is instrumental in the way that a person perceives of and interacts with the world. Therefore, it follows that personality should affect how learners understand and interface with educational technologies. In spite of this, very little research has been conducted on how personality impacts learner perception of video games.

Related work has been done, but the primary foci have often been on classifying gamers according to their motivations (King, Delfabbro, & Griffiths, 2010, Westwood & Griffiths, in press), examining specific non-student gamer populations (Griffiths, Davies, & Chappell, 2004, Choi & Kim, 2004), and the perceived negative aspects of gaming (Wood, 2008, Anderson & Bushman, 2001, Griffiths & Hunt, 1998).

This study aims to identify the relationships among undergraduate learners' personality traits and their video game preferences. Learners' responses to an online questionnaire are addressing the following research questions.

1. How do undergraduate learners' personality traits relate to their video game preferences?
2. What categories of learners emerge based on the combination of personality traits and video game preferences?

Methods

Participants

As of this writing, 164 undergraduate students from a large southwestern U.S. university have participated. All are enrolled in an undergraduate computer literacy course. The majority are juniors (40%), followed by sophomores (25%), seniors (23%), and freshman (12%). By gender, 64% are female and 36% are male. In age, they range from 18 to 57 years (mean = 26.6, sd = 8.2), with 84% of the sample being between 18 and 30.

Procedures

Participants voluntarily chose to complete an online questionnaire in partial fulfillment of their course's research participation requirement. The questionnaire was made available to students between September and December 2010.

Instrument

The Video Game Preferences section of the survey instrument asked participants to rate how important 37 characteristics were to their enjoyment of a video game on a scale from one (Not at all important) to five (A must-

have feature). The 37 game features were primarily derived from a previous study on the structural characteristics of video games (Wood, Griffiths, Chappell, & Davies, 2004) and each represents a manipulable design attribute.

The Personality section of the survey instrument asked respondents to indicate how accurately a series of 60 statements described them on a scale from one (Very inaccurate) to five (Very accurate). Goldberg's (1999) and Johnson's (2001) public domain representations of the NEO PI-R (Costa & McCrae, 1992) were used as starting points. These have shown comparable reliability and validity to the NEO PI-R, which is widely regarded as the best commercial instrument for measuring the constructs of the Five Factor Model of personality (Johnson, 2005, Johnson, 2001, Johnson, 2000, McCrae & John, 1992). For practical considerations, the 60 items that were anticipated to be most relevant to learners' video game preferences were included.

Data Analysis

Preliminary factor and cluster analyses have been conducted on the initial 164 responses. Approximately 200-300 total responses are anticipated. All final analyses will be completed well in advance of the EARLI 2011 conference.

Preliminary Findings

An exploratory factor analysis was conducted to examine the video game preferences of the initial 164 learners. A principle axis analysis using Direct Oblimin rotation produced a six-factor structure that accounted for 40% of the total variance, with communalities ranging from .29 to .66. Descriptions of the resulting factors follow.

1. Role-player: player enjoys characteristics of MMORPG games, such as taking on alternative identities, never-ending gameplay, and a fantasy setting.
2. Mobile gamer: player does not enjoy games with audio, realistic/3D graphics, and real-world settings.
3. Challenge-seeker: Player pursues challenges, such as problem-solving, overcoming obstacles, and finding hidden things.
4. Social gamer: player engages in gaming to meet new people, play with others online, and publicly display his/her skills.
5. Solo gamer: player prefers single-player games and does not wish to play with friends.
6. Casual kinesthetic gamer: player enjoys characteristics of casual Wii games, such as using physical actions to control gameplay, acting within limited amounts of time, and completing a game in a single session.

Next, a hierarchical cluster analysis using euclidean distance and Ward's linkage method was conducted. Three major categories of learners emerged, each having its own specific gaming preferences and personality traits. Descriptions of these groups follow.

1. Avid gamers show relatively high interest across the six gaming preference factors and are especially characterized as social, challenge-seeking, role-players. In terms of personality, they tend towards anger and excitement-seeking, while scoring relatively lower on the dimensions of morality and cooperation.
2. Casual gamers have a relatively intense preference towards solo and mobile play, but also share in the challenge-seeking of avid gamers. Their personality profile depicts relatively low levels of gregariousness, excitement-seeking, and assertiveness, while showing relatively high levels of self-consciousness, imagination, and cooperation.
3. Non-gamers are inclined to prefer mobile and solo play, however they do not share in the challenge-seeking of avid and casual gamers, nor do they show interest in other gaming factors. These individuals tend to have relatively lower levels of imagination and higher levels of self-discipline, achievement-striving, and gregariousness.

From these analyses, compelling preliminary evidence for the categorization of learners according to their gaming preferences and personality traits has been found. Further, underrepresented gamer types have been identified, as have items with greater and lesser ability to distinguish between learners. Therefore, the analyses have also informed the revision and refinement of the survey instrument.

Significance

As potentially influential variables in learning technology research and practice, EARLI members will become aware of the importance of considering learners' personality traits and preferences in their future designs. These factors are believed to significantly impact how learners perceive of and interact with educational technologies. Ultimately, this line of research is expected to result in an instrument that identifies learners based on their personality traits and perceptions of video games.

PAPER PRESENTATION

Digital Games in Pedagogical Contexts; Critics, Criteria and Quality

Vigdis Vangsnes, Stord/Haugesund University College, Norway

The aim of the research project "Digital Games in Pedagogical Contexts; Critics, Criteria and Quality" is to investigate digital games, an artifact primarily used in children's out of school life, as a didactic tool used in educational contexts, to gain knowledge about digital games for didactic purposes and to develop an analytical framework for discussing criteria and quality in digital games. A new media requires didactic reflections upon function, purpose and intention when it is used educationally. This will include a discussion about possible dichotomies between the didactics found in the object itself (the game) and the ideal general didactics as found in Norwegian hegemonic educational literature. What didactical implications will be problematized when the teacher want to orchestrate the game content as part of either learning or play activities in schools and kindergartens? The main research question is: How can we, by the help from dramaturgic theories, analyse, interpret and understand the games, and the gaming situation, as a media featured by its historical, sociological and cultural context; what will be the requirements for the analytical tools discussing criteria and quality? Didactics, supported by this artifact, is both methodologically and theoretically a research topic of both scholarly and public interest.

Relevance to EARLI domain and conceptual rationale: My field of research interest is about how the technology of mass communication is changing educational practices and creating new possibilities and new challenges when they are implemented in didactic settings. The media I have chosen to do my research on is computer games and the pedagogical use of these games. This topic has become more pressing recently as a result of the new Norwegian policy documents, General Plan for Kindergarten (MOK, 2006), The White Paper 17, An Information Society for all (MOC, 2006-2007), The White paper 41, Quality in Kindergarten (MOK, 2008-2009), and the White Paper 14, Computer games (MOC, 2007-2008). These policy documents indicates a stronger focus towards children's use of technology from early ages and demands both schools and kindergartens to consider digital tools and computer games as a natural part of the daily routines and the local curriculum.

The aim of the research project "Digital Games in Pedagogical Contexts; Critics, Criteria and Quality" is to investigate digital games, an artifact primarily used in children's out of school life, as a didactic tool used in educational contexts, in order to gain knowledge about digital games for didactic purposes and to develop an analytical framework for discussing criteria and quality in digital games. A new media requires didactic reflections upon who, what, why, how, when and where this new media is taken into pedagogical settings. This will include a discussion about possible dichotomies between the didactics found in the object itself (the game) and the ideal general didactics as found in Norwegian hegemonic educational literature. What didactical implications will be problematized when the teacher want to orchestrate the game content as part of either learning or play activities in schools and kindergartens? The main research question is: How can we, by the help from dramaturgic theories, analyse, interpret and understand pedagogical digital games, and the gaming situation, as a media featured by its historical, sociological and cultural context; what will be the requirements for the analytical tools discussing criteria and quality? Didactics, supported by this artifact, is both methodologically and theoretically a research topic of both scholarly and public interest.

Theory: It is a challenge to create a conceptual formulation and analytical approach/method that will function when it comes to analysing phenomena of multimedia or digital expressions that combine text, picture in motion, sound, music, animation and interaction. In the field of digital play research, a dichotomy has arisen between researchers who are interested predominantly in plays as plays (the ludologists) (Frasca, 2003) and those who claim that the plays first of all have a narrative structure (the narratologists) (Murray, 1997). Another way of understanding the phenomenon can be found in dramaturgic theories that see and analyse these games as a means of theatrical practice. I will use dramaturgic theory and models to analyse the way games are built in addition to an analysis of what kind of interaction they invite the players into. I analyze these games as means of a theatrical performance by using dramaturgic theories and concepts, inspired by Danish media- and dramaturgy researchers like Kjetil Sandvik, Janek Scatkowski, Birgitte Holm Sørensen (Sandvik 2004, 2006, 2006; Scatkowski 1989, 2006; Sørensen 2006). In my next part of my research I want to outline an analytical framework for discussing critics, criteria and quality when these games are put in pedagogical contexts. My research question in this follow up study will be: What requirements must be put forward for an analytical tool that aims to make visible and discuss aesthetical and pedagogical quality in pedagogical digital games?

Methodology

The study is based on a qualitative research design. The specified main research approach is phenomenological hermeneutical where dramaturgy and didactics constitutes my theoretical and analytical position. I will combine

several research methods in my research design. I suggested, inspired by the Danish media- and dramaturgy researchers to use dramaturgy as a complementary theoretic position for understanding digital games as means of a theatric phenomenon. This is a pure theoretical study examining digital games and research on the topic from different coherent perspectives. This first section contains a literature review/study of research on digital games. The next part of my study is a case study research (Yin 2008) which implies that we have used purposeful selection (Maxwell 2005), semi-structured interviews (Kvale & Brinkmann 2008) with 8 pre-school teachers, observations (Merriam 1998) of 5 year olds playing digital games in kindergartens (approximately 15 hours) and document analysis (Merriam 1998) of Norwegian policy documents. As a backdrop for our qualitative study we will make references to a national survey carried out by my research group in 2010 (DIGOB). In order to answer the research question and enhance the internal validity we have combined several qualitative research methods (triangulation) in our research design as well as respondent validation and quasi statistics.

The latest section of this research project is based on a phenomenological hermeneutic interpretation of theories on critics, criteria and quality in order to discuss how these theories are transferable to digital games and gaming situations. This part will be based on my two first ones. The theoretical discussion will be related to the thoughts and intentions of game producers and teachers expressed in interviews in addition to dramaturgic reception and interaction analysis based on critics of digital games. In my PAPER PRESENTATION I would like to present my plans for the final part of my research in order to discuss theoretical and methodological challenges according to discussing quality in pedagogical digital games.

PAPER PRESENTATION

Experts and Novices in Virtual Space: Spatial Behaviors, Learning, and Issues in Education

Michael McCreery, University of Nevada, Las Vegas, United States; P.G. Schrader, University of Nevada, Las Vegas, United States; Kathleen Krach, Troy State, United States

Because learning in virtual worlds is mediated by a three-dimensional representation of space, this research examines spatial ability in terms of novice and target (i.e., expert) behaviors within a popular virtual world, the World of Warcraft or WoW. Specifically, hundreds of in-game actions from five expert and 11 novice players' were directly observed over the course of 60 minutes of play and classified into one of five spatial categories (i.e., positioning, appropriation, interactivity, reasoning, and socio-spatial interactivity). Trend analyses across three segments of time (i.e., early, middle, and late) indicated that there were clear differences in terms of how experts and novices interact with and within WoW as well as when they engage in spatial behaviors. The findings have significant implications for education, research, and future design of virtual worlds.

INTRODUCTION

Three-dimensionality is a widely recognized, salient property of contemporary virtual environments. Because of the ability to represent the real world, many have argued that immersive environments allow users to interact with tremendous virtual landscapes, dynamically changing content, and players from various backgrounds and locations (Gee, 2003; Squire, 2006; Young, Schrader, & Zheng, 2006). In this way, virtual worlds support valuable learning goals like collaboration, situated problem solving, and authentic activity (Squire, 2006, Young et al., 2006). Unfortunately, research also indicates that individuals vary in terms of their spatial abilities, navigation, and cognitive abilities (Alexander, 2003; Glaser, Chi, & Farr, 1988; Jones, Gardner, Taylor, Wiebe, & Forrester, 2010; Lawless & Schrader, 2007). As a result, this research examines the differences between novice and target (i.e., expert) behavior within a popular virtual world (the World of Warcraft) as players negotiate the three-dimensional environment.

METHOD

Research Context

The World of Warcraft (WoW) was selected because it allows players to experience a wide range of quests, experiences, and activities while providing researchers with the ability to record their behaviors (i.e., video/screen capture). In these ways, WoW provided an authentic context to examine how initial, novice behaviors unfold.

Participants

Experts were defined to be players with two or more years of experience playing WoW, at least one year of high level play (i.e., end-game raiding experience), and at least one character at maximum level (i.e., level 80 at the time of this writing). By contrast, players who had no personal or direct experience with WoW, although experience in other games was permissible, were considered novices for the purposes of this research.

Participant's average age was approximately 25 (SD=6.1) for novices and 29 (SD=8.5) for experts. Participants' had a high school diploma or higher educational level. Four males and one female were identified as experts. One

male and 10 females were identified as novices. These gender approximations align with previous demographics associated with gamers (Yee, 2006) and the overrepresentation of females in colleges of education.

Procedures

Participants were directed to sit at alternating computer systems and wear an audio headset. The computer systems were identical iMacs equipped with a full version of WoW and a two-button PC mouse. A time sampling procedure, partial-interval recording (PIR), was used to collect data (see Goodenough, 1928). Specifically, every other 20-second interval within the observation period was evaluated and a psychologist experienced with MMOGs logged the type of behavior into the Behavioral Assessment Matrix (BAM; Figure 1). The BAM is a bi-dimensional direct observation instrument employed to assess behavioral data. The 60 minutes were divided into ten-minute intervals that corresponded to the first, middle and last ten-minute time period of play.

The categories associated with the BAM were informed by a combination of previous research and experiences with MMOGs (i.e., de Certeau's, 1988; Cole & Griffiths, 2007; Martey & Stromer-Galley, 2007; Webb, 2001; Williams, Ducheneaut, Xiong, Zhang, Yee, & Nickell, 2006). With respect to WoW, behaviors were identified in terms of movement and avatar positioning (i.e., spatial positioning), use of tool tips and asking for help (i.e., spatial realization), use of the quest log and mini map (i.e., spatial appropriation), dynamic interactions like quest gathering, non-player character interaction (i.e., spatial interactivity), and direct communication or initiating group contact (i.e., socio-spatial interactivity).

Data Analysis

Given the small sample size and the exploratory nature of the study, a combination of statistical significance testing, parametric trend analyses, and follow-up nonparametric time-trend analysis employing Spearman rho was applied to the data. Statistical significance was measured using General Linear Modeling (GLM) as an omnibus test followed by separate post-hoc tests.

RESULTS

Across each variable, experts showed higher scores than did novices. In all of the variables except social behavior, scores showed less variability amongst experts than amongst novices. Omnibus testing was used to investigate statistically significant differences for the dependent variables of ratings on spatial positioning, spatial appropriation, spatial interactivity, spatial realization, and socio-spatial interactivity for the independent variables of expertise (experts versus novices) and the three time points ($F(10, 76) = 1.464, p = .170$; Wilks' Lambda = .703; partial eta squared = .161). Statistically significance was found for the stand-alone independent variable of expertise ($F(5, 38) = 3.583, p$

Follow-up findings indicate statistically significant differences between experts and novices in the areas of spatial positioning ($F = 46.692(1, 42), p = .017$, partial eta squared = .129) and socio-spatial interactivity ($F = 166.484(1, 42), p(2, 42), p$

Linear and quadratic significance tests were run for behavioral trends. For novices, linear statistical significance was found for the variables of spatial positioning ($F(2,30) = 4.405, sig = .021$; $\rho = .426, sig = .013$), spatial appropriation ($F(1,30) = 2.861, sig = .101$; $\rho = .322, sig = .068$), and spatial interactivity ($F(1, 30) = 2.824, p = .103$; $\rho = .304, sig = .086$). Results indicate that these linear equations account for 90.50%, 77.67%, and 99.95% of the variance across each variable respectively. Amongst experts, linear statistical significance was found only for the variable of spatial appropriation ($F(2, 12) = 11.655, sig = .005$; $\rho = -.714, sig = .003$) indicating that a linear relationship accounts for 98.26% of the variance.

DISCUSSION

These findings have several implications for the field of education. As noted in previous findings (Anatonacci & Modaress, 2008; Delwich, 2006), novices require time to adjust to the environment and deal with the steep learning curve that comes with interacting with a new system (i.e., Spatial Appropriation). However, these findings indicate that participants resolve issues fairly quickly, approximately 30 minutes with this environment. Another important concern of previous authors (Delwich, 2006; Martin, 2008) is the need for social interaction and communication in order to achieve collaborative learning benefits. From the findings in the current study, it appears that when left unchaperoned, novices will require more time within the environment than the hour that was recorded, to begin to interact with other participants. Training students or providing more sophisticated, authentic tutorials within virtual worlds could address this acclimation period.

PAPER PRESENTATION

Game-based learning: A review on the effectiveness of educational games

Sylke Vandercruysse, Katholieke Universiteit Leuven, Belgium; Mieke Vandewaetere, University of Leuven - Campus Kortrijk, Belgium; Geraldine Clarebout, KU Leuven, Belgium

A new interest in the use of video games for learning has emerged and a number of claims are made with respect to the effectiveness of games in education. These educational games are as a new instructional technology with great potential. The suggested positive outcomes and effects have been mentioned repeatedly (e.g., Alessi & Trollip, 2001). In this review the learning effects of educational games are studied in order to gain more insights into the conditions under which a game may be effective for learning. A systematic literature search in three databases was conducted. Results reveal that effectiveness research on game-based learning is highly susceptible to a muddle of approaches, methodologies and descriptions of gaming for educational purposes. Some researchers did find a positive effect on learning and motivation, but this is moderated by different learner variables and depends on different context variables.

Background

Games as learning environments are considered as a new instructional technology with great potential (Becker, 2007). Positive outcomes and effects have been claimed and educational effectiveness is expected from the use of games. According to different authors, video games should directly contribute to knowledge construction and skills and attitudes acquisition (Hayes & Games, 2008; Ke, 2008; Papastergiou, 2009). Additionally, educational games should effectively motivate learners and this increase in motivation is assumed to lead to higher invested mental effort, to more intentionally processing of information, and to more enjoyable learning. So an optimistic stance is taken towards the potentials of games in education. In this contribution, we attempted to get some evidence on this assumed benefits of games. By looking at the results and findings from various experimental research, some key issues about the effectiveness of educational games will be illustrated.

Method

A literature search was performed in 3 databases, namely ERIC, PsycInfo, and Web of Science. The following descriptors were used: "game based learning", "serious game*", "educational game*", game* AND learning* and gaming AND learning*. The terms "study" or "research" were respectively used to focus the search since the aim of the study is to find empirical research studies. Only peer-reviewed articles were included and no date limits were set. With this search, 1,013 unique articles were found. All abstracts were read through. Those articles that complied to the following criteria were kept: the article describes (quasi-) experimental research that made use of a computer-based-game in an educational setting. Only 24 journal articles have been selected.

Notwithstanding research on educational games is flourishing, no univocal and generic definition has arisen and there is no agreement on what elements are crucial to constitute a game. Unfortunately, if no studies are referring to similar descriptions and categorizations, comparing the effectiveness of educational games is made impossible. Nevertheless, with this contribution we want to gain insight into the effectiveness of educational games for learning. Therefore, defining the educationally effective parts or elements of a game might be a first step towards a conceptual research framework. As Aldrich (2005, p. 80) stated, "Rather than thinking about games and simulations, it is more productive to think about the distinct elements.". Consequently, this review sketches the empirical research on the effectiveness of educational games by using a framework consisting of game-elements based on the work of among others (Alessi & Trollip, 2007; Becker, 2007; Bergeron, 2006; Prensky, 2001). These elements are: fun, play, rules, goals and objectives, interactivity, adaptivity, outcomes and feedback, win status, problem solving, competition/challenge, interaction and representation or story. So this framework of game-elements will be used to investigate the effectiveness of educational games.

Results and conclusion

Three key factors are indispensable in research focusing on the implementation of educational games: the environment, the mediating variables and the learning results. First, the reviewed articles show that games are used in a variety of domains (e.g., Science, History, Geography) and a variety of game formats (e.g., multiplayer games, virtual reality games) are taken into consideration. Additionally, it seemed that the chosen framework (see method) was not ideal to analyze the studies because they often lack a thorough description of the implemented game. This forms a problem to draw conclusions about which game-elements make the implementation of an educational game effective. In sum, this review showed that there is a clear gap between what is theoretically stated and empirically proved. Secondly, nine studies consider several moderating variables, e.g. learner characteristics such as gender, prior knowledge, etc. Not much evidence for the moderating influence of these variables on the learning outcomes has been found. Another moderating variable, motivation, has been examined in nine studies as well. Unfortunately, the results of the studies do not always show positive effects, meaning that the use of video games not always had

positive motivational effects and if they are, the results could also be attributed to other factors such as the Hawthorne effect, the cooperative goal structure, etc.

Thirdly, although some significant learning effects have been demonstrated in ten studies, prudence is called in stating learning effects of educational games since not all the studies (e.g. Ebner & Holzinger, 2005; Ke, 2008) found that game-playing resulted in significant better performances compared to non-playing conditions.

In sum, no generic effects are found concerning the implementation of games in educational settings on learning results and motivation, as described above. Possible causes are the muddle of approaches, methodologies and descriptions of gaming for educational purposes. The most ideal way to examine which factor(s) is(are) effective, is by manipulating various separate game-elements. By focusing on game-elements, one can more easily find which elements are crucial for defining the successful implementation of a game in educational settings.

PAPER PRESENTATION

Strategy Performance Mediates Effects of Continuous and Faded Scripts on Online Search Competence

Christof Wecker, University of Munich, Germany; Ingo Kollar, University of Munich, Germany; Frank Fischer, Universität München, Germany

Laboratory research has shown that scripts can stimulate productive interaction and thereby positively affect learning outcomes. In a prior field experiment we found positive effects of continuous and faded scripts on online search competence compared to unstructured collaboration, but no effect of the faded script beyond that of the continuous script. This paper presents further analyses from this study about the effects of these two types of scripts with respect to the performance of the strategy during the learning phase and the relation between the performance of the strategy and the development of online search competence. In a curriculum unit about Genetic Engineering with three inquiry cycles involving one online search phase each, three experimental conditions were implemented: No script, continuous script, and faded script. The performance of the strategy was measured based on recordings of learners' utterances and activities on the computer by means of screen-audio-capturing software. A time sample from the online-search phases was coded for the occurrence of activities suggested by the script. Both the continuous and the faded script had positive effects on the performance of the strategy, but these two conditions did not differ from each other in this respect. Learners' own performance of the strategy predicts online search competence, while their learning partners' performance of the strategy does not contribute further to the accuracy of predictions. The findings indicate that the main mechanism of developing online search competence during collaborative learning supported by scripts is by means of performing the strategy.

In prior research, computer-supported collaboration scripts have been developed to provide structure for successful collaborative inquiry learning (de Jong, 2006). Laboratory studies have shown that scripts can stimulate productive interaction and thereby positively affect learning outcomes (Kollar, Fischer & Slotta, 2007). These findings stimulated the question whether similar effects can be obtained in real-world settings with an extended timeframe. Furthermore, they led to the question whether fading a script allows learners to take over control of their activities and thereby fosters learning outcomes even further. We conducted a field experiment about the effects of a continuous and a faded script on the development of online search competence with respect to socio-scientific issues as a part of

scientific literacy. We found positive effects of both types of scripts compared to unstructured collaboration, but no effect of the faded script beyond that of the continuous script (Wecker, Kollar, Fischer & Precht, 2010). In the following, we present further analyses from this study concerning the questions (1) what the effects of these two types of scripts are with respect to the performance of the strategy suggested by the script during the learning phase and (2) how the performance of the strategy is related to the development of online search competence.

Method Participants and design. The sample comprised 129 students (60 girls, 69 boys; age: $M = 14.7$, $SD = 0.67$) from six ninth-grade classes from three urban high schools in three experimental conditions: No script, continuous script, and faded script. **Learning environment, task, and procedure.** A seven-lesson curriculum unit about Genetic Engineering was implemented by the classes' Biology teachers. The unit comprised three cycles about economic, ecological and health-related issues of Genetic Engineering. Each cycle consisted of three steps: background information on Genetics, online searches on the Web for arguments about the issue, and a whole-class discussion. The first two steps were performed in face-to-face dyads. Each student was equipped with a laptop. During online searches, both students saw the same web pages no matter who of them navigated. Students completed pre- and posttests before and after the unit. **Independent variable.** In the condition without script, students did not receive any support during collaborative online search beyond an introduction by the teacher that was identical in all three conditions. In the condition with a continuous script, students received complementary prompts in their web browser for five (partly iterative) stages of collaborative online search. One of the learners had the "operative" role of suggesting initial arguments, search terms, hits etc., whereas the partner had the "metacognitive" task of commenting on these suggestions. In the condition with a faded script, initially the same prompts were presented as in the condition with the continuous script, but their degree of specificity was reduced over time. **Data sources and instruments.** Screen-audio-capturing software recorded learners' utterances and activities on the computer. A time sample of 10 minutes from the beginning of the online-search phase of each cycle was selected for analysis. Occurrence of the activities suggested by the script for this phase was coded separately for both members of each dyad for segments of 10 seconds (Cohen's $k = .64$ to $.89$). The proportion of segments in which one of the activities belonging to the first step of the script was performed was used as an indicator of the performance of the strategy (Cronbach's $\alpha = .82$). Online search competence was measured in the pre- and posttests where students described how they would use the Internet to arrive at a position about a specific issue. The occurrence of the elements of the strategy suggested by the script in the solutions was coded and counted (pretest: ICC = $.51$; posttest: ICC = $.83$). **Results RQ1: Effects of continuous and faded scripts on performance of the strategy.** An ANOVA with the students' performance of the strategy as the dependent variable and script support and classes nested within the levels of script support as independent variables and the pretest as a covariate revealed a significant effect of script support, $F(2; 122) = 5.35$; $p = .01$; partial $\eta^2 = .08$. Both continuous and faded script had positive effects on the performance of the strategy, continuous: $F(1; 77) = 15.53$; $p = .00$; partial $\eta^2 = .17$, faded: $F(1; 78) = 7.56$; $p = .01$; partial $\eta^2 = .09$, but did not differ from each other, $F(1; 122) = 0.00$; $p = .98$. **RQ2: Role of performance of the strategy for online search competence.** A regression analysis with online search competence in the posttest as the criterion variable and learners' as well as their learning partners' performance of the strategy as predictors, while also controlling for prior online search competence was conducted. It showed that the learners' own performance of the strategy can significantly predict online search competence, $b = .25$; $p = .02$, while their learning partners' performance of the strategy does not contribute further to the accuracy of predictions, $b = .00$; $p = .98$. **Discussion** The findings indicate that the main mechanism of developing online search competence during collaborative learning supported by scripts is performance of the strategy suggested by the script. The association of the performance of the strategy with online search competence in the posttest makes it unlikely that scripts affect learning outcomes merely via exposure to and recall of prompts encountered before. Although faded scripts do not seem to raise online search competence more than continuous scripts do, sustained performance during fading, i.e. increasing self-regulation, may yield more robust outcomes, which should be investigated in future studies.

PAPER PRESENTATION

With a little help...: On the role of guidance in knowledge acquisition in complex, dynamic systems

Jens F. Beckmann, University of New South Wales, Australia; Natassia Goode, University of New South Wales, Australia

This study investigates the role of structural information, practice and fluid intelligence in the control of a computer-simulation of a complex, dynamic system. Eighty-nine subjects attempted to discover the underlying structure of an autoregressive system. After initially controlling the system with their limited knowledge, half of the subjects received direct instruction as to the actual underlying structure of the system. All subjects then controlled the system again. In contrast to the results of previous studies, structural information did confer an advantage in controlling the task, and subjects were able to translate the information into effective control actions without practice. Fluid intelligence moderated the extent to which subjects benefited from structural information. These results indicate that the efficacy and timing of instruction, along with learner characteristics, play a more important role in learning to control the outcomes of a system than the mode of instruction.

Knowledge acquisition through an unguided exploration often is referred to as scientific discovery learning. In this approach, the learner is seen as an independent and active agent in the process of knowledge acquisition, as they must develop hypotheses, design experiments to test them, and appropriately interpret the data. The problems that learners experience with discovery learning in hyper-media and computer simulations are well documented, and so far there is no clear evidence that favours discovery learning over more traditional forms of learning such as expository instruction. Reviews of the findings of numerous studies show that learners need extensive guidance in order to facilitate the acquisition of deep conceptual knowledge.

Complex dynamic systems are used to investigate how people manage complex and dynamic systems in the real world. They consist of a number of inputs (variables that the decision maker intervenes on) and outputs (outcomes that are generated by the system). The system is dynamic because the values of the outputs change in response to the problem solvers' actions, and independently over time. The values of inputs can be changed, which affects the values of the outputs via more or less complex causal structures that relate the inputs to the outputs. This is referred to as the underlying structure of the system.

Within the context of complex problem solving learners also experiencing challenges in acquiring knowledge of the underlying structure of the system through unguided exploration. However, instructions providing structural information have not shown effects on control performance. Studies so far suggest that structural information does not directly benefit control performance, as it seems knowledge needs to be independently acquired or practiced in the context of application.

Goal: The main goal of this paper is to determine whether the provision of structural information confers any additional advantage in controlling a complex system over actively acquired knowledge.

Hypotheses:

Subjects who acquire more knowledge about the underlying structure of the system should show better control performance (Knowledge Hypothesis).

Subjects who receive structural information should improve their control performance more than those who receive no additional information (Information Hypothesis).

Under conditions where problem solvers receive information, the magnitude of improvement is a function of their fluid intelligence (Intelligence Hypothesis).

Participants: Eighty-nine first year psychology students participated for course credit.

Design: Subjects were randomly assigned to one of two conditions (45 subjects in the Information condition, 44 subjects in No Information condition). Subjects were required to control a complex, dynamic system on two separate occasions (within-subjects factor). The between-subjects factor was whether or not they received structural information. Subjects were assessed on their structural knowledge, control performance for phase 1, control performance for phase 2 and performance in a test of fluid intelligence.

Procedure:

In the exploration phase participants were prompted to explore the system for two cycles of 7 trials each by changing any of the input variables and observing the effect upon the output variables. At the end of each trial, participants had to record what they had learned using the causal diagram that was displayed on the screen.

In the control phase participants had to manipulate the inputs to reach set values of the outputs for seven trials, which were indicated as lines on the output graphs (Control Phase 1). The causal diagrams remained on screen, providing access to the structural information extracted during the exploration phase. In the information condition participants then watched an instructional video that explained the actual underlying structure of the system. After each trial, the narrator explained how each of the outputs had changed, and how this reflected the underlying

structure of the system. A causal diagram was constructed on screen, to record this information. Participants in the no information condition did not receive any additional information. All participants then had to control the system again for seven trials, with different goals indicated on the output variables (Control Phase 2). In the complete information condition the causal diagram displayed onscreen was the correct and complete one. In the no information condition, the causal diagram that participants had initially created themselves was displayed onscreen.

Results:

Knowledge hypothesis: There was a significant positive relationship between structural knowledge scores and control performance in Phase 1, indicating that subjects who acquired more knowledge controlled the system better.

Information hypothesis: Subjects who received additional information performed better and improved at a greater rate from control phase 1 to control phase 2.

Intelligence Hypothesis: Problem solvers with a higher fluid intelligence tended to perform better overall, and improved more from control phase 1 to 2.

Discussion:

The present study examined the effect of structural information and fluid intelligence on the control of a complex problem-solving task.

Results suggest that the provision of structural information does confer an additional advantage in controlling a complex system over independently acquired knowledge, and that subjects can translate such information into effective control actions. However, the extent to which subjects can benefit from structural information appears to be moderated by their fluid intelligence.

While previous studies have found that a period of active practice is necessary before structural information can be translated into effective control actions, the current study found that the provision of structural information provided an immediate advantage over independently acquired knowledge.

In summary, it is not the mode of knowledge acquisition that seems important for system control, but rather the efficacy and timing of the instruction.

More intellectually capable individuals are able to make use of structural information more effectively than individuals who are less so. Our study extended on previous findings, as it was also found that subjects who are more intelligent are at a double advantage in comparison to those who are less intelligent with regard to acquiring and utilising structural knowledge: they are able to acquire more knowledge without assistance, and they also benefit more from direct instruction.

Overall, our results imply that the direct instruction has the potential to provide benefits over and above the effects of discovery learning. The crucial aspect of instruction, however, is that it is well designed.

PAPER PRESENTATION

Learning can be fun: The story of learning from computer games.

Skevi Demetriou, University of Bristol, United Kingdom

Computer games are a rapidly growing part of our culture and their impact on people of all ages and especially on youth is impressive. The potentially beneficial contribution of technological means and especially of computer games, on education and learning has been highly emphasised by educators and scholars worldwide. This is a study exploring the motivational properties of reward uncertainty and its impact on learning in the environment of an educational computer game. The investigations focused on positive reward prediction error and its relationship to successful or unsuccessful learning in the specific computer game context. An educational computer game especially designed for the purposes of this study was employed. The study, when conducted with 16 adults, found that for recall, prediction error prior to successful learning was again significantly higher [$M=17.55$, $SE=1.35$, $t(15)=3.51$, p

Computer games are a rapidly growing part of our culture [1]. The impact of games on people of all ages and especially on youth has lead to the development of a vast global community of users, affinity groups and entrepreneurs investing millions of dollars on game related projects [1]. Within this progression, the potentially beneficial contribution of technological means and especially of computer games, on education and learning has been highly emphasised [2].

Even though some scholars are rather sceptical regarding the link between computer games and learning, others don't hesitate to overtly acknowledge their potentially beneficial influence on children's education and learning, usually grounding it on the argument that fun learning is effective learning [3]. Some scholars in the area suggest that computer games are not the enemy, but may provide the best opportunity to engage children in real learning situations [e.g. 4]. From a broader view, the game element appears to carry added value in pedagogy, enhancing students' motivation and making learning derived from such instruction often more efficient compared to that achieved in more conventional settings excluding game features [5-7].

It appears to be that the prevalent source of interest in this research area is that computer games may possess the dynamic to motivate and engage people within learning contexts and especially children in a way that formal education often does not [8]. A review based on ninety four studies concluded that computer gaming may serve a range of functions and thus promote learning in many ways [9]. It is also pointed out that frequent computer gaming helps users adjust to the contemporary computer oriented society within which they live and act [10].

A better understanding of why both children and adults are motivated by computer games in order to identify the elements that promote their learning within such contexts, may help devise more effective learning experiences in and out of formal school settings. Previous research has emphasised the key role of uncertainty, competition, optimal challenge and interactivity among others in providing deeply engaging gaming experiences [e.g. 11-15]. The currently presented study focuses on the impact of uncertainty, and particularly reward uncertainty, on children's learning within computer gaming environments. Additionally, literature points out that satisfaction, and hence motivation, arises within a gaming environment due, partially, to encountering competitive challenges with unknown and uncertain results [16]. Therefore, competition and uncertainty seem to be some of the main engaging and motivating elements of computer games that contribute to the learning derived within such environments.

Attitudes towards school and school-type tasks seem to change as children go through primary and secondary school. Within this progression, motivation towards academic achievement can decrease, contrasting with children's increased commitment to their social relationships and also, the use of computers for socialising and gaming. Both within social domains and within gaming practices, the levels of uncertainty that are encountered are greater than in many learning tasks (i.e. school based learning is more predictable in its trajectories) and this may influence the motivation for children to engage and develop their knowledge in these areas. There is neuroscientific evidence for uncertainty enhancing the approach motivation provided by reward, and such evidence also suggests approach motivation can be considered as a function of prediction error – the difference between the reward value and its expected value.

Literature praises the motivational properties of competition and challenge especially in learning and gaming contexts [16-17]. Additionally, educational literature acknowledges a wider beneficial contribution of uncertainty in academic achievement [18] and in students' motivation to engage in learning activities [19]. Also, psychological evidence indicate that we are particularly excited by different levels of uncertainty when seeking rewards, with motivation peaking near 50% probability [20,21], exactly where moderate risk taking is required. However, purely educational research has rarely focused itself specifically on the motivational role of uncertainty especially in computer gaming environments.

Additionally, studies on animal learning on the primate brain, like that of Fiorillo et al. (2003) have provided clues on how reward uncertainty may increase motivation through its impact on dopamine [22]. This suggested a brain-basis for the pleasures of chance-involving tasks, such as gambling, and also the addictive aspects of computer-games [23]. Particularly, it was found that sustained activation of the dopamine neurons of the brain occurs in response to reward uncertainty [23,24], making implications of how reward uncertainty and particularly, prediction error (PE), could impact on learning through dopamine release. One camp of scholars supported an indirect impact of dopamine on memory encoding and/or recall due to its enhancing influence on attention (i.e. 25,26) whereas another favoured a direct impact of dopamine on declarative memory formation involving the hippocampus [i.e. 27,28]. It is important to mention here that, through neuroscientific explorations, PE was found to be proportional to the amount of dopamine generated in the ventral striatum of the brain, and particularly in the NAcc, hence relating to approach motivation [29]. Therefore, these mechanisms may shed light on how games, including learning games, may motivate and engage their players and also promote their learning. Based on the arguments mentioned above about what literature suggests, reward-uncertainty-promoting games may induce dopamine release in the brain in a way proportional to the PE. This is particularly important for learning since dopamine is found to be a "motivation enhancer" and a "learning promoter".

This study explored the motivational properties of reward uncertainty and its impact on learning in the environment of an educational computer game. The investigations focused on positive reward prediction error and its relationship

to successful or unsuccessful learning in the specific computer game context. An educational computer game especially designed for the purposes of this study was employed. The study, when conducted with 16 adults, found that for recall, prediction error prior to successful learning was again significantly higher [$M=17.55$, $SE=1.35$, $t(15)=3.51$, p

PAPER PRESENTATION

Evaluation VR Vs. CAI as Teaching Strategies among Students with ASD: A Meta-Analysis

Orit Hetzroni, University of Haifa, Israel; Juman Tannous, University of Haifa, Israel

Aim: Students with ASD demonstrate severe behavioral, communicative, social, and cognitive deficits. Such deficits interfere with the process of learning new skills and generalizing these skills beyond the learning setting (Mesibov, Shea, & Schopler 2005). Assistive technology (AT) has been found to be effective for teaching individuals with ASD. Computer assisted intervention (CAI) is a successful teaching instrument for children with ASD. The purpose of this study was to investigate differences and similarities between virtual reality (VR) and CAI as teaching instruments for children with ASD. **Method:** A meta-analysis was conducted to evaluate the differences and similarities between VR and CAI as teaching strategies for individuals with ASD. Studies were located between years 1980-2009. The search was restricted to elementary school age children. **Results:** Results indicate that practice was found to be a useful consideration in every process used for teaching children with ASD across different methods of intervention. All components of practice were found in CAI and VR intervention strategies used for teaching individuals with autism. **Conclusion:** Based on the results of this study a proposed model is suggested to represent basic components of practice as a key element in intervention strategies used for teaching elementary children with ASD using VR and CAI. This basic model can be represented using three basic learning processes derived from various learning theories: neurobiological, cognitive and behavioral.

Introduction

Students with Autism Spectrum Disorders (ASD) demonstrate severe behavioral, communicative, social, and cognitive deficits. Such deficits interfere with the process of learning new skills and generalizing these skills beyond the learning setting (Mesibov, Shea, & Schopler 2005). Over the years, many adapted intervention strategies and treatment methods were developed. As a result, an overwhelming number of strategies are available; each of them have different aspects associated with unique theoretical backgrounds, learning processes, environments appropriate for intervention as well as structure, and type of instruction. Such strategies are meant to increase the students' abilities in different domains, including behavioral, communicative, social and cognitive, taking into account the specific and unique learning profile of children who have ASD (Corsello, 2005). An overview of the theoretical background of different intervention strategies demonstrates that there is a steady use of structure, repetition, intensity and consistency across all strategies (e.g., Greenspan, & Weiber, 1998; Kerr, Smyth, & McDowell, 2003; Mesibov, Shea, & Schopler, 2005). This was evident beyond the domains learned and the theoretical background of any intervention method. Assistive technologies offer such unique intervention strategies used for individuals with ASD. The increased use of technology, which characterizes this era, did not skip individuals with ASD. Assistive technology (AT) has been found to be effective for teaching individuals with ASD. Computer assisted intervention (CAI) is a successful teaching instrument for children with ASD. CAI offers opportunities for multi-sensory interactions, controlled and structured environments, use of multilevel interaction functions, and individualized use and independence are some of the factors that can assist children with ASD in working with computers (Hetzroni & Tannous, 2004). Virtual reality (VR) is a combination of technologies, allowing creation and exploration of virtual environments, which are 3D computer-generated representations of environments that may have a realistic appearance, allowing an authentic simulation of situations, potentially helping participants to perceive the relevance of the real world, which maximizes the likelihood of generalized learning (Mitchell, Parsons, & Leonard, 2007). The use of training and practice in controlled environments has been found to be effective for children with ASD when later performing in natural environments (Hetzroni & Tannous, 2004). Offering such environments, CAI and VR interventions have been investigated for effectiveness as teaching strategies. The purpose of this study was to investigate differences and similarities between VR and CAI as teaching instruments for children with ASD.

Materials and Methods

A meta-analysis was conducted to evaluate the differences and similarities between VR and CAI as teaching strategies for individuals with ASD. For this purpose, a wide range search was conducted using several search engines including electronic data-bases, manual search through leading journals, leading researchers and reverse citation lists. Studies were located between years 1980-2009. The search was restricted to elementary school age children receiving intervention in the area of VR and CAI. Coding included documenting different dependent variables: Theoretical background, domain, target of intervention, research method, learning process, number of sessions, number of repetitions in session and across sessions, environment, structure, use of reinforcement, type of instructions,

generalization, age, and function level. Of the studies found using the above search methods, 20% were coded by independent coders for reliability purposes. Effect size was calculated for all intervention outcome studies for group design and single subject design studies based on their appropriate standards for calculating effect size measures.

Results and Discussion

Results indicate that practice was found to be a useful consideration in every process used for teaching children with ASD across different methods of intervention (i.e., CAI and VR). All components of practice were found in CAI and VR intervention strategies used for teaching individuals with ASD. Results demonstrate that elements of intervention structure, repetition, intensity and consistency were most commonly found in the studies. Thus, results of this study demonstrate that learning is highly efficient when practice is used along the intervention process; this evidence was found to be true beyond the domain of each study. Based on the results of this study a proposed model is suggested to represent basic components of practice as a key element in intervention strategies used for teaching elementary children with ASD using VR and CAI. This basic model can be represented using three basic learning processes derived from various learning theories: neurobiological, cognitive and behavioral. A careful view of the model may indicate that each component, presented in the model, addresses one of the difficulty areas associated with ASD. This model suggests that use of practice during intervention may play a critical role in the process of learning. By using practice, the learning process is much more efficient enabling the occurrence of generalization. Further research should investigate use of practice as an intervention method across other teaching and treatment strategies. Results also demonstrate that developing or selecting an intervention program can indicate whether modifications or adaptations to existing programs would be critical, by adding, changing, or omitting components associated with larger or smaller effects. Thus, effective programs are likely to become more potent. Costs associated with adopting and implementing new approaches are also minimized. Such approaches increase uptake of more effective interventions and teaching strategies in the field. Empirical data will be presented as well as the model.

PAPER PRESENTATION

Constructing professional circle of knowledge among special-education teachers

Roni Reingold, Achva-College of Education, Israel; Nira May, Achva-College of Education, Israel; Gali Grisaru, Achva-College of Education, Israel; Tzlil Levi, Achva-College of Education, Israel

Paulo Freire's pedagogical philosophy focuses on the potential of education for social transformation. According to Freire, structural reading of reality leads the pedagogical-educational praxis. He claims that a dialogical and reflective process that he names: "the professional circle of knowledge", can lead educators (teachers) to rewrite their personal and collective narratives, and to expand subjective liberating and empowering views (Freire & Shor 1987). In the current paper we report the findings of a unique attempt in Israel to develop a professional circle of knowledge during a six one-hour workshop meetings of experienced in-service special-education teachers. A qualitative evaluation research of this educational intervention was preformed, using combined qualitative methods, such as action research (since one of the researchers was the instructor of the workshop) and ethnographic research (since the other researchers analyzed D.V.D recordings of the meetings). The findings reveal that even though there were a lot of subjective and objective obstacles, the educational intervention succeeded and most of the teachers developed the skills of conducting a professional circle of knowledge. Never the less our findings led us to recommend that such educational interventions take place in earlier stages of teachers' professional education, either in initial teacher education, or in novice teachers' professional developments programs.

Paulo Freire (1921-1997) was one of the most influential thinkers in education in the last 40 years. He became a source of inspiration and hope for justice seekers, equality and freedom in the pedagogical-educational and socio-

cultural fields (May & Flavian, 2010). Freire's pedagogical philosophy focuses in the potential of education for social transformation. According to Freire, structural reading of reality leads the pedagogical-educational praxis. He claims, that a dialogical and reflective process that he names: "the professional circle of knowledge", can lead educators (teachers) to rewrite their personal and collective narratives, and to expand subjective liberating and empowering views (Shor & Freire 1987). Freire claims that the circle of knowledge does not end at the stage of attaining knowledge, it is composed of two additional stages: the stage of creating new knowledge, and the stage of awareness and exposure to reality. This circle enables participants in the educational process to understand the sources of their knowledge and be aware of why and how hegemonic culture and ideology controls them. It also enables them to develop a mental gap from that hegemonic culture and ideology and facilitate the ability to influence. Hence, the expansion of consciousness is authentic when the removal of the veil from reality is united with dialectic practical dynamics of transformation of reality. In Freire's terminology: the pedagogical and political praxis (Freire, 1970). The main tool to create the circle of knowledge is the dialogue, which in Freire's conception contained communicative and epistemological aspects and has a political dimension (May, 2006). The dialogue reveals Freire's educational-social viewpoint, which opposed any kind of official authorized educational oppression. The nature and contents of the dialogue reflect his social-political opinion, the goals and objectives of the educational-political praxis, the nature of educational leadership and the guiding ethical-moral principles of Freire. Analysis of the contents of the dialogue enables us to become acquainted with the epistemological perception of Freire, the way to create knowledge and the role of knowledge in an emancipated, just and equal society structure (Freire, 1984). In the current paper we report the findings of a unique attempt in Israel to develop a professional circle of knowledge during six one hour workshop meetings of experienced in service special education teachers. We have chosen to try to help special education teachers to develop a professional circle of knowledge, since we believe that not only their students but they themselves are suffering from being excluded in the Israeli society.

Methodology

12 special education teachers in one small school in Israel participated in an evaluation research about the possible influence of educational intervention, based on Freire's pedagogical philosophy. Three questions in an open questionnaire were handed prior to the beginning of the educational intervention. The teachers were asked about their main difficulties in schools, their sources of knowledge, and their main helpers in searching to solve school problems. Then a six one hours workshop meetings were performed and were examined using combined qualitative methods, such as action research (since one of the researchers was the instructor of the workshop) and ethnographic research (since the other researchers analyzed D.V.D recordings of the meetings). Beside some quantitative data, such as the percentage of every participant in each of the meetings, the researchers examined, who suggested topics for discussions and who suggested the ways of solutions. Moreover they examined if the topics and the offered solutions were traditional (conservative) or more radical, wide and essential. The content of all the six meetings was content analyzed on the basis of the principles of critical discourse analysis (Van Dijk, 2001).

Findings

At the beginning, the participants reflected a high professional self and collective efficacy. They declared in the questionnaire and in the first meeting that they get all the help they need from their colleagues whenever they have to solve problems or to design lessons: "We are one strong and unified family; we can solve every problem together and do not need someone from the outside". Hence, they resisted participation in an open workshop and when the headmaster insisted and pressured some were very passive. Even the more active participants did not want to present real problems or suggested conservative and partial solutions. As time passed (even though there were only six meetings), some or even most of the participants acknowledged that the sense of togetherness is partially faked, they expressed satisfaction from the opportunity to express their one and unique voice. They began to deeply understand the reality in which the Israeli ministry of Education controls the educational system, and as a result the special education teachers and students suffer from inequality and even oppression. The teachers became more and more active from one meeting to the next one. They talked more (in correlation with the instructor talking less), they suggested the topics for the discussions (meaning the problems they have to deal with) and more real, complex and deep solutions for the difficulties. The real, open and structured dialogues influence them to define the problems wider and to find more essential solutions.

Recommendations

Even though the educational intervention can be regarded as success, we recommend that such educational interventions will take a place in earlier stages of teachers' professional education, either in initial teacher education, or in novice teachers' professional development programs.

PAPER PRESENTATION

Nurses in the Netherlands. Do they calculate correctly?

Tecla Lampe, Cito, Netherlands; Theo Eggen, Cito, Netherlands; Gerard Straetmans, Cito, Netherlands

In 2007, several reports in the Netherlands stated that the nurses' medication calculation skills cannot measure up to the demands of their work. In 2010, these calculation skills were assessed by an empirical study. 2,661 nurses answered 30 multiple-choice items on paper. The nurses worked in academic and general hospitals, including revalidation centres. On average, this sample of nurses passed 21.6 items (sd 4.55) out of 30. The items were calibrated by the One Parameter Logistic Model. The mean ability of the nurses was estimated .484 (sd .399). Afterwards, six experts set a national standard, based on the test results. They rated a set of 40 representative items, according to a modified Angoff's standard setting procedure. The experts agreed upon an average cut-off score of 31.17 items (sd 2.37) of this set of 40 items. Despite the small number of raters, rater agreement was .6743. The agreed upon average cut-off score corresponded to a so called 'national standard' of .784 on the estimated ability scale of nurses' calculation skills. Considering this national standard, over 80 percent of the 2,661 nurses in our representative sample appeared to lack sufficient calculation skills. This conclusion confirmed the findings reported in 2007.

Nurses can make medication errors due to a lack of medication calculation skills. For instance, because they do not know the relation between micrograms and milligrams. Several reports state that nurses' calculation skills cannot measure up to the demands of their work (McMillan, 2010; De Jong & Koster, 2007). Therefore testing the medication calculation skills recurrently seems an imperative measure to guarantee the nurses' capability. Aim In 2010, Cito, the Dutch national Institute for Test Development, did a national study to assess the level of medication calculation skills of nurses in Dutch academic and general hospitals and revalidation organizations. The ultimate purpose of this research is to develop a computerized adaptive test package (Straetmans & Eggen, 1998). By this adaptive test the calculation skills of nurses can be determined in an efficient way. Despite the fact that nurses then complete a rather short computer based test, they can still get a very reliable estimation of their arithmetic skill level.

Methodology

Beforehand, Dutch educational and branch organisations for nursing had to agree upon the contents of the test. The target group for this test were to be nurses who completed senior secondary vocational education and higher professional education. Subject matter experts (experienced nurses) constructed a large set of multiple choice items intended to measure the relevant medication calculation skills. The items covered various topics, e.g. solid and liquid medication application, infusion, transfusion, and gasses. For instance, the item in figure 1 is related to the topic of infusion. 36 different test forms were assembled, each consisting of 30 items. Figure 1 Example of item A patient must have two litres of NaCl 0,9% per 24 hours. The drip satchel (500 ml) was started at 8:00 am. At 2:00 pm the physician orders to give this patient one litre per 24 hours, instead of two litres. At what dripping rate (ml/hr) must the dripping pump be set ever since 2:00 pm? A at 27.8 ml/hr B at 41.6 ml/hr C* at 41.7 ml/hr Then, nursing organizations requested academic and general hospitals (including revalidation organizations) to participate in this study. In the period January till March 2010, 2,661 nurses took the test voluntarily to examine their calculation skills. They were asked to answer 30 multiple-choice items on paper. They were also asked to fill in some additional general data, like, gender, age, years of experience, and previous education. The testing time was one hour at most. The nurses took the test in the organizations where they worked, supervised by impartial surveillance. The organizations were evenly spread over the country. The test results were analyzed and the items were calibrated using the One Parameter Logistic Model (Verhelst & Glas, 1995). Afterwards, six Dutch experts of nursing practices and education participated in a standard setting procedure (modified Angoff procedure). The goal of this procedure was to agree upon a national performance standard of nurses' medication calculation skills. Forty representative items were selected, based on both the content specifications and the estimated item parameters. The experts judged these items independently. Then, differences between their judgements were discussed, also considering empirical item

difficulties. Finally, the experts judged the same set of items for a second time, and reached a common standard in the discussion afterwards.

Findings

The sample consisted of 2,661 nurses: $N_{\text{female}} = 2,295$, and $N_{\text{male}} = 282$. 78% of the participating nurses was evenly divided over three categories 25-34, 35-44, and 45-54 years of age. 67% of the nurses completed senior secondary vocational education, of which 51% worked over 15 years. The 27% of the nurses who finished higher professional education were less experienced. Only 28% worked over 15 years. On average, the 2,661 nurses passed 21.6 (sd 4.55) out of 30 items in the test. Test analysis showed an average reliability (Cronbach's Alpha) of .78 in 36 test forms and an average standard error of measurement of 2.08. Each item was taken by 148 nurses on average (sd 45.1). Although the sample size was quite small, a preliminary calibration of 495 items was possible. Model fit was moderate: $R^2 = 1561.816$; $df = 1357$; $p = 0.0001$. The mean ability of the nurses in the sample was estimated .484 (sd .399). The experts agreed upon an average cut-off score of 31.17 (sd 2.37) of the 40 items in the standard setting procedure. Despite the small number of six raters, rater agreement in the last round was .6743. Thus, the raters agreed fairly upon the standard of the test presented. 26% of the variance could be explained by the items. After the last round no average difference was found between the standards of the separate raters. Unfortunately, the residual percentage of 74% was rather high, indicating that the raters did not judge the items consistently. Regularly, the judgements of a particular item changed between raters mutually.

Conclusions

The agreed upon average cut-off score corresponded to a so called 'national standard' of .784 on the estimated ability scale of nurses' calculation skills. Considering this national standard, over 80 percent of the 2,661 nurses in our representative sample appeared to lack sufficient calculation skills. This conclusion confirmed the findings reported in 2007. Hospitals are recommended to improve their nurses' calculation skills. A computerized adaptive test package can provide a reliable and efficient method to assess these skills. Finally, a standard setting procedure involving more raters is recommended.

PAPER PRESENTATION

What makes the difference? Measuring Teachers' Counselling Competency

Simone Bruder, DIPF, Germany; Mara Gerich, Institute of Psychology, Technische Universität Darmstadt, Germany; Julia Klug, TU Darmstadt, Germany; Bernhard Schmitz, Technical University of Darmstadt, Germany

Counselling parents and pupils is an everyday task of teachers at school and can therefore be considered a key aspect of teachers' professional competencies. Especially counselling toward learning strategies is an important counselling aspect. The aim of the present study is to examine which aspects make teachers become better counselors. Counselling competency is measured with a case scenario with an open-answer format. The instrument measures counselling competency closely related to behavior and is based on the model of counselling competency of Bruder, Klug, Hertel, Kelava & Schmitz (submitted). The model includes the dimensions counselling-skills, diagnostic/pedagogical knowledge, cooperation/perspective taking and coping. Furthermore, variables from teacher development research and expertise research like reflected experience, support by others, motivation for counselling and understanding of teacher role have been included in the study. Data of 96 middle-school teachers was collected. For distinguishing between teachers with better results in the tests and lower results cluster analysis was conducted. Results show that teacher scores can be clustered into two groups. Further analysis shows that the group with higher test scores also shows more reflected experience in counselling than participants with lower scores concerning the overall test score. Regarding to the dimension counselling-skills teachers with higher test scores also show more support by others and diagnostic/pedagogical knowledge is significantly associated with a better understanding of teacher role. It can be presumed that counselling competency is influenced by different teacher attitudes.

Theoretical framework

In addition to teaching, education, and grading, counselling parents and pupils is an everyday task of teachers at school (KMK, 2004). The goals of teacher counselling are, for example, to support parents and pupils in their learning strategies, their education, and their school careers. Counselling competence of teachers has been implemented into newer concepts of teachers' professional competencies (Baumert & Kunter, 2006). In particular, counselling with respect to learning difficulties and learning strategies has achieved more importance in recent years in Germany. According to these findings, parental involvement in learning and homework has been shown to increase students' positive outcomes throughout children's schooling, including their high school years (Eccles & Harold, 1996; Epstein, 1991; Epstein & van Voorhis, 2001; Fan & Chen, 2001; Grolnick & Ryan, 1989). Despite this need for teachers' counselling competence, theory and research on counselling in schools has still been rare. To support teachers in improving their counselling competence it is important to specify aspects of counselling-competencies that are particularly important for teachers. For that reason Bruder, Klug, Hertel and Schmitz (2010) developed a model of counselling competence. The model was created by searching through the literature about counselling in general, counselling in schools, and short-term therapy, and trying to find the key aspects of counselling (Hertel, Bruder, & Schmitz, 2009; McLaughlin, 1999; McLeod, 2003; Reid, 1990; West & Cannon, 1988). The model includes the four dimensions counselling skills, diagnostic/pedagogical knowledge, cooperation/perspective taking and coping (Bruder, Klug, Hertel, Kelava & Schmitz, submitted). The dimension counselling skills contains the scales active listening, paraphrasing and structuring the talks. The second dimension diagnostic/pedagogical knowledge includes the scales searching for reasons, defining the problem, strategy knowledge (concerning learning), and goal orientation. The third dimension cooperation/perspective taking focuses on the scales cooperative actions, perspective taking, and resources/solution orientation. The last dimension coping includes the scales coping with criticism and dealing with difficult situations. These dimensions can be seen as main components for counselling interviews with parents. Based on this four dimensional model a case scenario with an open answer format has been developed to measure counselling competency. Validation studies show that it correlates significantly with a self-report about counselling and a situational judgment test (SJT).

The aim of the present study was to examine which aspects are important to differentiate between teachers who are good counsellors and teachers who are less good to find references for supporting teachers in their counselling competency.

Methods

96 middle school teachers participated in the study. 61.5% of the teachers were female. Concerning the age, 63.5 of the teachers were between 30 and 49 years old, 7.2 % were younger and 29.1 % were older.

The study has taken place in a bigger study measuring counselling competency and diagnostic competency of student teachers in the first phase, student teachers in the second phase and practicing teachers. Participants filled out different tests (case scenarios for both competencies, a short form of the SJT, knowledge tests for both competencies and self-reports for expertise in both fields). Results here are only presented for the case scenario and the teacher sample.

The case scenario included 12 open questions to a case of a pupil with learning difficulties and the mother asking for help. The answers have been rated with a detailed rating-system. The instrument was pre-tested on a sample of 125 teachers and the interrater-reliabilities (intra-class-correlations) for the ratings of the case scenario are higher than .79.

To measure expertise in counselling, a questionnaire with self-constructed scales was developed because no existing questionnaires were found. It contained the scales reflected experience (10 items; Cronbach's alpha = .76), support by others (6 items; Cronbach's alpha = .78), motivation for counselling (6 items, Cronbach's alpha = .73) and understanding of teacher role (2 items, Cronbach's alpha = .63)

Results

Results of cluster analysis show two significant clusters for the overall score as well as for the scores of the four dimensions of the case scenario. Taking in account that the self-reported expertise scales influence these clusters it can be seen, that teachers who gain higher scores in the overall score report more reflected experience ($F(1, 4.14)$, $p = .05$), teachers who show better results in the dimension counselling skills have more support by others ($F(1, 4.37)$, $p = .05$) and teachers in the better cluster of the dimension diagnostic/pedagogical knowledge report a better understanding of teacher role ($F(1, 6.13)$, $p = .05$).

Theoretical and educational significance

The results of our study show that two significantly differing groups of teachers, one with a higher and one with a lower counselling competency can be found. The variables reflected experience, support by others and understanding of the teacher role are influencing if teachers show better results in counselling competency or lower results. These results can be useful in fostering teachers in counselling competency. Reflected experience and support by others e.g. colleagues or experts should be established in trainings or in supervision groups and fostered. Furthermore, as role understanding seems to be important to develop diagnostic/pedagogical competency in counselling talks, this aspect should be taken into account in teacher education in general. As counselling competency still is not that much implemented in teacher education but as it is an important part of their everyday work, it seems useful to support teachers or becoming teachers in knowing that counselling is part of their teacher role.

PAPER PRESENTATION

Individual and contextual influences on vocational teachers' innovative work behaviour

Gerhard Messmann, Institute for Educational Science, University of Regensburg, Germany; Regina Mulder, Universitaet Regensburg, Germany; Markus Hirschmann, University of Regensburg, Germany

In contemporary workplaces, innovations are required to deal with problems and challenges arising from societal transformations. For instance, vocational colleges are required to be responsive towards increasing diversity of students and demands of the world of work by developing innovative solutions within complex learning environments.

Innovative work behaviour of employees that comprises all work activities carried out to generate, promote, and realise innovative ideas is central for the development of innovations. In addition, reflective activities are a component of this behaviour.

To foster innovation development, information is required about factors that are facilitative of this behaviour. According to psychological theories and prior research, attention must be paid to individual factors such as employees' attitude, norms and perceptions and to contextual factors such as characteristics of work. Therefore, the central research question is: What individual and contextual factors influence vocational teachers' innovative work behaviour?

In order to address this question empirically, a questionnaire study with vocational teachers comprising three points of measurement was conducted. N=343 teachers (response rate: 32,4%) completed the online-questionnaire at T1. N=80 teachers (response rate: 8,6%) responded three times. Innovative work behaviour as well as individual and contextual factors and teachers' background characteristics were measured. Data are analysed in a cross-sectional and a longitudinal approach by applying structural equation modelling. First results indicate that individual characteristics and variables related to the social context are more strongly related to innovative work behaviour than objective characteristics of work.

Theoretical background and aims

In contemporary workplaces, innovative products and processes that are new, applicable and useful are required to deal with problems and challenges arising from ongoing economic and technological transformations (Messmann, Mulder & Gruber, 2010). For instance in vocational colleges, the increasing cognitive and cultural diversity of students as well as the changing demands of the world of work, that these students are prepared for lead to challenges and problems. Vocational colleges must be responsive towards these transformations (Nijhof & Streumer, 1994) and realise innovative solutions related to the development of complex learning environments (Messmann & Mulder, 2009).

Innovative work behaviour of employees such as vocational teachers that comprises all work activities carried out to generate, promote, and realise innovative ideas is central for the development of innovations (Janssen, 2000; Kanter, 1988). In addition, reflection is an important component of this behaviour (Messmann & Mulder, 2010). Reflective activities are necessary to regulate the process of innovation development as well as to refine and improve one's own actions based on one's experiences (Kolb, 1984; Kolodner, 1997; Van Woerkom, Nijhof & Nieuwenhuis, 2002).

To foster innovation development, information is required about individual and contextual factors that are facilitative of this behaviour. According to the theory of planned behaviour (Ajzen, 1991), attention must be paid to employees' attitude, perceived subjective norm and perceived behavioural control towards innovative work behaviour. According to self-determination theory (Deci & Ryan, 2000), attention must be paid to employees' perception of autonomy, competence and social relatedness. In addition, prior studies on innovative work behaviour (De Jong, 2007) suggest that characteristics of the work group, the supervisor and work tasks are important. In relation to the context of

vocational teachers' work, the central research question therefore is: What individual and contextual factors influence vocational teachers' innovative work behaviour?

Methodology

In order to address this question empirically, a questionnaire study with teachers in vocational colleges in Germany was conducted. Within the design of the study, both a cross-sectional and a longitudinal approach were pursued. Therefore, data were collected at three points of measurement between February and June 2010. Innovative work behaviour and its corresponding dimensions "opportunity exploration", "idea generation", "idea promotion", "idea realisation" and "reflection" were measured three times using a self-assessment questionnaire based on respondents' critical incidents with innovations (Messmann & Mulder, 2010); individual factors ("attitude towards innovations", "meaning of work", "perceived competence", "perceived autonomy", "perceived influence", "flexibility", "intrinsic motivation") and contextual factors ("collegial relatedness", "perceived support", "job demands", "job complexity", "job routines", "amount of collaborative work") were only measured at the first point of measurement using scales that had been used and proved satisfying in previous studies; teachers' background characteristics (age, gender, education, tenure, leading function, job field, type of employment) were also only assessed once.

Altogether, 1060 vocational teachers from 15 colleges could be addressed. The vocational colleges were selected because they were involved in projects or activities that could be associated with school development and innovations. The selected colleges represented the different job fields within the German vocational system. At the first point of measurement, N = 343 teachers completed the online-questionnaire. This results in an overall response rate of 32,4 % for all colleges. Therefore, we assumed that the sample was representative of the basic population of teachers that were addressed. If all three points of measurement are taken into account, the sample size dropped to N = 80 teachers from 12 vocational colleges. Consequently, with an overall response rate of 8,6 % for all colleges the representativeness of this sample was not that high anymore. However, since the longitudinal approach was applied in addition to the cross-sectional approach and since it provides opportunities to draw causal interpretations (De Lange, 2005) this limitation was accepted. Data will be analysed by applying structural equation modelling in order to capture the relations between innovative work behaviour on the one hand and individual and contextual factors on the other hand. Moreover, in a structural equation model, relations among the dimensions of innovative work behaviour and among the various explanatory variables can be modelled adequately as well.

Expected results

First results of a correlation analysis indicated that individual characteristics such as teachers' "attitude towards innovations" and "perceived influence" as well as variables related to the social work context such as "perceived support" and "collegial relatedness" are strongly related to the dimensions of innovative work behaviour; by contrast, for objective characteristics of work such as "job demands" or "job routines" only few significant relation were found. Based on these first results as well as on theoretical and empirical evidences, we expect that these tentative results will also be reflected by models that take into account complex relations among variables.

PAPER PRESENTATION

A Methodology for Enacting Professional Practice in the Technical Communication Classroom

Andreas Karatsolis, Carnegie Mellon University, Qatar

During the last decade, the ACM, the IEEE and other professional organizations have acknowledged that there is a problem with the way communication is taught in science-based curricula: the writing, speaking, and presentation skills students learn in the classroom do not match what is expected of them in the workplace. As a solution to this problem, many undergraduate colleges simply added a dedicated technical communication course to their curriculum. However, such courses most often focus on technical editing skills instead of engaging students in disciplinary practices and making the connection between the classroom and the workplace. This paper presents a framework for enacting professional practice within disciplinary technical communication classrooms. This approach is based on principles from situated cognition theory and is articulated over three layers: practice of technique in individual aspects of the communication act, simulation of actual communication deliverables and performance of actual communication for a real-world audience. Examples from two technical communication classrooms are presented as evidence of this model's potential to engage students in professional disciplinary practices and to support an authentic exchange between the academic and the professional context.

Since the mid 1990s there has been a sustained interest in promoting student-centered curricula [1], especially in disciplines (such as Computer Science) where self-directed learning is critical, as the knowledge base and skills required to succeed evolve rapidly. In fact, the question no longer seems to be whether a student-centered curriculum is preferable, but rather which tools (multimedia, intelligent tutors etc.) can be used to support such a curriculum, especially in terms of student engagement and active participation.

However, according to theories of situated learning, the distinction between a student-centered (or learning) curriculum and a teaching curriculum does not lie on student interest or engagement. A learning curriculum consists of situated opportunities for the development of new practice and evolves precisely out of participation in communities of practice [2]. This is not a novel idea for work done in the disciplines; for example, the ACM IEEE/CS Computing Curriculum report states that "mastery of the discipline includes not only an understanding of basic subject matter, but also an understanding of the applicability of the concepts to real-world problems" [3]. For the purposes of developing effective communication skills, such statements point directly to the need of engaging students with real audiences in real contexts through professional genres, as the field of technical communication has been advocating for years [4,5]. This turn towards practice might at first look problematic, especially since we have evidence that the interaction between clients and students (or participants and researchers) is often messy [6]. We do know that some practices lend themselves to an apprenticeship model, such as midwifery or tailoring or butchery, where novices learn from more experienced, full participants, but enacting such an approach in the classroom, or for a whole curriculum, seems more complicated, mainly because we have been lacking methodologies to bring the academic and the professional context closer together.

This paper presents such a methodology and provides evidence of its effectiveness for enacting authentic professional practice and making connections to real audiences and clients based on the experiences of two professional communication courses, one for Computer Science and one for Information Systems. The model itself is grounded on situated learning theory, where a tripartite framework is proposed: where one has to learn the technique (or acquire technical skills) first, then participate in simulated instances of the practice, and finally participate in real performances or real use. The first step (practicing technique) can be a solitary activity, the second part (simulation) can be based on imitation of practice by others and the third part (performance) can be supported by guided participation in use by more knowledgeable others [7]. In the next three sub-sections, each of the steps will be briefly elaborated upon.

Practicing Technique

The development of expertise in most fields requires a certain degree of technical skill which can only come through sustained practice. In music or in sports, it takes months or years of practicing technical skills before one can perform in a concert or a game. Similarly, in developing both courses, we decided that practicing technical writing and speaking skills was a critical step in enacting this model. Most technical communication courses make this the focal point of the work that students do, but in our case we decided that recitation sessions or online modules would allow students practice without taking up classroom time. These practice sessions were directly related to the patterns they were encountering in classroom discussions of different genres. For example, when discussing the problem/opportunity section of proposals requires a detailed narrative form, the technical skill practiced was nominalizations, in order to understand positioning characters and actions in the subject and verb position respectively.

Engaging in Simulation

The second step towards developing expertise with communication skills is to begin simulating the practice. In both courses, students work on projects where they have to simulate practice: for example, they have to develop job application materials in response to a job or internship advertisement, or they have to write a proposal on a technical

project in response to a request for proposals the instructors create for a real organization. Students, therefore, have to understand the affordances and constraints of real genres and produce responses for real audiences, with the exception that these audiences do not receive the materials or act upon them.

These opportunities to simulate practice are framed by discussions and instruction on the ways the genre is enacted in the world. After analyzing the effectiveness of published examples, students can imitate the most effective strategies and apply them in their own projects.

Performing

The last step of the model requires students to engage with real audiences ("clients") and perform in communication events which are evaluated both by the instructors for the purposes of the course, but also by the clients.

In the Computer Science technical communication course, students are introduced to real communicative performance through a user guide assignment. As user manuals are rarely targeting specific audiences, it is critical for some clients to find people who can help them rewrite or develop from scratch user guides for their constituents. For example, in the Fall 2010 semester students developed user guides for tools and technologies intended to assist people with disabilities. Their client is MADA, the center for assistive technologies in Qatar, but their audience (who they will have to interact with for feedback and requirements specifications) is disabled people. This interaction makes students feel accountable for the quality of documentation they are producing. At the same time, the clients (MADA in this case), expect artifacts they could utilize with little or no revision.

Finally, after presenting examples of how this methodology was enacted in these two professional communication courses, we will discuss the implications of such a framework for creating networks of coordinated activity between the academic and the professional world.

PAPER PRESENTATION

Technologies at work". A sociohistorical analysis of human identities and communication

Ingela Holmstrom, School of Humanities, Education and Social Sciences, Sweden; Sangeeta Bagga-Gupta, University of Orebro, Sweden

This paper presents preliminary results from an ongoing study that is part of Project-KIT, Communication, Identity and Technology. The project focuses the role that technology play vis-à-vis issues of communication and identity and is particularly interested in young peoples' everyday life inside and outside institutional school settings. Life spheres of deaf youngsters who have received cochlea implants (CI) are of specific interest. Project-KIT is also interested in the sociohistorical genesis and the role that technology has and currently plays in shaping issues of human identity and communication in different settings. Framed within sociocultural perspectives and postcolonial theories, the project is using ethnographic approaches with a two-fold empirical base. The study presented here relates to one of these: archival data. The second will comprise video documentation and field notes from studies of everyday social practices in a diverse range of settings where young people with CI are members. The contribution of the theoretical frameworks and the specific data chosen to understand issues related to communication and identity will be highlighted in this presentation. Deaf people have, in research, not uncommonly been focused from two dominating perspectives: a medical/psychological and a linguistic/cultural point of departure. These two will be used as a contrastive backdrop against which our analysis will be presented. Our empirically based exploratory analysis indicates, among other things, how technology impinges upon and shapes human identity in different ways over time. In addition, different languages also appear to become reduced to a "technology" by certain groups during different historical phases.

This presentation is built upon a paper-in-progress where preliminary results from a study that is part of the ongoing Project-KIT, Communication, Identity and Technology are presented. The project focuses upon the role that technology plays vis-à-vis issues of communication and identity and is particularly interested in young peoples' everyday life inside and outside institutional school settings. Project-KIT aims to increase knowledge about everyday life inside and outside school arenas for deaf children and young people with cochlea implants (CI). Our research focus is on interaction and social practices, not on the individual children and young people themselves. The project has a clearly defined interest also in the sociohistorical genesis and the role that technology has played in shaping issues of human identity and communication in institutional settings. Framed within both sociocultural perspectives and postcolonial theories, the ongoing and planned studies in this project use ethnographic approaches with a two-fold empirical base. The study presented here relates to one of these: archival data. The second empirical base will be built around studies of everyday social practices where young people with CI are members. The empirical base for the study presented here comprises of archival materials that span over a century: from the end of the 1800's to the present. More specifically the empirical materials include periodicals published by three different national NGO's. The

first periodical of these, published by the Swedish National Deaf Association, was founded in 1891, the second, published by the Swedish parent's national association was formally instituted in 1972 and the third NGO's periodical we have included in our study, is published by the parents association of children who have received CI was grounded in 1995. Documentary films and blogs that specifically cover the themes raised in this study from more recent years have also been incorporated in the empirical materials that are being analyzed.

The contribution of the theoretical frameworks and the specific data that has been chosen for trying to understand issues related to communication and identity will be highlighted in the presentation. Deaf children/adults (with or without CI) have, in research, not uncommonly been focused from two dominating normalizing perspectives: a medical/psychological and a linguistic/cultural point of departure. These two will be used as a contrastive backdrop against which our analysis will be presented. Preliminary findings of the large amount of data in this specific study give rise to a complex set of issues. Our exploratory analyses indicate, among other things, how technology impinges upon and shapes human identity in different ways over time and space. Among other things, we will show that different professional communities and interest groups tend to focus different types of technologies: While what can loosely be called "the hearing society", e.g. non-signing hearing parents of deaf children, non-signing hearing researchers, etc appear to primarily focus technologies that support and enhance audiological skills (e.g. telephones, hearing aids, surgically implanted hearing aids including CI) and have attempted to identify voice-based communication technologies, signing parents (deaf and/or hearing) and signing researchers (deaf and/or hearing) appear to have a different interest agenda. Our analysis of archival material suggest that the latter appear to be more focused upon visually oriented communication technologies. Interestingly, the Deaf community appears to have always had an explicit interest in various types of technologies and have often had a head-start in the usage of technologies. Furthermore, their interests appear to be attuned towards a non-hearing agenda. In other words, a central preliminary finding of our ongoing analysis of archival data suggests that different stake-holders within and around Deaf communities tend to focus different types of technologies. Our preliminary findings also suggest that different languages (for instance an oral language, a written language and/or a signed language) appear to become reduced to a "technology" by certain groups during different historical phases.

PAPER PRESENTATION

Toward the virtual music school? A study of artefact use in musicians' communities of practice

Nicolae Nistor, Ludwig-Maximilians-Universitat Munchen, Germany; Doris Lipka-Krischke, Ludwig-Maximilians-Universitaet Munich, Germany

Communication technologies reach domains such as music education, in which learning happens typically situated in communities of practice, and is supported by knowledge reification and the joint use of cultural artefacts (Wenger, 1999). In this context, we regard knowledge as including a fixed and a negotiable component (Assmann & Czaplicka, 1995). Correspondingly, we hypothesize artefacts to include fixed and adaptable components, used differently in the social practice. Knowledge reification and artefact use are likely to be affected by technology mediation; little research is available on these topics. Therefore, the present study explores the possibilities of a community-based virtual music school by examining (1) the use of cultural artefacts (here: sheet music) and (2) the effects of technology mediation. In case studies varying the communication medium, participants' expertise and their degree of acquaintance according to a 2x2x2 factorial design, we observe that artefacts are used in two ways: A fixed component corresponding to canonical knowledge is used in a way shared by the entire community; an adaptable component corresponding to newly negotiated knowledge is shaped as a result of knowledge reification. Technology affects the negotiation constraints and costs, and interacts with expertise and degree of acquaintance. Besides theoretical insight into the cultural artefact use, our contribution offers positive empirical evidence of the feasibility of community-based virtual music schools.

Rationale

Communication technologies presently reach domains such as music education, for which they seem to be inappropriate at first sight. Typically, musicians learn situated in communities of practice (Wenger, 1999), where knowledge communication is supported by reification and the joint use of cultural artefacts. There is little empirical evidence of the use of symbolic resources such as artefacts (Gillespie & Zittoun, 2010), and the effect of technological mediation on artefact use is even less studied. Therefore, our study explores the possibilities of a community-based virtual music school by examining (1) the use of cultural artefacts (here: sheet music) and (2) the effects of technology mediation.

Theoretical background

Cultural artefacts are objects with a special meaning in the context of a given practice. According to the activity theory (Engeström & Sannino, 2010), artefacts mediate the subject-object interaction. Wenger (1999) regards artefacts as

reified knowledge about the community practice, supporting certain “ways of doing things” and hampering others. In this sense, artefacts support the communication of cultural knowledge.

The use of cultural artefacts. Cultural knowledge, described by Wenger as related to the “ways of doing things” (i.e. procedural knowledge), consists of two components: (1) basic knowledge, shared by all the community members – not negotiable (canonical knowledge; Assmann & Czaplicka, 1995) and (2) newly constructed knowledge, shared only by a part of the community members. Correspondingly, we may hypothesize two components of the artefacts involved in the cultural knowledge communication: (1) a fixed component, i.e. reified basic knowledge, difficult to change (here: printed musical text) and (2) an adaptable component, shaped in the social practice (here: hand-made notes added to the printed musical text). Thus, the use of cultural artefacts will mainly consist of (1) community practice performance, as dictated by the canonical knowledge and supported by the artefact, which remains unchanged, and (2) knowledge construction and reification, resulting into the adaptable parts of the artefact.

Media effects. The communication medium determines the negotiation constraints and costs of the shared knowledge. A communication medium with lower social presence is expected to alter the quantity and quality of knowledge communication, including the artefact usage.

Research questions

Q1. How do participants use the printed musical text in face-to-face and mediated settings? (a) What types of notes do they add? (b) To what extent do the add-ons refer to procedural knowledge? (c) To what extent is the add-on content negotiated?

Q2. How do the participants perceive the negotiation of the musical performance in the face-to-face and mediated setting with respect to (a) grounding costs (b) satisfaction with the results?

Methodology

We conducted eight case studies according to a 2x2x2 factorial design, comprising the factors communication medium (face-to-face vs. e-mail), participants’ expertise related to Gregorian music (high vs. low) and their degree of acquaintance (high vs. low). The participants were eight adult musicians, individually invited to a face-to-face or mediated musical session with a singer, and asked to explain their interpretation idea of the antiphon “Salve Regina”. Printed text material was used, which could be annotated. The experiment was completed when both persons agreed on the musical interpretation. An interview and add-ons analysis followed, the latter was based on four categories: content, structure, emphasis, and procedural notes.

Results

Q1 (a). The added notes were placed between the printed lines, near to the passage to be explained (fig. 1), and consisted of conventional symbols, sometimes more detailed text. In the mediated setting, the participants – especially those with higher expertise – produced more add-ons. (b) All add-ons were procedural notes; emphasis notes could be subsumed to this category, as well. No media effects could be observed. (c) In the face-to-face setting, all add-ons were discussed with the singer, often using gestures. In the e-mail setting, the participants had made some notes only for themselves, which were not discussed. Expertise was associated with the occurrence of more technical terms, in-depth details and practical aspects of the performance. Acquainted participants referred also to common and private experience.

Q2 (a). The formulation, production and display costs were perceived higher in the mediated setting. This effect was attenuated by higher expertise. (b) The participants’ were satisfied with the results. No media effects could be observed in this respect. Higher expertise was associated with higher satisfaction.

Discussion

Participants’ use of cultural artefacts appears to focus on the fixed artefact components, and respectively on the musical knowledge reified into it, thus acknowledging the canonical character of the original text (Assmann & Czaplicka, 1995). All added notes refer to details surpassing the scope of the neume notation, and expressing personal views, locally negotiated and reified (Wenger, 1999). These observations sustain the hypothesis of fixed and adaptable artefact components, corresponding to the canonical, and respectively negotiable knowledge involved. The artefact use may thus be dichotomized in (1) an exact performance of the community practice, as dictated by the canonical knowledge and supported by the involved artefacts, while leaving the artefact unchanged and (2) construction and negotiation of new knowledge, and its reification into the adaptable artefact component.

The artefact use is obviously complicated by technology mediation; media effects appear to interact with expertise and acquaintance degree. Expertise is not only a condition of better practice, it also provides adaption flexibility – and predicts satisfaction.

The present experiment offers positive empirical evidence of the feasibility of a community-based virtual music school, which could be organized – similarly to the traditional one – around experts and cultural artefacts. Nevertheless, the small number of cases examined restrains the validity of our study; further research is needed to enlarge the empirical basis.

PAPER PRESENTATION

Grammar at secondary school: how students build grammar concepts in a collaborative setting

Xavier Fontich, UAB - Universitat Autònoma de Barcelona, Spain

Studies conducted in the last decades in different countries like the UK, Canada, France or Spain propose to look at grammar as a necessary content for second language acquisition and written composition instruction. Some of these studies explore students' grammar concepts and point out the difficulty to separate language and reality or to integrate pragmatics, semantics and form. These obstacles are conceived of as a consequence of a transmissive instructional mode focused on formal descriptions of grammar phenomena. Our two research questions are: (i) How do students can build their grammar knowledge within a collaborative setting? (ii) How can we elaborate an analysis model for exploring it? The oral data that we analyze come from students' interactions in small groups in a natural classroom setting in Barcelona (Spain). Students explore the pronoun system in Catalan and Spanish through inter and intralinguistic analysis. We contrast an initial and a final dialogue in one of the sample groups. The instrument designed describes the discourse flow linking metalinguistic content and argumentative interaction. We can see that in the initial dialogue the group is stuck in a disputative talk. In the final dialogue the group is well able to develop an exploratory talk and metalinguistic notions are richer although students do not attain the final solution. Promoting a link between metalinguistic content and argumentative interaction seems to be a necessary although not sufficient condition for grammar learning.

School objectives in linguistic education refer to a communicative use of language on behalf of future citizens in a society with high literacy demands. In achieving these communicative skills, grammar plays an important role, according to studies conducted in the last decades in different countries like the UK, France or Spain. These studies propose to overcome the view on grammar as a peripheral scholar object and rather to look at it as a necessary content for SLA (Second Language Acquisition) and written composition instruction, as well as a content that can be studied in its own momentarily apart from the dynamics of communication (James, 2002; Trévisse, 2008; Camps, 2008). In this sense, we ought to explore altogether a model of a school grammar to be implemented in real classrooms, and a model of research procedures to explore the triggering processes of this implementation (Durán, 2009). This submission links a practice-based research and a research-based practice since activities are brought into the arena collaboratively by secondary school teachers in collaboration with researchers. The results of this cooperative action have an influence on educational policy in regard to both the role of grammar in the official curricula and teacher education.

Our study is inspired by research carried on in Canada, France and Spain in the last decade that explores the construction of the students' grammar concepts (Camps, 2000; Fisher, 2004; Camps & Zayas, 2006; García-Debanco & Paolacci, 2010). It points out that students find it difficult to separate language and reality, to integrate pragmatics, semantics and form, to overcome a simple and linear perspective on the sentence, or to integrate declarative and procedural knowledge. These obstacles are conceived of as a consequence of a transmissive instructional mode focused on formal descriptions of grammar phenomena. A new research emerges from this previous research based on the following objectives: to design and implement a new model of grammar teaching and to explore the argumentative discourse held by students under this model. Our two research questions are: (i) How do students build their grammar knowledge within a collaborative setting? (ii) How can we elaborate an analysis model for exploring it? Students in 4th grade of secondary school (15-16 years old) in Barcelona (Spain) deal with conflictive grammar

questions related to the pronoun system in Catalan and Spanish. These questions arise from inter and intralinguistic contrasts of data from two sources: automatic translators' results and speakers' sentences gathered by the students. They work in a collaborative setting and follow a lexical and pragmatic-semantic-formal approach to basic grammar phenomena (subject, verb, accusative, argument...). The oral data that we analyze come from the students' interaction in small groups in a natural classroom setting. We contrast an initial and a final dialogue in one of the sample groups. The first task was "Look at the sentences you have just analyzed and choose the easiest and the most difficult one, explaining why you think they are so". This group chose Dalí painted that portrait of Lincoln. The final task asked the students to discuss a sentence where the argument and its pronoun appeared altogether: "[Hi] anaven [a l'aula]" They used to go [there] [to the class]. In order to describe and interpret the interaction carried on we have designed an instrument that approaches the discourse flow from two complementary perspectives: metalinguistic content and argumentative interaction. The first one results from all those metalinguistic expressions used in order to reason about grammar problems, identified by the metalinguistic statement unit, ranging from pragmatics to semantics and form. The second one refers to the different ways in which argumentation is linguistically shaped, identified by the argumentative episode unit, which can be additive (explaining, expanding, adding, accepting, and concluding) or reactive (diverging, contradicting, clarifying, and challenge). Combining these two approaches we can approach the reflective process that is going on concerning both the collaborative construction of grammar concepts and the discursive moves that contribute to it.

As preliminary results of our analysis, we can see that in the initial dialogue the group is stuck in a disputative talk where grammar notions appear to be rigid and intuitive, although pertinent regarding the content of the activity. The statements of the dialogue are focused on whether "of Lincoln" is accusative or dative with a cumulative and disputative talk (Mercer, 2000). Certainly of Lincoln is not accusative neither dative but as an event noun portrait has an argument structure AGENT – PATIENT identical to the structure of the verb to portrait. Regarding the semantic and lexical perspective of our intervention we can read students' mistake as a partially attained solution, since they are being sensitive to semantics (an argument structure) and to pragmatics (Dalí is an agent, Lincoln is a patient). Students show a lack of metalinguistic repertoire concerning semantic dimension and that is why they use formal notions (dative, accusative) instead of semantic ones. They also show a lack of argumentative repertoire. In the final dialogue, after having worked within this model for a month, the group is well able to develop an exploratory talk and metalinguistic notions are focused from the three different perspectives: semantic, pragmatic and formal. Students do not attain the final solution but they do integrate this time a wide range of concepts: coreference, null subject, pragmatics, complementary distribution and syntactic function. We interpret exploratory talk as being at the same time cause and consequence of this larger repertoire of metalinguistic concepts. Students use more concepts and they can talk about many more phenomena and link them to one another. And a greater collaboration and a more versatile attitude enhance this integration of grammar knowledge.

We have argued that through a more collaborative interaction the group creates richer argumentative discourse and metalinguistic content becomes more ductile. At the same time we are able to analyze the communicative flow through an instrument that approaches metalinguistic content and argumentative interaction. In teaching grammar we must promote a link between these two perspectives as a necessary although not sufficient condition for grammar learning.

PAPER PRESENTATION

The state of cognitive and learning styles research within education: a critical review.

Carol Evans, University of Exeter, United Kingdom; Michael Waring, University of Loughborough, United Kingdom

This paper aims to clarify the state of styles research within higher education institutions and schools across a variety of cultural contexts through a systematic review of the associated literature between 1999-2010. The term 'styles research' is used to capture the range of literature within the styles field (learning styles, cognitive styles; approaches to learning, thinking styles, intellectually styles; dispositions to learning and learning patterns). The systematic review involved multiple phases: An advanced search of ERIC and screening of abstracts and titles; hand searching of six international peer reviewed journal special editions; screening of full papers; in-depth quantitative and qualitative review of 486 full papers as well as a further detailed layer of analysis of 130 full papers to consider the nature and impact of specific educational designs on learners from a styles perspective. Whilst there is evidence of strong pragmatic science combining rigour and relevance in styles research in educational settings, this needs to be developed further. Implications of this review for policy, research and practice are discussed in relation to developing and enhancing our understandings of how styles research, as part of the individual learning differences domain, can be used effectively and critically within educational settings to inform and enhance teaching and learning including assessment.

This paper explores the state of cognitive and learning styles research within educational settings (schools and higher education institutions), through the undertaking of a systematic literature review (1999-2010). This review is highly relevant to the EARLI community in considering how styles can be used with other individual learning difference (ILD) variables to enhance learning within a global networked society.

The review is timely given recent and highly significant outputs (Evans et al., 2010; Kozhevnikov, 2007; Peterson et al. 2009; Pashler et al 2009; Rayner & Cools, 2010; Zhang & Sternberg, 2009), seeking to move styles research forward by addressing key concerns: a lack of consensual theory; confusing terminology; difficulties in identifying valid and reliable measures; and vague practical implications (Coffield et.al., 2004; Sharp et al. 2008; Evans & Sadler-Smith, 2006). In undertaking this in-depth review, the authors are able to give a clear, accurate and thorough picture of how styles research is currently being used within educational contexts to inform future work to enhance the quality of learning environments. In addition, it is able to counter and question findings based on superficial analysis of the styles field (Pashler et al., 2009).

An automated advanced search of peer-reviewed journals (1999-2010) within the Education Resources Information Center (ERIC) adopting a broad definition of styles to include (learning styles, cognitive styles; approaches to learning, thinking styles, intellectually styles; dispositions to learning and learning patterns) was undertaken. The search yielded 14,661 peer-reviewed studies. Systematic review and screening of abstracts by two independent reviewers lead to selection of 486 full papers for further scrutiny which also included a further six international peer reviewed journal special editions focusing on styles research between 2004-2010. A second layer of analysis was undertaken to look in detail at specific styles interventions in relation to design of learning environments including e-learning environments as well as a focus on assessment. To ascertain the nature and impact of styles research within educational settings, for each paper, the following information was collected:

Nature: Journal type/subject area; lead author and country of origin of study; Higher education institution /School; style instruments used (including theoretical framework); focus of the article and reported outcomes.

Methodology: methods; research design; nature of sample; construct validity and reliability.

Impact: degree of collaboration within/across school(s)/HEI(s) nationally/internationally; capacity building; consolidation or development.

Descriptive statistics were employed to ascertain frequencies in relation to: journal distribution and dominance; distribution of articles per year; country of origin of articles; method; nature and number of styles instruments used; size of research samples; subject area of research. Thematic analysis (Braun & Clarke, 2006) involving the research foci and recorded outcomes of each of the articles was also undertaken. To identify aspects of capacity building (demonstrable growth of knowledge or skills of the research subjects following the research intervention or development of ideas from it) and consolidation or development (the extent to which it either replicates existing evidence or extends the evidence with new findings) it was necessary to cross reference the full articles with the broader established literature base associated with styles research.

The styles research field is a dynamic one (Evans, et al., 2010) particularly within the field of application of styles research to e-learning. There is a considerable volume of work considering styles in relation to design of learning environments although this appears to mainly preclude discussion of the relationship between cognitive styles and assessment excepting work within the students approaches-to-studying tradition (SAL).

There is substantial evidence of the robust and measured use of 'strong versions' of styles models (Sharp et al., 2008) with the majority of work (84%) emanating from a HEI context rather than a school context. 27% of studies focused specifically on the impact of the introduction of new approaches to teaching and learning; results were mixed. Whilst a broad range of cognitive and learning styles models were in evidence, the top five most cited models, (Kolb; 1976-99; Biggs, 1987-2001; Entwistle 1983-1998; Witkin, 1962-71; Felder & Silverman/Soloman, 1996-2007), were used in over 50% of the studies. Paradigm shift was in evidence in the growing number of qualitative and mixed methods within a field dominated by quantitative research methods. Rigour (reliability and validity) were strengths in over 50% of the articles. There are a number of implications of the findings of this review for policy development, research and practice. Researchers need to work collaboratively to help each other improve existing models and instruments, as well as to develop common definitions of concepts rather than profligate more models. More is needed on how different style constructs relate to one another and which are best suited for which specific contexts (Santo, 2008). In considering styles within educational contexts, connecting and strengthening understanding of styles in relation to relevant educational theory such as dual coding is important. In addition, considering styles holistically, working in tandem with other variables to impact on behaviour and performance is vital. A key finding of the research was the importance of addressing student beliefs and conceptions of learning when trying to affect changes to teaching and

assessment in order to achieve desired learning outcomes. Clarifying what a styles pedagogy constitutes is important and conceptual clarification in the form of the Personal Learning Styles Pedagogy (Evans & Waring, 2009) is a definite move forward in explaining how styles can be used in an expansive and integrated way (Zhang & Sternberg, 2009). The operation of a hierarchy of styles is important in explaining why certain styles matter in certain contexts (Kozhevnikov, 2007; Nosal, 1999). Fundamentally, the latest advances in our understandings of styles need to be able to be translated clearly to wider audiences. Explicit guidance supported by critical evidence-based research showing how one can effectively use knowledge of styles in real settings and in association with other approaches to enhance learning is in evidence moving beyond the overly simplistic matching hypothesis. Whilst there is evidence of good work, much more is still needed to confirm when and how styles matter though replication and refinement of studies both longitudinally and across contexts.

PAPER PRESENTATION

Between-class variability in student attribute effects on grades

Jan Hochweber, DIPF, Germany; Eckhard Klieme, Deutsches Institut für Intern. Pädagogische Forschung, Germany; Ingmar Hosenfeld, University of Koblenz-Landau, Campus Landau, Germany

Most measurement experts agree that grades should be based only on students' achievement. Nevertheless, research indicates that teachers use non-achievement factors in determining grades. Moreover, student background variables (like gender, SES) have been shown to influence grades controlling for achievement. In our study, based on a large and highly representative sample of eighth grade students, we focused on the impact of classroom environment variables on the relationship between students' mathematics achievement, motivation, and background and their mathematics grades. Classroom environment was represented by students' attributes aggregated to the class level and teachers' perceptions of achievement level, learning climate, and social background of their classes. Multilevel analyses with cross-level interactions were used to investigate whether these variables had an impact on the effects of student math achievement, interest, effort, and parental education on grades. Across all classes, student achievement was clearly the most important predictor of grades but interest and effort had significant effects over and above achievement. However, the student attributes' effects varied significantly and substantially between classes. Class achievement level was positively related to the student achievement slope. The impact of interest on grades was found to be higher in classes with an unfavourable learning climate, and lower in classes with high student achievement and interest. Effort was found to have a higher effect on grades in classes with an adverse social background and a low achievement level. An adverse social background and a low achievement level went along with a stronger grade bonus of students with high-educated parents.

Most measurement experts agree that grades should be based only on students' achievement (e.g., Brookhart, 1994, 2008). Nevertheless, research indicates that teachers use non-achievement factors in determining grades (e.g., Brookhart, 1993; McMillan, 2001). Moreover, student background variables (like gender, SES) have been shown to influence grades over and above achievement (e.g., Bennett, Gottesman, Rock & Cerullo, 1993). The relationship between grades and these various factors is likely to be influenced by both teachers' grading practices and the classroom environment; however, the large majority of studies has dealt exclusively with differences in teachers' grading practices (cf. Brookhart, 1994). In our study, we focused on the impact of classroom environment variables on the relationship between students' achievement, motivation, and background and their grades.

Research questions

We hypothesized the following relationships between classroom environment variables and the classroom-specific effects of student attributes: (1) Considered as a means to establish control (Pace & Hemmings, 2007), grades should be related more closely to student motivation in "difficult" than in easy-to-handle classes. Rakoczy et al. (2008) found that students' involvement contributed stronger to grades in classes with a negative student-teacher relationship. In a study by Howley et al. (2001), teachers in "troubled" schools tended towards an "ethos of effort", confounding effort and achievement when assigning grades. Thus, our first assumption was that student motivation is more closely related to grades in "difficult" classes (low levels of achievement and motivation; adverse social background). (2) Social psychological research indicates that judgment accuracy depends on task demands and available attentional resources (e.g., Kruglanski & Sleeth-Keppler, 2007). Target stimuli may be lengthy or complex and thus difficult to process; important information may go unrecognized if the judge is cognitively busy. Classrooms are busy places, characterized by a "multidimensionality" of events, by "simultaneity", "immediacy", and "unpredictability" (Doyle, 1986). The more cognitively demanding teaching a class is, the more likely it seems that a teacher misses or misinterprets information regarding student achievement. Accordingly, our second assumption was that the relationship between student achievement and grades is weaker in "difficult" classes. (3) Effects of student background variables on grades are typically explained in terms of expectancy effects (e.g., Jussim, 1989). These are more likely to occur if constraints are put on task-related interactions between teachers and students (Jussim, Smith,

Madon & Palumbo, 1998). If a teacher's cognitive resources are frequently used up by task-irrelevant interactions, e.g., attempts to establish an orderly learning environment, her or his judgments should be more susceptible to perceptual biases. Consequently, our third assumption was that the relationship between student background variables and grades is stronger in "difficult" classes. Finally, we assumed these moderating effects of the classroom environment themselves to be affected by teacher characteristics, specifically, classroom management abilities. Effective classroom managers are able to prevent and deal with inappropriate student behaviour, maximize time on task, and foster motivation to learn. We hypothesized that the impact of classroom environment on the relationships between student attributes and grades is diminished in well-managed classrooms.

Methods

Sample

We used data from a study aimed at testing the mathematics proficiency of all eighth grade students in a large German federal state. The highly representative sample consisted of 31,038 students in 1,470 classes. The assessment was supplemented by surveys among students, mathematics teachers, and school principals.

Instruments

Our outcome variable was the student-reported math grade assigned in report cards at the middle of eighth class. Four student attributes were used as predictors of these grades: math achievement (measured by a standardized test); interest in math; effort in math; and parents' education. Interest and effort were considered as aspects of student motivation, parents' education as a student background variable. Concerning classroom environment, a first group of predictors contained students' test achievement, interest, and parental education aggregated to the class level. Another group of predictors represented the teachers' view of their classes: The teachers had to estimate their classes' (1) achievement level. A (2) learning climate scale and a (3) social background scale were each composed of four factors the teachers reported as compromising their lessons. Finally, a classroom management scale was created based on four items from the student questionnaire.

Analyses

We applied multilevel analysis (level 1: students; level 2: classes), regressing the math grades on student attributes at the student level. To determine the extent of variation in these attributes' effects, and to explain this variation by the class level variables, random slopes and cross-level interactions were specified.

Results

Across all classes, student achievement was clearly the most important predictor of grades but interest and effort had significant effects over and above achievement. Parental education had only a weak effect on grades. However, these attributes' effects varied significantly and substantially between classes and were found to be related to aspects of the classroom environment. In line with expectations, class achievement level was positively related to the student achievement slope. The impact of interest on grades was found to be higher in classes with an unfavourable learning climate, and lower in classes with high average levels of student achievement and interest. Effort was found to have a higher effect on grades in classes with an adverse social background and a low achievement level. An adverse social background and a low achievement level went along with a stronger grade bonus of students with high-educated parents.

Finally, we examined whether these interactions were affected by classroom management. We found an increased bias in favour of children of high-educated parents when a weak achievement level and a flawed classroom management coincide.

Conclusion

Explaining differences in student attribute effects on grades may help to identify when inappropriate grading practices are more likely to occur. Our results indicate that it is worthwhile to take into account the specific demands and challenges that certain classroom environments pose to the teacher, as well as individual teachers' capability of dealing with particularly "difficult" classes. It might turn out that under certain circumstances, an improvement in teachers' classroom management skills would not only foster student learning, but also improve grading practices.

PAPER PRESENTATION

Planning Work Plans for Pupils - Interdisciplinary teacher team collaboration in a primary school

Nils Otto Steen-Utheim, University of Oslo, Norway

This paper reports on a study of interactions in an interdisciplinary teacher team constructing work plans for their pupils (age 11-13). The study aims to provide knowledge about what characterizes the teachers' team-talk and

interaction while they work on a shared artifact and how it contributes as a structuring resource for the teachers' working process. We ask: What characterizes the teachers' talk and interaction during planning and construction of the work plans? How does the work plan function as a structuring resource in the teachers' collaboration/talk and interaction? Transcripts from 15 interdisciplinary teacher team meetings are analyzed with the aim to identify team-talk patterns and how these emerge during planning and construction of work plans. Focus has been specifically on conversational moments that entail accounts of classroom experience and that signal problems of professional practice. Results from this study can be divided into three main findings: First, the teachers' collaborative talk is in a large degree oriented towards administrative and procedural aspects dominated by a pattern of coordination. Second, the work plans can be structuring the teachers' talk towards an orientation on learning content and joint reflection on problems of practice. Thirdly, this orientation is enabled by the fact that the teachers collaboratively construct the work plans, prompted by template structures in the work plans such as learning goals, assignments and subject resources.

Aims

This paper reports on a study of interactions in an interdisciplinary teacher team constructing work plans for their pupils (age 11-13). Work plans have become increasingly common in Scandinavian countries in the late 1990's. This study aims to provide knowledge about what characterizes the teachers' team-talk and interaction while they work on a shared artifact, i.e. work plans for pupils, and how it contributes as a structuring resource for the teachers' working process.

A work plan is a document that describes the students learning assignments within the different school subjects over a certain period of time (1 to 3 weeks). Time is allocated from the school subjects to work on work plans on the pupils' weekly schedules, during which the pupils can choose what, when and to some extent how they work on different assignments as described in the work plan (Klette, 2007). In this paper we take a socio-cultural perspective on learning (Vygotsky, 1978) and focus on how work plans can function as a structuring resource for their collaboration.

Much of the teachers' planning activities in primary schools in Norway are now conducted in interdisciplinary teacher teams. Such teams are often implemented in order to promote a collaborative mode of teaching and more comprehensive education for students. Another rationale for organizing the teachers in teams is to create a professional learning community with the ultimate goal to improve the pupils' learning (McLaughlin & Talbert, 2006). Researches on professional learning communities indicate that well-developed communities have positive impact on both teaching practice and student achievement (Little, Gearhart, Curry, & Kafka, 2003; Vescio, Ross, & Adams, 2008). On the other hand there are pitfalls. For example, Scribner et al. (2007) indicates that such collaborative structures may cultivate groupthink and unduly convergent thinking. At the same time it is pointed out that we in fact know little about how these teams actually work on a level of micro-ethnography and discourse analysis of interactional data (Havnes, 2009; Scribner et al., 2007). Hence, we ask:- What characterizes the teachers' talk and interaction during planning and construction of the work plans?- How does the work plan function as a structuring resource in the teachers' collaboration/talk and interaction?

Methodology

The empirical data is gathered from a primary school in a middle-class rural district with about 150 pupils. In this paper we draw on data from the team meetings where the teachers create and discuss work plans for the pupils. The core data consists of audio and video recordings from 15 team meetings over a period of 18 months whereas the sizes of the team vary from 4 to 8 persons due to organizational changes during this period. Each team meeting lasts for approximately 1 hour.

Transcripts from the meetings are analyzed with the aim to identify team-talk patterns and how these emerge during planning and construction of work plans. Focus has been specifically on conversational moments that entail accounts of classroom experience and that signal problems of professional practice (Horn & Little, 2010).

Findings

Results from this study can be divided into three main findings: First, the teachers' collaborative talk is in a large degree oriented towards administrative and procedural aspects dominated by a pattern of coordination. Second, the work plans can be structuring the teachers' talk towards an orientation on learning content and joint reflection on problems of practice. Thirdly, this orientation is enabled by the fact that the teachers collaboratively construct the work plans, prompted by template structures in the work plans such as learning goals, assignments and subject resources.

Theoretical and Educational significance

This study's theoretical contribution adds to the research literature on how collaboration on a shared artifact, in this case a planning tool, can be a structuring resource for professional development. In the same way Little et al. (2003) reports on how teachers looking at student work, the construction of work plans collaboratively seem to support as a structuring resource for professional development. This knowledge has educational significance for school leaders' and teachers' awareness on collaborative planning work in schools and contributes to understanding the interdependency between organizational and content aspects of planning work.

PAPER PRESENTATION

What is Learning to learn? An updated theoretical exploration.

Cristina Stringher, INVALSI, Italy

Within European policy, learning to learn is key to lifelong learning and to the maintenance of learning competences needed for the demanding and ageing knowledge-based economies (European Working Group on Basic Skills, 2002; European Council, 2005, 2006). However, limited agreement exists among researchers on a shared definition and on its constituents (European Network on Learning to Learn, 2006; Hoskins & Fredriksson, 2008). A recent attempt to assess this concept in European countries has come to the conclusion that more theoretical work is needed to ground assessment into a clear definition of learning to learn constituents (Kupiainen, S., Hautamäki, J., Rantanen, P., 2008). This theoretic exploration aims at a clarification of the concept, by analysing definitions and models from different paradigms and approaches, the ultimate goal being to extrapolate L2L qualities for lifelong learning. The methodology is a review of existing literature with a qualitative comparative analysis of 40 definitions sought, out of 90 studies examined. A two-step analysis is being presented: in the first section, a distinction is made between L2L and other related concepts; in the second section, possible differences and similarities in the conceptualization of L2L are detected and described by analysing definitions and models. The study output is a meta-definition together with a list of components which could form a basis for future L2L operationalization and assessment purposes. A concept map with relations among components as described in literature is also provided.

Empowering young people and creating favourable conditions for them to develop their skills, to work and to participate actively in society is essential for the sound economic and social development of the European Union, particularly in the context of globalisation, knowledge-based economies and ageing societies where it is crucial that every young person is given the possibility to fulfil his or her potential (European Commission, 2007). This is why learning to learn has been included among the eight key competences by the European Parliament (2006). Political attention at the European level matches and follows scientific interest in this concept: dozens of researchers worldwide have variably defined and explored it, sometimes from very different epistemological backgrounds, accounting for the diversity of approaches and the resulting interdisciplinarity (Bateson, G., 1977; Hounsell, D., 1979; Candy, P., 1990; Gibbons, M., 1990; Smith, R., 1990; Boekaerts, M., 1999; Hautamäki, J., 2002; Deakin, C.R., Broadfoot P., & Claxton G., 2004; to cite but those that attempted modeling this idea). According to anthropologist Jules Henry, learning to learn has been and still is Homo Sapiens' essential evolutionary task (Henry, J., cited in Smith R., 1990). Similarly, Edgar Morin maintains that knowledge of one's knowledge must appear as a primary necessity. Moreover: knowledge of one's knowledge, which implies the integration of the knowers into their own knowledge, must be a principle and a permanent necessity for education (Morin, 2001, 11 & 31). For Goleman (1999), the most basic

knowledge of all is how to learn. This opinion is shared by many scholars who refer to it as not only a concept, but an educational objective (Tuijnman, 1992); a fundamental competence, like numeracy or literacy (European Group on Basic Skills, 2003); the most urgent point in the agenda together with educational reform for the development of people (Candy, 1990); and even utmost ability for life in XXI century (Burgogne, 1998, cited in Claxton, 2002). Candy however warns the reader to make learning to learn a slogan at risk to lose its power for overuse. Twelve years after Coffield adds to it, stating that for too much time learning to learn remained an empty expression, not so much studied, a vacuum slogan, notwithstanding its unanimous utility, most of all if there is no consensus on its definition (Coffield, 2002).

Rationale of this essay is to contribute to some degree of order in the theory of learning to learn, avoiding the risk to reduce it to an umbrella term good for all purposes. The complexity of this task is however evident from the very beginning, not only for the wide disparity of definitions found in literature, but also considering that any meaning associated with learning to learn derives from how learning is conceptualised: considering that a recent publication has reviewed 41 influential frameworks on thinking and learning (Moseley et al, 2005), the burden seems unbearable. In addition, the components deserve an analysis on their own, since there is no agreement among scientists about what they actually mean and do.

The modest end of the paper is therefore to accurately describe learning to learn from definitions taken from the literature and identify those characteristics that contribute to a meta-definition. The author has been involved in a European study to measure L2L and this paper derives from contributions to the European L2L Network (Hoskins & Fredriksson, 2008; Kupiainen, S., Hautamäki, J., Rantanen, P., 2008) and from subsequent independent study. The methodology is a qualitative review of worldwide literature with a comparative analysis of four major L2L models and forty definitions sought out of ninety studies examined, accounting for a diachronic representation of learning to learn studies to date. The essay unfolds into three sections: in the first one, the priority has been setting boundaries for learning to learn and this is achieved by distinguishing learning to learn from other related concepts, with which it entertains multiple relations - some hierarchical, others horizontal. In the second section, learning to learn definitions and models are introduced in order to identify the characteristics of learning to learn, recognize common features in definitions and compile a components list. In the third section, a meta-definition and a concept map of L2L components with some of their relationships are provided.

The difficulty to define intelligence has not prevented scholars from trying and measuring this concept. A similar attempt can be made for learning to learn. The pairing of these two concepts is no coincidence, as they share several similarities like this analysis reveals, while differences are also highlighted.

The theoretical and educational significance of this research lies in the opportunity to set a new basis for learning to learn operationalization. Conclusions include broad strands of thought for future endeavours to assess its characteristics, as assessment seems preliminary to any effort to promote learning to learn across the lifespan.

PAPER PRESENTATION

Gender discrimination or differences in preschool? – empirical answers

Susanne Kuger, University of Bamberg, Germany; Katharina Kluczniok, Otto-Friedrich-University of Bamberg, Germany; Jutta Sechtig, University of Bamberg, Germany

The bases of this study are two (implicitly discussed) assumptions found in literature on early childhood education: a) gender-related differences in children's experiences and behaviour during the preschool years exist and b) these differences between boys and girls increase during the years of preschool attendance. Using data from the German longitudinal study BiKS-3-10 this paper analyses everyday activities of 96 boys and girls in their first and last year of preschool with regard to gender-specific differences in activity patterns, domains of child support, social setting, and type of teacher-child interaction. Moreover preschool teachers' educational recommendations about best time for school enrolment and individual strengths and weaknesses of the children are studied. Results display only few differences between boys and girls, which are not even in line with common stereotypes and most important, diminish during the preschool years. What seems most important to notice is that the few differences found are rooted in the children's own choice and initiative of activities. The preschool teachers encourage a very limited amount of gender-specific activity patterns only, although ascribing strengths and weaknesses more stereotype-like to boys and girls. Results are interpreted as caution not to reduce attention to possible problems, but to focus more closely on differential development between single children than groups of children.

Background and concern of the paper

The topic of 'gender' is as present in educational science and practice today as it has been for many years. Coming along you can find a number of problems, fears, and sometimes even implicit accusations. A review of the literature body shows that in contrast to discussions in the 1960ies to 1980ies, which focused on disadvantaged girls, latest developments concentrate on the boys' problems in learning achievement and overall educational success. The question is how to react. The range of possible educational settings, recommendations, and interventions to cooperate in solving the existing problems is large, yet the number of empirical research findings and evaluations is small, more even so when looking at the preschool level.

Looking at best-practice, there are numerous advisory guidelines debating on 'gender-sensitive' work in preschools. There are recommendations in curricula, gender-related preschool concepts and projects. They all follow the common goal to reduce gender stereotypes as well as gender-related disadvantages and thus foster gender-independent promotion of children. An underlying assumption of most of this work seems to be that the range of biological, genetic, and enculturational differences between boys and girls can be found in the children's and teachers' behaviour during everyday preschool life. Yet often you find that in the focus of attention of these papers is not the children's or teachers' behaviour with each other or in class itself, but other matter of fact gender-related differences such as an unequal proportion of male and female preschool teachers, uneven numbers of boys and girls in early or late school enrolment, or differential development of single developmental domains for the two sexes (e.g. interpersonal relations, socio-emotional adaptation, school achievement).

Two aspects seem to be discussed (implicitly): a) Gender-dependent differences in the boys' and girls' everyday preschool experiences and behaviour do exist and b) these differences increase during the preschool years. Searching for empirical foundations for these assumptions displays that the number of studies in preschool settings that focus on children's experiences and behaviour – with regard to gender-related differences – is rather small. The question if and if so what kind of gender differences in the children's and teachers' behaviour can be found still remains unanswered.

Research questions

The current study therefore analyses whether various aspects of gender-related behaviour differences in children and teachers are a topic in preschool education and if that were the case, how important that topic is. Using data of the German longitudinal study BiKS-3-10 two steps of analysis are conducted: 1) It is assumed that a teacher's educational behaviour towards a child is lead by his or her educational perception of that particular child: Do teachers ascribe gender-related strengths and weaknesses to children or else do they suggest different dates of school enrolment (early, regular, or late) for boys and girls? 2) Are there any gender-related differences in the children's preschool activities, in the developmental domains fostered by the children's everyday activities, in the social settings of boys and girls during preschool days, or in the teacher's role towards a child? Moreover this second step of analyses is divided in two. To cover different perspectives and agencies in everyday preschool, two actors – the child and its teacher – are studied: Do children choose activities or settings gender-related in their own initiative and/or do preschool teachers encourage gender-related activities or settings?

Design, sample and method

The data used was assessed observing a BiKS-3-10 subsample of 96 children and their preschool teachers in 51 German preschool settings during the children's first year (2006) and last year (2008) of preschool. The preschool teachers answered questionnaires regarding their perception of the children's strength and weaknesses at these two points in time and also their recommendations for time of school enrolment for every single child. The observational measure that was used discriminates 16 child activities, 22 domains of fostering child development, as well as seven types of interaction between child and teacher. Results were obtained via univariate difference tests for mean differences of boys and girls (ANOVAs) of relevant categories at both measurement points. Two paths of displaying the results are chosen: All difference tests are inspected in respect to their original outcome in order to uncover complex patterns of child and teacher behaviour. In addition the overall hypothesis of differences between girls and boys is looked into after adjusting results for multiple testing.

Results

The teachers' perceptions of the children's strengths and weaknesses display slight and more stereotype-like differences between boys and girls at both measurement points. School enrolment recommendations on the contrary display no such gender-related bias. The teachers' recommendations are not different for early, regular, or late enrolment for girls and boys at any point in time. The results for the children's activity patterns show only minor differences between girls and boys, which are not all in line with common stereotypes and even, diminish during the preschool years. Moreover the differences found are mainly the result of the children's own choice of activity and setting. Hardly at all do teachers encourage behaviour and settings in parallel to common gender stereotypes.

Interpretation and implications

Interpretations of results are concluded along the lines of heterogeneity of preschool experiences, the importance of influences other than institutional preschool settings, the onset and development of gender stereotypes in the course of child development, and teacher's intentions. The conclusions are that variance between single children is by far larger than variance between the sexes and that the problems boys are having in their school careers later on are not necessarily initiated in experiences and behaviours during the preschool years. Yet teachers and parents should be aware not to reduce their attention to and caution of beginning difficulties during the early years. As long as the sources of gender-related biases in frequency of failure during educational careers are unknown all those responsible during a child's preschool years should be aware of a large number of unknowns yet still focus more often on commonalities of boys and girls than on differences.

PAPER PRESENTATION

Systematic Observation and Documentation of Children's Learning – Effects on Child Care Quality

Corina Wustmann Seiler, Marie Meierhofer Institute for the Child, Switzerland; Heidi Dr. Simoni, Marie Meierhofer Institute for the Child, Switzerland

Systematic observation and documentation of children's learning processes is understood as a quality criterion of professional practice as well as an important professional competence (Tietze & Viernickel, 2007). The method of systematic observation and documentation of children's learning called "Learning Stories" developed by Carr (2001) in New Zealand and adapted for German-speaking countries by the German Youth Institute (Leu et al., 2007) is therefore commonly used in childcare centres as an instrument for promoting early learning processes of children. However, up to now there are no evidence-based findings on the extent to which systematic observation and documentation of children's learning further develop – as it is assumed and implemented in practice – the quality in the early childhood education and care system.

The study is based on a control and comparison group design with two measurement points: prior to the beginning of implementing systematic observation and documentation of children's learning (baseline t1, September 2009) and at the end (outcome t2, November 2010). The sample consists of 38 childcare centres: N=12 as intervention group working with "Learning Stories", N=13 as a waiting control group and N=13 as a comparison group working with another (different) observation and documentation method, developed by the German Infans Institute ("Infans Concept", see Laewen & Andres, 2007). Child care quality is assessed via standardized written questionnaires by the teaching personnel and childcare centre directors and via standardized external observations.

Systematic observation and documentation of children's learning processes is understood as a quality criterion of professional practice as well as an important professional competence (Tietze & Viernickel, 2007). Current key elements of early childhood education are to support the individual learning processes of the child and to create a stimulating learning environment. The method of systematic observation and documentation of children's learning called "Learning Stories" developed by Carr (2001) in New Zealand and adapted for German-speaking countries by the German Youth Institute (Leu et al., 2007) is therefore commonly used in childcare centres as an instrument for promoting early learning processes of children. The goal of the Learning Stories approach is to support the child in the development of an identity as being a "competent learner". The approach does not restrict attention to the children themselves but also includes teachers and parents. The method is directly integrated into the everyday practice of the childcare centre. The interplay of systematic observation and documentation, educational planning and reflection, and mutual exchange processes among all persons involved – children, teachers and parents – sensitizes all to become aware of individual learning processes and to better support stimulating learning environments in childcare settings.

However, up to now there are no evidence-based findings on the extent to which the "Learning Stories", as a method of systematic observation and documentation in early childhood education and care settings, further develop – as it is assumed and implemented in practice – the quality in the early childhood education and care system. Therefore the study aims to fill a research gap as to what dimension the Learning Stories method in fact has an effect on the quality of early child care and education. Following Tietze's (1998) structural-process model of child care quality, the aim is to shed light on whether and how changes manifest themselves in the different quality dimensions of process quality, orientation quality and structural quality. The following research questions are to be investigated:

- What effects do systematic observation and documentation of children's learning using the "Learning Stories" have on the quality of early child care and education?

- What specific effects can be found in the quality dimensions process quality, orientation quality, and structure quality?

It is assumed that (1) working with the "Learning Stories" leads to improvement and further development of child care quality and (2) childcare centres that implement systematic observation and documentation of children's learning show higher quality than childcare centres with no observation and documentation of children's learning.

The basis of the research project is the implementation of systematic observation and documentation of children's learning using the "Learning Stories" in selected Swiss childcare centres. The study has a control and comparison group design with two measurement points: prior to the beginning of implementing systematic observation and documentation of children's learning in childcare centres (baseline t1, September 2009) and at the end (outcome t2, November 2010). The sample consists of 38 childcare centres: N=12 as intervention group working with "Learning Stories", N=13 as a waiting control group and N=13 as a comparison group working with another (different) observation and documentation method, developed by the German Infans Institute ("Infans Concept of Early Child Care and Education", see Laewen & Andres, 2007). The implementation of systematic observation and documentation of children's learning using the "Infans Concept" already started in January 2009 with the comparison group (approximate half a year before the start of implementation in the intervention group).

Child care quality is assessed via standardized written questionnaires by the teaching personnel and childcare centre directors (structure and orientation quality; Nt1=515) and via standardized external observations (process quality) based on the German versions of the "Infant/Toddler Environment Rating Scale Revised" (Tietze et al., 2005), the "Early Childhood Environment Rating Scale – Revised Edition" (Tietze, Schuster, Grenner & Robbach, 2007), the "Early Childhood Environment Rating Scale-Extension" (Robbach & Tietze, in prep.) and the "Caregiver Interaction Scale" (Arnett, 1987).

The baseline results (t1) indicate significant group differences in some scales of orientation and process quality. In most of the scales the comparison group shows higher quality ratings than the intervention and control group. These results can be interpreted by the slight advance of the comparison group at baseline t1. Nevertheless, it already demonstrates effects of systematic observation and documentation of children's learning on the quality of early child care and education.

The paper will focus on the longitudinal results, based on the theoretical background, the methods and the research design. Finally implications for practice and research will be discussed.

PAPER PRESENTATION

Educational process quality in preschools on target-child-level

Wilfried Klaas Smidt, Bamberg University, Germany

The study refers to educational process quality on target-child-level, which goes more into detail than quality measured on preschool-class-level. Process quality, which can be covered with high-inferential quality ratings and low-inferential observations of children's and teacher's activities, is based on different theories. Nonetheless, there is still a lack regarding a strongly theory-based conceptualization of rated process quality. Moreover, little is known about the relation between process quality and observed activities. Therefore, the study considers how rated educational process quality can be conceptualized and how observed activities of children and preschool teachers covary with process quality. In all, 132 children and 64 teachers from 51 preschools in two German federal states participated. Data from the first, second and third year of preschool are used. To examine the conceptualization of process quality confirmatory factor analysis were conducted. The relation of children's and teacher's activities with process quality was examined using multiple regression analysis and conditional change score models. Results support a four-factor-model with focus on global and domain-specific contents. Teacher's scaffolding-behaviours and children's experiences, which can be subsumed under a "high-yield-activity" approach, are positively related with educational process quality. In sum, the study provides further evidence for the differentiation between global and domain-specific quality and the importance of activities representing scaffolding- and high-yield-activities-concepts for the educational process quality.

The study refers to educational process quality on target-child-level, which goes more into detail than quality measured on preschool-class-level. In contrast to measures of educational process quality on class-level (e.g., "Early Childhood Environment Rating Scale", Harms, Clifford, & Cryer, 2005; Sylva, Siraj-Blatchford, & Taggart, 2006) measurements focussing on educational quality on target-child-level (e.g., "Emerging Academic Snapshot" EAS, Ritchie, Howes, Kraft-Sayre, & Weiser, 2001) go more into depth and cover important details regarding dynamic every

day activities and interactions of individual children with peers and preschool teachers. Such educational processes can be covered with high-inferential quality ratings and low-inferential observations of children's and teacher's activities (e.g., Soar & Soar, 1982). Process quality can be conceptualized with reference to different theoretical approaches. With regard to domain-specific theories (e.g., Carey & Spelke, 1993; Wellman & Gelman, 1992) process quality can be differentiated into global (e.g., climate, care routines) and domain-specific contents (e.g., literacy, numeracy) (e.g., Cullen, 1999). Assumptions about the potential of certain experiences that foster children's cognitive development (e.g., pretend play, literacy) can be made with reference to "high-yield-activities" (e.g., Layzer & Goodson, 2006). The crucial role of preschool teachers in encouraging children in a developmentally appropriate manner is often specified with concepts such as "scaffolding" or "sustained shared thinking" (e.g., Siraj-Blatchford, 2009; Wood & Wood, 1996). Despite this substantial body of information for understanding the features of educational process quality only few studies have investigated a strongly theory-based conceptualization of rated process quality on target-child-level, especially with emphasis on domain-specific theories. Furthermore, considering the target-child-level there is still a knowledge gap about the relation between rated process quality on the one hand and observed children's activities (in terms of high-yield-activities) and preschool teachers scaffolding behaviours on the other hand. Therefore the study addresses two research questions: How can the rated educational process quality on target-child-level be conceptualized? How do the observed activities of children and preschool teachers covary with the process quality?

The study refers to data from the longitudinal study BiKS (educational processes, competence development and selection decisions in pre- and primary school age). Data from the first (spring 2006, $n = 102$ children), second (spring 2007, $n = 99$ children) and third year of preschool (spring 2008, $n = 96$ children) are used. In all, 132 children and 64 teachers from 51 preschools in the German federal states Bavaria and Hesse participated. Educational process quality on target-child-level was captured with a standardized time-sampling observation and rating instrument (Target Child Observation; Kuger, Pflieger & Rossbach, 2006a; 2006b). The Target Child Observation allows documentation of the daily experienced activities of individual target children in preschool classes. Several areas are taken into account (e.g., activities of the target child, role of the preschool teacher). Moreover, the Target Child Observation considers specific "domains of support", which represent several contents (e.g., literacy- and numeracy-related abilities), that can be supported by different activities (e.g., pretend play, gross motor). The coding procedure assumes that on a typical morning (8 a.m. to noon), two target children per preschool class were each observed three 20 consecutive one-minute intervals. Trained observers coded the frequencies of specific target-child- and preschool-teacher behaviours. If children and teacher were involved in more than one activity, the predominant activity was coded. With respect to the domains of support, a maximum of six domains could be coded per one-minute interval. Every 20-min period is supplemented with a 10-min block for rating the educational quality of the preceded observation phase on a seven-point scale from 1 ("inadequate quality") to 7 ("excellent quality"). Once the whole 30-min period was completed for the first child, observers shifted to the second child for the next 30-min period. This procedure was repeated three times. For conceptualizing the rated process quality a four-factor-model with two global factors with an emphasis on promotion of social and general cognitive abilities and two domain-specific factors emphasizing the promotion of literacy- and numeracy-related abilities was specified with confirmatory factor analysis (e.g., Brown, 2006; Bollen, 1989). For investigating the relationship between process quality and children's and teacher's activities, four theory-based clusters of children's and teacher's activities were created: "high-yield-activities" (e.g., pretend play, blocks), "high yield domains of support" (e.g., oral language, counting), "other domains of support" (e.g., gross motor, music), and "scaffolding" (role of teacher: e.g., helping, encouraging). The impact of children's and teacher's activities on the rated process-quality was examined cross-sectional using multiple regression analysis and longitudinal conducting conditional change score models (e.g., Menard, 2002; Finkel, 1995). Results support the hypothesized four-factor-model with focus on global and domain-specific contents. The specified model fits best in the first and third year of preschool and somewhat poorer in the second year indicating interference and change in the internal structure of educational process quality, especially with respect to the increasing importance of literacy- and numeracy-related contents for the day-to-day experiences of the target children which begins at that time. Teacher's scaffolding-behaviours and children's experiences, which can be subsumed under a "high-yield-activity" approach, covary with educational process quality. The cross-sectional and longitudinal results reveal, that scaffolding behaviours and high yield domains of support are positively related to the level of the global and domain-specific process quality and on its change over time, whereas the relation of the "other domains of support" is more often negative. To summarize, the study provides further evidence for the differentiation between global and domain-specific quality and the importance of activities representing scaffolding- and high-yield-activities-concepts for the educational process quality. The findings clearly stress the crucial role of preschool teachers, demanding a stronger emphasis on "scaffolding"-behaviours towards the children with goes along with a provision of a wide range of cognitive challenging high-yield-tasks.

PAPER PRESENTATION

Transition to primary school in Germany

Gabriele Faust, University of Bamberg, Germany; Jens Kratzmann, University of Bamberg, Germany; Franziska Wehner, University of Bamberg, Germany

Embedded in the longitudinal study BiKS 3-8 parents and teachers rated if school beginners had psychosocial problems respectively if they managed to start school successfully. Parents' ratings showed that except physical problems the psychosocial problems under study (anxiousness/ depression and attention problems) already prevailed nine and three months before school entry. Contrary to the widespread "Transition view" and in accordance with the "paradoxical theory" of Caspi and Moffitt and their coworkers these results point to rather long lasting personality and behavior problems and not to short term maladaptation during school start. Boys, the younger ones of the cohort starting school concordant with the official age regulations and children with poor prior knowledge were identified to start school less successfully. Transition programs therefore should not be limited to a short time period around school entry, but should start earlier. During the first weeks in school special attention should be given to the mentioned groups at risk.

Theoretical Background

General pedagogic and elementary school literature views school enrolment as an important and often problematic turning-point for a child and its parents (Griebel & Niesel, 2004; Speck-Hamdan, 2007; Brostßm, 2007; Margetts, 2000). One third to half the children are supposed to have transition problems (Griebel & Niesel, 2004; Grotz, 2005; Beelmann, 2000; Kienig, 2002).

The national and international accepted theoretical concept is the Transition Theory (Griebel & Niesel, 2004). It poses that school enrolment is one of the "critical, normative life events" which is tied to new challenges and is accompanied by a profound restructuring of identity (Filipp & Ferring, 2002; Griebel & Niesel, 2004). To help children in coping with those upcoming changes institutions like the family, kindergarten, and elementary schools should communicate about the transition in terms of a co-construction and accompany it with cooperation measures (Griebel & Niesel, 2004; Niesel, 2007; Margetts, 2003). National empirical research is rare, only a few and smaller international studies focused on the relationship between cooperation and school enrolment (Bowes et al., 2009; Brostrßm, 2000; Fabian, 2000). Next to cooperation measures family-factors and protective-factors on the child level should be included (e.g. high self-esteem or high social competence).

Because of rare existing empirical evidence and an existing alternative theory for explaining crisis-laden developments the Transition Theory should be questioned. According to the 'paradoxical' theory by Caspi and Moffitts, changes in personality and newly developing patterns of behavior are especially unlikely in periods of transition. Instead of changes, already-existing person-specific tendencies and familiar behavior are activated and reinforced (Caspi & Moffitt, 1993; Beelmann, 2006).

Thus, this paper is concerned with the following questions:

1. Do children show signs of "school enrolment crises"? How many children are thereby affected?
2. Which individual and/or contextual factors predict "school enrolment crisis"?
3. Which individual and/or contextual factors foster a successful school enrolment?

Method

This paper is based on data from the DFG research group BiKS ('Educational Processes, Competence Development and Selection Decisions in Pre- and Primary School Age') in Germany. The BiKS study analyses preconditions and processes of competency development in pre- and elementary school age as well as decisions involving the transition from kindergarten to elementary school. The longitudinal study started with 547 children at age 3 and data is collected every six months in spring and autumn. Our analyses are based on parents' and teachers' ratings. Measures are taken from child-centered questionnaires.

Three of the seven syndrome scales from the Child Behavior Checklist 4-18 by the research group CBCL (Dßpfner et al., 1998) were used to evaluate possible "school enrolment crises": Anxious/Depressed, Attention Problems and Somatic Complaints. The measurement was done nine months and three months prior to and three months and nine months after school enrolment.

Successful coping with school entry was measured with three scales after school enrolment. With regard to the FEES 3-4 (Measurement of Emotional and Social School-Experiences of Elementary School Children; Rauer & Schuck, 2003), questions on autonomy, willingness for exertion, and joy of learning were developed.

As causal variables characteristics on the family and child level as well as characteristics on the institutional level were taken into account. On the family level, the educational background of the parents was included in the analyses. On the child level, age upon school entry, gender and mathematic skills (K-ABC, Kaufman & Kaufman, 2003) prior to school enrolment were used. On the institutional level, the quality of the kindergarten was included which is measured by the kindergarten assessment scale (KES) (Tietze et al., 2007). Cooperation of kindergarten and elementary school is measured by questions about the child's participation in cooperation activities. Regression models were used to determine the occurrence of psychosocial "school enrolment crises" and a successful school entry by the influence of individual and contextual characteristics.

Results

Our analyses show that psychosocial problems do not initially arise in the context of school enrolment. The strongest predictors are the autoregressors, i.e. the same problem occurs at least nine months prior to school enrolment. Therefore, these are not "school enrolment crises" but continues personality- or behavioral problems. These findings are incompatible with assumptions of the Transition Theory. Rather, the theoretical concept of Caspi and Moffitt is reinforced: Not a missing "transition competence" is responsible but relatively stable personality traits and behavioral patterns that lower or foster the ability to take advantage of learning possibilities in kindergarten and elementary school.

The analyses of psychosocial problems as well as those of an unburdened, successful school entry show similar risk- and protective factors. Mostly, and with high impact, they occur at the level of individual characteristics. Gender, age upon school entry and precursory skills at preschool age have a strong influence. Boys start school less successful than girls. Older preschoolers cope better with school enrolment than younger children. Precursory skills have a preventive effect as regards to attention problems. They also predict autonomy and willingness for exertion.

Furthermore the global quality of the kindergarten prevents anxious-depressive adaption problems. On the other hand the transition accompanying measures in the context of cooperation between kindergarten and elementary school do not prevent psychosocial problems nor do they support an unburdened school entry. Based on these results, it is not advisable to focus accompanying measures too much on the period of the transition and on all preschoolers equally. If relatively stable personality traits and long-term behavioral problems rather than an assumed "transition competence" are responsible for a difficult school entry, it seems more important to foster the further development of the child as early as possible in the day-care center. Special attention needs to be given to first graders who are male, youngest, and have limited precursory skills.

PAPER PRESENTATION

Associations Among Achievement Goal Orientations, Emotions, and Self-efficacy

GONUL SAKIZ, MARMARA UNIVERSITY, Turkey

This study explored the associations among perceived mastery and performance approach goal orientations, academic enjoyment, academic anxiety, and academic self-efficacy beliefs reported by Turkish college students. A self-report survey was administered to 100 third-year undergraduate students taking Statistics course in a teacher training department of a major teaching and research university in Istanbul, Turkey. Structural equation modeling was used for data analysis. The results showed that mastery approach goal orientation was significantly positively related to academic enjoyment and academic self-efficacy beliefs and significantly negatively related to academic anxiety reported by students. Performance approach goal orientation, on the other hand, was significantly positively related to academic anxiety and academic self-efficacy. Academic anxiety was significantly negatively associated with academic self-efficacy. No significant association were detected between performance approach goal orientation and academic enjoyment and between academic enjoyment and academic self-efficacy. Overall, the structural model explained 21% of the variance in students' academic enjoyment, 22% of the variance in academic anxiety, 60% of the variance in academic self-efficacy beliefs.

Literature Review

Goal orientations influence students' attitudes toward learning. Students in learning environments adopt different goals. There are two major goal orientations identified in academic environments. One is mastery (intrinsic, learning) and the other is performance (extrinsic) goal orientation. Research shows that students who adopt mastery oriented goals use more effective learning strategies and prefer more challenging tasks whereas students who adopt performance oriented goals use less effective learning strategies and prefer easy tasks (Ames & Archer, 1988). Mastery oriented students focus more on learning, development, improvement, and understanding whereas performance oriented students focus more on doing better than others, demonstrating behaviors that would lead to public recognition, praise, and positive attributions toward one's ability (Ryan, Pintrich, & Midgley, 2001). Elliot and

McGregor (2001) subcategorized mastery and performance goals as approach and avoidance goals. Individuals who adopt approach goals aim at approaching success and desired outcomes whereas those who adopt avoidance goals aim at avoiding failure. For example, students adopting performance approach goals may aim at doing better than others or wishing to be perceived more able than others while students adopting performance avoidance goals may aim at avoiding seen less able than others. Students adopting mastery approach goals aim at understanding the subject content and improving the acquisition of new skills while students adopting mastery avoidance goals try to avoid failing to comprehend the content or material and acquisition of skills. Avoidance goals in general are accompanied by anxiety, distress and worry towards the new challenge. Although there has been a few research conducted in the past to investigate the influence of goal orientations on students' academic emotions and academic self-efficacy beliefs, the participant selection in those studies were dominantly limited to middle school students especially studying in the United States. Therefore, exploring the associations among given variables through the consideration of different developmental levels and cultures by using diverse methodological techniques would be beneficial. Besides, understanding the consequences of different types of goal orientations on college students' emotional and motivational outcomes would help us develop better instructional designs stimulating the development or enhancement of proper goal orientations for students.

Research Question

The current study examined the following research question: What are the relationships among Turkish undergraduate students' achievement goal orientations and their reported academic enjoyment, academic anxiety, and self-efficacy beliefs? For this exploration, only mastery and performance approach goals were included in the investigation because research reports reveal more influential role of approach goals on motivation and learning and, therefore, recent studies mainly use approach goals in their investigations (Phan, 2010). Besides, because avoidance goals include emotional features like worry, distress, fear, and/or anxiety within them, there would be a strong association among avoidance goals and emotional factors included in the structural design and would cause overlooking at other potential significant associations among variables.

Method

Participants and Procedure

One hundred junior college students majoring in Education in a university in Istanbul, Turkey participated in the study. The average age of participants in the study was 21.60 (SD = 1.74). Because the particular department involved in this study mainly preferred by female students a greater number of female students (n = 91, 91%) than male students (n = 9, 9%) participated. Students responded to the survey items with respect to their Statistics course. Each item was responded on a 7-point Likert type scale ranging from "not at all true of me" to "very true of me".

Goal orientations. Three items in mastery approach goal orientation subscale and two items in performance approach goal orientation subscale were taken from the Achievement Goal Orientations Questionnaire (Elliot & Murayama, 2008). **Academic anxiety.** Three items in academic anxiety subscale were taken from the Academic Emotions Questionnaire (AEQ, Pekrun, Goetz, & Perry, 2005). Five items in this subscale were taken from the Reactions to Tests (RTT) scale (Sarason, 1984). One item was taken from the Motivated Strategies for Learning Questionnaire (MSLQ, Pintrich, Smith, Garcia, & McKeachie, 1991, 1993).

Academic enjoyment.

Four items in academic enjoyment subscale were taken from the Parental Locus of Control Scale (PLOCS, Campis, Lyman, & Prentice-Dunn, 1986). Self-efficacy. Six-item self-efficacy subscale was taken from the Motivated Strategies for Learning Questionnaire (MSLQ, Pintrich, Smith, Garcia, & McKeachie, 1991, 1993). Data Analysis Structural equation modeling (SEM) was performed using AMOS. Results The internal consistency reliability estimates for the Mastery Goal Orientation ($\alpha = .830$), the Performance Goal Orientation ($\alpha = .809$), the Academic Anxiety ($\alpha = .929$) the Academic Enjoyment ($\alpha = .915$), and the Academic Self-efficacy ($\alpha = .886$) were all satisfactory. The Measurement Model

The full measurement model provided an adequate fit to the data. The factor correlations are presented in Table 1. The Structural Model The hypothesized model provided an adequate fit to the given data [$\chi^2(240, N = 100) = 436.765$, $p = .00$, CFI = .967, TLI = .959, RMSEA = .091 (with 90% CI lower bound = .078 and upper bound = .105)]. As depicted in Figure 2, mastery approach goal orientation was significantly positively related to academic enjoyment [$b = .448$, $p < .05$]. Academic enjoyment was not significantly associated with academic self-efficacy [$b = .059$, $p > .05$]. Academic anxiety was significantly negatively related to academic self-efficacy [$b = -.242$, p

Educational Implications Nurturing mastery approach goal orientation in teacher training programs is especially important. Teacher goal orientations have been reported to have significant influence on students' adopted goal

orientations (Roeser et al., 1998) which means the more mastery oriented the teacher, the greater possibility that their students will become the mastery oriented. Therefore, the instructors in teacher training departments need to put more emphasis on mastery goal orientation by encouraging challenge, effort, participation, understanding, interaction, and peer collaboration.

PAPER PRESENTATION

The mediating role of mastery goals between the learning environment and school investment

Jaap Schuitema, University of Amsterdam, Netherlands; Thea Peetsma, University of Amsterdam, Netherlands;
Ineke van der Veen, University of Amsterdam, Netherlands

This study investigated the relationship between developments in students' mastery goals, their perception of the learning environment and their investment in school. Mastery goals have been associated with several positive outcomes, such as effort and persistence in learning and may, therefore, be an important mediating factor in the relationship between the learning environment and school investment. 648 first year students in secondary education participated in the study (age 12). A self-report questionnaire was administered four times. The first measurement was at the start of secondary education, the second half way through the first year, the third measurement at the beginning of the second year of secondary education and the fourth half way through second year. The questionnaire included scales to assess investment in maths and English and mastery goals concerning maths and English. In addition, two aspects of the learning environment were measured: students' perceptions of autonomy support and the extent to which teachers stressed the relevance of what is being learned. The results indicate that developments in students' perceptions of the learning environment during the first year of secondary education were positively related to developments in both mastery goals and school investment. Further analysis showed that mastery goals partly mediated the effect of the learning environment on students' investment in school.

It is increasingly recognized that the learning context is an important factor in explaining students' motivation for school (Pintrich, 2004). Several aspects of the learning environment, such as autonomy support and the emphasis given by teachers to the relevance of what is being learned, have been found to have a positive effect on students' motivation and learning behaviour (e.g. Assor Kaplan & Roth 2002). In addition, research has identified individual motivational factors that affect learning behaviour in school. The higher students' mastery goal orientation the more they self-regulate their learning and the higher their academic achievement (Urdu & Midgley, 2000). Little is known, however, about how these aspects of the learning environment and students' mastery goals are related to each other. Even less is known about how these relationships develop over time. In this longitudinal study we aimed to give more insight into the relationships between developments in students' mastery goals, their perception of the learning environment and their investment in school. We investigated to what extent the development in mastery goal orientation mediates the effect of the learning environment on school investment.

Theoretical background

Achievement goal theory proposes a distinction between mastery goals and performance goals (Schunk, 1996). Mastery goal oriented students focus on the mastery of learning tasks and developing competence. In contrast, performance oriented students are concerned with demonstrating their ability to others. Mastery goals more than performance goals have been associated with several positive outcomes, such as effort and persistence in learning (Wolters 2004). Mastery goal orientation, therefore, may be an important mediating factor in the relationship between the learning environment and students' investment in school. In this study we focused on two aspects of the learning environment that we expected to be related to a mastery goal orientation and investment in school. The first aspect is the amount of support for student autonomy. Students need a sense of freedom of choice about their own learning process. Autonomy for students is considered to promote their interest in learning and their focus on the mastery of skills (Deci & Ryan, 2000). Secondly, we argue that students are more inclined to adopt a mastery goal orientation if they perceive what is being learned as relevant to their own lives. It is important for teachers to help students understand the relevance of a certain learning task to themselves and to relate the content to their prior knowledge.

Method

648 students in secondary education participated in the study. The students were from all levels of secondary education and at the start of the study the students were on average 12 years old. A self-report questionnaire was administered four times: The first at the start of secondary education, the second half way through the first year, the third measurement at the beginning of the second year of secondary education and the fourth half way through second year. All items in the questionnaire were rated on 5-point Likert scales. Perceived autonomy support was measured with the short form (six items) of The Learning Climate Questionnaire (William & Deci, 1996). To measure the emphasis given by teachers to the relevance of what is being learned we combined three items from the Teacher

as a Social Context questionnaire (TASC; Belmont, Skinner, Wellborn & Connell, 1988) with three items of a scale measuring 'connection to students' worlds' adapted from Thoonen, Slegers, Peetsma and Oort (in press). As most motivational constructs show subject-specificity, we investigated mastery goals and students' investment concerning two different subjects. Maths and English were selected because all students take these subjects, and they are usually considered important. We used five items of the school investment scale from Roede (1989) to assess, maths investment and English investment. This scale measures the onset of student action, the degree of intensity of action and perseverance with the action. Mastery goal orientation was also measured for both maths and English. We used the scale 'task orientation' of the Goal Orientation Questionnaire of Seegers, van Putten and de Brabander (2002). The data were analysed using multivariate latent growth curve modelling with Mplus. The rate and level of growth of the different variables were related to each other. We examined models in which the effects of changes in perceptions of the learning environment on developments in school investment are mediated by developments in mastery goal orientation. We fitted separate models for maths investment and English investment and we controlled for gender and ethnic background differences and school level.

Results

The data of the first two measurements in the first year of secondary education have been analysed. The results indicate that developments in students' perceptions of the learning environment were positively related to developments in both mastery goals and school investment. Moreover, further analysis showed that mastery goals partly mediated the effect of the learning environment on students' investment in school. An additional direct effect of emphasis on relevance was found on maths investment and an additional direct effect of autonomy support on English investment. In the paper we include the analyses of the third and fourth measurement.

PAPER PRESENTATION

Investigating the link between social goals and learning strategies

Ronnel King, The University of Hong Kong, Hong Kong; Dennis McInerney, Hong Kong Institute of Education, Hong Kong; David Watkins, University of Hong Kong, Hong Kong

Research in cross-cultural psychology has indicated that people from different cultures are motivated by different types of goals. In collectivist cultures, the power of social goals may be especially salient. However, studies on student motivation usually focus only on two types of goals: mastery and performance goals, thus neglecting the potential role of social goals. The aim of the present study was to investigate how different types of social goals, i.e. social affiliation, social approval, social concern, and social status goals were related to learning strategies in a collectivist culture. 697 secondary students from Hong Kong answered the relevant questionnaires. Results indicated that social concern and social status goals were the most adaptive type of social goal. Implications are discussed.

Introduction

Achievement goal theory has become a dominant paradigm for examining student motivation (see Maehr & Zusho, 2009 for review). However, a weakness of this body of research, particularly that emanating from goal theory, is that it limits itself to examining two types of goals, usually mastery and performance goals, while failing to account for social goals, which may also be powerful constructs in explaining student motivation. This might prove constricting given that research has shown that students pursue multiple goals in the classrooms (Boekaerts, 2009) and that schools are inherently social domains (Martin & Dowson, 2009). Moreover, this limitation is even more glaring in the collectivist Chinese cultural context where academic motivation is inherently social (Yu & Yang, 1994). A better model for examining a range of goals and their potential impacts is Personal Investment Theory (Maehr & Braskamp, 1986; Maehr & McInerney, 2004) which posits a broader range of goals including task, ego, social solidarity and extrinsic goals, with the latter three having a social dimension.

The aim of this paper is to examine how four different types of social goals (social affiliation, social approval, social concern, and social status) drawn from Personal Investment Theory influence adaptive and less adaptive learning strategies (deep, surface, and achieving) in a collectivist non-Western context.

Method

The respondents were 697 Hong Kong secondary school children. To measure their social goals and learning strategies, the students were given two self-report instruments: the Chinese versions of the Inventory of School Motivation (ISM-C) (Watkins, McInerney, & Lee, 2002) and the Learning Process Questionnaire (LPQ, Biggs, 1992).

Social goals. Four types of social goals were measured using the ISM-C:

- O Social Affiliation: Interest in belonging to a group when doing schoolwork (e.g. "I can do my best work at school when I work with others.")
- O Social Approval: Seeking praise and recognition for schoolwork (e.g. "At school I work best when I am praised.")
- O Social Concern: Concern for other students and a willingness to help them with their school work (e.g. "It is very important for students to help each other at school.")
- O Social Status: Seeking social power and status through schoolwork (e.g. "I work hard at school to be put in charge of a group.")

Learning strategies. Three types of learning strategies were measured using the LPQ

- O Deep Strategies: Understanding what is to be learnt through inter-relating ideas and reading widely (e.g. "I try to relate what I learn in one subject to what I have learned in other subjects.").
- O Surface Strategies: Reproducing bare essentials often using rote learning (e.g. "In most subjects I try to do enough just to make sure I pass, and no more.").
- O Achieving Strategies: Securing high performance by using regulatory schemes like study skills, time management, and exam-oriented techniques (e.g. "When a test is returned, I correct all the errors I made and try to understand why I made them.").

In the preliminary analysis, we first examined the descriptive statistics and alpha estimate of internal consistency for each scale. We used structural equation modelling (SEM) to test the relationship between social goals and learning strategies with social goals as predictors. We began by establishing the measurement portion of the model within a CFA framework (Anderson & Gerbing, 1988) and then proceeded to the full SEM.

Results

The internal consistencies (α) of all measures were all acceptable (range of $\alpha = .66 - .84$) except for the surface strategies scale ($\alpha = .54$). The measurement model indicated good fit to the data ($\chi^2/df = 2.70$, $p < .001$, CFI = .922, TLI = .903, RMSEA = .049). The correlations show that almost all the social goals were unrelated to surface learning strategies, while being positively related to both deep and achieving learning strategies.

Personal Investment Theory claims that students' goals are proximal predictors of various learning strategies and other educational outcomes (see Maehr & McInerney, 2004;). Consistent with this line of reasoning, we hypothesized that social goals would act as predictors of different learning strategies. We first tested a model where all the social goals had paths going to the three types of learning strategies.

Results indicated that Model 1 ($\chi^2/df = 2.704$, $p < .001$, CFI = .922, TLI = .903, RMSEA = .049) fit the data well; however there were some non-significant paths. We deleted these non-significant paths and came up with Model 2 ($\chi^2/df = 2.656$, $p < .001$, CFI = .921, TLI = .905, RMSEA = .049). Since Model 2 was nested within Model 1, we performed a chi-square difference test (Loehlin, 2004). Results indicated that Model 2 was not significantly different from Model 1 (change in $\chi^2 = 10.545$, change in $df = 7$, $p = .59$), thus we adopt Model 2 since it is more parsimonious (See Figure 1).

The final model indicates that social concern goals are positive predictors of deep and achieving strategies and negative predictors of surface learning strategies. Social status goals are positive predictors of deep and achieving strategies. Social affiliation and social approval goals were not significant predictors of any of the learning strategies.

Conclusion

The aim of this study was to explore how different types of social goals are related to various adaptive and less adaptive learning strategies. Social concern and social status goals were positively related to deep and achieving strategies and social concern negatively related to surface strategies. Apart from this latter finding no other social goal was related to surface strategies. Neither social approval nor social affiliation goals were related to any of the learning strategies. Of the social goals considered, only two appear to exert a proximal influence on the learning strategies that students adopt.

These findings will be elaborated upon in the PAPER PRESENTATION, with implications for practice and research being drawn.

PAPER PRESENTATION

Students' multiple goals in the classroom: an exploratory study on goal salience and motivation

Karin Smit, University of Leiden, Netherlands; Monique Boekaerts, Leiden University, Netherlands; Frank Busing, Leiden University, Netherlands

The goals that students pursue in the classroom influence their educational outcomes and well being. Recently, several researchers (e.g. Boekaerts, 2008) urged to shift the focus from studying learning goals to a range of goals for a better fit between goal theory and students' reality. In this study 487 students from pre-vocational secondary education completed the Goal Identification and Facilitation Inventory (Boekaerts, 2009), registering students' preferences for 16 different types of goals, based on Ford and Nicholl's goal taxonomy. The Intrinsic Motivation Inventory (Ryan & Deci) is used to determine students' motivation. Multidimensional unfolding techniques and first order correlations revealed the empirical structure of goals. Preliminary results show that ego goals (superiority, individuality, material gain) are ranked least important and show no relation or a negative relation with motivation. Students rank personal wellbeing goals as most important. These goals are moderately related to motivation. Goals connected with learning are ranked in between personal wellbeing goals and ego goals. Their relation with motivation is relatively strong. These results will be completed in January 2011 using additional restricting variables in the unfolding model to make the interpretation more profound (Busing, 2010). Furthermore, a cross validation will test the results that are obtained by the unfolding analyses. The consequences of these findings for interventions to utilize students' goal preferences in the classroom and to bridge the gap between non-learning goals and learning goals will be discussed.

Extended summary

Aims

In pre-vocational secondary education, interest in schoolwork does not always come naturally. To enhance students' motivation, teachers try to provide students with goals related to school activities. Urdan (2004) argued, however, that many teachers send mixed and contradictory goal messages. Apparently, we have little knowledge about the multiple goals that students bring into the classroom and how they interact. Therefore, we need a shift from studying a single type of goal (learning goals) to a wider range of goals.

Boekaerts (2008) developed the Goal Information and Facilitation Inventory (GIFI) based on Ford and Nicholl's taxonomy of goals, to examine 16 different types of goals, including learning goals, personal wellbeing goals, task goals, social goals and ego goals. This study aims to further develop the goal model proposed by Boekaerts.

Method

Sample. A sample of 487 students (211 boys, 256 girls, 20 missing) from the third and fourth years of pre-vocational secondary education across four schools in an urban area in the Netherlands took part in this study. Students were on average 16.1 years old ($SD = .82$).

Instruments. Students received a self report questionnaire (GIFI) and made a ranking order with the 16 types of goals from most important to least important. These goals are Tranquility (I don't want to feel stressed at school), Equity parents (I want to get along with my parents), Belongingness (I want to be liked by classmates), Positive self evaluation (I want to feel good about myself), Social responsibility (I want to be respectful to classmates and teachers), Self determination (I want to have a choice in what I do at school), Management (I want to be organized), Mastery (I want to understand the learning material), Resource acquisition (I want to receive help when I need it), Material gain (I want to have pretty clothes), Resource provision (I want to give help to classmates when they need it), Safety (I don't want to take risks), Individuality (I want to be different), Entertainment (I want schoolwork to be fun), General equity (I want to keep my promises) and Superiority (I want to be better than others).

Motivation was measured using the Intrinsic Motivation Inventory (IMI) by Ryan & Deci with four items on Pleasure (e.g., I think schoolwork is interesting), Cronbach's alpha was .90, and five items on Effort (e.g., 'I put a lot of effort into schoolwork'). Cronbach's alpha was .70. Both scales were scored on a five point Likert scale from 'I fully agree' (5) to 'I don't agree at all' (1).

Analyses

Multidimensional unfolding is an exploratory technique and results in a spatial configuration in which the preference from each student for each goal is taken into account to determine which of the 16 goals are most dominant in the ranking and which goals are negligible in terms of the ranking (Busing, 2010). A first order correlation analyses is used to look at the relations between goals and motivation.

The unfolding method showed that most students in our sample ranked the personal wellbeing goals Equity parents and Positive self evaluation as their most important goals. Both goals are weakly related to motivation. Ego goals (Superiority, Individuality, Material gain) were ranked as least important by most students. This is in accordance with Boekaerts (2008) who found a clear distinction between ego goals and the other goals that students bring into the classroom. Furthermore, Superiority showed no relation with motivation. Material gain showed a very weak, negative

relation with motivation. Individuality also showed a very weak, negative relation with Effort. Goals connected with learning (e.g. Mastery, Management) were ranked in between personal wellbeing goals and ego goals. Their relation with motivation is relatively strong.

The results of this study will be completed in January 2011 using additional restricting variables in the unfolding model (Busing, 2010), showing the position of pleasure and effort in relation to the multiple goals. Furthermore, results that are obtained by the unfolding analyses will be tested by means of a cross validation.

Discussion

It is clear that wellbeing, especially related to oneself and to parents, is important to students. Goals related to learning, on the other hand, are not very prominent, even when reported in a school context. In the light of the Dual Processing Self-regulation Model (Boekaerts & Niemivirta, 2000) these are important findings. According to this model students who are mainly concerned with their wellbeing, are active on the wellbeing path, using their energy to prevent negative events from occurring in the learning environment (prevention focus). Students, who are mainly concerned with learning and task related goals, focus on learning and mastery goals and are active on the mastery path.

This study enables us to set up interventions to help students to become aware of the goals they bring into the classroom and how these goals are entangled, and focus on volitional strategies and coping strategies that students can use to shift their attention from the wellbeing path to the mastery path. We assume this will enhance and increase students' motivation, persistence and achievement.

PAPER PRESENTATION

Strategies of selection, optimisation, and compensation of teachers over their career cycle

Anja Philipp, University of Frankfurt, Germany; Mareike Kunter, Goethe-University, Institute of Psychology, Germany

Approximately one-third of German teachers feel burned-out (Schmitz, 2004). At the same time, 17% of the 7600 German teachers Schaarschmidt and Kieschke (2007) investigated feel engaged. Continuous exposure to the demands associated with teaching can take its toll and if teachers are not able to conserve their resources they might burn-out. The theory of selective optimisation with compensation (SOC; e.g. Baltes & Baltes, 1989) states that individuals who allocate their resources effectively are able to counterbalance demands. The question arises which SOC strategies teachers use to invest their resources so that they can remain engaged. The goal of this study was to investigate whether teachers increasingly focus on their primary goals and give up related tasks (selection), optimise their time spent on preparation, correcting tests or evaluation of students and compensate by appreciating cooperation with colleagues. Results from a questionnaire study in which 1748 German teachers reported on their professional activities and well-being indicate that the number of tasks teachers engage in does not change over the career cycle. However, there seems to be a shift in the priority of tasks and a selection occurs. More experienced teachers rather spend more of their time for administrative tasks than for activities such as excursions or school projects. The results indicate that it is necessary to have a flexible system at each school which allows teachers from the age of 55 to spend more time on selected tasks (e.g. administrative tasks).

Approximately one-third of German teachers feel burned-out (Schmitz, 2004). At the same time, Schaarschmidt and Kieschke (2007) show that 17% of the 7600 German teachers they investigated feel engaged. The question arises if teaching leads inevitably to burnout or if it is possible for teachers to invest their resources in a way so that they

remain engaged. The theory of selective optimisation with compensation (SOC; e.g. Baltes & Baltes, 1989) states that individuals who allocate their resources effectively are able to counterbalance demands. First, individuals can select certain goals they want to achieve. Teachers could focus on teaching itself as the primary task of their profession and give up other related activities such as going on excursions, taking part in school projects or to supervise students during their breaks. Second, SOC theory points out that individuals can choose how they allocate or optimise their resources to achieve their goals. Teachers as knowledge workers could optimise their time spent on preparation for class, time spent on correcting tests or evaluating students. And third, individuals can compensate for lost resources by using alternate means to achieve their goals. Teachers could rely more on cooperation with their colleagues as a buffer against constantly high demands. With increasing age, the continuous exposure to the high demands associated with teaching can take its toll and if teachers are not able to conserve their resources successfully they might burn-out. The following research question arises: Do teachers increasingly focus on their primary goals and give up related tasks, optimise their time spent on preparation, correcting tests or evaluating students and compensate by being ready to cooperate with colleagues with increasing age?

Method:

Sample 1748 of the 1940 teachers who took part in the first wave of the COACTIV study ("Professional Competence of Teachers, Cognitively Activating Instruction, and the Development of Students' Mathematical Literacy") are the basis for the current analysis. COACTIV is a complementary study to the German PISA study (wave 2003/2004). The mathematics teachers of the PISA pupils filled in questionnaires on different topics such as their professional competence or well-being. Teachers came from 198 schools which were representative of German secondary schools in terms of state and school track; they were 25 to 65 years old ($M=47.25$; $SD=9.35$) with a high percentage of older teachers (48% > 50 years); 49.8% of them were female and 71.2% worked part-time. 192 questionnaires had to be discarded due to more than 30% of missing values in the relevant variables. Missing values of the remaining participants were imputed using expectation-maximisation algorithm (EMA) by the Software Norm (version 2.03). Instruments A list of tasks (individual preparation, preparing and correcting tests, evaluating students, meetings, taking part in school projects, excursions, individual training, administrative tasks and school conferences) was provided and teachers were asked how many hours they spent on each task within one week. Also, a ratio was calculated to which percentage teachers spent their time each single activity and included in single regression analyses. Appreciation of cooperation in school was assessed with a scale especially designed for the COACTIV study containing 4 items. Items were prompted by the instruction: "What do you especially appreciate at your school?" (example: "the cooperation on pedagogical questions."). Statistical Analysis Regression analyses in Mplus (version 5) were conducted to examine changes with increasing age under control for school as cluster variable. To assess curvilinear changes, age square was calculated and included in the regression.

Results

Selection) With increasing age, there was no change in the overall number of tasks. At closer examination of the ratio of time spent on different tasks it became clear that with increasing age teachers spent more time on excursions, but then again a decline from the age of 55 (quadratic trend, $\beta_{age^2}=-0.49$; $p_{age^2}=.49$, $p_{age}=.09$, $p_{age}=.20$, $p_{age}=.11$, $p_{age}=.58$, $p_{age^2}=.48$, $p_{Optimisation}$) Teachers invested less time in the preparation ($\beta_{age}=-.58$, $p_{age}=.44$, $p_{Compensation}$) Teachers of all ages similarly appreciated cooperation. Discussion The number of tasks teachers engage in does not differ over the career cycle. Overall, there seems to be a shift in the priority of tasks and a selection occurs. The results indicate that teachers rather spend more of their time for administrative tasks than for activities such as excursions or school projects. There seems to be a trend away from the demands of teaching towards administrative tasks for teachers from the age of 55. Interestingly, they spend more time in meetings with parents which many teachers regard as quite demanding. Also, teachers as knowledge workers have the potential to optimise their time spent on preparation and by doing so they gain time to focus on other activities. Teachers of all ages appreciate cooperation similarly which can be regarded a resource. These results indicate that it is necessary to have a flexible system at each school which allows teachers from the age of 55 to select certain goals, e.g. by giving them more time for administrative tasks.

PAPER PRESENTATION

Measuring Procrastination in Fifth and Sixth Grade

Lisa Roese, Bergische Universität Wuppertal - Fachbereich G, Germany

A step towards the developmental perspective on procrastination behavior was explored in the current study by examining the interindividual tendencies of procrastinating behavior among students of fifth and sixth grade. In this study a slightly modified questionnaire by Helmke und Schrader (Aitken Procrastination Scale, Aitken, 1982, German translation by Helmke & Schrader, 2000) with additional items of Tuckman Procrastination Scale-Deutsch (TPS-D by Stßber, 1995) was administered to assess trait procrastinating behavior. $n=84$ participants rated the extent to which they engage in procrastinating behaviors. The test took place at school during a method training week (regarding learning strategies and not on how to prevent procrastination, so no impact on procrastinating behaviors was expected) and after an interval of four months. Procrastination behavior occurred on both occasions with statistically similar means and standard deviations $x_1=48.59$, $SD_1=10.74$ and $x_2=48.48$, $SD_2=10.20$, suggesting stability over a period of four-months ($T(80)=.118$, $p=.90$). The relationship between the whole scale of procrastinating behavior on occasion I and occasion II yielded a correlation of .67. The internal consistency of the whole scale was $\alpha=.76$ for both occasions. The factor analysis of procrastination on occasion I matched well regarding Helmkes & Schraders (2000) suggestion with three main factors, on occasion II the structure was different. Further research is required, especially regarding a larger sample.

Researchers have dealt with studies on procrastination since thirty years, including studies on correlates and the nomological web of procrastination, its consequences and up to designing intervention programs for procrastinators who suffer on their procrastination.

Steel (2007) summarizes the state of the art in his meta-analysis. Not yet examined is, at which age students start to procrastinate and how stable procrastination at this age is. Knowledge concerning the starting point of procrastination is important for developing guidelines on prevention of procrastination and successful intervention programs, e. g. at school.

Aim of this study was to identify procrastination within fifth and sixth graders and investigate its structure and long-term stability. The administered questionnaire consisted of 20 items of German translations of Aitkens Procrastination Inventory by Helmke and Schrader (2000) and of Tuckman Procrastination Scale (Tuckman, 1991; Tuckman Procrastination Scale-Deutsch, Stßber, 1995), using a five-point scale for responses which ranged from never to always. The items were slightly modified to make sure that all students understand each question and to relate the content to the students' school life and studying. To avoid acquiescence nine items had a reversed polarity. The test was administered twice at school with a retest interval of four months. A total of 84 students participated on both occasions.

Descriptives and Cronbachs Alpha were used to decide which items were applicable to measure procrastination in students at this age. T-tests for paired samples and Pearson's correlation coefficients were used to assess stability of items and total scores. Separate factor analyses were made for both occasions to identify the structure of procrastination. Two items were deleted for structural reasons during the analysis.

Procrastination occurred on both occasions with similar means and standard deviations regarding the total scores $1=48.59$, $SD_1=10.74$ and $2=48.48$, $SD_2=10.20$, suggesting an overall stability over a period of four months ($t(80)=.118$, $p=.90$). The item scores were also stable.

The correlation between the total scores on the two occasions was estimated at $r = .67$. Elliot had found a correlation of .77 with a hiatus of 10 years in his study (Elliot, 2002, cited in Steel, 2007).

The correlations between the items on occasion I and II varied between .25 and .58, with an average of .37. Correlations of 4 items of 18 were not significant (Item 3, Item 9, Item 11 and Item 13).

The internal consistency of the total scale was estimated at $\alpha=.76$ for both occasions. Deletion of another item wouldn't have improved the internal consistency any further.

Tuckman Procrastination Scale was regarded to be unidimensional (Tuckman, 1990). Helmke and Schrader (2000) put forth that a three-factor structure is adequate for their instrument, with Delay (e. g. "I postpone my tasks, even when I know they need to be done."), lack of foresight (e. g. "I use breaks in between classes to start doing my homework.")

and punctuality (e. g. "I'm late for class."). Tuckmans items matched the content of the first two factors of Helmke and Schrader (2000) and therefore, we expected a three-factor structure for our questionnaire.

Separate factor analyses for the data on both occasions were not entirely consistent with the suggestion that a three-factor structure is adequate for our instrument. In both our analyses (occasion I and II) we found a method factor with loadings of the items with reversed polarity. Items with reversed polarity to reduce acquiescence have to be carefully used with procrastination questionnaires with students of this age in further studies. With this sample, reversely polarized items influenced the factorial structure of the instrument.

Nevertheless, the instrument appears to be a reliable tool to repeatedly assess trait procrastination among fifth and sixth graders. The factor structure might be different in this sample with younger students, compared to university students. Further research regarding age differences in procrastination and stability is required.

PAPER PRESENTATION

Daily stressors and resources of beginning teachers: Content, appraisal & the role of self-regulation

Uta Klusmann, Christian-Albrechts-Universität Kiel, Germany; Mareike Kunter, Goethe-University, Institute of Psychology, Germany

The relevance of teachers' stress experiences to their health and to student outcomes has been demonstrated in various studies (Melamed et al., 2006; Klusmann et al., 2008). The present article aims to identify which work-related positive and negative events contribute to beginning teachers' stress on a daily basis. Additionally, we investigate whether personal teacher characteristics such as self-regulation skills are associated with the experience and with appraisal of these positive and negative events. The data base consists of daily reports obtained from 376 beginning teachers over 14 days. Results revealed that positive and negative events most often correspond to lessons given, preparation work or interactions with colleagues. Events that were appraised as particularly meaningful related to professional development and interaction with principals and mentors. While teachers' self-regulatory skills were related to the appraisal of the events, content and frequency of daily events were not. The results underline the importance of taking into account the day-to-day perspective, and of expanding research to the person-environment interaction rather than focusing exclusively either on personal or environmental characteristics.

Theoretical background and aims of the Study

Teaching is among the professions most often examined by researchers interested in negative emotional and motivational work-related experiences such as chronic stress and burnout (OECD, 2005; Klusmann et al., 2008; Schaufeli & Enzmann, 1998). Although burnout is conceptualized as a long-term consequence of job stress, previous research has shown that the first classroom experiences can already be particularly stressful (Fives, Hamman, & Olivarez, 2007; Veenman, 1984). In explaining motivational and emotional experience at work, previous research has mostly concentrated on either broad personality characteristics (e.g. self-efficacy or emotional stability) or on general characteristics of the work environment (e.g. work load, experience of support). In our study, we focus on the day-by-day experiences of beginning teachers and aim to identify daily stressors as well as resources for well-being. In so doing, we aim to learn more about the everyday situation of beginning teachers and to go beyond single-measurement assessment of the work environment. Additionally, we used an idiographic-nomothetic approach by applying an open answer format in order to avoid offering a particular set of resources and stressors. Based on Transactional Stress Theory (Lazarus & Folkman, 1984) we assume that particular personal characteristics influence the appraisal of daily stressors as well as resources. Previous research has suggested teachers' self-regulation to be of particular importance for occupational well-being (Klusmann et al., 2008). Based on Conservation of Resources Theory (Hobfoll, 1989), the optimal balance between work engagement and distancing oneself from one's work (resilience) is the most adaptive self-regulatory style in the work context (Hobfoll & Shirom, 2001). We thus address the following two research questions: (1) Which daily stressors do beginning teachers experience and what are their resources to cope with them? a. What is the nature of daily positive and negative events and how frequently do they occur? b. Does appraisal of positive and negative events depend on the particular nature of the reported event? (2) What role do teachers' self-regulation skills play in the experience of daily stressors and resources? a. Do teachers experience different stressors and use different resources depending on their self-regulatory patterns? b. Does teachers' appraisal of the stressors and resources differ depending on their self-regulation?

Method

Procedure

The present study is part of a larger project investigating the development of student teachers' professional competence in Germany. Participants in the main study were invited to take part in a 14-day online-diary study on their emotional and motivational experience. The sample consists of 376 student teachers in the first and

second year of the compulsory induction programme that follows the first, university-based, phase of teacher training in Germany (52% female, mean age = 27 years, SD = 4.2). On average, 291 student teachers completed an online questionnaire each day. Measures In a prequestionnaire Self-regulation was measured by the scales Engagement and Resilience from the Occupational Stress and Coping Inventory (AVEM; Schaarschmidt et al., 1999). Work engagement reflects the willingness to invest energy and time and resilience reflects the ability to distance oneself from work and to cope with failure. Latent profile analyses of the engagement and resilience subscales were used to identify the different self-regulatory patterns (Klusmann et al., 2008). In the diary phase participants were asked to name the positive and negative events occurring during the day. Afterwards, each event was appraised in terms of personal importance on a 4-point scale. The open answers were coded into 23 categories by two trained raters and further summarized into 8 categories for the present analysis.

Results

The participants reported a total of 10,512 work-related events. Of these, 4,261 were negative, 6,251 positive. The most frequent occurrence of positive events was "Within Lesson" (26%; e.g. "managed to handle the difficult eighth grader"), "Preparing Lesson" (17%; e.g. "good idea for my next maths lesson") and "Interaction with colleagues" (17%; e.g. "laughing with colleagues during break"). The most frequently reported negative events were related to "Within Lesson" (32%, e.g. "many interruptions during German class") and "Preparing Lesson" (30%, e.g. "did not finish my preparation"). However, not all events were appraised as equally important: Most important among the positive events was 'professional development in school' (e.g., "interesting lesson of my mentor observed", $M = 3.61$, $SD = .66$), 'Interaction with principals and mentors' (e.g. "positive feedback of my mentor", $M = 3.32$, $SD = .74$) and 'within Lessons' ($M = 3.12$, $SD = .70$). Out of the negative events the subjective meaning was highest among events in the same content categories: 'professional development in school' ($M = 3.27$, $SD = .69$), 'Interaction with principals and mentors' ($M = 3.54$, $SD = .58$) and 'within Lessons' ($M = 3.52$, $SD = .58$). Secondly, teachers' self-regulation was neither related to the overall frequency of positive and negative events nor to a particular content area. But teachers' self-regulation was related to the appraisal of the positive and negative events. On average beginning teachers with adaptive self-regulation, i.e., with high engagement and high resilience, rated positive events more important and negative events less negative than teachers who showed low resilience.

Discussion and Implications

The major aim of the present study is to gain deeper insights into student teachers' daily experience by going beyond single-measurement assessments of situational and personality characteristics. The results indicate, first of all, that the most frequent positive and negative events are not automatically the most important. Secondly, one and the same content area, e.g. preparation of lessons, can be stressful as well as uplifting. Thirdly, personal characteristics like teachers' self-regulation are relevant for the appraisal of everyday situations. The study has several implications for research and practice. Whereas most studies to date have focused either on personal or situational factors in the stress process, we considered the interplay between these factors. In practice, awareness of beginning teachers' typical daily stressors and resources can help to improve pre-service and in-service training and provide mentors and principals with valuable insights. PAPER PRESENTATION

Assessing Enterprise Capability in Secondary Schools

Peter Davies, University of Birmingham, United Kingdom; Amanda Hughes, Staffordshire University, United Kingdom

Three strands of enterprise capability have been identified in the literature: aspiration to run a (for-profit or not-for-profit) enterprise (e.g. Kourilsky and Walsatd 2007), self-efficacy towards enterprise (e.g. Shapero 1975, Zhao et al., 2005) and understanding factors likely to affect the success of an enterprise (e.g. Kourilsky and Walstad 2007). Previous research assessing students' enterprise capability have addressed one or two but not all three of these dimensions. This study presents a new tool for assessing enterprise capability in secondary schools which includes all three dimensions. Some key findings are (i) four subscales within enterprise self-efficacy: project planning; working with people and information; risk evaluation and management; pricing and profit; (ii) findings of previous research on the distinctiveness of (and gender differences in) aspirations towards for-profit and not-for profit organisations is supported; (iii) aspiration to running for-profit and not-for-profit organisations is significantly associated (through multivariate regression) with higher enterprise self-efficacy but only weakly associated with whether either parent owns their own business; (iv) the items measuring enterprise understanding displayed reasonable levels of discrimination except for those referring to sunk costs which higher scoring students believed were as relevant to decision-making as lower scoring students; (v) no statistically significant association was found between the measurement of 'enterprise' understanding and aspiration to run an organisation; (vi) There was a weak negative association ($p = .066$) between self-efficacy towards enterprise and the measure of enterprise self-efficacy.

Aims 1. To develop a new tool for assessing enterprise capability in secondary schools which includes dimensions for self-efficacy, aspirations, knowledge and awareness. 2. To investigate subscales within these dimensions and relationships between dimensions.

Methodology

Three strands of enterprise capability have been identified in the literature: aspiration to run a (for-profit or not-for-profit) enterprise (e.g. Kourilsky and Walsatd 2007), self-efficacy towards enterprise (e.g. Shapero 1975, Zhao et al., 2005) and understanding factors likely to affect the success of an enterprise (e.g. Kourilsky and Walstad 2007). This paper presents results from the development of an exploratory instrument which is sufficiently short to be practicable for schools to use to assess each of these three strands of enterprise capability. Previous self-efficacy scales in relation to enterprise (e.g. Zhao et al. 2005) have been developed for use with graduates, notably those enrolled on MBA programmes and have used a definition of enterprise which is restricted to 'for-profits'. Whilst drawing on this literature we have developed a new set of items more suited to school age students and embracing self-efficacy towards not-for profit activities. Our items on aspirations follow Kourilsky and Walstad (2007) include items on for-profits and not-for profits and this differentiated is supported by exploratory factor analysis (Maximum Likelihood with oblique rotation). Our items to assess understanding take the form of posing an enterprise problem and asking students whether each of a series of items would provide information relevant to deciding about this problem. We developed the instrument using a sample of 436 15-16 year old students in three schools. Some changes were made to the instrument on the basis of results from each of these schools. This paper focuses on the items common to the whole sample and the understanding items which were introduced only for schools two and three (n=340).

Findings

Some key findings are (i) The data suggest four subscales within enterprise self-efficacy: project planning; working with people and information; risk evaluation and management; pricing and profit; (ii) findings of previous research on the distinctiveness of (and gender differences in) aspirations towards for-profit and not-for profit organisations is supported; (iii) aspiration to running for-profit and not-for-profit organisations is significantly associated (through multivariate regression) with higher enterprise self-efficacy but only weakly associated with whether either parent owns their own business; (iv) the items measuring enterprise understanding displayed reasonable levels of discrimination except for those referring to sunk costs which higher scoring students believed were as relevant to decision-making as lower scoring students; (v) no statistically significant association was found between the measurement of 'enterprise' understanding and aspiration to run an organisation; (vi) There was a weak negative association ($p=.066$) between self-efficacy towards enterprise and the measure of enterprise self-efficacy.

Theoretical and educational significance

Policy interest in enterprise education (e.g. Davies 2002, European Commission 2004) derives from expectations about its impact on the number of future, successful, for-profit businesses and not-for-profit social enterprises. Whilst, the formation and contribution of small businesses has been the traditional policy concern, the role of social enterprises has been rising in prominence, notably in the light of initiatives such as the 'Big Society' idea promoted by the Coalition Government in England (Cabinet Office 2010). However, school-based initiatives in Europe to improve enterprise capability generally take place without any measurement of effects on students. The data from this study indicate that this instrument has properties which make it a useful tool for measuring students' enterprise capability. The identification of subscales also indicates areas of knowledge and awareness as well as self-efficacy and aspiration which are appropriate to address in enterprise curricula in schools.

PAPER PRESENTATION

Big fish in a little pond aspire less: Cross cultural generalizability and mediation

Benjamin Nagengast, University of Oxford, United Kingdom; Herb Marsh, University of Oxford, United Kingdom

Being schooled with other high-achieving peers has a detrimental influence on student's self-perceptions: School-average and class-average achievement has been consistently shown to have a negative effect on academic self-concept and career aspirations, the Big-Fish-Little-Pond-Effect. Individual achievement, on the other hand, predicts academic self-concept and career aspirations positively. Research from western and developed countries implies that the negative contextual effect on career aspirations is mediated by academic self-concept. Using data from PISA 2006 (397,500 15-year-old students from 57 countries), we test the generalizability of this mediation model in science using a general multilevel structural equation modeling framework. Individual achievement was positively related to academic self-concept and career aspirations in almost all countries. The positive effect on career aspirations was mediated by self-concept in 54 countries. The negative effects of school-average achievement on self-concept and career aspirations were evident in the large majority of the countries in our sample. After controlling for self-concept at the school-level, the direct effects were substantively reduced in most of the countries – evidence for total and partial mediation of the contextual effect of school-average achievement on career intentions.

Aims

Academic self-concept, the perception of one's own academic performance, is a desirable academic outcome and an important predictor for future academic achievement and engagement. While individual achievement is positively related to academic self-concept, school-average achievement is negatively related to academic self-concept: Being schooled with higher-ability peers substantially reduces academic self-concept, all other things being equal, the Big-Fish-Little-Pond-Effect (BFLPE, see Marsh, Seaton et al., 2008). Similarly, negative contextual effects of school-average achievement have been found on the intentions and aspirations of pursuing further education or careers in a subject area (Alwin & Otto, 1977). Academic self-concept has been shown to mediate this relationship (Marsh, 1991): The negative effect of achievement on career aspirations disappears when self-concept is controlled for. While the BFLPE for academic self-concept is known to generalize to a wide range of countries and cultures (e.g., Seaton et al., 2009), less is known about the generalizability of the negative contextual effect of achievement on career aspirations and the mediation of this effect by academic self-concept. The present study fills this gap by focusing on achievement, academic self-concept and career aspirations in science, a subject with important policy implications for developed and developing countries.

Methodology

The BFLPE, the negative contextual effect of school-average achievement on academic self-concept and career aspirations, is tested with data from the Program for International Student Assessment (PISA) 2006. The subject focus is on achievement and motivation in science. The study uses nationally representative samples of a total of 397,500 15-year-old-students from 57 countries that vary in their cultural orientation and developmental status. Tests of the Big-Fish-Little-Pond Effect are implemented with doubly-latent multilevel structural equation models (Marsh et al., 2009). The mediation effect of academic self-concept on the relations between achievement and career aspirations at the individual and school-level is implemented within the general multilevel mediation framework introduced by Preacher et al. (2010). This framework allows the separation of direct, indirect and total effects of achievement on career aspirations on the student- and school-level. The main hypotheses are tested in the total sample and in multigroup analyses in each of the countries separately. The country-specific effects obtained in these analyses are related to country-level predictors (cultural orientations and economic development level).

Findings

Total sample: As expected, individual achievement was positively related to both academic self-concept and career aspirations in science. In line with previous research on the Big-Fish-Little-Pond-Effect, there were significant negative contextual effects of school-average achievement on both variables. The multilevel mediation analysis (see Figure 1) showed that the effect of individual achievement on career aspirations was completely mediated by academic self-concept. The negative contextual effect of school-average achievement on career aspirations was partially mediated by academic self-concept.

Multigroup analysis: These findings generalized well over the 57 countries: The effects of individual achievement were positive and statistically significant in 51 (academic self-concept) and 43 countries (career intentions) respectively. Both effects were correlated with economic development and individualistic cultural orientation at the country-level. The contextual effects of school-average achievement were negative and significantly different from zero in 51 (academic self-concept) and 34 countries (career intentions) respectively. Only the contextual effect on academic self-

concept was negatively related to both country-level individualism and economic development. Generalizing the mediation effects found in the total sample, there were significant indirect effects of achievement (i.e. mediated by academic self-concept) on career intentions at the individual level (54 countries) and the contextual level (37 countries). Furthermore, there was evidence that the total effects of achievement on career intentions were only partially mediated by academic self-concept in some countries: The direct effect of individual achievement after controlling for academic self-concept remained positive and statistically significant in 24 countries. Similarly, the contextual direct effect remained negative and statistically significant in 16 countries.

Theoretical and educational significance

Our results demonstrate the negative effects of school-average achievement on self-concept and career aspirations in science in the largest and most comprehensive set of countries to date. More importantly, they show that the negative effect on career aspirations is partly mediated by academic self-concept. These effects generalize across a wide-range of countries with diverse cultural and developmental backgrounds attesting their universal nature. These findings run counter to the prevailing practice in many educational systems that stream or track students into classes or selective schools based on their abilities. While the presumed beneficial effects on achievement are modest at best (e.g., Hattie, 2002), academic self-concept suffers compared to comprehensive schooling and the intentions to pursue science-related careers are markedly reduced. As there is a growing shortage of students pursuing science-related subjects in higher education in many industrialized countries (OECD, 2007) and this trend has been much lamented for its economical and societal consequences, our results point to the potential of increasing students' self-concepts for solving this crisis.

PAPER PRESENTATION

Development of Academic Self-Concept and Mathematics in Adolescence

Johan Korhonen, Abo Akademi University, Finland; Karin Linnanmäki, Abo Akademi University, Finland;
Pirjo Aunio, Niilo Mäki Institute & University of Helsinki, Finland

This paper reports a longitudinal study on students' mathematical skills and academic self-concept in the end of compulsory school and secondary education. The preliminary analysis was done with data from grade 9 and the main analysis will include data from secondary education (Autumn 2010). Students' mathematical skills and academic self-concept were highly related at time point 1. Students aiming for the more academic track (upper secondary) have higher academic self-concept, higher mathematical skills, and higher parental education level. There are no gender differences in mathematical skills and academic self-concept. The preliminary results show the importance to follow these students in their transition to secondary education to find out if these groups also differ in terms of development in academic self concept and mathematics skills.

Introduction

Mathematics is an important skill in everyday life. Students' mathematics achievement and positive academic self-concept are quality indicators of work-force preparation in the global marketplace (Evans, 2005). Students' self-perceptions of their competence or ability are at the core of several psychological theories aimed at explain learning gains and achievement-related choices. Academic self-concept is defined as mental representations of one's abilities in academic domains (Marsh & Craven, 1997). Academic self-concept has been found to be highly related to

achievement, even after controlling for prior achievement (Eccles, Wigfield, Harold, & Blumfeld, 1993; Trautwein, Ludtke, Köller, & Baumert, 2006). The relationship is problematic when trying to establish which skill affects the other. Marsh, Hau and Kong (2002) argue that academic self-concept and academic achievement are reciprocally related and mutually reinforcing: improved academic self-concept will lead to greater achievement, and greater achievement will lead to improved academic self-concept. The reciprocal model needs to be reconfirmed in other cultural settings because the main support for the model has been largely based on responses from students from English-speaking countries like Australia, Canada and the United States (Marsh et al., 2002). The development of mathematic skills and mathematical learning difficulties in adolescent has gotten far less attention than variation in mathematical development in younger children (Aubrey & Godfrey, 2003; Aunola, Leskinen, Lerkkanen & Nurmi, 2004; DeSmedt, Janssen, Browens, Verschaffel, Boets & Ghesquiöre, 2009; Fayol, Barrouillet & Marinthe, 1998; Passolunghi, Mammarella & Altođ, 2008). Taipale (2009) shows that there are significant differences in mathematical skills between the two different educational tracks (secondary education) in the Finnish school system. Students attending the more academic track, upper secondary school, outperform their peers who attend vocational education.

Aims

The main aim of this study is to examine the relationship between academic self-concept and mathematical skills and how these develop from compulsory school to secondary education. The intentions of the study are twofold, firstly it offers a chance to enhance the generalisability of the Marsh et al. model and give valuable information about mathematical development in adolescent students. Secondly, on national level there is a need of specific information about how our dual secondary education system affects Swedish speaking students' mathematical development and the development of their academic self-concept.

Methodology

Participants. In present study the sample from the first data collection (2008) consists of 980 students (boys N=476 and girls N=501) from 14 different compulsory schools in Swedish speaking areas in Finland. All students were measured at the end of ninth grade (mean age 15,8 years, SD 4.94). The second data collection will take place in autumn 2010 when the students are attending either vocational or upper secondary education.

Methods of data collection. Mathematical skills of students were assessed with the KTLT-test (Räsänen & Leino, 2005), which is a standardized test for grades 7-9 (13-16 years). The test identifies students with difficulties in basic mathematics and difficulties in applying these abilities in a context. A low score in the test indicate low achievement in mathematics. The test consists of 40 tasks. The tasks are not placed in difficulty order, although the more difficult tasks tend to be in the end of the test. The test is a paper and pencil test and the students have 40 minutes to do the test. The reliability estimate of the mathematical achievement test at time point 1 was 0.89. Academic self-concept was measured with items from the Perceived Competence Scale for Children (Harter, 1982), loading on the academic self-concept subscale (8 items). The test was translated to Swedish by multilingual research team. The reliability estimate for the academic self-concept subscale at time point 1 was 0.84. Information about the students' family background was and will be collected on both measurement times and school type (vocational or upper secondary) will be confirmed at the time of second data collection.

Procedure. The present study is part of a longitudinal study following the students over a period of four years. The study started with permission to test students from 14 different schools in Swedish speaking areas in Finland. A pilot study was first conducted to ensure the quality of measurements. The main data collections are done by trained research assistants. The mathematics test was done with group of students in their regular mathematics lesson. The academic self concept scale was done in similar way with group of students during a regular lesson.

Findings

The preliminary results with the data from the first measurement show that academic self-concept and mathematical skills are related ($r = .44$, $p = .12$, $p = .17$, $t(812) = -12.819$, $p = .84$), higher mathematical skills ($t(828) = -12.999$, $p = .84$), and higher parental education level ($t(688) = -5.812$, $p = .45$). There are no gender differences in mathematical skills ($t(828) = 1.338$, $p = .181$, $d = .09$) and academic self-concept ($t(812) = -.444$, $p = .657$, $d = .03$). In Earli 2011 we will present results based on longitudinal data with two measurements point by using Latent growth curve analysis with parallel processes and time-invariant (parental education, gender) and time-varying (type of secondary education) covariates.

Theoretical and Educational Significance

In comparison to existent research literature this study examines the development of mathematical skills in adolescent that has not got that much attention. Furthermore, the reciprocal model of academic self-concept and academic achievement has not been verified in a Nordic setting before. The literature offers two competing theories

of self-concept development in male and female (for a review see Nagy et al., 2010) and this study will give valuable information about these issues. The preliminary results indicate that students aiming for upper secondary education have higher levels of mathematical skills and academic self-concept. It is important to follow these students in their transition to secondary education to find out if these groups also differ in terms of development in these two domains. In the Finnish school system emphasis lies on the training of basic skills and little effort is set on enhancing students' academic self-concept. This study can provide evidence for the benefits of focusing on both domains in Finnish compulsory and secondary education.

PAPER PRESENTATION

The Reciprocal I/E Model: An Integration of Relations Between Academic Achievement and Self-concept

Jens Moller, University of Kiel, Germany; Jan Retelsdorf, IPN - Leibniz Institute for Science and Mathematics Education, Germany; Herb Marsh, University of Oxford, United Kingdom; Olaf Koller, IPN, Germany

This paper proposes the integration of two of the major models of relations between academic self-concept (ASC) and achievement— the reciprocal effects model (REM) and the Internal/External frame of reference model (I/EM) and— and tests the resultant reciprocal I/E model (RI/EM). The model predicts (a) positive effects of mathematics and verbal achievement and ASCs on subsequent mathematics and verbal achievements and ASCs within the same domain and (b) negative effects of mathematics and verbal achievements and ASCs on subsequent achievements and ASCs across domains. Drawing on a representative sample of $N = 1508$ students, the authors investigated the development of mathematics and verbal grades and ASCs from grade 5 to grade 8 (using three waves of data collection). Structural equation modeling supported the validity of the RI/E model, revealing positive longitudinal effects of prior achievements and ASCs on subsequent achievements and ASCs within domains and negative longitudinal effects of prior achievements on subsequent ASCs across domains. There were also small negative effects of prior ASCs on subsequent achievements across domains. The results are interpreted as indicating a strong domain specificity of academic achievements.

In this paper, we propose and test a comprehensive model that integrates two of the major theoretical models in the field: the reciprocal effects model (REM) and the Internal/External frame of reference model (I/EM; Marsh, 1986).

The Reciprocal Effects Model

The REM proposes: (a) strong positive paths from prior measures of achievement and ASC to subsequent measures of the same construct, (b) positive paths from prior ASC to subsequent achievements, and (c) positive paths from prior achievements to subsequent ASC. Most REM studies have provided empirical support both the effects of prior achievement on subsequent ASC and the effects of prior ASC on subsequent achievement in diverse subjects. However, the REM is restricted to longitudinal relations between ASC and achievements within domains. Here, we extend the REM to incorporate more than one domain.

The Internal/External Frame Of Reference Model (I/EM)

Empirical research has shown that mathematics self-concepts (MSCs) and verbal self-concepts VSCs are nearly uncorrelated, whereas mathematics achievement (Mach) and verbal achievement (VAch) are substantially correlated. Marsh proposed the I/EM to account for this unexpected pattern of relations. The I/EM proposes (d) high positive correlations between mathematics and verbal achievements; (e) small or near-zero correlations between MSCs and VSCs; (f) strong positive paths from achievements to corresponding ASCs; (g) weak negative paths from achievements to contrasting ASCs.

The Present Investigation: Integration of the I/EM and REM: The Reciprocal I/E Model

Testing the complete RI/EM requires longitudinal data sets with repeated measures of ASCs and achievements in more than one domain. Based on the RI/EM, we formulated the following additional predictions for the combination of both domains across all three waves of data (h) support for the REM generalizes over the mathematics and verbal domain when both domains are considered in the same model; (i) support for the I/EM generalizes over time when longitudinal data are considered; (j) weak negative effects of ASCs on contrasting achievements (controlling for prior achievement and ASCs).

Method

Sample

The initial sample comprised $N = 1508$ grade 5 students (49% girls; age at T1: $M = 10.88$ years, $SD = 0.56$) from 60 schools who were representative of the federal state of Schleswig-Holstein, Germany.

Measures

School Grades. We obtained students' grades on their last report card in grades 5 (T1), 6 (T3), and 8 (T5) for German as (first language) and mathematics.

Self-Concept. We defined domain-specific self-concepts as the general belief of doing well or poorly in the corresponding domain (e.g.: ?In math, I do quite well?). Reliabilities (Cronbach's α) of the domain-specific self-concepts were good (German: T2: .85; T4: .88; T6: .90; mathematics T2: .90; T4: .90; T6: .91).

Analytical Issues

Missing Data. We used the STATA routine ICE to create $m = 5$ complete data sets. All information available (SES, cognitive abilities, etc.) was used to improve the imputation model. Subsequent analyses were then conducted five times and the results were combined.

Structural Equation Modeling (SEM). We estimated structural equation models (SEM). All self-concept constructs were specified as latent variables. School grades, however, were measured with a single indicator and included as manifest variables in all models.

As our sample consisted of students nested in classes, we corrected standard errors (Mplus option: type = complex) to account for this fact in all of our analyses.

Results and Discussion

Reciprocal Effects Model (REM)

Our analyses of the links between mathematics achievement and MSC supported the REM, $\chi^2(37) = 337.90$; CFI = .969; TLI = .944; RMSEA = .073; SRMR = .037 for math as well as for the verbal domain, $\chi^2(37) = 360.25$; CFI = .963; TLI = .934; RMSEA = .076; SRMR = .035. Hypothesis (a-c) were supported.

The Internal/External Frame Of Reference Model (IEM)

As predicted, the two horizontal paths (mathematics achievement to MSC; verbal achievement to VSC) were consistently substantial and positive, whereas the two cross paths (verbal achievement to MSC; mathematics achievement to VSC) were consistently negative. Together with the positive correlations between the two achievements and the weak correlations between the two self-concepts, these results support hypotheses d-f.

The Reciprocal I/E Model (RI/EM)

The goodness of fit indices were satisfactory for the full model based on the total sample—mathematics and verbal constructs over all waves of data collection, $\chi^2(182) = 1142.84$; CFI = .954; TLI = .931; RMSEA = .059; SRMR = .039. The new prediction formulated on the basis of the RI/E model was that the cross-domain effects of prior ASCs on subsequent achievements would be weakly negative. For example, the effects of T2 VSC on T3 MAch (-.06) and the effects of T2 MSC on T3 VAch (-.08) were both negative, but both effects were marginally nonsignificant (.10 p p

In summary, there is some support for the prediction that prior ASCs would have small negative effects on achievements in the noncorresponding domain (prediction j). Although the support for the prediction of negative effects is not strong, there is no evidence that the effects are positive.

PAPER PRESENTATION

Predicting Expert Ratings of Essays Quality: A Coh-Metrix Analysis

Scott Crossley, Georgia State University, United States; Danielle McNamara, University of Memphis, United States

This paper reports on a series of studies in which human judgments of essay quality are assessed using Coh-Metrix. The goal of these studies is to better understand the relationship between linguistic features of essays and human judgments of writing quality in terms of linguistic features of text related to coreference, connectives, syntactic complexity, lexical diversity, spatiality, temporality, and lexical characteristics. These studies have analyzed essays written by both first language and second language writers. The results support the notion that human judgments of essay quality are best predicted by linguistic indices that correlate with measures of language sophistication such as lexical diversity, word frequency, and syntactic complexity. In contrast, human judgments of essay quality are not strongly predicted by linguistic indices related to cohesion. Overall, the studies portray high quality writing as containing more complex language that may not facilitate text comprehension.

AIMS

The quality of a writing sample rests in the judgments made by an expert rater. In most cases, trained raters assess writing quality and the value they assign to that writing can have important consequences to the writer. Such consequences are especially evident in the values attributed to writing samples used in student evaluations (i.e., class assignments) and high stakes testing.

Our goal in this paper is to better understand how the linguistic features present in writing samples help explain human judgments of text quality for both first language (L1) and second language (L2) writers of English. We focus on the interrelations between holistic essay scores and the incidence of linguistic features as reported by the computational tool Coh-Metrix (Graesser, McNamara, Louwerse, & Cai, 2004). Understanding the linguistic features that underlie text quality can assist in understanding the linguistic processes involved in essay rating as well as help improve the type of feedback that writers.

METHODOLOGY

We report on a variety of studies in this paper that examine how linguistic features in text predict judgments made by expert raters. In all cases, trained, expert raters evaluated essays using holistic scoring rubrics. Comparisons between the human ratings and the linguistic indices reported by Coh-Metrix examined relationships between the textual features of the essays and the quality scores assigned to the essays. A variety of statistical analyses were conducted including multiple regressions to predict holistic essay quality scores and discriminant function analyses (DFA) to classify high and low proficiency essays.

FINDINGS

Human judgments of essay quality (native speakers of English)

McNamara, Crossley, and McCarthy (2010) investigated the potential for Coh-Metrix features to explain human judgments of essay quality for 120 untimed argumentative essays. Statistical analyses demonstrated that three linguistic indices, the number of words before the main verb, the measure of textual lexical diversity (MTLD), and CELEX logarithm frequency including all words, were predictive of essay quality. A DFA using these variables correctly classified 52 of 80 essays in a training set ($df=1$, $n = 80$) $\chi^2 = 7.16$, p $df = 1$, $n = 40$) $\chi^2 = 6.20$, p $F(1, 118) = 15.85$, p $r = .47$, $r^2 = .22$, adjusted $r^2 = .20$. Higher scored essays were characterized by greater linguistic sophistication (i.e., more sophisticated lexical features and more complex syntax).

Human judgments of essay quality (non-native speakers of English)

Crossley and McNamara (in press) examined the predictive ability of Coh-Metrix to estimate essay quality in a corpus of 514 scored argumentative essays written in English by native speakers of Cantonese under timed conditions. A linear regression analysis using selected Coh-Metrix variables and 344 essays in a test set yielded a significant model, $F(5, 338) = 28.278$, p $r = .543$, $r^2 = .295$. Five variables were significant predictors in the regression: D (lexical diversity), word familiarity, CELEX content word frequency, word meaningfulness, and aspect repetition. The model for the test set ($n = 170$) yielded $r = .454$, $r^2 = .206$. The model for the entire data set yielded $r = .509$, $r^2 = .259$. Similar to McNamara et al. (2010), higher writing quality was a function of increased linguistic sophistication in the text and also decreased cohesion.

Writing development as a function of grade level (first language writers)

Crossley, McNamara, Weston, and McLain-Sullivan (under review) investigated the strength of Coh-Metrix indices distinguish differences in human judgments of essay quality as a function of grade level (9th grade, 11th grade, and college freshmen essays). Untimed, argumentative essays were collected from 202 students. An ANOVA showed significant differences in human assessments of essay quality between the three levels of writers, $F(2, 201) = 80.056$, p $2 = .446$. Essays written by 9th grade students received the lowest score ($M = 1.653$; $SD = 0.766$) followed by 11th grade essays ($M = 2.979$; $SD = 1.133$) and essays written by college freshmen ($M = 3.757$, $SD = 0.924$). Nine Coh-Metrix indices (number of paragraphs, word concreteness, CELEX word frequency for all words, incidence of positive logical connectives, D (lexical diversity) average number of modifiers per noun phrase (syntactic complexity), content word overlap, and average word polysemy) were used as variables in a DFA to classify the essays based on grade level. The DFA correctly allocated 95 of the 135 essays in a training set ($df=4$, $n=135$) $\chi^2 = 95.325$, p $n=67$) $\chi^2 = 58.104$, p

THEORETICAL AND EDUCATIONAL SIGNIFICANCE

The results from these studies indicate that human judgments of text quality are best predicted by linguistic indices that correlate with measures of language sophistication such as lexical diversity, word frequency, and syntactic complexity. By contrast, human judgments of text quality are not strongly predicted by linguistic indices related to cohesion or models of text comprehension. Broadly speaking, the studies reported in this paper portray high quality writing as containing more complex language that may not facilitate reading rate or text comprehension.

Overall, we find that the use of the text evaluation tool Coh-Metrix can help us better understand the interplay between linguistic features and human judgments of essay quality. Understanding how linguistic features in an essay may influence human judgments of quality may lead to better models of writing development and help promote

writing competency in developing writers. The use of automatic text assessment tools to predict essay quality may also prove useful in providing automatic feedback to classroom students and users of intelligent tutoring systems.

PAPER PRESENTATION

Improving L2 Writing Quality – A series of Two Intervention Studies

Phuong Nam Nguyen, UvA, Netherlands; Wilfried Admiraal, University of Amsterdam, Netherlands; Gert Rijlaarsdam, University of Amsterdam, Netherlands

Vietnamese EFL higher education faces challenges as a result of conflicting cultures reflected in different writing genres and pedagogies. For instance in L1 (Vietnamese) writing, the genre of argumentative writing does not even exist. L1 learners write on a literature theme to prove their understanding and development of moral and community values. Writers' own voice is not asked for. Content for L1 essay writing is prepared in pre-writing classroom activities as an agreement between teachers and learners. This implies that activities like free writing advocated in ESL methodology do not fit the learners: they experience free writing as unproductive.

We set up two intervention experiments (pretest-posttest control design with switching replications) with 66 EFL intermediate students.

The first intervention, model analysis, was based on text pattern knowledge and its efficacy in probing ideas and structuring text organization (Reynolds & Perin, 2009). We observed a positive effect on the perceived value of idea generation in free-writing: after the intervention, students used more of the generated ideas in their final text.

The second experiment was to test the efficacy of collaborative writing and free-writing in students' enriching arguments and voice. An effect of collaborative writing was observed on various aspects of argumentation, however, this effect was at the cost of the quality of voice. In free writing, students displayed a tendency to increase their own voice, however with a lower quality of argumentation, less counterarguments, multi-faceted arguments, and lower text organization cohesion compared to the small-group discussion condition.

Objective and background

Two main challenges in L2 argumentative writing in Vietnam are 1) the genre with specific requirements for an own stance in an issue at stake, voice, and a particular structure of text does not even exist in L1 Vietnamese writing 2) L1 and L2 writing pedagogy gap does exist. L1 writing focuses on literary themes for moral development and does not require a strict essay writing organization with a tree structure, topic sentences and then supporting sentences cohesively connected and developing the topic sentence. Additionally, L1 writing content is fully prepared in advance as a negotiation between teachers and learners and does not require learners' own voice/or own ideas. Learning activities designed in L2 writing course books like free writing does not show to be effective because students expect something to be productive for their end writing product.

Interventions

The first intervention, model analysis, was based on text pattern knowledge and its efficacy in probing ideas and structuring text organization (Reynolds & Perin, 2009). Students examined an argumentative text for how ideas were organized in a hierarchy/tree structure with topic sentences and supporting sentences, how the stance of the author was stated, and how those features related to intention of the author. In the control group, students were instructed about organizational structure, cohesion and unity of an academic essay following the guidances from the coursebook of their writing class, without analyzing a sample.

The second intervention, collaborative writing, was based on research on small-group discussion in promoting creativity (Mouchiroud & Bernoussi, 2008). Students worked in small groups discussing pro and con arguments, level of importance and relevance of the arguments, planning the organization of the target text. In the control group students looked at the picture depicting the issue as a prompt for them to do free-writing. They selected information

from the free-writing version that they found relevant, important, took a position on the issue and arranged the ideas in a text organization scheme

Research design

Both experiments were carried out in eight weeks (six meetings per week of 2.30 hrs each) in Tra Vinh University, Mekong Vietnam. Subjects (66 students of EFL intermediate level, aged 22-27) were randomly divided into two groups. Both interventions were evaluated using a pretest-posttest control group design with switching replications (Shadish, Cook, & Campbell, 2002).

In experiment 1, both groups received the experimental treatment, but on different moments of time. One group got the intervention (model analysis), and then did free writing on the topic and built a text content structure for themselves using the ideas they highlighted as worthwhile in their free writing. The other group did the free-writing activity without the experimental treatment and served as control group. Then both groups swapped: the second group got the experimental intervention, while the first group did not. Texts were administered before the experiment, in between and after groups swapped. Free-writing productions and argumentative text productions were rated for (i) fluency (free-writing productions, text productions; (ii) idea generation (number of ideas), (iii) perceived value of free-writing (ideas selected for final text production; (iv) text quality (quality of argumentation, voice, and overall quality). Perceived self-efficacy of writers on their meta-cognitive writing strategies was measured with questionnaires

In experiment 2, both groups received the experimental treatment, but again in different moments of time. The first group worked collaboratively and the second group did free writing individually and served as control group. Then both groups swapped: the second group got the experimental intervention and the first group did free writing individually. Free-writing productions and argumentative text productions were rated for the same variables as in the first experiment, with a more detailed analysis of argumentation (acceptance, relevance, and sufficiency of arguments; anticipating and refuting counterarguments; argument organization) and quality of voice in terms of assertiveness and self-identification of writers.

Results

The first intervention proved that model analysis worked out well on writers' idea generation. In both panels the experimental group profited from the independent variable. In panel 1, group A(experimental) gained benefits from the intervention. They created a significant gap with group B (control) in the total number of marked idea clusters in free-writing 1 ($t(60)= 3,448$; $p=0,001$). In panel 2 , after swapping conditions, group B who was now experimental group increased significantly in the total number of marked idea clusters in free-writing 2 and sealed the gap with group A ($t(63)=-,408$; $p=0,685$). More importantly, in both panels, the intervention created a significant effect for experimental group in the proportion of number of idea clusters in free-writing used in the final text. In the first panel group A (experimental) created a significant difference with group B (control) in free-writing 1 ($t(54)$; $F=8,801$; $p=0,005$; $\eta^2= 0,142$). After swapping, in panel 2, group B (experimental) benefited from the intervention and created a similar proportion of ideas coming back with group A ($t(52)$; $F=0,005$; $P=0,815$, $\eta^2=0,001$)

Although a dramatic and sustained improvement in fluency and self-efficacy of both groups was found during the course of experiment, there was no direct effect of the first intervention upon the improvement. Regarding intervention 2, we are in the process of interrater between 7 M.A. graduates in English for substantial reliabilities of results involving argumentation, voice, and overall text quality so official statistics and final results should come later. Within the boundary of our first rounds of rating the texts collected we claim that different writing classroom conditions could create an upward trend of the argumentative quality or of voice expression. Collaborative writing offered writers more complex argumentation (more counterarguments, multi-faceted reasoning, and higher level of text organization cohesion) at the cost of voice; while free-writing offered a stronger voice reflected in self-identity and assertiveness, however a downward trend in argumentation and text cohesion.

PAPER PRESENTATION

Textual Production: What is the impact of linguistic and metalinguistic competences?

Ana Cristina Conceicao Silva, ISPA, Portugal

Dimensions of linguistic development, such as lexical and syntactic development, and metalinguistic competences, such as morphological and syntactic awareness, have been associated, by literature, to writing and textual production, but there are no studies analyzing, specifically, the impact of these knowledges and competences in textual production's quality.

The participants were 47 children frequenting 4th grade, all from high social-cultural classes. These children were evaluated in tasks measuring lexical development, syntactic development, morphological awareness development and syntactic awareness development. It was also asked to the children to write a composition about a theme previously selected. These compositions were evaluated by two independent judges according to defined criteria. The results point to the inexistence of correlations between linguistic knowledge and textual production's quality and to the existence of medium level correlations between metalinguistic knowledge and textual production's quality. It was also detected positive and significative correlations between linguistic and metalinguistic tasks.

The conceptual and structural dimensions of narrative must be transformed in text and, in that process, linguistic and metalinguistic know ledges (and the level of children's development in those competences) will be, necessarily, involved and will have implications in textual quality. Thus, for example, the cohesion and continuity of narrative depends on the form how children are able to use connectors, pronouns and conjunctions, and on the children's capacity to reflect about its adequacy in the text. Children begin to acquire narrative cohesion primarily in an oral level and only after in written texts. These two dimensions appear to be correlated (Cox, Shanahan & Sulzby, 1990).

Several studies that analyze written compositions' in school context, refer the importance of lexical development in texts' quality (Berninger & Swanson, 1994). The textual production also implies, the capacity to group words in way to constitute phrases that express in a correct way what is intended to write. In this way, the syntactic construction is one of the processes inherent to textual production (Torrance & Jeffery, 1999).

Metalinguistic development is particularly associated to processes of revision that occur during writing and in post writing moments, because it facilitates much more fine judgments about the various dimensions of a text. The revision implies processes of change in texts to adequate it to writing conventions, namely orthographic, syntactic and also to the coherence of the text. In that way, revision requires from the text's author a conscious linguistic knowledge about words and its morphological structure, phrases and speech. When children enter school they tend to effectuate mechanical changes in word's choice, while older children make alterations at a word's orthography level and in phrases in order to improve cohesion and coherence.

One of the dimensions that is object of analysis during writing and revision is orthography. Several authors refer the importance of morphological awareness in orthographic knowledge (Gombert, 2003; Nunes & Bryant, 2004; Nunes & Bryant, 2006).

Syntactic awareness is influent in textual production's process because it has also implications in the revision of texts. According to several authors, performs a important role in textual production's quality (Hacker, Plumb, Butterfield, Quathamer & Heineken, 1994; Graham, Schwartz & MacArthur, 1995; Graham, De la Paz & Swanson, 1998). In fact, the quality of revision, as a process that allows the writer to reflect and make changes in the text with the objective of approximating the text to the sense wanted (Singer & Bashir, 2004), seems to depend on the capacity to reflect about grammatical structure of a phrase and to correct it according to the sense that the author wants to give to his text, capacity related to syntactic awareness's development (Capovilla, Capovilla & Soares, 2004).

Dimensions of the linguistic development, such as lexical and syntactic development, and metalinguistic competences, such as morphological and syntactic awareness, have been associated, in several studies present in literature, to writing and textual production, but none of these studies tried to analyze, specifically, the impact of these several competences in the quality of textual production.

The aim of this study is analyze the relations lexical and syntactic development, and metalinguistic competences, such as morphological and syntactic awareness, and textual production's quality.

The participants were 47 children frequenting 4th grade, all from high social-cultural classes. These children were evaluated in tasks measuring lexical development, syntactic development, morphological awareness development and syntactic awareness development. It was also asked to the children to write down a composition about a theme previously selected.

The analysis of children's performance in linguistic and metalinguistic tests points to high levels of success in all tasks. The use of Pearson's correlation test showed the inexistence of significative correlations between the variables relative to lexical and syntactic development and textual production's quality

The results with the same test showed the existence of a positive and significative correlation of medium level, for a significance level of 0,01, between the variables relative to syntactic awareness development and textual production's quality and the existence of a positive and significative correlation of medium level, for a significance level of 0,01, between the variables relative to morphological awareness development and textual production's quality.

Some of the literature reviewed points to the idea that lexical and syntactic development positively influences writing in general (MacArthur, 2001, cit. Singer & Bashir, 2004; Singer & Bashir, 2004; Berninger & Swanson, 1994), but none of the studies found were centered specifically in the matter of textual quality. In fact, this type of relations between oral language development and writing has been detected mostly in initial phases of writing learning (Shanahan, 2004).

The correlation obtained between morphological awareness development and textual production's quality can be explained by the role played by morphological awareness in aspects related to orthographic knowledge and with the ability to mobilize that knowledge, in a conscious way, according to the objectives that the writer has for his text (Gombert, 2003; Nunes & Bryant, 2006). In a less direct way, some of the literature puts the hypothesis of the existence of the influence of morphological awareness development in dimensions relative to narrative coherence, that remits to the ability of the subject to reflect about the meaning of words, defining and adjusting its meaning to the intentionality and communicative situation of the text (Koch, 2002).

About the correlation obtained between syntactic awareness development and textual production's quality, this can be explained by the positive influence that this type of development seems to have in aspects related to global cohesion of a text (Curto, Morillo & Texidô, 2000, cit. Martins, 2009). This idea allow us to conceive also the possibility of the existence of the influence of syntactic awareness development in the quality of causal and temporal relations expressed in the text, in the quality of exposition of a possible conflict and its resolution and in the quality of the episodes written, influencing indirectly the textual coherence.

PAPER PRESENTATION

Improving academic writing skills: effects of online teaching modeling

Maria Beatrice Ligorio, University of Bari, Italy; Paola Francesca Spadaro, University of Bari, Italy; Cesarea Giordano, University of Bari, Italy

In this presentation the case of a blended university course on E-learning at a specialized level for Work Psychology is discussed. During such course third-six students first read the material assigned to them, then they posted online critical reviews about the readings. After getting feedback from their teachers, the students later share and discuss about teachers' comments on some of the reviews. The course was structured into four units; for each of them this activity was repeated. A complex category system was built to assess the quality of the reviews. We found that: a) the pick of improvement was recorded from the first to the second unit, b) students benefitted most when getting vicarious feedback on their writing, c) the most sensitive dimension to change was grammar, which reported the highest frequency of errors at the start of the course.

Introduction

University students often do not display adequate academic writing skills. Especially in the Italian university contexts, this is due to the fact that students are very seldom required to write. Most of the time students face the task of writing a dissertation of the end of their academic journey without never been required to write an essay in three or four years. AimsThis study is aimed at exploiting the effects on university students' academic skills of a blended course inspired to socio-constructivism (Allen & Seaman, 2006; Bonk & Graham, 2006). We are convinced of the fact that some of the suggestions coming from collaborative learning (Joiner, Littleton, Faulkner, Miell, 2000) and teaching how to write (MacArthur, Graham & Fitzgerald, 2006) can be empowered when applied into a well-designed blended context.

Context

This blended course was offered at the University of Bari (IT), during the academic year 2009-10. The subject was on E-learning and it was part of the specialized curricula of Work Psychology. Thirty-six students attended the course, 9 male and 27 female. The participants' average age was 24. Students were organized in four 9-members random groups. The course lasted thirteen weeks and it was divided into four units. The course had a jigsaw structure: each

group got nine different readings, one per member; all four groups received the same readings. Students from different groups reading the same material were called "alter-ego". The digital version of the material was posted online. The teacher assigned a research question for each unit. Student had to read the assigned material and write a short critical review (300 words maximum) about it reporting (a) the main points, (b) the contribution to the research question, (c) the unclear and underdeveloped points, (d) a personal opinion, and (e) a comparison with previous material read. 'Alter-ego' students could discuss and compare their impressions on the reading and about their reviews drafts via the online platform. All the reviews had to be posted online and students had to read them. This was an important starting point, because it was supported the idea that a good answer to the research question was possible only after combining – as in a puzzle – all the material distributed within the group. For each unit, the teacher gave feedback online randomly on two reviews for each group. All students were required to read the commented reviews in order to see the types of corrections and to transfer them to their own writing. In this way, teachers' comments were socialized and discussed.

Analysis and findings

144 reviews were produced during this course. They were all analyzed with a category system composed by the following three areas: a) grammar; b) formal academic features (citations and references); c) linguistic style; d) critical skills (capability of reporting the core point of the material read; well-argued the personal point of view, and quality of the contribution to the research question). Three analysts coded independently 40% of the data; discordances were discussed and later two of them coded the whole data set. A 5-point-Likert scale was used to assess each review. An overview of the results at the first unit shows that all students reported some of these errors. The highest mean was reached by the grammar mistakes: 2.93 against the 2.26 of academic features errors, 1.99 on language style and 1.32 on critical skills. In order to assess a quality increase during the course, the total score of the reviews of each unit was compared. Contrasting reviews of the first unit to those produced during the last unit, we found: a) a remarkable decrease of grammar errors ($t(51,3)=4.96$; $p(t(73))=-2.916$; $p(t(73))=3.33$; although those using a colloquial style hardly changed during the course; c) however, the critical skills, especially in reference to the contribution to the research question, did not improve significantly. For all these dimensions the pick of improvement was recorded at the passage from the first to the second unit. We also looked at the specific effects of teachers' comments by comparing the quality of the reviews produced by: a) the students that had a review commented in the previous unit; b) the so-called "alter-ego"; c) all the other students. The students most decreasing their errors were the "alter-ego", followed by the students whose reviews were commented in the previous unit. Other students had the highest presence of errors.

Discussion, educational significance

From our results we learn that: a) the pick of improvement was recorded at the passage from the first to the second unit, b) "alter-ego" students are the ones benefitting most from the teacher modelling, c) the most sensitive dimension to change was grammar, which reported also the highest frequency of errors at the start of the course. One of the practical implications from this study concerns the positive effects of teachers' feedback as modeling. Second, the benefits of the jigsaw course structure for the purpose of enhancing writing skills. Third, the fact that different allocated students in the course structure (subjects of feedback, alter-egos, the others) benefitted differently from this sort of feedback. Fourth, the promise of workload reduction for the teachers in terms of reducing the need of giving feedback to each an every single student, since the vicarious feedback seems to be the most effective one in terms of leading to students' self-regulation.

PAPER PRESENTATION

How student teachers learn in relation to the quality of their teaching

Maaïke Endedijk, University of Twente, Netherlands; Mieke Brekelmans, Utrecht University, Netherlands; Paulien Meijer, Utrecht University, Netherlands; Jan Vermunt, Utrecht University, Netherlands

One of the aims of preservice teacher education programs is to develop student teachers' conceptions and skills necessary for their further professional development as a teacher. Although a widespread assumption is that an independent meaning-oriented way of learning is needed to become an expert teacher, empirical evidence on the relation between student teachers' learning and the quality of their teaching practice is lacking. The current study adds to the existing body of knowledge by investigating this relation. Student teachers' learning orientations were

studied with the revised version of the Inventory Learning to Teach Process (ILTP). Student perceptions of teacher Control and Affiliation, perceptions of teachers themselves, and teacher awareness of student perceptions as measured by the Questionnaire on teacher interaction (QTI) were used as indicators for quality of teaching practice. All full-time student teachers of a Dutch school-based teacher education program for subject-teaching in upper secondary school were asked to volunteer in this study. This resulted in a set of 126 cases (90%) with both QTI and ILTP scores. Results show that student teachers having problems with directing their own learning also have problems in creating an effective classroom climate. Results of this study may imply that a possible approach to support student teachers with severe classroom management problems is to help them developing their learning orientation in order to become more proficient in acquainting the conceptions and skills to develop their expertise.

Aims

Preservice programs, especially one-year post-graduate teacher education programs form a time-limited intervention in the professional development of teachers. Therefore, one of the aims of many preservice teacher education programs is to develop student teachers' conceptions and skills necessary for their further professional development during the teaching career. Multiple studies have suggested that an independent and meaning-oriented way of learning is regarded as being preferable for becoming an expert teacher: Student teachers engaging in this type of learning are expected to learn successfully in and from a combination of theory and practice (Mutton, Burn, & Hagger, 2010), to be able to continue lifelong learning after graduation (Cornford, 2002), and to handle the challenges of the complex and dynamic learning environment of everyday practice (Hammerness, et al., 2005). Consequently, the quality of student teachers' learning is expected to be related to the quality of their teaching practice. Nevertheless, as Fallon (2008, p. 837) has concluded, "the field of teacher education and teacher learning is deep and rich in normative and logical reasoning, but shallow in empirical knowledge". Although a widespread assumption is that an independent meaning-oriented way of learning is needed to become an expert teacher, empirical evidence on this relation is lacking. Therefore the main research question of this study is: What the relation is between student teachers' way of learning and quality of their teaching practice?

For the context of school-based preservice teacher education, Oosterheert and Vermunt (Oosterheert & Vermunt, 2001) used the concept of learning orientation to denote typical combinations of learning conceptions, and learning- and regulation activities. Their research has shown that individual differences in learning to teach could be categorised in four learning orientations: survival-oriented learning, reproduction-oriented learning, dependent meaning-oriented learning, and independent meaning-oriented learning. Quality of teaching can be indicated by means of different aspects of teaching (such as subject specific-, organisation of learning-, moral-, interpersonal aspects). An important factor for student learning is classroom social climate. How students perceive the social climate of their classroom, and especially the way students perceive their teachers interpersonally, is strongly related to student academic achievement and well-being (Wubbels, Brekelmans, den Brok, & van Tartwijk, 2006). According to interpersonal theory Control and Affiliation are primary to all interpersonal perceptions. In this study we will use student perceptions of teacher Control and Affiliation, perceptions of teachers themselves, and teacher awareness of student perceptions (discrepancy between self- and student perceptions) as indicators for quality of teaching practice.

Methodology

Student teachers' learning orientations were studied with the revised version of the Inventory Learning to Teach Process (ILTP), developed by Oosterheert, Vermunt, & Denessen (2002). The instrument consists of ten scales with Likert-type items reflecting learning conception of student teachers, preferences for learning and regulation activities, and emotion regulation. Perceptions of Control and Affiliation were estimated with the Questionnaire on teacher interaction (QTI, Wubbels et al. 2006). Both student and teachers filled in the QTI, resulting in student ratings, teacher self ratings, and discrepancy ratings (absolute value of self rating score minus student rating scores). By aggregating ratings of students from the same class, students were treated as multiple observers of the quality of the teaching practice of their teachers. Internal consistency of both dimensions was sufficient. To study the relation between learning orientation and the scores on the dimensions of the QTI, analyses of variances were applied.

Student teachers' learning and their teaching practice has been studied in a Dutch postgraduate one-year teacher education program preparing for subject-teaching in upper secondary school. In this program, student teachers spend half of their time doing practice either as an intern or while having a paid job as a teacher. The other half of their time they spend learning at the university. All full-time student teachers of this program were asked to volunteer in this study. This resulted in a set of 126 cases with both QTI and ILTP scores. Five student teachers had cancelled their participation, because of lack of time, illness, pregnancy, other expectations, and one left the teacher education program.

Findings

Based on the scores of the ILTP-scales, all student teachers were categorized in one of the learning orientations. In total, 21.4% of the student teachers had a survival-oriented way of learning, 25.4% a reproduction-oriented way of learning, and 20.6% a dependent meaning-oriented way of learning. The largest group (32.5%) had an independent meaning-oriented way of learning. Results show that there were no significant (p

Theoretical and educational significance

The aim of this study was to explore the relation between student teachers' learning and the quality of their teaching. Results indicated that survival oriented student teachers, who have problems with directing their own learning, also had problems with creating and maintaining an orderly classroom social climate. Since this study was a descriptive study with one measurement occasion, the question whether (1) a survival-oriented way of learning leads to less quality of teaching, or (2) problems in creating a positive classroom management leads to a survival way of learning, or (3) a third factor is responsible for the found relation between student teacher learning and their teaching practice (e.g., personality factor, quality of educational program) remains unanswered and demands further investigation. Results of this study may imply that a possible approach to support student teachers with severe classroom management problems is to help them developing their learning orientation in order to become more proficient in acquainting the conceptions and skills to develop their expertise.

PAPER PRESENTATION

Promoting strategic knowledge in teacher training: cognitive modelling in video-based cases

Jan Henning, University of Regensburg, Germany; Bernd Meidenbauer, University of Regensburg, Germany;
Klaus-Peter Wild, University of Regensburg, Germany

This study investigated how the acquisition of strategic knowledge in teacher education can be promoted. Strategic knowledge is understood here as a type of practical knowledge that explicitly features the reflexive use of theoretical knowledge. The acquisition of strategic knowledge is an important goal in teacher education because this knowledge is assumed to enable student teachers to effectively deal with problems of classroom practice. Recent research indicates that the acquisition of strategic knowledge can be supported by learning from video-based cases, however with somewhat limited success. In this study, these recent approaches are complemented by an additional instructional method, namely cognitive modelling. Therefore, the research question addressed in this study is: Does the use of cognitive modelling in video-based case studies enhance prospective teachers' acquisition of strategic knowledge? To answer this question an experimental field study with a between-subjects design was conducted. Participants (N=175) were student teachers attending an online pedagogical introductory course. Participants were randomly assigned to a treatment group, which received video-based cases along with cognitive modelling, and a control group, which received video-based cases with a textual description of the teacher's actions. As expected, results showed significantly higher scores on strategic knowledge in the treatment group with medium effect sizes. These findings suggest that cognitive modelling is an effective instructional method to improve the acquisition of strategic knowledge by the use of video-based cases in teacher training.

Aims

Theory and research stress the importance of knowledge as a central element of the teaching profession. Thus a great deal of teacher training is committed to impart knowledge via lectures and seminars. Yet, this theoretical knowledge often is prone to stay inert, that is, it cannot be used or applied in practical situations. Therefore it is argued that a knowledge base of teaching also has to comprise practical knowledge (Verloop, van Driel & Meijer, 2001). The acquisition of practical knowledge, however, is also difficult, because student teachers often fail to interrelate this practical knowledge with theoretical knowledge. In response to this problem the promotion of strategic knowledge (Shulman, 1986; de Jong & Ferguson-Hessler, 1996), is important. Strategic knowledge can be considered as a type of practical knowledge that explicitly features the reflexive use of theoretical knowledge. Hence, this knowledge enables student teachers to effectively arrange an organized line of action to solve a problem of classroom practice by making use of relevant theoretical knowledge. Thus the question arises how strategic knowledge can be fostered in teacher training.

A common approach to foster practical knowledge in teacher training is the use of video-based cases. Research yielded positive findings for different instructional uses of video-based cases. However, the use of video-based cases alone often failed to promote longer term transfer of theoretical principles into practice (Moreno & Valdez, 2007). This might be due to the limited feasibility of video-based cases to promote strategic knowledge. The arrangement of particular necessary procedures to solve a problem of classroom practice is a mental process, which cannot be observed and seldom is articulated by teachers. Therefore video-based cases lack the capability of revealing the

strategic knowledge that teachers bring to bear tacitly when they encounter certain problems in the classroom. To this end, additional instructional methods are required.

Cognitive modelling is particularly suitable for the direct and transfer-oriented imparting of strategic knowledge (Mandl, Gräsel, Fischer, 2000). It usually involves that a skilful model demonstrates solving a typical problem of a particular domain in a realistic context. The model articulates its cognitive processes at planning and performing necessary actions and expounds possible implications. By this externalization (e. g. thinking aloud) the cognitive processes that determine a particular behaviour are revealed and made communicable. Research findings provide evidence for the effectiveness of cognitive modelling in central educational settings (e. g. Pedersen & Liu, 2002). Yet only a few attempts have been made to implement cognitive modelling techniques in teacher training. Despite showing encouraging results, these efforts did not make use of the full potential of the instructional method. They either did not reveal the cognitive processes underlying the models actions (Moreno & Ortegado-Layne, 2008) or used a cognitive modelling technique in an unrealistic and decontextualized presentation format (Nirula & Paskin, 2008). Therefore, the research question addressed in this study is: Does the use of cognitive modelling in video-based case studies enhance prospective teachers' acquisition of strategic knowledge?

Methodology

To answer the research question a field study with an experimental between-subjects design and an intended sample size of 200 participants was conducted. Participants were student teachers that attended a pedagogical introductory course in a multimedia web-based learning environment. Student teachers from three consecutive terms were sampled. As homogeneity of variance was given for all variables, the data from the terms was aggregated. Participants (N=175) were randomly assigned to a treatment group, which received video-based cases along with cognitive modelling, and a control group, which received video-based cases with a textual description of the teacher's actions. Strategic knowledge was assessed by participants' written solutions to a video-based case, which they independently had to work on. A coding rubric was used to quantify the data. To control possible moderating factors participants' study motives, general study interest and specific study motivation were measured by questionnaire at the outset of the term. Additionally, online questionnaires captured participants' topic-specific interest, prior knowledge, perceived practical relevance and self-efficacy as well as the perceived case-related self-efficacy before and after the treatment. To analyse the data ANOVAS and general linear models were computed.

Findings and educational significance

As expected, results showed significantly higher scores on strategic knowledge in the treatment group with medium ($d=0.51$) effect sizes. Furthermore, analyses showed no significant moderating effect for any of the included control variables. The results suggest that cognitive modelling is an effective instructional method to improve the acquisition of strategic knowledge by the use of video-based cases in teacher training. During the presentation the theoretical framework and further findings of the study will be elaborated.

PAPER PRESENTATION

Starting points to integrate information and communication technology into teaching

Susanna Pontinen, University of Eastern Finland, Finland; Stina Hacklin, University of Eastern Finland, Finland

Nowadays information and communication technology (ICT) is part of everyday life. Children, adolescent, working age and elderly persons use ICT and with the exception of the elderly ICT is seen as natural part of generations' life. However, at school the meaning of ICT is not as important as outside school. Why school differs from the rest of society? We are interested in this issue and explore how in teacher education context in Finland first-year elementary school student teachers construct their meanings about using ICT in education. In our research we used discourse analysis and analyzed class teacher students learning diaries in order to find out how they construct their generation as "digital natives". We also analyzed how they describe their ideas to integrate ICT in education. We found that it is not obvious for all the student teachers to be classified as a member of "digital natives". Student teachers value their technical competences but they do not necessarily construct the connection between everyday life and school life competences. They also construct differences between themselves and their own school teachers and between everyday technology and suitable school technology. Student teachers construct the meaning of educational use of ICT in three ways - as inclusion to the society, as improving pupils' learning and as a new possibility to teaching and learning.

Nowadays information and communication technology (ICT) is part of everyday life. Children, adolescent, working age and elderly persons use ICT and with the exception of the elderly ICT is seen as natural part of generations' life. However, at school the meaning of ICT is not as important as outside school. Why school differs from the rest of society? We are interested in this issue and explore how in teacher education context in Finland first-year elementary school student teachers construct their meanings about using ICT in education.

Recent educational research on learning and technology has paid attention how to integrate information and communication technology into the learning environment. A broad definition of a learning environment includes teachers, students and other people, the computers and their roles. Studies have shown that teachers' pedagogical perceptions play important role in the integration process. This means that technological infrastructure is only starting point to use ICT in education but not a guarantee. Digital technologies have also raised questions about differences between the people in the learning environment. Teachers and students are classified into different generations according to their use of ICT – nowadays students are seen as the first "digital natives" and teachers as "digital immigrants". In the context of teaching and learning differences between generations are too wide and more attention should be paid on variation within the generations.

The aim of our research was to find out how student teachers construct their generation as "digital natives". We also analyzed how they describe their ideas to integrate ICT in education. As a research data we had student teachers' learning diaries which they wrote as a part of students' obligatory course on ICT in education at the University of Joensuu (now University of Eastern Finland). Learning diaries included student teachers description of their aims for the course, their reflections about their competences to use ICT in education and their school experiences about educational use of ICT.

The course was conducted at the end of their first semester when student teachers' pedagogical studies were just beginning. The course consisted of lectures (5 hours), working in groups (10 hours) and a written examination. On this course, the students were instructed to design a learning module, i.e., a project or a smaller learning unit, such as one lesson. In the learning module students were guided to integrate ICT into the learning and teaching processes in a school context. The students were given a free hand with the task. In other words, they could choose the topic and the age of the target pupils based on the Finnish National Core Curriculum for Basic Education. The only guideline was that the learning module should employ ICT in any form they seemed suitable. Students documented learning modules and wrote descriptions about the intended progress of pupils' learning. These descriptions are analyzed earlier and the results indicated that student teachers just tend to "update" familiar teaching methods by adding new technologies.

In order to better understand student teachers' choices just "update" their teaching methods learning diaries were analyzed more deeply. In our presentation we focus to show the results of this analysis. In our research we used discourse analysis. Discourse analysis is a research approach to examine how student teachers construct social world, thus how they talk about integration of ICT in education. By talking students do not only report their thoughts, they also construct things and also written documents can be seen as spoken language because those text are written at least for the student her/himself. In analyzing process we concentrated on student teachers rhetorical strategies they use in learning diaries.

As a result of our analysis we found that it is not obvious for all the student teachers to be classified as a member of "digital natives" and membership of the new generation does not mean that all the teacher students are equal and confident to use ICT in education. Student teachers value their technical competences but they do not necessarily construct the connection between everyday life and school life competences. They also construct differences between themselves and their own school teachers and between everyday technology and suitable school technology. Student teachers construct the meaning of educational use of ICT in three ways - as inclusion to the society, as improving pupils' learning and as a new possibility to teaching and learning.

The results indicate student teachers cannot directly transfer their technical competences to their pedagogical thinking and educational use of ICT is partly based on hesitation. Students also maintain the culture of uncertainty and see ICT integration as a new way to teach. Despite of these challenges most of student teachers are eager to use ICT in education and they are satisfied with their ideas to integrate ICT in education. The results conform previous research results but also raise interesting questions for future research. How student teachers describe social inclusion in other contexts? How student teachers maintain and accept uncertainty in other contexts? How student teachers ideas to integrate ICT in education develop during teacher education?

PAPER PRESENTATION

Student Teacher Reflections and Actions in Preservice Teacher Education, a Curriculum Framework

Sari Yrjanainen, University of Tampere, Finland; Eero Ropo, University of Tampere, Finland

Purpose of the study is to investigate student teachers' reflections and actions during preservice teacher education. Theoretical framework for the data collection and analyses is based on the curriculum model developed for the university teacher education.

We apply a three-stage model in describing the teacher student learning processes during the teacher education. This model is under construction to become a curriculum model for the teacher education program. On the first level of the model are the autobiographical and individual identity development processes. Second level describes social processes of becoming a member of the profession and teacher community. Third level describes learning processes at the cultural and contextual level.

The informants of the study were math and sciences teacher students (n=121, in 2005-2008) in the secondary teacher education program. Data were collected by interviews, observations of lessons and the narratives that the students wrote.

The methodology of analyses is qualitative and we can call it like "bricolage".

General description

Purpose of the study is to investigate student teachers' reflections and actions during preservice teacher education. Theoretical framework for the data collection and analyses is based on the curriculum model developed for the university teacher education.

Teacher education is traditionally based on three cornerstones, namely subject matter knowledge, educational theory, and teaching practice. In Finland, preservice secondary teacher education, consists of subject studies and pedagogical studies. Students preparing for teacher profession study their major subject(s) for the first three years of their candidate and master level studies at the subject departments. Pedagogical studies (60 ECTS) is done at the faculties of education.

Pedagogical studies consist of two parts. Theoretical studies consist of courses dealing with, for instance, society and school, individual development and learning, and curriculum and instruction. Shulman's (1987) theorizing of the pedagogical content knowledge is important in analyzing the student teacher learning in different domain areas. It contains content knowledge, knowledge of educational goals and purposes (curriculum), and knowledge of teaching methods and didactics.

Teacher practice is typically done in a university practice school. Students give about 30 lessons during their teacher studies. What those lessons in the actual school situations are, depend on several contextual, situational and autobiographical factors (Ropo 2004, Connelly & al. 1997; Meijer & al. 1999, Sotto 1994, Grossman, 1995).

We apply a three-stage model (Ropo 2009) in describing the teacher student learning processes during the teacher education. This model is under construction to become a curriculum model for the teacher education program. On the first level of the model are the autobiographical and individual identity development processes. The student has to

develop a personal teacher identity, applicable knowledge and skills to teach and reflect (cf. Schön 1983, 1988; Rodgers 2002a, 2002b). Second level describes social processes of becoming a member of the profession and teacher community (see e.g. Ropo 2004, Ropo & Värri 2000). Third level describes learning processes at the cultural and contextual level. It is necessary to understand why education is needed and schools exist.

We apply this curriculum model into the analyses of empirical data of student narratives and observations of teacher practice. The studied empirical questions were the following:

- 1) How do the different curriculum levels appear in the teacher student written narratives about school and their own learning as teachers
- 2) How do the curriculum levels appear in the teacher student actions and reflections about actions in teacher practice

The above questions are closely related to our overall purpose to describe and understand the teacher students' emerging perspectives on the role of classroom and school discourses in shaping their identity, conceptions of science and knowledge, and their understanding of schools as educational institutions.

Concerning actions in the teacher practice we apply the concepts of positioning and affordance. Positioning is understood in this paper as a discursive concept. It refers to communication strategies a student applies towards a partner of a discourse. It is sometimes described as a role that the student takes in a specific situation but it is more dynamic and varying (see Van Langenhove & Harré 1999). Positioning is not, however, possible without perception of affordances in the discursive situations. Tanner and Jones (2002) defined an affordance as "a potential for action, the capacity of an environment or object to enable the intentions of the student within a particular problem situation". We also apply the discourse concept in understanding the structure of lessons. The word "discourse" is shorthand for "discursive formation," which is what Foucault (1972) called communication that involves specialized knowledge of various kinds. Foucault's definition of discourse is "systems of thoughts composed of ideas, attitudes, courses of action, beliefs and practices that systematically construct the subjects and the worlds of which they speak". Discourse according to Foucault (1977, 1980, 2003) is related to power as it operates by rules of exclusion. Discourse is therefore controlled by objects, what can be spoken of; ritual, where and how one may speak; and the privileged, who may speak.

Methods

The informants of the study were math and sciences teacher students (n=121, in 2005-2008) in the secondary teacher education program. Data were collected by interviews, observations of lessons and the narratives that the students wrote.

After their first teacher practicum they wrote novice teacher essays in which they reflected on their ideals and efforts in the classroom activities during the practice teaching. The data of the selected students (15) were collected by videotape during the authentic teaching situations at the practice schools. After the video recording the researcher watched the recording with each student using the think-aloud method. In this session the students were asked to reflect their solutions and reasoning during the lesson. This discussion was tape-recorded. The analysis is based on the hermeneutical and autobiographical approach and we have used discourse analysis also (Bruner, 1996; Pinar, 1978; Riesmann 2002; Roth, 2005). The methodology of analyses is qualitative and we can call it like "bricolage" (Berry 2006).

Results

The results show that student reflect in their narratives mostly issues and developmental processes related to the levels one and two in the curriculum model. Myself as a teacher (level one) and myself as a teacher in the school (level two) were the most common themes. Level three were not reflected or there were only random reflections concerning that level.

The teacher students converse with themselves, reflectively. These processes can be described as the first level processes in the above mentioned curriculum model.

In the student practice and interviews concerning the practice sessions students reflected mostly level one (how sure they were about themselves as teachers in the practice sessions), and level two processes (what is their own role and what kind of positions to take in the practice teaching situations). Level three processes appeared in the relation to

individuality of pupils in the practice classes. They were interesting differences between the students in how much teacher students were able to individualize their instruction. We will report more explicitly results from four cases representing different action types in respect to practice teaching. These results report the applied the discourses, affordances and positions in the practice sessions. Implications of the study for teacher education will be discussed in the paper.

PAPER PRESENTATION

An investigation into the analogies used for teaching the mole in secondary classrooms

Chemistry, Science Education, Secondary school

Su Chi Fang, The University of Melbourne, Australia; Christina Hart, The University of Melbourne, Australia;

David Clarke, University of Melbourne, Australia

The mole is a fundamental concept in chemistry. Using analogies when introducing the mole is common in textbooks. However, what type of analogies and how they are used in introducing the mole in classrooms needs to be investigated.

This paper is part of my PhD research program in which I intended to look into the reasons why the mole concept is difficult to be taught and learned by comparing two countries (Australia and Taiwan). Data included video records of the lessons and the chemistry teachers' and students' interviews. The aims of this paper are (1) to explore what are the analogies used to introduce the mole concept, and (2) to inquire into how these analogies play a role in helping learning the mole concept.

The findings showed that using analogies in introducing the mole was popular in secondary classrooms. The analogy of 'a dozen' was employed the most frequently. In addition, a second group of analogies like 'packages of rice' or 'trucks of oranges', and a third group related to chemical reactions were also used in classrooms. In fact, different analogies highlight different aspects of the mole concept. However, it seems that these analogies were used without making explicit the aspect they actually address. Moreover, the essence of the mole concept, that it depends on a proportional relationship, was not conveyed by these analogies. Suggestions about effectively using analogies in teaching the mole concept are also presented.

Using analogies in teaching and learning chemistry is deemed a powerful strategy because analogies provide a bridge connecting between the unfamiliar target concept and familiar analogy (Duit, 1991). Previous research has showed that generally in textbooks the mole concept was introduced with analogies, such as a dozen (Staver & Lumpe, 1993). However, what kinds of analogies are used and how they are used in teaching and learning in classrooms has not been previously explored. Therefore, the aims of this paper are (1) to identify what analogies are used to introduce the mole concept. (2) to inquire into the role these analogies may play in helping students' learning of the mole concept. This study is positioned as a classroom study, based on the perspective that learning science is not only a personal meaning making process but also a social interactive activity. Seven chemistry classrooms were participating in this study, including two year-8 and three year-10 classrooms in Taipei, and two year-11 classrooms in Victoria. Data generation included videotaping the lessons, teacher and student interviews. Analysis of the empirical data was based on a content analysis of the mole concept.

In these seven classrooms, a dozen was the most frequently used analogy in the lessons on the mole. The analogies could be categorised into three different groups: (1) The number group, (2) The mass group (3) The chemical reaction group. The number group includes analogies such as a dozen, a box etc, and they stress the point that the mole represents a number, 6×10^{23} . The analogies in this group suggest that it is possible to count and know exactly what the number is. The mass group comprises analogies like trucks of oranges and packages of rice. The mass group of analogies emphasized the situation where the number involved is huge, so 'weighing' is used as a strategy to quantify the amount. Therefore, within this context, 'weighing instead of counting' is the point and exactly how many there are is NOT important. The analogies in the chemical reaction group are not directly related to the mole concept, but implicitly involve the application of the mole in chemical reactions, for example, monkey and banana, and the process of baking a cake.

Teachers used one or more of these analogies at the time when they introduced the mole. However, it appeared that their students accepted the number group most readily. The number group of analogies seemed to be easier to grasp because the connections between the analogy 'dozen' and the target 'mole' are straightforward (Duit, 1991). In other words, it is simple to relate a number to the term, 'mole', just like we relate 12 to a dozen. In contrast, the connections between the analogy 'packages of rice' and the 'mole' were not explicit. Also whenever the mass group of

analogies was presented, the teachers did not explicitly make the link with the mole. The teachers alluded to 'weighing instead of counting', but they did not explain how this strategy works with the mole in chemistry. Consequently, the students could not actually see the connection between these analogies and the mole and in interviews they did not refer to them as helpful for their learning. The third group of analogies seems to be more problematic because the analogies concern the ratio between reactants and products in chemical reactions and not the mole concept itself. This connection, again, was not made explicit and the students did not appear to find this type of analogy meaningful.

Nevertheless, these analogies used in the classrooms do not perfectly match the mole concept. They were limited in that they did not explain the proportional relationships between 12C and other elements. An activity that is more analogous to the use of the mole concept in chemistry will be provided. Two significant issues pertaining to how teachers can use analogies more effectively in science teaching are discussed. First, the connection between the analogue and the target should be made as explicit as possible to the students. In other words, students' attention should be guided and directed to the intended way of using the analogy (Coll, 2006), otherwise students might see and interpret analogies in a different way from their teachers (Treagust & Harrison, 2006). Second, it is important that teachers discuss "the scope and limitations of an analogy" (Justi & Gilbert, 2006, p. 128) with students. For instance, in the case of mole, although 'a package of rice' is a promising analogy for students to learn the mole, the meaning it conveys is still limited, since this analogy cannot reflect the essence of the use of the mole in chemistry. Therefore, as Justi and Gilbert (2006, p. 129) suggested, teachers might adopt "discuss and guide" approach rather than "show and tell" when they teach with analogies.

PAPER PRESENTATION

A Practice of Science as Varied as the Members of the Science Classroom Community Culture and Education, Inquiry learning, Science Education

Michele Koomen, Gustavus Adolphus College, United States

This paper reports on a qualitative study of nine culturally, linguistically and academically diverse students as they studied insect biology and ecology in their inclusive seventh grade life science class. Three fundamental data collection methods of qualitative research (student observations, interviews and artifact analysis) framed the data collection portion of this study. Constant comparative and microanalysis frameworks for grounded theory were used to systematically analyze the data set resulting in a practice of science that is different for each of the nine youth: A practice of science that is fragile and tentative and tied with the language of science; a practice of science that is dutiful and pragmatic although absent in passion or curiosity, and a practice of science positions one student to be dis/abled. Implications of this study to the greater research community and insights for instructional practice and structure of learning opportunities for all students are discussed.

Aims/Purpose

Many, many science classrooms across the world represent our global society and as such are rich in diversity, language, culture and ability. The United States is no exception to this new normal where 20 percent of school-aged children have at least one parent who is an immigrant and 5 percent of the students were immigrants themselves with language minority students speak an amazing 400 + languages (Nieto, 2004). On top of the growing linguistic and cultural differences in the school age population, science classrooms increasingly are places where students with exceptionalities are mainstreamed (Hobbs & Westling, 2002) as a result of legislative initiatives such as the Individuals with Disabilities Education Act (IDEA, 1990) and subsequent amendments (IDEA, 2004). Science for all Americans (AAAS, 1989, 1993) call for egalitarian access to science education is based on beliefs that all youth can learn science. The theme of the 2011 EARLI conference is "Education for a Global Networked Society." If our science classrooms illustrate the richness of our global society, doesn't it make sense that we try to understand how some members of that global diversity contextualize and experience learning as we position ourselves to embrace education for a global networked society? This paper will describe a research study focused on learning for students from diverse backgrounds who have been underserved in the education system (Basu & Barton, 2007; Upadhyay, 2008).

Theoretical Frameworks

Research featuring members of our global society by nature would be complex and necessitate interdisciplinary theoretical frameworks including: 1) science for all; 2) critical feminist theory; 3) a practice of science using inquiry and 4) public policy. Science for all Americans (AAAS, 1989, 1993) call for egalitarian access to science education based on beliefs that all children can learn science. If science is to be for all a research lens using critical feminist theory is appropriate because critical theory does not merely describe a situation, place or practice but attempts to "realize a society that is based on equality and democracy for all its members" (Cohen, Manen and Morrison, p. 28). Researchers would agree that inquiry is defined as a process of posing questions, generating and analyzing data, drawing

conclusions, communicating the results, applying the conclusions back to the original question and perhaps following up with a new question (Sandoval, 2005; Cuevas, P., Lee, O., Hart, J., & Deaktor, R, 2005). Science is considered to be one of the most valuable subjects for inclusion of students with exceptionalities because they, like all students, can benefit greatly by the systematic study of the universe with promotion of scientific reasoning and inquiry (Mastropieri & Scruggs, 1992 & 1994; Bell, 2002).

Methodology

This study featured nine students who represent as a group: diverse cultures (Hmong and African-American); second language acquisition (Hmong); special education (LD and EBD) and gifted and talented who attended a public middle school in an urban metropolitan area with 88 percent students of color. An interpretive research design was guided by the following research question (a) What are the experiences of learning and the underlying contexts and structures for the nine students in their science classrooms? On-site data collection included 19 video taped science teaching and learning episodes across 13 weeks with extensive field notes, individual semi-structured interviews of students (3) and teacher (2) over the course of the research, and examination of student artifacts and projects. The analytic process was based on immersion within the data with repeated sorting, coding, and constant comparison characteristic of the grounded theory method (Morrow & Smith, 1995).

Results

Several important findings illuminate a practice of scientific inquiry that is as varied as the students who make up the class. Inquiry for William and Dion is experienced as fragile and tied to language arts. Their perception of practicing science is that it is more about understanding the words of science and moderated by their academic difficulties that make it seem that all they ever do is have "boring long lectures" or "whole packets to read." For Mai, her practice of science is pragmatic. Her desire is simply to look "good" in the classroom by taking on a "bored" affect about science, getting her work done and "listening to my teacher." Her practice of science is dutiful and devoid of passion and curiosity.

Finally, the practice of science for Dion is dis/abled. At the surface, Dion appears to realize the intent of the reform efforts of science for all, however, taking a closer look at the meaning of these experiences finds that Dion is positioned in this class as dis/abled with an identity that is compromised and negative. His teacher, Maren does many things well. She has high expectations and strong beliefs that all of her students can learn. However, Maren, unintentionally, positions Dion as dis/abled rather than able by assigning other adults to work with Dion and assigning him a front row center seat near the overhead projector where she can keep an "eye" on him. Skrtic (1991) describes this view as a naive pragmatism or "a mode of analysis and problem resolution that is premised on an unreflective acceptance of the assumptions that lie behind social practices" (p. 150). In this case, this naive pragmatism reproduces a status quo for Dion that positions him at a "functional" level and places him within a classroom learning community as dis/abled.

Significance

This study sheds some light on how we might re-imagine what we mean by science for all. First of all, we need to think reflectively as to how we position our more challenging students within the classroom culture. It might be easier to keep an eye on a student by placing him or her front and center, but what message does this present to the other students within the classroom about said students. Secondly, inquiry science still encompasses reading and literacy skills. How can these skills be de-emphasized so that our students with exceptionalities are not excluded from the meaning and intention of an equitable science for all? These findings may help us to design instructional programs that better meet the needs of our complex and diverse classroom populations as we move toward more culturally responsive teaching pedagogies.

PAPER PRESENTATION

Scaffolding teachers in inquiry-based learning and teaching through design

Computer supported Learning Environments, Inquiry learning, Science Education

Alexia Sevastidou, University of Cyprus, Cyprus; Costas Constantinou, University of Cyprus, Cyprus; Eleni Kyza, Cyprus University of Technology, Cyprus

This study explores teachers' ability to make the transfer from inquiry-based learning to inquiry-oriented science teaching. Prior research has demonstrated that teachers encounter many challenges in conceptualizing inquiry-based approaches. The purpose of this study is to give evidence, through the cases of two pairs of pre-service teachers, about constraints and affordances of design-based learning as a method for enculturating teachers in an inquiry-based learning and teaching framework in science. Our research was conducted during a professional development course about new technologies and learning in science. Participants were presented with the task of designing web-based

inquiry learning environments on a specific platform that offers tools for reflective inquiry; they received scaffolding for this task through their participation in the course and through their interaction with a web-based teacher learning environment. Data is drawn from two cases of participants who shared similar characteristics, namely in educational background, age and teaching experience, but displayed markedly different performance: one case succeeded in working with relevant scaffolding and in translating challenges with inquiry-based learning into design knowledge; the other case failed to do so. We discuss the implications of this study for efforts to engage teachers in complex design tasks, with the intent to help them grapple with the nature and complexity of inquiry-based pedagogy. Even in the cases where teachers do not find their way around the design task, they gain valuable experiences and insights into inquiry as a teaching and learning framework.

Background

As inquiry-based teaching and learning in science education is increasingly becoming a more consistent paradigm with the needs of today's societies (Sawyer, 2006), exploring ways for introducing teachers in this framework has become a significant task.

Inquiry, the pursuit of open questions, is a fundamental scientific practice, and it is also recognized as a valuable, authentic context for science learning. Required teacher competencies for teaching science as inquiry include scaffolding students in complex tasks like framing questions, grappling with data, creating and critiquing explanations, in some cases, publicly (Crawford, 2007). As reported in prior studies, teachers encounter many challenges in adopting an inquiry learning and teaching framework: they are not prepared for the role of giving students intellectual space as well as structure in open-inquiry approaches; even when they intend to use scaffolding, they hardly listen to students, they tend to be directive, they have trouble in supporting the negotiation of ideas and conceptual evolution and, at the same time, introduce students to inquiry processes (van de Valk & de Jong, 2009; Holbrook & Kolodner, 2000).

Purpose

The purpose of this study was to explore the transfer from teachers' own learning to designing teaching and to identify affordances of a design-based learning approach as a way to scaffold teachers in developing an inquiry-based learning and teaching framework. Our main research questions were: a) what are the challenges that teachers encounter when asked to design an inquiry-based learning environment with scaffolding features? b) How do teachers respond to tools that aim to scaffold their design process?

Method

Participants were ten science teachers enrolled in 13 three-hour sessions of a professional development course about new technologies and learning in science. The course assumed a design-based learning approach and was structured around three key features: a) a design task that engaged teachers in the design of inquiry-based learning environments, b) a design tool, STOCHASMOS, a web-based authoring tool that employs inquiry scaffolding features and c) design scaffolds, provided through a web-based teachers learning environment, in the form of (i) design principles, through the structured presentation of research-derived theoretical and practical information, (ii) prompts for planning and reflecting on the design task and (iii) web-based peer collaboration activities. Throughout the course, participants were grouped in pairs. Each pair developed a web-based inquiry-learning environment, which they submitted as an assignment at the end of the course.

Data collection and analysis

The study used data from multiple sources including: (a) researcher's notes from participants' observations; (b) teachers' written definitions of inquiry; (c) log files recording participants' interactions with the scaffolding provided on the course web-based environment; (d) participants' final learning products, the web-based learning environments that they designed as part of their course work, (e) interviews with teachers after the completion of the course.

Data were analyzed qualitatively using the constant comparative method (Glaser & Strauss, 1967). Different kinds of analyses (e.g. the analysis of the teachers' definitions, the analysis of their final learning product) were synthesized to triangulate findings. In each of these, we tracked the emerging themes for each pair of participants and iteratively compared them to the themes emerging from the analysis of the other pairs.

Findings

The data analysis showed that challenges with inquiry-based learning and teaching were exemplified in the learning environments that teachers designed. Teachers' difficulty in balancing between space and structure was evident in the way they designed scaffolding for students, and in the underlying inquiry patterns on which they structured their environments' activity sequences. Subsequent analysis, which drew on the framework proposed by Quintana et. al (2004), revealed that all pairs followed the same trend in the distribution of the three types of scaffolding prompts

across their environments (figure1,2): process management prompts presented more than the 50% of all prompts provided, reflection and articulation prompts were used at a lower frequency, while sense making prompts were scarcely employed. Teachers seemed to be concerned about the flow of activities and over-emphasized the sequence of steps that students needed to follow; in effect, they often prescribed situations rather than designing opportunities for learning; they used many routine directions as scaffolding prompts, in a way that is inconsistent both with inquiry and with the platform's designer intentions.

Another finding was that four out of five pairs of teachers responded in a common way to the scaffolding provided by the web-based environment: they accessed scaffolding, submitted reflections but did not engage in a constant reviewing process of their design judgments. Data from two cases of participants capture the range of the affordances and constraints of design-based learning as a method of enculturating teachers in an inquiry-based learning and teaching framework. Even though these two pairs shared similar backgrounds, they had contradicting performances and experiences with design-based learning. According to our analysis pair1 produced the least coherent whereas pair5 the most coherent inquiry-learning environment (table 1). Their experiences with design-based learning are illustrated in the excerpts below:

...we realized that this (design) was a recurring process, although at first we were thinking that we finished with our driving question and so we will move on... somewhere along the process you realize that all stages are interconnected and affect each other, and we returned, reviewed and moved forward (pair5, interview)

...recording our design decisions was not helpful for us...many times we wrote that we will do something and then we found out that it doesn't work. This was stressful. We had to do it because we already described it... (pair1, interview)

Conclusion

The teachers who participated in our design-based learning approach faced similar challenges in designing inquiry-based learning. Four out of five pairs interacted with the reflective scaffolding provided in a similar way. Design as a task was useful in exemplifying challenges with inquiry-based learning and teaching, giving them a more tangible than theoretical character. Being reflective through the whole process of design allowed one pair of teachers to overcome challenges brought about through the design task. As prior research informs us that teachers' ability to teach science as inquiry is affected by the complex interactions of contextual or personal factors, there is further need to explore approaches that engage teachers in reflective practices, like design, as a means of enculturating them with inquiry as a teaching and learning framework.

PAPER PRESENTATION

Exploring the graphical representations in the high-school Earth Science textbooks

Comprehension of Text and Graphics, Instructional Design, Science Education

Yi-Chun Chen-, National Taiwan Normal University, Taiwan, Province of China; Fang-Ying Yang, National Taiwan Normal University, Taiwan, Province of China

By classifying graphical displays, the main purpose of this study is to examine the graphical representations in earth science textbooks used in the senior high school in Taiwan. The material to be analyzed is the tenth-grade earth science textbooks. There are 5 versions of the textbooks. Three versions with highest rates of adoption in schools are involved in the study. Based on previous studies and considering the structure of scientific knowledge (Duschl, 1990), each graphic is classified with respect to its form and content aspects. There are four categories regarding the form of graphical representation: Real Photo, Apparatus Photo, Diagram and Graph. To analyze the content of each graphic, we adopt the goal-of-science hierarchy for teaching science proposed by Duschl (1990). Accordingly, five content categories are applied to the analysis, namely Data, Concept, Relation, Theory and Map or Figure. In so far, we have examined one version of the to-be-analyzed textbooks. Some preliminary findings are presented here. First, it was found that the highest number of the category in form is Graph. Second, regarding the content of graphical representation, our analysis shows that the proportion of each category differs in topics. Considering the first four categories in the content of graphical representation, Concept is dominating in every topic. Such a result implies that concept teaching takes up the highest proportion of the knowledge organization in the textbook. The topic characteristics also affect the proportion of the distribution. The study is still in progress. More findings will be presented in the conference.

Objective

By classifying graphical displays, the main purpose of this study is to examine the graphical representations in earth science textbooks used in the senior high school in Taiwan.

Theoretical Background

According to the constructivist theory of learning, students develop their own understanding by internalizing information either through words or graphics in science textbooks. Words and graphics are different systems of knowledge representation. They differ not only in the displayed form but also in the internal structure. Compared to words, graphics are composed of discrete and easily identified elements that are polymeric or nonnotational (Vekiri, 2002). Paivio's (1986) dual coding theory suggests that verbal information and pictorial information are processed in different cognitive systems and stored in different memory areas (Anderson, 1995). Accordingly, the graphics along with texts would bring about additive effects on learning. The "visual argument" theory also supports that graphics communicate information more effectively in that they insert low demands on working memory (Vekiri, 2002). However, the use of graphics is not always beneficial for the acquisition of knowledge. Schnotz & Bannert (2003) found that reading of graphics is task-dependent, and individual difference must be considered. They argued that graphics facilitate learning only if individuals have low prior knowledge or if the subject matter is visualized in a task-appropriate way. These dissimilar results may be owing to the problems regarding definitions and entities of graphic representations. In literature, there are few relevant studies (Vekiri, 2002). Thus in the study, an attempt is made to examine the graphical representations in the high-school earth science textbooks.

Methodology

Material The material to be analyzed is the tenth-grade earth science textbooks. There are 5 versions of earth science textbooks used in the senior high schools in Taiwan. Three versions with highest rates of adoption in schools are involved in the study. Currently, four topics related to "Global Warming" are being analyzed, including Atmosphere, Ocean, Natural Hazard and Climate Change. **Method** Based on previous studies and considering the structure of scientific knowledge (Duschl, 1990), each graphic is classified with respect to its form and content aspects. The classification details are interpreted as follows:

1. The form of graphical representation There are four categories regarding the form of graphical representation: Real Photo, Apparatus Photo, Diagram and Graph. Apparatus Photo means that the graphic is photo taken by equipments such as telescope, microscope, satellite and so forth. In other words, it can't be read by raw eyes (Real Photo). Diagram is the part, structure, simulation or operation of real objects, abstract entities or processes (Vekiri, 2002). The water cycle and the formation process of a typhoon belong to this category. Graph is the relation, sequence, statistics or values showing how two or more variables are related to each other. Noticeably, some textbook authors used more than one form in creating graphics.

2. The content of graphical representation To analyze the content of each graphic, we adopt the goal-of-science hierarchy for teaching science proposed by Duschl (1990). The bottom of the hierarchy is data collection where all science investigations begin. After collecting sufficient data, scientists would seek the lawlike relationships or patterns in collected data to develop science theory. The process is a rational feedback loop which suggests that scientific theory is subject to change. New theories would either emerge from different interpretations on existing data because of the development of new technology or from newly found data. In either case, the theory development restarts from data collection. Based on the hierarchy, the content of graphics was sorted into five categories, namely Data, Concept, Relation, Theory and Map or Picture. The first four categories are adopted from the themes of the goal-of-science hierarchy. Notably, since in textbooks, data are usually presented to students in lawlike patterns, Relation in our coding scheme indicates the relation between science concepts. The category of Map or Picture is an additional category. According to Vekiri (2002), Map is the feature (or data) and their location (or distribution) in real territory while Picture shows people, objects or scenes. Each graphic is allowed to be assigned to more than one category if necessary. **Data analyses** After coding, descriptive and Chi-square analyses are employed for further statistical analysis.

Results and Discussion

The study is still in progress. In so far, we have examined one version of the to-be-analyzed textbooks. Some preliminary findings are presented here. As shown in Table 1, numbers of graphics in each topic are not equally distributed. Across the four topics, the highest number of the category in form is Graph, followed by Diagram, but in the topic of Natural Hazard, it is Apparatus Photo (25.00%) coming in the second place. Regarding the content of graphical representation, our analysis shows that the proportion of each category differs with topics. For instance, Map or Picture is most frequently seen in Natural Hazard but in Atmosphere, it is Concept that appears most often. Besides, different topics have different scopes and aims. For example, in the topic of Natural Hazard, the textbook is full of real disaster photographs, satellite photographs, weather map etc. Whereas, the topic of Atmosphere and Ocean focuses more on illustrating relevant concepts. Considering the first four categories in the content of graphical representation, Concept is dominating in every topic. The result implies that concept teaching takes up the highest proportion of the knowledge organization in the textbook. The topic characteristics also affect the proportion of the

distribution. For example, the percentage of Theory in Climate Change is higher than those in other three topics because theories about climate change are by nature uncertain. Consequently, a lot of graphics in this topic are devoted to making predictions and building theoretical models. As mentioned before, some graphics may carry more than one category of form or content. Table 2 shows the numbers of categories found in individual graphics as well as their counts and proportions. In the form aspect, no more than 2 categories are ever found in one graphic while there might be up to four categories found in the content of a graphic. As seen in the Table 2, Climate Change and Natural Hazard have the highest variety in the number of categories. The results suggest that since the two topics deal with multi-dimensional problems, the use of multiple representations in graphics is necessary to convey relevant knowledge.

PAPER PRESENTATION

The Speed of Data Extraction from Decorated Graphs

Irit Aharon, University of Hifa, Israel; Billie Eilam, Faculty of Education, University of Haifa, Israel

Quantitative graphics combine quantitative information with pictorial elements. One example is the decorated graph, commonly used for communicating quantitative information in mass media and school textbooks. This prevalent mode of representing information calls for the examination of possible effects of decorative pictorial elements on individuals' ability to read the graph. Therefore, the present study investigated students' response time, required for extracting simple data from different types of decorated graphs. Participants comprised 9th graders (n=86 boys and girls). Three sets of graphs were used, each containing 24 items, presented successively in a random sequence on a computer screen: (a) pie graphs, (b) bar graphs, and (c) scatter graph. Each set comprised 6 different graphs, each presented in four different types of graphical design: a plain graph lacking any decorative elements; a graph placed on a background picture; a graph with a picture beside it; and a graph composed of illustrated specifiers. For each graph, students responded to a dual-choice question by pressing one of two assigned computer keys. Differences were found between students' response time to the different graphic types. Furthermore, for plain graphs but not for decorative ones, response time shortened as the number of data points increased. Findings suggest that decorative elements change students' focus of attention, requiring additional time for processing the perceived information. This extra time is required for distinguishing presented quantitative data from accompanying decorations. These findings bear direct implications for the design of learning materials, including, textbooks, tasks sheets, tests, and computer programs.

Graphs are powerful tools for presenting and analyzing quantitative information. As such their use and comprehension by students are extensively researched (e.g. Shah & Hoeffner, 2002). In the last few decades, due to the accessibility of graphical tools, the display of quantitative data has undergone a revolution. Pictorial elements are combined with quantitative information to create decorated graphs that are more appealing to the casual observer (Tufte, 1983). This mode of presenting quantitative information has become prevalent in mass media and textbooks. Some assume that these decorative elements enhance observer's ability to identify patterns, group visual elements into an object or a figure, and elicit semantic contexts relevant to the information presented in the graph, thus decreasing time on task. Others claim that these additions to the display divert observer's attention from the main information and increase the time required for its extraction (Kosslyn, 1994; Tufte, 1983;). Nevertheless very little research has been done on the effect of decorative elements on the interpretation and comprehension of graphs. The aim of the present study was to assess the effect of pictorial elements on the speed of students' extraction of simple data from different types of decorated graphs

Method

Participants: Eighty two students (33 boys and 49 girls) ages 14-15 participated in the study. They all learned in the ninth grade, at a private school in northern Israel. All students were of medium-class background.

Instruments and variables:

Graph types, graphic types and complexity. Three sets of graphs, each containing 24 items, were presented successively but in a random order, on a computer screen: (a) pie graphs, (b) bar graphs, and (c) scatter graph. Each set consisted of 6 graphs differing in their complexity, expressed in an increase in the number of data points. Every graph was presented in four different types of graphical design: a plain graph lacking any decorative elements; a graph placed on a background picture; a graph with a picture beside it; and a graph composed of illustrated specifiers.

Speed of data extraction. For each graph students responded to a dual-choice question, by pressing one of two assigned computer keys. Time (response time) between the appearance of each graph and the pressing of the appropriate key was measured in seconds (accuracy of ± 0.1 sec) Correct responses were distinguished from erroneous ones.

Spatial ability was assessed using the following tests from the Kit of Factor-Referenced Cognitive Tests (Ekstorn, French, Harman & Dermen, 1976): The Flexibility of Closure tests (CF): hidden figures (CF-1) and hidden pattern (CF-2); and the Speed of Closure tests (CS): Gestalt completion (CS-1) and snowy pictures (CS-3).

The spatial ability tests were administered prior to the graphs task with a week interval between each test. Students were classified as having low (bottom 25% of the distribution of students' scores), average (middle 50%) and high ability score (top 25%) for each separate ability.

Findings

Average response time to data extraction questions for the full graphs set, and the total number of errors were calculated for each student.

Average response time was significantly longer for low-spatial ability students with regard to CF(1+2) tests ($F(1,38)=4.745$, $p(1,43)=4.078$, $p \leq 0.05$) but not with regard to the CS-1 test ($F(1,24)=0.389$, $p>0.05$). No significant differences were found between low- and high- spatial ability groups with respect to the total number of errors. As may be expected, correlation between average response time and total number of errors show a significant increase in number of errors as the average response time decreases ($r(80) = -.315$, p

A general linear model for repeated measures was conducted to determine differences in response time with regard to within-subject variables of graph type, graphic type and complexity; and between subject variables of spatial ability: CF and CS-3. Differences were found in students' response time to the different graphic types (Pillai's Trace $F(2,77)=60.682$, $p(3,76)=5.501$, $p(5,74)=74.000$, p

Conclusions

Findings indicate that decorative elements have a certain affect on the speed of data extraction from graphs. Longer response time for extracting data from decorated graphs especially those with a picture on the side suggests that decorative elements change students' focus of attention and thus require additional time for processing the perceived information. Moreover, the decrease in time response with increase of number of data points in plain graphs may hint at students' application of Gestalt grouping processes during data extraction. The absence of the effect in the decorated graphs suggests a possible interference between decorating elements and grouping processes. Altogether, the present data may imply that excess time is needed for distinguishing presented quantitative data from accompanying decorations.

These findings bear direct implications to the design of learning materials including textbooks, tasks sheets, tests and computer programs. Students at all ages and levels of education encounter major difficulties while reading and comprehending graphs (e.g. Shah & Hoeffner, 2002;). It seems that the addition of decorative elements to the graphs would present little assistance in coping with these difficulties and could lead to their enhancement. Further research is needed to assess the possible affect of decorative elements on graph comprehension.

PAPER PRESENTATION

Educational and school effectiveness for different groups of students in China

Assessment methods, Secondary school, The role of research on learning and instruction in developing education systems

Sally Mary Thomas, University of Bristol, United Kingdom

This paper reports key findings from a UK DFID/ESRC funded study: Improving Educational Evaluation and Quality in China. In collaboration with key stakeholders (national and local policy makers, teachers, students) the study aims to develop innovation in school evaluation and guidelines for implementation to enhance school improvement efforts in mainland China. The specific focus of this paper will explore the nature and extent of educational effectiveness in mainland China, using innovative quantitative methodology (multilevel modelling) to analyse longitudinal examination, student background, school process and context data from 120+ senior secondary schools. The findings indicate significant differences in effectiveness between schools and regions in China as well as significant differential effectiveness within schools for different groups of students – a key issue related to equity. Other findings include the

considerable influence of school input, process and context factors on student's attainment and progress at senior secondary school. The implications of the findings are discussed in terms of educational policy and practice in mainland China and internationally.

Introduction

This paper presents key findings from a UK Department for International Development [DFID]/Economic and Social Science Research Council [ESRC] funded study: Improving Educational Evaluation and Quality in China (IEEQC, 2010). Overall the study aims to provide quality in-depth data to enhance understanding of the complex nature of school effectiveness in China and how local context may play a key role in determining definitions of educational effectiveness & quality. Understanding education quality, learning and evaluation processes also assists in achieving wider goals including social justice and cohesion and equal opportunities, especially for girls and disadvantaged students.

The study objectives include:

1. To identify and define the dimensions of secondary school effectiveness in China, using innovative quantitative (multilevel) techniques to create "value added" measures for different student outcomes and student groups, across three regional (west & east) LEAs, and to compare and contrast these findings to equivalent results from the UK and elsewhere.
2. To develop new theoretical insights and models of educational and school effectiveness in China that highlights the potential role and impact of different educational priorities and contexts.
3. To contribute to educational policy development (and capacity building) by providing robust and relevant new evidence, in an area where empirical data is lacking.

Theoretical framework and methods

In mainland China, raw measures of pupils' academic outcomes and entrance levels to higher education are frequently viewed as the key indicators of school quality. As a result schools with disadvantaged intakes tend to be judged unfairly, while complacency is possible amongst schools with more able pupils, and it is difficult to identify best practice. An alternative 'value added' approach aims to provide a fairer approach to accountability and evaluating school performance than the 'raw' examination results (Thomas et al, 2007). Essentially this is achieved by adjusting for students' previous attainment and other relevant factors outside the control of the school to estimate their progress, in comparison to students in other schools. The concept of value added is, therefore, both an indicator of a school's effectiveness and a tool for head teachers and their staff to use to analyse the extent to which they have effectively raised pupil achievement. Value added evaluation methods emerged from empirical studies of effective schooling that can be traced back more than 40 years and subsequently to improved statistical methodology. The latter developments involved the establishment of comprehensive and longitudinal datasets and sophisticated analysis techniques (multilevel modelling) used to create 'value added' measures of school effectiveness outlined above. The findings of school effectiveness research, largely conducted in western countries, demonstrate that schools do have a significant impact on children's attainment and progress and also that there are substantial differences between the effects of some schools (Teddlie & Reynolds, 2000). However, empirical studies of school effectiveness have only rarely been reported in mainland China, which is also notably missing from international comparative studies of school effects. Of the few limited and small-scale studies conducted to date the findings are intriguing, suggesting that senior school effects may account for up to 40 percent of the total variance in students' academic achievement and that in rural areas the equivalent figure may be higher (Peng et al, 2006, Ding & Xue 2009). Across a landscape as huge as mainland China, more large-scale and representative studies are clearly needed to provide robust quantitative evidence about the range and extent of school effectiveness in order to inform local and national policy development.

Data sources

IEEQC study 2 uses innovative quantitative methodology (multilevel modeling) to analyze the 2009 Entrance Examination to Higher Education (EEHE) examination scores, 2006 prior attainment scores and other pupil, class and school background data, collected from 97,532 students in 120+ senior secondary schools across three western and eastern LEAs in China.

Findings and Discussion

The findings from the application of a variety of different MLwin models indicate that in mainland China there are substantial and statistically significant differences between the estimates of senior secondary schools' value added effectiveness and that these differences vary across regions. Not surprisingly, across three LEAs and different subject outcomes, the percentage of total variance in student's unadjusted EEHE scores attributable to differences between schools is considerable, ranging from 20% to 40%. However, after controlling for students previous attainment on

entry to senior secondary school the equivalent figures are somewhat reduced (13% to 28%). Estimates of differential school effects in terms of different academic subjects and for different student groups (eg by gender) are also reported as well as the impact of a variety of student intake, classroom, school process and contextual factors on student and school performance are examined in detail. The findings are discussed in relation to how school effectiveness, educational quality and equity may be better understood and evaluated in the Chinese context and the implications of the findings for educational quality in other international contexts.

Educational Importance of the Study Improving the quality of education and student learning is a major goal in both developed and developing countries, given the clear links drawn between better student access and outcomes and poverty reduction and stronger economic growth (EFA, 2004). In this context, school effectiveness research has stimulated and focused educational policy makers' attention on the potential to raise overall levels of educational standards and student achievement. For example, western governments such as the UK have placed a strong focus on encouraging schools and teachers to use innovative evaluation methods and data to inform their own evaluations of the education they provide as well as to feed into accountability and inspection frameworks, and these approaches have been linked to improved student outcomes. However, there is very little comparable empirical research evidence on the range and extent of school effectiveness in mainland China and this paper aims to address this crucial gap. This evidence will inform new policy developments in mainland China; especially given the far-reaching educational reforms currently in progress (MOE, 2009). Moreover, the findings regarding school effects in China across different regions critically develops and extends the international and comparative educational effectiveness research.

PAPER PRESENTATION

Teaching for understanding: A perspective on university-students' learning for a globalized world?

Deep learning, Higher education, New Modes of Assessment

Antonia Scholkmann, Technische Universitat Dortmund, Germany; Bianca Roters, Technische Universitat Dortmund, Germany

When it comes to university learning, mere acquisition of declarative knowledge is no longer enough to meet the demands of a globalized world. Only if students develop skills and competencies to deal with what they have learned, teaching has reached the goals that universities stand for in Western societies. The levels of how well students are able to understand a complex scientific theory or the implications of a scientific argument might be a potent indicator for state-of-the-art university learning, as show results from an in-depth analysis of n=274 qualitative essays on the content of a scientific text. The essays were created by first-year students of Educational Psychology, taught in traditional or problem-based classes, and then classified in different levels of understanding according to a framework with references to the SOLO-taxonomy by Biggs and the taxonomy by Bloom. Results show significant variation amongst these answers, giving important hints for further discussion about the potential of the concept of understanding for teaching and testing academic success.

Introduction to Problem

The objective of student learning in higher education as a main teaching goal stands without doubt as most challenging alike: Universities and colleges are the most prominent locations for learning to take place in Western societies. But what is it that has to be learned in order to meet the demands of a globalized world, and which skills for the 'knowledge age' should universities and colleges aim to teach for?

Some evidence can be seen from research on 'state-of-the-art' teaching approaches such as problem based learning (PBL) and reflective teaching. Those approaches not only focus on fostering the acquisition of generic skills and competencies such as presenting, communication or reflecting – all of which are doubtless important domains of university learning. More importantly, these approaches claim to also enhance students' capabilities to deal with the knowledge they have acquired in a non-trivial, constructivist and even innovative way.

But what puts students in the place to apply what they have learned to new situations, problems, tasks? How can knowledge be operationalized in a cross-cultural and cross-curricular manner, so that it reflects not only declarative aspects? Which kind of testing knowledge-acquisition is appropriate and fair to students of various academic disciplines and taught by different teaching methods? And, with respect to the internalization of education: Are there certain indicators of knowledge that occur across cultural and national boundaries?

Theoretical Approaches

Our paper focuses on student learning being more than mere knowledge acquisition, but the acquisition of skills and competencies that allow dealing constructively with the specific content of a certain field or discipline. Dealing professionally with what one has learned becomes more and more superior to mere acquisition of declarative facts, as

shows research on expertise (Leinhardt & Greeno, 1986; Bereiter & Scardamalia, 1993), reflection (Schön, 1983; Moore, 2004) and satisfaction and success of students (NSSE, 2010).

A concept which might help bridge all the different approaches to knowledge-related student learning is the ability to understand the content of a concept or the implications of an academic argument. We hold this idea of 'understanding' (Marton & Booth, 1997; Dahlgren, 1997) to be a central domain of university teaching. Different levels of understanding can be seen with respect to university learning, as has shown significant prior research (Wahlström et al., 1997), with some inconsistencies concerning relation to a specific teaching method (Rahimi, 1995). Given these implications the research question for this study was: Can the concept of understanding be applied as a global indicator for university learning across different countries and different teaching approaches?

Empirical Evidence

As part of a greater research project which investigates learning through different teaching methods in different universities in Sweden, the Netherlands, Switzerland and Germany, we tested for students' understanding of a complex text. By bringing together qualitative and taxonomic approaches such as Biggs' Solo-taxonomy (Biggs 2003) or the domains of Bloom (see Anderson & Krathwohl, 2001), a framework was developed to classify qualitative answers with respect to different levels of complexity in understanding.

The texts to which we will refer to in our presentation were $n = 274$ answers by first to third year students in courses of developmental psychology from Switzerland and Germany. These students were taught in either 'traditional' form or enclosing an amount of problem-based elements during the academic term. All students gave written answers to the question "What is the text about?" after reading it. Stimulus was an essay on conditions and consequences of brain development (Høyther, 2006). Tests with further groups are under way in Germany, Sweden and the Netherlands. Results from the initial sample show significant differences between the levels of understanding displayed between students in both courses (PBL vs. non-PBL), thus differentiating them in at least five groups. Amongst the answers there can be seen a pattern going from only capturing the innermost fundamental message of the text via understanding one or more than one argumentative figures given by the author, and, at the higher levels, capturing also the implication of examples and differentiating aspects to foster these arguments and connect them to an overall academic discourse.

No statistic effect could be seen for age, gender, previous studies or any predictor of academic achievement on the performance in this test, thus indicating its diagnostic uniqueness. "Missing-the-point"-answers give important hints for further theoretical refinement of the concept 'understanding'.

Implications and Relevance

The implications of this study follow a twofold way: firstly, new contributions might be inferred from the idea of 'understanding' as core concept for university learning in bringing together related concepts such as reflection, comprehension and expertise. Secondly, conceptualizing university learning from the angle of how well students are able to understand complex scientific arguments rather than simply reproducing facts allows for new ways of testing academic success, and at the same time fosters ideas of combining more alternative teaching approaches like PBL with competence-oriented testing.

PAPER PRESENTATION

Research synthesis on the effectiveness of early education programs focused on social development

Franziska Egert, German Youth Institute, Germany; Andrea G. Eckhardt, German Youth Institute, Germany

A growing body of evidence reinforces the assumption of the positive impact of early childhood education programs on the individual development of young children. While (quasi)experimental research findings clearly indicate positive effects on cognitive and academic achievement, the effects of early education programs on the social development are inconsistent, ranging from positive to negative. Therefore, the research synthesis examines to what extent center based childhood education or specialized trainings in early education programs affect the social emotional development of children birth to six years of age. To obtain eligible studies published between 1960 and 2010, electronic search in international databases and hand search in reviews and renowned journals was conducted. An extensive coding scheme was developed a) to retrieve relevant information on study design, program characteristics, structural features of center based care settings as well as child characteristics and, further, b) to cluster and characterize the studies included in the research synthesis.

The research synthesis presents eligible studies that provide sufficient findings on the impact of early childhood programs. The synthesis contributes to existing knowledge and organizes the current state of the art with an emphasis on type and quality of studies. Furthermore, it provides lineages of research from 1960 to 2010. The findings

summarize the evidence of effectiveness of education programs and deduce principal contributions on structural program features for policy makers and child care providers.

Aims

Over the last decade, a number of studies had been conducted that investigate the impact of early childhood programs on child development. In general, findings indicate positive effects on cognitive and academic development. The impact of early educational programs on social development are, however, less conclusive. Results from (quasi-)experimental studies rang from positive effects to negative effects.

In order to provide a better understanding of the inconsistency, a research synthesis was conducted. The synthesis targets on (quasi-)experimental studies that assess the effects of various early childhood programs on the social development of children birth to six years of age. It aggregates the evidence of program effectiveness of research conducted between 1960 and 2010. Focused categorization of eligible studies were used to gain a systematic overview of relevant research and to explain differential effects due to study design, program features, child care setting and child characteristics. The purpose of this presentation is a) to depict the search process and b) to present the findings of the research synthesis by characterizing eligible studies.

Methodology

The research synthesis was conducted to provide detailed information on the state of the art in the field of early childhood education program effectiveness. The methodological framework of the research synthesis consists of five major steps.

First, an electronic search in the databases ERIC, PsycINFO, Francis, BEI, AEI, ProQuest Dissertations and Theses, WISO and FIS and, in addition, a hand search of publications was conducted and approximately 3.000 citations found. Secondly, titles and abstracts of the citations found were reviewed in terms of a) having an (quasi-) experimental design, b) evaluating early education programs that target at the social development of children under 7 years, and c) using quantitative assessment instruments. In a third step, full papers of the citations were screened with a short form using 21 selective criteria. Studies had to fulfil scientific inquiries with regards to study design, assignment and matching procedure, outcome measurements, sample characteristics and program features to be included in the synthesis. Approximately 70 studies met the selective criteria Fourth, the relevant literature was reviewed with an extensive coding scheme with 79 questions that extract more detailed information on the studies. The whole reviewing and screening process was conducted by two independent reviewers; disagreements were solved through discussion. In a fifth step, the relevant studies were analyzed and categorized with regards to information gathered in the extensive coding scheme.

Findings

The electronic search and hand search of publications resulted in 3.087 findings of relevant publication. After titles and abstracts were screened from all citations 724 publications were identified. From these approximately 70 studies met the selection criteria to be included in the research synthesis.

It has to be noticed, that quite a number of studies had to be excluded during the coding process because of missing comparison groups or insufficient information on statistical analysis. The following synthesis of study characteristics is based on the 19 results. Findings from the complete sample will be presented at the conference.

Publication characteristic: Publication years of studies relevant for the synthesis range from 1982 to 2008. However, most of the studies (70%) are published in the last 15 years. The majority of studies (80%) of the studies were conducted in North America (13 in the United States and 2 in Canada) while 20% were accomplished in Europe (3 in Germany and 1 in Sweden). About one third of the studies are characterized as unpublished (e.g., governmental reports, dissertations and thesis). The inclusion of unpublished papers is important to prevent and reduce publication bias. Because of the high ratio of unpublished papers included, screwed results caused by a lack of unpublished findings are not expected.

Study design: Most accurate estimations of the program effectiveness can be derived from random-assigned controlled experiments. Nevertheless, the current state demonstrates a lack of accurate experimental designs, because only 3 out of 19 studies used an experimental design with random assignment. All of them were conducted in the United States. Focusing on the participants, the sample size of studies included in the synthesis reach from 40 children to 3.376 children. Aggregating the data of all relevant studies, the overall sample consists of N = 9.496 children. Nevertheless, most of the studies (17) had child outcomes measurements at age 3 to 6, whereas only two

studies offered outcome data below the age of three. Due to the lack of studies aiming at children below three years, it is not possible to synthesize general program effectiveness based on the findings of this age group.

Early education program and the child care setting: About one third of the child care programs evaluations (N = 7) included in the syntheses aim at children at risk, all of the programs were conducted in the United States of America. Children at risk can either be disadvantaged due to socioeconomic status of the family, migration background or due to developmental risks of the children or a combination thereof (not including children with physical or mental impairment). The other two thirds of the studies do not aim at a specific group of children. About half of the study participants are cared for in mixed age groups (N = 9), ranging from 0-6 years (child care centers ranging from 0-6 years or German Kindergarten ranging from 3-6 years) or homogenous groups (preschool or Pre-k serving 4 year olds and kindergarten serving 5 year old children; N = 10).

Theoretical and empirical significant evidence based conclusions are necessary for policy decision makers and child care providers to offer appropriate and effective services for young children. The research synthesis summarizes the evidence of effectiveness of early childhood programs by reviewing the state of the art across-the-board. Furthermore, it provides particular knowledge of structural program features that impact the level of effectiveness which lead to improved child outcomes.

PAPER PRESENTATION

Who Benefits from Meta-cognitive Instruction and Under What Conditions?

Tova Michalsky, Bar-Ilan university, Israel; Zemira Mevarech, Bar-ilan University, Israel

The purpose of the present study is twofold: (a) to examine who benefits from meta-cognitive instruction and under what conditions; and (b) to analyze the meta-cognitive processes that higher and lower achieving, activate under the different conditions. The present study is a continuation of a previous study (Author, 2007) in which we examined the differential effects of meta-cognitive support provided at different phases of elementary school students reading scientific texts: before (beMETA), during (duMETA), after (afMEA), or without meta-cognitive support (noMeta). In the present study, we focused on the differential effects of these methods on higher and lower achievers' scientific literacy, and we analyzed the meta-cognitive processes that the pupils indeed activated under the different conditions.

Theoretical Framework

The main goal of the current science education reform is the enhancement of science literacy for all students. Science literacy (SL) involves the abilities to comprehend scientific phenomena (the big ideas) and to communicate these ideas to others (PISA, 2006.). Clearly, reading scientific texts plays an essential role in enhancing science literacy, because in reading students must learn how to access, evaluate, and interpret scientific information from books, periodicals, databases, electronic communication systems, and other resources (National Research Council [NRC], 1996). It is widely believed that reading comprehension and reading strategies could be enhanced by explicit meta-cognitive instruction implemented by the regular classroom teacher (Author et al, 2005, 2007; Simonsen & Singer, 1992). Although the effects of metacognitive instruction has been documented (Author et al, 2005, 2007) many research questions are still open. In particular, who benefits from meta-cognitive instruction and under what conditions? The specific format of the meta-cognitive instruction and its potential transferability are not fully known. The purpose of the present study is threefold: (a) to examine the different conditions under which metacognitive instruction is most efficient in enhancing SL (b) to compare the effects of this conditions on higher and lower achieving students' SL; and (c) to analyze the meta-cognitive processes that higher and lower achieving students activate under the different conditions.

Research Design

Four research condition were employed: metacognitive instruction – before reading (beMETA), during reading (duMETA), or after reading (afMETA) – and a control group received none (noMETA). The metacognitive instruction was based on Mevarech and Kramarski's (1997) IMPROVE method.

Participants - Participants were 108 fourth grade pupils (mean age: 9.5 years, SD = 0.77) who studied in four heterogeneous classes, randomly selected from four Israeli elementary schools.

Data collection – All students were pre- and post-tested on Israel national, standardized test based on PISA (Organization for Economic Co-operation and Development, 2002) science literacy tests (SLT). The students were asked to 'think aloud' continuously while they were answering the pre and post tests. All 'thinking aloud' protocols were audio-taped and transcribed verbatim.

Data analysis –quantitative analyses: The SLT included 15 items: 9 open-ended questions and 6 multiple-choice items such as "What did the pupils want to research in this experiment? (a - The effects of light on the beans' seeds, b - The effects of the number of seeds on the beans' growth, c - The effects of the amount of water on the beans' growth, or d - The effects of the ground on the beans' growth). Each item was scored as either 1 (correct) or 0 (incorrect), with the total score ranging from 0-15. Inter-judge reliability, was assessed by two experts in science education, the reliability coefficients ranging from $r = .82$ to $.95$ for all skill dimensions.

Qualitative analyses- the analysis of "thinking aloud" data followed Marshall and Rossman's (1999) four stages, namely, organizing the data, generating tentative themes, testing the emergent themes, and searching for alternative explanations. In doing so, data analysis crystallized participants' metacognitive process during reading scientific text.

Results

The quantitative analysis indicates significant main effects of science literacy for both the learning conditions ($F(3,100)=6.38$, p Also the interaction between learning conditions and achieving groups was significant ($F(3,100)=15.24$, p The analyses show no significant differences between conditions for the higher achievers, whereas the lower achievers in the afMeta significantly outperformed their counterparts in the beMeta, who in turn significantly outperformed their counterparts in the duMeta, whereas the noMeta students achieved the lowest mean scores. For the lower achievers the main effect for time and the time*treatment interaction were statistically significant for all five components, $MSe = 16.21$, $F(1, 41)$, p $\eta^2 = 0.46$ and 31.25 , respectively; formulating hypotheses, 92.36 , $\eta^2 = 0.43$ and 37.12 , $\eta^2 = 0.31$, respectively; identifying dependent variables, 122.32 , $\eta^2 = 0.51$ and 43.25 , $\eta^2 = 0.35$, respectively; identifying independent variables, 146.14 , $\eta^2 = 0.57$ and 48.34 , $\eta^2 = 0.37$, respectively; and describing results and drawing conclusions, 101.21 , $\eta^2 = 0.48$ and 37.68 , $\eta^2 = 0.32$, respectively. Post hoc analyses of the lower achievers adjusted mean scores based on the pair-wise comparison t-test indicated that on the SLT all five components (describing phenomena, formulating hypotheses, identifying dependent variables, describing results and drawing conclusions), the afMETA group statistically significantly outperformed all other groups; the beMETA research group statistically significantly outperformed the duMETA group; and the noMETA group attained the lowest mean scores (all p values)

The qualitative analysis provides deeper understanding of these findings. It focuses on the meta-cognitive processes that higher and lower achievers indeed activated in the different conditions. The qualitative analyses revealed two interesting phenomena: (a) higher and lower achievers activate different kinds of meta-cognitive processes; and (b) the exposure to the different kinds of meta-cognitive support indeed resulted in the activation of different kinds of meta-cognitive processes (see table 1).

Educational Significance

The study has both theoretical and practical implications. Theoretically, the study shows how young children at the age of fourth grade pupils employ metacognitive strategies under different conditions. In addition the study indicates in what way higher achievers differ from lower achievers. Practically, the study provide evidence on efficient condition in developing SL in elementary schools.

PAPER PRESENTATION

Accuracy of Immediate and Delayed Judgments of Learning in Worked Examples and Problem Solving Tasks

Martine Baars, Erasmus University Rotterdam, Netherlands; Tamara Van Gog, Erasmus University Rotterdam, Netherlands; Fred Paas, Erasmus University Rotterdam, Netherlands; Anique de Bruin, Maastricht University, Netherlands

The assessment by a student of how well information is learned is called a judgment of learning (JOL). Only with an accurate JOL can a learner judge accurately what information needs to be restudied and how study time can be allocated efficiently. In Experiment 1, primary school children in grade 3 engaged in solving arithmetic problems, gave immediate or delayed JOLs and rated their invested mental effort. It was found that immediate JOLs were more accurate than delayed JOLs. Moreover, participants in the immediate JOL condition more often chose to restudy

problems they did not manage to solve during the first test, suggesting more efficient study time allocation. Whether this also positively affected learning could not be established due to lack of learning gains in both conditions. In Experiment 2 it is investigated whether these findings can be replicated with secondary education students and worked examples are included to investigate effects on learning.

Research has shown that students' judgments of what information they have or have not yet learned play an important role in self-regulated learning: these judgments guide study time allocation and subsequent restudy choices (Metcalfe, 2009), and as a consequence, need to be accurate to result in optimal study choices. Research on Judgments of Learning (JOLs) has mainly focused on language learning tasks (e.g., word pairs or texts; see Thiede et al., 2009). Immediate JOLs are given immediately after studying an item (e.g., text or word pair), whereas delayed JOLs are provided after studying several items. By comparing the JOLs to the performance on those items on a subsequent test, their accuracy can be measured. Research on word pairs has shown higher accuracy of delayed JOLs prompted by the first word of the word pair (Nelson & Dunlosky, 1991). This "delayed-JOL effect" was not found, however, for learning texts with JOLs prompted by the title of the text (Maki, 1998). When providing learners with additional instructions such as to generate keywords (Thiede et al., 2005) or summarize the texts (Thiede et al., 2003), they are able to establish the accessibility of information from the text at a delay, and delayed JOLs become more accurate than immediate ones. Little is known about JOLs in the kind of procedural problem solving tasks typically seen in math and science curricula. Because self-regulated learning is also considered important in those domains, we aim to investigate JOLs in problem solving tasks. Problem solving differs from texts and word pairs in important ways. A JOL about problem solving concerns knowledge of a procedure. Learners are not supposed to judge whether they have learned the answer to this particular problem, but rather, should judge whether they know the solution procedure required for solving this type of problem.

Consequently, as with texts, only a "title", that is, a description of the problem type, is available when making a JOL. Therefore, we hypothesized that as in texts without any additional instructions, immediate JOLs would be more accurate than delayed JOLs with problem solving tasks. Experiment 1. Participants were 76 Dutch third graders who were randomly assigned to either the Immediate ($N = 35$) or Delayed ($N = 41$) JOL condition. The study was run in group sessions in classrooms (both conditions present in each session). It consisted of five phases: pretest, learning phase, first test, restudy, and second test. In the learning and test phases, the children were asked to solve four arithmetic problems, one of each of the following types: addition without carrying, addition with carrying, subtraction with borrowing tens and subtraction with borrowing tens and hundreds. During the learning phase, the children provided JOLs on a 5-point rating scale (Dunlosky & Lipko, 2007; Thiede, et al., 2003) immediately after each problem or after all four problems, depending on their assigned condition. At the end of the learning phase children could indicate which problems they would like to solve again (cf. restudy in research with texts or word pairs). Subsequently, they completed the first test, were allowed to 'restudy' problems, and completed the second test. JOL accuracy was measured by means of gamma correlations between JOLs and first test performance.

Accuracy of restudy choices was measured by comparing whether a problem was chosen for restudy or not, to performance on the first test (i.e., if a problem was not chosen for restudy, 1 point was given when it was performed correctly and 0 points when it was performed incorrectly; vice versa if a problem was chosen). A t test performed on the JOL accuracy data revealed higher accuracy in the immediate JOL condition than in the delayed JOL condition ($t(74) = 2.05$, $p = .04$, $r = .23$), which confirmed our hypothesis. For the analysis of restudy choice accuracy, data from half of the participants had to be excluded because they did not restudy only those problems they had indicated. There was a significant difference between the conditions in restudy choice accuracy, $t(36) = 2.29$, $p = .03$, $r = .36$: Children in the immediate JOL condition made more accurate choices than children in the delayed JOL condition. This higher accuracy of study choices did not lead to better learning outcomes, because no learning gains were found in either condition. Since the children in Experiment 1 were quite young (i.e. 8-10 years), the procedure of giving delayed JOLs based only on the titles of problems might have been too difficult.

To establish whether age affects the accuracy of JOLs prompted with the title of a problem, secondary school students will be involved in a second experiment on JOLs and problem solving tasks. Furthermore, to be able to investigate the effect of restudy choices on learning gains, a worked-examples condition will be added: Research on the worked-example effect has shown higher learning gains of instruction consisting of examples compared to problem solving for novices (Sweller, 2006; Paas & Van Gog, 2006). Experiment 2. Approximately 120 Dutch secondary education students will participate in this experiment. A 2x2 factorial design with factors JOL (Immediate vs. Delayed) and Problem Format (Worked Examples vs. Problems) will be used. Students will be randomly assigned to one of the four conditions. The study will be run in group sessions in classrooms (all conditions present in each session). Consistent with Experiment 1, there will be five phases: pretest, learning phase, first test, restudy, and second test. In the learning and test phases, the students will solve/study problems about electrical circuits and during the learning phase

they will provide JOLs immediately after each problem or once after all problems, depending on their assigned condition. It is hypothesized that immediate JOLs will be more accurate than delayed JOLs, that students in the worked examples condition show greater learning gains, and that accuracy of restudy choices positively affects learning gains—at least in the worked examples condition. Data collection is finished in 2010 and results will be available well before the conference.

PAPER PRESENTATION

Promoting Metacognition in Industry Courses for Trainees in Lower Level VET programmes

Nadine Kipfer, IFFP, Switzerland; Ursula Scharnhorst, IFFP, Switzerland; Nicole Grolimund, Eidgenössisches Hochschulinstitut für Berufsbildung, Switzerland

Observations in industry courses with trainees in lower level vocational education and training (VET) programmes showed that they are rather passive learners. Previous research in vocational schools showed that a metacognitive training helped these trainees to become more strategic and to perform better in school tasks. The present research involves the development of a metacognitive training embedded in industry courses to support the acquisition of occupational knowledge and skills of car mechanic assistants. We expect the training to foster the apprentices' use of cognitive and metacognitive strategies in learning and problem solving. It should further enhance the trainers' efficacy in offering differentiated forms of support and guidance. Multiple research steps were conducted: (1) Field observations helped to understand the particular learning and teaching context of industry courses and to identify the occurrence of difficulties. (2) An online questionnaire was administered to assess the perception of trainers concerning trainees' cognitive and motivational learning difficulties. Trainers were also asked to describe their usual instructional approach. These first two steps allowed to identify which strategies should be trained and how their use may be fostered. (3) In collaboration with the trainers, different training components were developed, which they can integrate in their occupational-specific goals. Finally, the trainers implemented the training in their industry courses. (4) First effects have been analysed. In the paper we will present and discuss the developed metacognitive training components and first qualitative results regarding their use by the trainers.

Swiss VET programmes comprise theoretical courses at vocational school, work-based training in a host company and industry courses. The latter combine theoretical and practical aspects of VET and are also a part of the final certification. The purpose of industry courses is to instruct the competent use of machines and tools of the specific trade by teaching the trainees the corresponding knowledge and skills. Besides, soft skills (methodological, personal and social competencies) should be fostered.

Our research focuses on competencies taught in industry courses for car mechanic assistants. 'Car mechanic assistant' is one of the newly created occupational profiles in Switzerland which is trained in a two-year, lower level, VET programme.

Trainees in industry courses are often expected to solve tasks, which are organized in work stations, in an autonomous way. First observations showed that they often have difficulties to self-regulate the corresponding learning and working processes by using effective strategies to plan, monitor and control their problem solving and memorize it. In other words, they are often too passive learners.

Concerning the trainers, our observations revealed that they do not sufficiently encourage the trainees to use strategies and to develop their metacognitive awareness. Their support often focuses on the product of the tasks and not enough on the learning and problem solving processes.

A previous quasi-experimental research (Berger, Kipfer, & Býchel, 2009) showed that a metacognitive training in the vocational school setting helped the trainees to become more strategic learners and to be more aware of their own cognitive functioning in classical school tasks (e.g. mathematical and text comprehension tasks). However, it was pointed out that these positive effects may be limited and their transfer on practical problem solving contexts (e.g. at the workplace or in industry courses) was not assessed.

Considering these limitations, we adopted a design-based research approach to develop a metacognitive training in collaboration with industry course trainers so that the training components can be embedded or blended into their occupation-specific and practice-oriented training programme. The embedded metacognitive training should improve teaching and learning in industry courses: The trainees should become more strategic learners if they follow

such a training. And trainers should become more competent in fostering cognitive and metacognitive strategies of their trainees besides teaching specific course contents.

Different research steps were conducted: (1) Detailed exploratory observations of teaching and learning in industry courses were undertaken. These observations were discussed with trainers to identify strengths and also major weaknesses of trainees. (2) Further, 32 trainers, who are currently teaching car mechanic assistants in industry courses, completed a questionnaire about their perceptions of the trainees' cognitive and motivational learning difficulties as well as about their own instructional approach. The results indicated which strategies should be trained and how their use may be encouraged. (3) Two working groups composed of researchers (experts of metacognitive theory and intervention) and vocational trainers (experts of occupational practice) were established. They regularly met to discuss useful and possible changes in the teaching and learning arrangement of industry courses, thus trying to adapt and enrich the trainers' instructional approach. They also developed a script for incorporating metacognitive training components directly into the content-based, practical learning goals of the industry courses. (4) Finally, the trainers implemented these new components in their courses and the effects on teaching and learning were assessed. Multiple instruments were used to assess the effects and the practicability of this training: (A) Each trainer followed a group of trainees (approximately 10) during 8 days. (B) Each day, researchers interviewed trainers about the experiences done of the current day. (C) At the end of the 8 days, they were interviewed about their experiences in implementing the metacognitive training. (D) The trainees answered a metacognitive questionnaire before and after the 8 days of intervention. (E) The trainees were also interviewed after the solution of a specific practical task. (F) The training sessions were videotaped and coded according to an observation grid. A total of 40 apprentices from four different industry course centers participated in the study.

The paper will focus on the developed metacognitive training components and on first qualitative data concerning trainers' efficacy to implement and promote the use of metacognitive training components.

PAPER PRESENTATION

Is it helpful to force readers to search an available text? Effects of comprehension skills and JOLs

Amelia Mana, University of Valencia, Spain; Eduardo Vidal-Abarca, Universidad de Valencia, Spain

This paper examines whether forcing readers to search information in the text enhances their performance on comprehension questions. Furthermore, we are interested in study if comprehensions skills and the reader's judgments of learning (JOL) moderate that effect. To do this, we conducted an experiment in which 18 skilled and 17 less-skilled readers from 8th grade read two texts and answered eight questions per text on a computer using Read&Answer, a software tool that records the whole text-reader interaction (i.e. reading sequence). After reading each question, students rated their confidence about giving the right answer using a scale from 0 (I'm completely unsure to be able to give the right answer) to 100 (I'm completely sure to give the right answer). Students were randomly assigned to be in either the Non-Forced condition (n=18), where they were told that they were free to refer back to the text whenever they wanted, or the Forced condition (n=17), where students were required to refer back to the text in all questions. Results showed that both high and less-skilled readers in Forced condition outperformed readers in Non-Forced condition, showing a facilitative effect of forcing readers to search in both skills levels. However, this effect was different depending on the JOLs, being especially helpful for medium-level JOLs (40%-60%). On-line data of search process allows us to explain the reasons of to force to search effect

Answering questions from an available text has specific metacognitive demands due to the high level of interaction between the reader, the text and the questions, which involves monitoring and self-regulation processes (i.e. whether to search in the text or not, or what information to search). In a recent study, Vidal-Abarca, Mana, Gil & Martínez, (2009) found that readers seem to have self-regulation problems. Readers often decided not to search the text even though they were not certain to give the right answer, which seems a risky decision. The current work sought to test whether forcing readers to search the text after every question would facilitate their comprehension, and whether reading skill and their certainty of giving the right answer without re-reading the text moderates this benefit.

Comprehension monitoring has been investigated within the framework of the Judgments Of Learning (JOL) paradigm (Maki, 1998), in which students assess their level of learning or comprehension after studying some information and then they perform a learning task. JOLs predict the students' decisions to search the text, which may also explain performance (Thiede, Anderson & Theriault, 2003). In a previous study Vidal-Abarca, et al. (2009) found that high-skilled and especially less-skilled readers often decided not to search (around 50% and 70% of the time respectively) when they were not totally sure about providing the correct answer (JOLs 40-60).

Our specific interest in this study was to examine in detail the effect of forcing readers to search the text on final performance and to analyze whether comprehension skills and JOLs modulate this effect. We expected that forcing readers to search would be helpful for both less and high-skilled readers and we also expected different benefits from different JOLs.

Method

Eighteen high-skilled and seventeen less-skilled readers from 8th grade read two texts and answered eight questions per text. After reading each question, they made a JOL by responding to the following question: "How sure do you feel to give the right answer to this question without rereading the text?", though students knew they would have the text available. Students had six options from 0 (I am completely unsure to be able to give the right answer) to 100 (I am completely sure to give the right answer), using intervals of 20 units. Then, students in Forced condition had to search the text in all questions whereas students in Non-Forced condition were free to search the text at their will. Students performed the task on a computer using software Read&Answer (Vidal-Abarca et. al, in press) which recorded readers' actions (i.e. search decisions, what information were read and the final response)

Results and discussion

As we had predicted, readers in Forced condition ($M=10.35$; $SD=2.51$) marginally outperformed readers in Non-Forced condition ($M=8.66$; $SD=2.65$), $F(1, 31)=3.923$, $p=.057$, $\eta^2p^3=.11$. High-skilled readers ($M=10.55$; $SD=2.5$) also outperformed less-skilled readers ($M=8.35$; $SD=2.45$), $F(1, 31)=7.095$, $p^3=.19$, with no effect of interaction. Thus, we can conclude that forcing readers to search in the texts is beneficial for both less and high-skilled, because both groups improve their performance in forced condition. Our results also showed that the benefit of forcing students to search depends on the level of JOL (see fig. 1). For low-level JOLs (0-20), forcing readers to search was not helpful since the scores distribution (scores 0, 0.5 and 1) was the same in Forced condition than in Non-Forced condition for both groups ($X^2(2, 81)=.903$, $p=.637$; $X^2(2, 72)=.301$, $p=.860$, less and high-skilled respectively). For intermediate-level JOLs (40-60), forcing readers to search was helpful for both groups because they obtained significantly better scores (more scores 1 and less 0) in Forced condition than in Non-Forced condition ($X^2(2, 111)=9.254$, p $X^2(2, 85)=6.106$, p $X^2(2, 131)=10.691$, p Force condition are explained by the increase of searching opportunities, since in Non-Forced condition readers decided not to search less than 50% of the times in medium JOLs and high-skilled only 8.5% in high JOLs. Thus, forcing high-skilled readers to search is always helpful, while forcing less-skilled readers to search is only helpful in medium JOLs.

Detailed analyses of readers' behaviour when they search the text, more specifically the strategy of "using relevant information" (going directly to answer the question after reading a relevant piece of information) may explain the benefit of forcing readers to search. Forcing readers to search did not affect the frequency for readers to visit relevant information (high-skilled 74% and less-skilled 62%). However it affects the usefulness of using that information; only in Forced condition high-skilled readers, when used relevant information, obtained significantly better scores than less-skilled ($X^2(2, 203)=15.546$, p

In conclusion, forcing readers to search information in the text helps them to get better comprehension scores; however comprehension skills and JOLs modulate this effect. Forcing readers to search is helpful almost always for high-skilled readers and only helpful in intermediate-level JOLs for less-skilled readers. Furthermore, forcing high-skilled readers to search helps them to better interpret relevant information.

PAPER PRESENTATION

Enhancement of students' reading motivation and reading activity

Katrin Arens, University of Gottingen, Germany; Rainer Watermann, University of Goettingen, Germany;
Marcus Hasselhorn, DIPF, Germany

This study deals with the issue how to promote students' reading motivation after the transition from primary to secondary school with a school-based intervention. Respective interventions might have to facilitate students' needs for competence, autonomy, and relatedness as preconditions of intrinsic motivation stated by self-determination theory. However, reading motivation is shown to be primarily predicted by reading achievement. Thus, the implementation of skill development techniques fostering students' need for competence might be sufficient to promote students' reading motivation. In a pretest-posttest-follow-up design, three literacy training conditions were realized in a German secondary school attend by girls only. In order to promote students' need for competence, the teacher of one class directly taught several reading strategies. In a second class this literacy training was combined with an extended form of jigsaw, which was expected to facilitate all three needs described in the self-determination theory. A third class served as a control group. Both forms of literacy instruction were capable of increasing students' reading motivation in the short term. However, only the teacher-directed condition also showed a significant effect on reading activity. At follow-up the groups did not differ with respect to students' reading motivation and reading activity. The results hint again at the unjustified liability to overestimate the potency of cooperative learning methods in order to foster students' motivation. In fact, the effectiveness of cooperative learning seems to depend on the concomitant learning conditions.

Due to the decrease of students' reading motivation and reading activity after the transition from primary to secondary school (e.g. Jacobs, Lanza, Osgood, Eccles & Wigfield, 2002), school-based interventions are requested to counteract this unfavourable development. However, there is still a debate on the classroom practices and instructional methods suited to foster students' reading motivation after the transition to secondary school. According to self-determination theory (Deci & Ryan, 2000) intrinsic motivation depends on the satisfaction of needs for competence, autonomy and relatedness. Consequently, learning environments facilitating these needs might enhance students' reading motivation. However, it has been shown that students' reading motivation is primarily influenced by reading achievement (McElvany, Kortenbruck & Becker, 2008). Accordingly, skill development techniques emphasising students' need for competence might be sufficient to promote students' reading motivation.

The purpose of this study was to conduct initial steps for testing which of these both approaches might be adequate to enhance students' reading motivation during the first months after the secondary school transition. As in Germany the transition to secondary school takes place after the 4th grade, 5th grade students of a girls-only school were randomly allocated to one of three literacy training conditions. These different forms of literacy training were realised by the teachers over about six weeks immediately after students' transition to secondary school. In one class the teacher directly taught five reading strategies in order to develop students' literacy skills facilitating students' need for competence in turn. In the second class ($N = 27$), this skill development technique was embedded in a learning environment prone to satisfy all three basic needs stated by self-determination theory. For this purpose the literacy training was combined with an expanded form of the cooperative learning method of jigsaw. The classical form of jigsaw was used first, since it has been empirically shown that it is suited to foster students' intrinsic motivation through its positive impact on the three basic needs described in self-determination theory (Hänze & Berger, 2007).

The classical way of jigsaw was extended twofold: To augment the probability to satisfy students' need for competence, teacher-directed lessons were included. Secondly, a practical phase was supplemented, during which students were asked to exercise the instructed reading strategies in teams. This practical phase was assumed to facilitate students' need for autonomy, competence and relatedness simultaneously. A third class served as a control group ($N = 28$), for which the reading instruction method and contents of literacy lessons were not predetermined. The students' level of intrinsic reading motivation and reading activities were assessed in a pretest-posttest-follow-up design using psychometrically sound measures of PISA 2000.

Analyses of covariance with teaching condition as between-subject factor were conducted. In order to differentiate between short-term and long-term effects two steps of analyses were conducted. First, posttest scores of reading motivation or reading activity were taken as dependent variables with pretest scores as a covariate. In the second step follow-up scores were examined controlling for pretest and posttest data. In view of the small sample size the level of significance was set at $\alpha = .10$. With posttest reading motivation as dependent variable the effect of teaching condition marginally failed to gain statistical significance ($F [2,68] = 2.24, p = .12$). Nevertheless, pairwise post-hoc analyses revealed that both forms of literacy instruction were capable of enhancing students' reading motivation in the short term with no significant difference between the two experimental conditions themselves. In the second analysis of covariance based on follow-up data there was no significant effect of teaching condition on reading motivation ($F [2, 63] = 0.25, p = .78; n.s.$). With respect to reading activity a slight superiority of the teacher-directed condition compared to the combined instruction and the control group could be shown for the short-term ($F [2, 68] = 2.41, p = .10$, partial $\eta^2 = .07$). Inspection of group mean levels indicated a decline of students' reading activity in the combined instruction and control group between pretest and posttest while it maintained in the teacher-directed

condition. In the analysis of covariance integrating follow-up assessment no group differences in students' reading activity could be shown ($F [2, 63] = 0.71, p = .47; n.s.$).

These results indicate that at least in the short term a skill-based intervention approach facilitating students' need for competence is equally capable of promoting students' reading motivation as is an extended form of jigsaw addressing all three basic needs. Consequently, methods of cooperative learning should not be one-sidedly approved as the best way of enhancing students' motivation and these results hint again at the potency of teacher-guided learning. However, this implication must not be overgeneralized, as other cooperative learning methods than jigsaw might yield superior effects on students' intrinsic motivation and the sample of this study was restricted to German 5th grade girls. Thus, further research is still necessary in order to better understand whether there are instructional tools capable of alleviating or even stopping the decline of students' reading motivation and reading activity in the first months after the transition to secondary school.

PAPER PRESENTATION

Effects of motivation on transfer: A meta-analysis

Andreas Gegenfurtner, University of Turku, Germany

This meta-analysis (148 studies, $k = 197, N = 31,718$) examined effects of motivation on transfer in professional training. Based on prevailing theories in research on training motivation, the analysis included relations of transfer with motivation to learn, motivation to transfer, pre- and post-training self-efficacy, goal orientations, expectancy, and instrumentality. Results of the primary meta-analyses indicated the presence of moderator effects. Four alternative theory-driven moderator analyses tested study design artifacts with regard to instruction and knowledge type; the transfer context; time; and assessment conditions. New directions for future theory development and research are suggested, and practical implications of the findings are discussed.

1. Aims and Hypotheses

The study aimed to examine the relationship between motivation and transfer in professional training. Based on prevailing theories in training motivation research, analysis included motivation to learn, motivation to transfer, self-efficacy, goal orientations, expectancy, and instrumentality (Bandura, 1977; Dweck, 1986; Noe, 1986; Vroom, 1964). Although motivation is widely believed to be important for knowledge application and transfer (Noe, 1986; Pugh & Bergin, 2006; Renkl et al., 1996), little systematic investigations exist on the size, direction, and boundary conditions of motivation-transfer relationships. Specifically, an analysis of the boundary conditions of existing theories could contribute to future theory development. Therefore, this study also sought to identify potential moderating effects of study design artifacts. Four moderator effects were hypothesized. First, we assumed that instruction (lecture-based instruction vs. active learning; Iran-Nejad, 1990; Schwartz & Bransford, 1998) X knowledge type (declarative, procedural, self-regulatory; Schraw, 2006) would moderate motivation-transfer relationships. Second, we hypothesized that near transfer contexts would be more motivating than far transfer contexts for both social, physical, and modal dimensions (Barnett & Ceci, 2002). Third, we hypothesized that training length X measurement time would function as boundary conditions (Beier & Kanfer, 2010; Cole, 2008), with higher correlations for longer trainings and shorter time lags between the end of training and the transfer measure. Finally, we assumed that assessment criterion (transfer assessed as subsequent use, frequency of use, increased effectiveness, or correct performance) X source (self, peer, supervisor, external) would influence the size of motivation-transfer correlations, being highest for self-ratings of increased effectiveness due to the presence of self-serving bias (Mullen & Riordan, 1988).

2. Method

2.1. Database

Moderator estimation techniques available in psychometric meta-analysis seemed appropriate to address the study goal. To be included in the database, a study had to report an effect size r or other effect sizes that could be converted to r (b coefficient, t statistics, F , Z , Cohen's d). We searched the PsycINFO and Web of Science databases for the period of 1986 through 2010. We also cross-referenced previous literature reviews, and contacted researchers to send unpublished manuscripts, conference papers, or dissertations. A total of 148 articles were located and coded.

2.2. Meta-analytic procedure

We used the meta-analysis methods by Hunter and Schmidt (2004). Using full artifact distribution analysis, correlations were corrected first for sampling error and then for error of measurement. We computed population correlations, 80% credibility intervals around population correlations, and the percentage of variance explained.

2.3. Moderator analysis

Spans of the 80% credibility interval (Whitener, 1990) and the percentage of variance explained (Hunter & Schmidt, 2004) were used to detect moderator biases. Theory-driven hierarchical sub-group analyses were used to estimate confounding moderator effects.

3. Results

3.1. Study characteristics

The 148 articles reported 197 independent data sources with 376 effect sizes. Total sample size was 31,718 participants, with a mean age of 30.72 years ($SD=9.42$) and 6.88 years of work experience ($SD=6.47$). 43.62% of the participants were female ($SD=25.26$).

3.2. Estimating population correlations

Complete results of the primary meta-analyses are shown in Table 1 (appendix 1). In all motivational dimensions, the span of the 80% credibility interval and the percentage of variance explained indicated the presence of moderator effects.

3.3. Estimating moderator effects

To account for effect size heterogeneity, we conducted four theory-driven analyses of possible moderator effects.

3.3.1. Effects of instruction and knowledge type. Results indicated that, for declarative and self-regulatory knowledge, correlations between motivation and transfer tended to be higher for active learning than for lecture-based instruction. For procedural knowledge, the pattern was reversed.

3.3.2. Effects of transfer context. Results indicated higher correlations for near transfer contexts at social and modal dimensions. Contrary to our expectations, however, the pattern was reversed for the physical dimension.

3.3.3. Effects of training length and measurement time. For short trainings, correlations tended to be highest for transfer measures at immediate training end. For longer trainings, correlations were highest for measures 1 to 8 weeks post-training.

3.3.4. Effects of assessment criterion and source. Irrespective of the assessment criterion, self assessments tended to show highest motivation-transfer correlations.

4. Discussion

This meta-analysis examined the relationship between motivation and transfer in professional training. Overall, it can be concluded that motivation is an important prerequisite for knowledge application and training effectiveness (Noe, 1986; Pugh & Bergin, 2006; Renkl et al., 1996). However, the size and direction of motivation-transfer relationships was found to be moderated by study artifacts. Identification of these boundary conditions added to the understanding of motivation in professional training.

4.1. Implications for theory development

Implications for theory development are on global and local levels. On a global level, it seems that research on transfer efficiency needs to consider the profound impact of motivation that has been reiterated in this meta-analysis. Without denying the relevance of cognitive factors for transfer (Paas & Van Gog, 2008; Van Merriënboer & Sweller, 2005), motivational and affective dimensions can refine existing theory models (Schnitz et al., 2009).

On a local level, moderator analyses illustrated temporal dynamics of goal orientation. This finding is unexpected, since Dweck (1986) and others (Brett & VandeWalle, 2001) conceptualized goal orientations as stable motivational traits. This would imply a certain stability over time. Future research may further explore our meta-analytic finding of goal orientation's variance as a function of increased time lag in professional training.

4.2. Practical implications

Practical implications are significant for organizational training and for research practice. First, concerning organizational training, results indicated that traditional lecture-based trainings had high motivation-transfer relationships for procedural knowledge only; when training programs focus on declarative or self-regulatory knowledge, active learning may be more effective.

Second, concerning implications for research practice, the study identified biasing effects of study design artifacts. Decisions on assessment criteria, rating sources, and measurement times influence size and direction of motivation-transfer relationships, as does the similarity between the training and the transfer situation. Ideally, the use of longitudinal multitrait-multimethod designs may seem to help minimize the biasing effects of study artifacts, making individual research outcomes more rigorous and robust.

PAPER PRESENTATION

Relation between personal computer uses at home and achievement motivation in science

Normand Roy, University of Montreal, Canada; Roch Chouinard, University of Montreal, Canada

The aim of this study is to validate a motivational model including information and communication technology (ICT) personal uses as a predictor. Technology is now part of everyday students' life. OCDE (2006) study had shown that 90% of the students frequently use computers at home. Moreover, recent studies showed that students who use ICT at home have better grade in key subject matter (Beltran, Das et Fairlie, 2008; OCDE, 2006). To achieve the aim of this study, several auto-reported attitude scales in science and socio-demographic questions were administered to a sample of about 332 French-Canadian students (boys and girls) from five junior high-schools in grade 8th at the beginning of the school year. Cluster analyses were first conducted to create three ICT user profiles. From those profiles, achievement motivation models based on an Expectancies-values model (Chouinard, Karsenti and Roy, 2007) were tested with a multi-group structural equation. Our results showed difference between profiles. Users with various usages have higher motivation whatever uses they make of ICT. However, social-gamer users, who use ICT mostly to communicate and play games, have lower scores on motivational scales, akin to casual users. Moreover, the only negative indicator of the model is communication uses. Students in casual or social-gamer profiles who passed more time in front of a computer to communicate (chatting and emailing) also show less commitment in science. Nonetheless, teachers and parents should not think computers as a negative factor on general commitment in science, but should favour positive uses of computer at home.

Aims

Studies showed great incomes of using ICT for student in many contexts (BECTA, 2003); many variables must be studied to be able to define models and effective pedagogy with ICT. One of the key elements is to determine which factors could prevent or enable the effectiveness of the use of ICT in school. Some research groups think that the use of computers at home could greatly impact school achievement (Beltran et al., 2005; Locke and Andrews, 2004; OECD, 2003; Piette, Pons and Giroux, 2006). Studies by these groups showed emphasis on the relation between computers and grades. However, motivation could give a more global picture of the learning process and the school achievement. Researchers have showed that motivation could be linked to achievement-related behaviours, such as effort and achievement (Bandura, 1997; Pintrich & Schunk, 1996; Shernoff, Csikszentmihalyi, Schneider, & Shernoff, 2003).

Therefore, in the present study, we examine the relationship between the frequencies of use of computers at home and motivational attitudes in science.

Methodology

Participants

Data were collected in October 2005 from students who were attending five French-speaking public high schools in the Montreal area (Canada). The seven classes selected for recruitment were all regular science classes enrolled in 7th and 8th grade; all students in each classroom were asked to participate. The sample consists of 332 French-Canadian students (179 boys and 153 girls).

Procedures

The questionnaire was completed during students' science classes at the beginning of the school years. Several self-reported attitude scales from different sources were compiled into one. This questionnaire took approximately 25 minutes

Measures

Motivational scales

Six scales were used to test our achievement motivation model: Self-Efficacies in science, Mastery-Approach Goals, Performance-Approach Goals, Work-Avoidance Goals, Interest for studies in science, Commitment in science.

Self-Efficacies in science has been taken from the SMTSL Attitude Scales (Hsiao-Lin, 2005), was used to measure participants' competence beliefs ($\alpha = .72$).

Three types of goals have been measured with an instrument produced and validated by Bouffard et al. (1998). The Mastery Goals Subscale ($\alpha = .83$) entailed seven statements assessing the extent to which participants wished to master the content of their science courses. The Performance Goals Subscale ($\alpha = .68$) consisted of six statements measuring the degree to which participants set personal goals to be amongst the best in their class and to obtain high marks in science. The Avoidance Goals Subscale ($\alpha = .65$) was comprised of six statements measuring the degree to which participants set their goals to do the least possible work to pass.

To measure interest for studies in science, a new scale of six items was created ($\alpha = .88$) by the researchers.

General commitment in science represents the challenge given by a task in science. The subscale General Commitment ($\alpha = .71$) was adapted from a French version of Fennema and Sherman's (1976) Mathematics Attitudes Scales, translated and validated by Vezeau, Chouinard, Bouffard and Couture (1998), combined with items from Hsiao-Lin and his collaborators (2005).

Items from all of these scales were rated on a six point Likert-type scale, ranging from 1 ("Strongly disagree") to 6 ("Strongly agree") for motivational scales

ICT Usages

ICT usages were measured with seven different questions about how many times students use ICT for : email, chatting, word, play games, learning programs, research for personal and research for school works. Their usage was measured with a scale ranging from 1 (Never) to 4 (Almost every days).

Data Analysis

Multi-group structural equation modeling with latent variables was performed with Amos 17.0. Profiles were composed with a two-steps cluster analysis based on ICT usages (email, chatting, word, play games, learning programs, research for personal and research for school works) performed with SPSS 18.

Findings

Clusters analysis showed three profiles. The first cluster, or multi-users, reported using all types of uses more often than other students. The second cluster, or social-gamer users, was using ICT especially to communicate and play games. The last cluster, or casual users, used ICT less often than the other two profiles. Results showed some distinctions between clusters in the multi-group SEM models (multi-users/social-gamer users/casual users respectively).

Use of ICT for pedagogical applications has a positive relation with self-efficacies in science ($\beta = .24^*/.32^*/.31^*$) for all profile. Communication usage has a negative relation with interest ($\beta = -.03/-.23^*/-.09$) and commitment in science ($\beta = -.06/-.20^*/.06$), only for those of the social-gamer profile. Entertainment has positive relation with self-efficacies in science ($\beta = .16/.19^*/.25^*$).

Motivation part of the model has some similarities between profiles. Self-efficacies have high positive relation ($\beta = .66^*/.62^*/.59^*$) with mastery-approach goals. Mastery and performance-approach goals have positive relation with general commitment in science ($\beta = .06/.19^*/.25^*$) and $.86^*/.86^*/.98^*$ respectively).

Two surprising results are observed. The work-avoidance goals have no direct relation with commitment in our achievement motivation model, and therefore were removed from the final model. Moreover, interest in science has little relation on both achievement goals. We observe a negative relation between interest and performance goals only for multi-users ($\beta = -.71^*$), and a relation between interest and mastery-approach goals only for social-gamer users ($\beta = .34^*$).

Significance of the research

Our research sheds new light on personal uses for computers. It seems that the type of usage, combined with the amount of time passed in front of a computer, is related to your motivation in science. Teachers and parents should not see computers as a negative influence on school performance, but should instead think to promote pedagogical use of the computer. Negative impact of computers is mostly observed in students with a limited usage of computers: social-gamer and casual users, limited to communication uses. Our hypothesis is that good and diverse use of technology allows student to develop computer skills and facilitate learning of science. However, relation between personal use and motivation is not causal. It is difficult to determine if motivation in sciences increase ICT usage or good ICT uses increase motivation. To further investigate the subject, studies designed for more in-depth exploration

of computer usage at home would be required. Moreover, we should delve into the relation between computer uses, computer competencies and motivation at school.

PAPER PRESENTATION

Engineering Undergraduates' Goal Setting for Their Future and Its Motivational Implications

Wen-Ting Chung, Arizona State University, United States; Jenefer Husman, Arizona State University, United States; Jonathan Hilpert, Indiana University Purdue University Fort Wayne, United States

Undergraduate students are engaged in a learning process in which they are expected to explore, evaluate, and determine their majors, and invest time and efforts in the chosen profession in order to achieve anticipated future careers and lives. In the US, engineering, compared with other majors, has been identified as a field that students are most likely to switch to other majors or drop out. This study investigated engineering undergraduates' goal setting for their future, and its relationships with their future time perspective, perceived instrumentality of their coursework, self-efficacy, and perceived active learning strategy use. Our results suggested that (1) engineering students set goals in many domains their future; however, only engineering-relevant professional goals (e.g., get accepted into civil engineer's corps) rather than academic goals were associated with their reported use of deep learning strategies in engineering courses; (2) engineering students who perceived more connectedness between their current course learning and their future as engineers set more professional goals relevant to engineering. Our results imply that engineering instructors might need to consider fostering students to develop their future goals beyond academic level because it is the long-term professional goals which are mostly likely to motivate students' to actively seek meanings and gain deep understanding about their course materials. In our final paper, we will also discuss the theoretical contribution regarding the relationships between Goal setting and other critical motivational variables.

Theoretical Framework

Undergraduate students are engaged in a learning process in which they are expected to explore, evaluate, and determine their majors, and invest time and efforts in the chosen profession for achieving anticipated future careers and lives. In the US, engineering has been identified as a field that students are most likely to switch to other majors or drop out. Our research team has been interested in examining how engineering students' future time perspective (FTP) could impact their classroom behaviors as well as academic and professional trajectories.

FTP theory has been growing in popularity among educational psychology researchers (Seginer, 2009). The theory suggests that individuals mentally construct episodic future paths which guide and dictate present behaviors and decision making (Husman & Shell, 2008; Nurmi, 2005; Zimbardo & Boyd, 1999). However, there is little research designed to examine what the content of students' mental representations of the future looks like and its impacts on students' academic and professional paths. This study primarily investigated engineering undergraduates' goal setting, and its relationships with other critical motivational variables.

Research hypotheses: (1) Students who perceived more connectedness between their current learning and engineering future would report more academic and professional goals relevant to engineering. (2) Students who reported more academic or professional goals relevant to engineering would also reported that they (a) engaged more in using deep leaning strategy, (b) had higher confidence to succeed in engineering courses, and (c) perceived their current learning in engineering courses was more useful for their future; (3) Students' goal setting partially mediated the relationships between connectedness to engineering and deep learning strategy use as well as perceived instrumentality.

Methods

Participants

Participants (N=366) were recruited in a large sample of post-secondary mechanical and aerospace engineering students from a variety of undergraduate courses.

Open Ended Measures

Future Goals – Participants were asked to describe ten important future goals and list the age at which they would like to achieve those goals. We coded their personal goals using an emergent approach; six categories emerged: Academic, Professional, Monetary, Domestic, Community Building, and Personal. For the purposes of this study, we focused on professional and academic goals relevant to engineering. An Academic goal would be “to graduate”; an Engineering Academic goal would be “to graduate as an engineer.”

Survey Measures

Connectedness to Engineering– measured using an adapted version of the connectedness subscale of the FTPS (Husman & Shell, 2008). Example items: “One should be taking steps today to help realize future engineering goals.”

Perceived Instrumentality (PI) – measured using the endogenous subscale of the Perceived Instrumentality Scale (Husman et al, 2004). Example items: “I will use the information I learn in [Engineering Course] in other classes I will take in the future,”

Deep learning strategy use – measured using the knowledge building subscale of the Student Perceptions of Classroom Knowledge Building Scale (SPOCK) (Shell, et al., 2005). Example items: “In [Engineering Course], I focus on developing my own understanding of the important ideas in what I am studying or reading.”

Self-efficacy – measured using Motivational Strategies for Learning Questionnaire (MSLQ) (Pintrich et al, 1993). Example items: “I am confident I can do an excellent job on the assignments and tests in this course.”

Analysis and Results

Hypothesis 1

Bivariate correlations were conducted between Connectedness-to-Engineering and the number of Goals, either Academic (not significantly correlated, $r < .01$) or Professional (weakly significantly positively correlated, $r = .14$). To further examine whether engineering-relevant goals were correlated with Connectedness-to-Engineering, engineering relevant and non-engineering goals were separated within either professional or academic goals.

Non-engineering goals (either academic or professional) are normally distributed, but engineering relevant goals (either academic or professional) were positively skewed. Approximately half of the student did not report explicit engineering goals. For both Academic and Professional goals, students’ were split into two groups: Students who reported ANY or NO engineering related goals.

Bivariate correlations were first conducted between Connectedness-to-Engineering and non-engineering goals. As expected, the results were not significantly (non-engineering academic: $r = -.05$; non-engineering professional, $r = .04$). To determine if students who reported engineering goals also reported significantly higher Connectedness- to-Engineering, two t-tests were conducted. Students who reported engineering academic goals were not significantly different from those that did not. Students who had Engineering Professional Goals reported significantly higher Connectedness-to-Engineering, $t(364) = -3.02$, $p < .01$.

Hypothesis 2

To determine if there is a relationship between students reporting of an engineering Academic or Professional goal and the variables of interests, a series of t-tests were conducted: (1) Engineering Academic Goal: the results were significant for Self-efficacy, $t(364) = -2.06$, $p < .05$, and PI, $t(364) = -3.29$, $p < .01$; (2) Engineering Professional Goal: the results were significant for deep learning strategy use, $t(364) = -2.69$, $p < .01$, and PI, $t(364) = -2.17$, $p < .05$.

Hypothesis 3

Bivariate correlational analysis between Connectedness-to-Engineering and students’ reported strategy use and their motivational beliefs replicated previous research. Reported learning strategy use ($r = .24$), and PI ($r = .30$) are significantly related to Connectedness-to-Engineering.

These findings indicate that students who are Connected to their future as engineers are more likely to have professional engineering goals as well as to use deep learning strategies and perceive engineering courses as instrumental. We further examine the potential of students’ future professional goals to partially mediate the relationship between students Connectedness- to-Engineering and their motivational beliefs and approaches to learning.

When split into two groups, the relationship of PI to their Connectedness-to-Engineering is lower for students who reported engineering professional goals ($r = .15$, $p = .06$); who do not report ($r = .29$, $p < .01$). The relationship of deep learning strategy use and their Connectedness-to-Engineering is lower for students who reported engineering professional goals ($r = .17$, $p < .05$); who do not report ($r = .38$, $p < .01$).

Significance

Our results imply that engineering instructors might need to consider helping develop students’ future goals beyond academic level because it is the long-term professional goals which motivate students to actively seek meanings and gain deep understanding about their course materials. Our final paper will also discuss the theoretical contribution regarding the role of Goal setting and its relationships to other motivational constructs.

PAPER PRESENTATION

Research Ethics Education: a descriptive map

When we have decided to realize a study on Ethic education we developed a literature review, in order to know the different perspectives using by the researchers in this field. Because of the great number of empirical approaches developed in the research practices and the different themes faced by the researchers in any topic we have decided to conduct a systematic review.

Systematic Review is used in order to determinate what is know and what is not know about a topic of interest, reflect on the processes and perspectives of the relevant body of research, explore the underlying methodological decisions and theoretical influences and suggest future directions for researchers (Paterson & Thorne, 2003).

The aim our systematic review is to know the current research landscape about ethic education. What kinds of researches are realized? Which are the theoretical frameworks the researchers take into account in developing their works? What are the predominant methods used?

The objective of the inquiry is to delineate a descriptive map of the studies in order to define ethic education from the ground-up that is describing ethic education as it is developed in the research practice.

The finding of the systematic review will be a descriptive map, which give to researchers a tool to clarify the "state of the art" on researches in ethic education and to discuss where placing ourselves as researchers in this field.

The research

This study is part of a complex theoretical and empirical research on ethic education with primary school's children. Two main focuses compose the research: a theoretical focus and an empirical one.

The theoretical focus aims to develop a theory of Ethics education grounded in the ancient Greek philosophy, with particular attention to the Aristotle's idea of Ethics and in the current Gilligan's perspective on the ethic of care. The empirical study is oriented to realize a research with children on virtues, in order to outline which kind of education enables children to develop an ethical disposition to virtues.

In order to develop this research project, from both the theoretical and the empirical side, one of the main aspects is to place our work in the current paramount of researches on this topic. From the theoretical perspective, we choose to place the project in the Virtue Ethics approach. From the empirical perspective the choice was more difficult, because of the great number of empirical approaches used in the research practices and the different topics faced by the researchers.

In order to place our study in the present research's landscape we decided to develop a literature review to know the different perspectives using in ethic education's research projects. The recent increase of sources in delivering primary studies changes the way in which researchers realize literature review on a particular topic and systematic reviews (both meta-analysis and meta-synthesis) become the new methods to reviewing the studies (evaluating and interpreting them) in order to synthesize the scientific literature.

Aim

Systematic Review (Meta-Synthesis) is used in order to determinate what is know and what is not know about a topic of interest, reflect on the processes and perspectives of the relevant body of research, explore the underlying methodological decisions and theoretical influences and suggest future directions for researchers (Paterson & Thorne, 2003).

The aim of the systematic review we have conducted is to know the current research landscape about ethic education. What kinds of researches are realized? Which are the theoretical frameworks the researchers take into account in developing their works? What are the predominant methods used?

The objective of the inquiry is to delineate a descriptive map of the studies in order to define ethic education from the ground-up that is describing ethic education as it is developed in the research practice.

Methodology

The review is conducted on primary studies, which were collected searching through Electronic databases - three databases were included in the study: ERIC, A+Education and ERC – and the research was conducted combining thesaurus's criteria - the different –subjects» that concern the moral education's category – and time's criteria – the last 5 years. The discussion of the criteria adopted is part of the presentation.

The analysis process of the articles aims to interpret and synthesize the findings in order to realized a theoretical description (comprehensive and thickly), which is useful to explain theories, methods and models used in ethic education's studies.

Findings

The result of this systematic review on the research in ethic education is a descriptive map, which outlines:

- the different perspectives in ethic education;
- a list of key words, which give an idea about what are the concepts that perform ethic education in the researches practice;
- a list of topics that concern the ethic education today.

Significance

The great number of projects in ethic education gives new efforts to the researchers in this field as well as increases the complexity of the research landscape. Which is the –quality» of these studies?

In order to answer this prime question it's firstly necessary to design a descriptive map, which gives to the researchers a paramount of what is the idea of ethic education in the research practice (i.e. approaches, methodologies and methods). The finding of the systematic review will be a descriptive map, which give to researchers a tool to clarify the "state of the art" on researches in ethic education and to discuss where placing ourselves as researchers in this field.

PAPER PRESENTATION

Figures' value and place - a learning study on arithmetic in grade seven

Mona Holmqvist, University of Gothenborg, Sweden

This study aims to describe in what way pupils in grade seven experience the base 10 positional numeration system (place-value system) before and after three different designed lessons in a learning study, each one given to one group of students (A, B and C). By analyzing the three video-recorded research lessons differences in the students' ways of developing knowledge can be answered by what actually happened in the class room. The model used in this study is learning study with three different designed research lessons, one per students group, where the results of the former is due to the developed design of the later. The design of the research lessons are based on variation theory. In total 52 students participated in three different groups (A=13, B=19, C=20) together with their five teachers and one researcher. A test was taken by the students before and after the research lesson, which included 8 questions and 5 of those have sub queries, which resulted in 23 as a total score. A delayed post-test was given the students four weeks after the research lessons. The results from the pre- and post-test show a change in learning outcome which varies in the different groups of students (A +4, B +1, C +14).. In lesson C at least one critical aspect, namely the difference between ten and tenth, hundred and hundredth, and so on this was offered the students to discern which was not offered in the other two lessons in the same distinct way.

Aim

This study aims to describe in what way pupils in grade seven experience the base 10 positional numeration system (place-value system) before and after three different designed lessons in a learning study, each one given to one group of students (A, B and C). By analyzing the three video-recorded research lessons differences in the students' ways of developing knowledge can be answered by what actually happened in the class room. When the students solve two different kinds of arithmetical tasks; how to use decimal terms in addition and decimal factors in multiplication, their knowledge on the base 10 positional system are crucial. One hypothesis is that the different ways of solving the two tasks, in which one requires knowledge about place-value, affect their possibilities in different ways. The multiplication $0.5 * 0.5$ does not require knowledge about the base 10 positional numeration system as it is possible to count the amount of decimals in the factors (two) and by that put the dot two steps to the left (0.25). But the addition of the terms 0.2 and 0.22 is difficult to solve without knowledge about the base 10 positional numeration system. Otherwise it is easy to get the sum 0.24 instead of 0.42.

Methodology

The model used in this study is learning study (Marton & Tsui, 2004) with three different designed research lessons, one per students group, where the results of the former is due to the developed design of the later. The design of the research lessons are based on variation theory (Marton & Booth, 1997), which means critical aspects of the object of learning are offered the students in different ways. This variation of in what way the features are offered gives the students different ways to experience and by that learn. In total 52 students participated in three different groups (A=13, B=19, C=20) together with their five teachers and one researcher. The learning study started with two meetings with the teachers to present the theory which the study is based, variation theory, and to plan tests and lessons. The test was given to another class to see if the questions where suitable and the time it takes to answer the questions were reasonable (10-15 minutes). The test included 8 questions and 5 of those have sub queries, which resulted in 23 as a total score. The test was taken before and after the research lesson in each group, and a delayed post-test was given the students four weeks after the research lessons.

Findings

The results from the pre- and post-test show a change in learning outcome which varies in the different groups of students. In group A, 27% of the answers were correct in the pre-test and 31% in the post-test (+4). Group B showed the less improvement – from 51% in the pre-test to 52% in the post-test (+1). Finally, in group C the results increased from 50% to 64% (+14). This was due to the finding of at least one critical aspect, namely the difference between ten and one tenth, hundred and hundredth, and so on. In lesson C this was offered the students to discern which was not offered in the other two lessons in the same distinct way. The results also show in what way the students' abilities to solve the addition and multiplication tasks develop.

Theoretical and Educational significance of the research

In previous studies, children's difficulties with base ten numeration was studied in a teacher training course (Sawada & Atkinson, 1981). The results in a study of 106 students shows that work with a nondecimal numeration system including new number symbols and names can lead to heightened awareness and appreciation of difficulties that children might have in understanding base ten numeration. In another study, preservice teachers' knowledge of decimal numeration was tested (Stacey, Steinle, Baturo, Irwin & Bana, 2001). The results showed that pre-service teachers had inadequate content knowledge of decimals and were confused about the size of decimals in relation to zero. The results of the study described in this abstract shows both how the aspects critical for learning are possible to find by examining the students' learning outcome in relation to what happens in the research lessons. It seems as the knowledge on the base 10 positional numeration system, or lack of such knowledge, are important not only to solve additions and multiplications correct, but also to understand why a multiplication with decimals ends up in a product smaller than the factors; $0.5 * 0.5 = 0.25$. If the students understand the base 10 positional numeration system and the difference between the left and right side (ten and one tenth), they might understand multiplication of decimals as a division as the term is divided several times in smaller parts. The lack of an overall comprehension seems to make it difficult even for students at later levels of the educational system, and as pre-service teachers also seem to lack this kind of knowledge it is an area important to study.

PAPER PRESENTATION

Conjoint analysis as an instrument to measure student perceptions of education quality

Margriet van der Sluis, Maastricht University, Netherlands

In this paper we apply conjoint analysis to measure students perceptions. Conjoint requires respondents to simultaneously evaluate aspects following trade offs and is therefore seen as more realistic than traditional survey methods. Our students repeatedly ranked descriptions of 4 courses, existing of 9 quality aspects with varying scores. Subsequently, the students completed a traditional survey with statements on several aspects of educational quality, including the 9 aspects used in the conjoint task. 334 students of administrative, social pedagogical and building studies, aged 17-19, participated in the study. The scores of the conjoint task, indicating the relative importance of aspects, appear to yield a different insight in the ideas of students towards aspects of education quality than the survey questions. Some aspects with high average scores in the survey, lost significance in the conjoint task, whereas other aspects gained significance. By systematically comparing both methods on subgroups we further explore the differences and argue that conjoint is a valuable addition to traditional surveys in educational research.

Conjoint analysis as an instrument to measure student perceptions of education quality AimsFor school administrators, teachers, policy analysts and educational researchers, it is important to know how students value different aspects of educational quality and what they find important. Especially in secondary and higher (vocational) education, student evaluations are used more and more to shape or improve the educational practice. Often, however, students' opinions are measured with traditional surveys, in which aspects of quality are assessed independent of each other. Shaping the educational practice though, is in fact full of trade-offs. There is a limited budget, and there are choices to be made in which part of the educational process the investment is most worthwhile. Conjoint analysis uses the principle of trade-off and might therefore do more justice to reality. This article explores the use of conjoint analysis in the field of educational quality. The aim is to find out what students find important when being forced to make choices, and to compare this with how they evaluate the same aspects in a traditional survey. MethodologyOur study uses conjoint analysis (Batsell & Louviere, 1991; Leslie & Ettenson, 2000; Neil, 1992; Jeffries & Maeder, 2005; de Wolf, 2000). In a conjoint study, a hypothetical product or service is defined in terms of a few important characteristics. Instead of valuing the characteristics separately, the respondent simultaneously evaluates and combines the information on multiple product-service characteristics.

The objective of conjoint analysis is to determine what combination of a limited number of indicators is most influential on respondent choice or decision-making. We chose to include 9 characteristics in the study. In a pre-study among students this number turned out to be manageable. We wanted the 9 characteristics to fulfill three requirements. Firstly, three in a pre-study described perspectives are reflected in the characteristics: the labor market

perspective, the educational effectiveness perspective and the social economic perspective. Secondly, the set of characteristics encompasses both process and product aspects of education. And finally, each characteristic plays a significant role in the present-day Dutch Vocational Education and Training (VET) sector. We assigned two or three possible values to each character. Participants were shown four sets of four profiles on the computer. The values were assigned to the profiles according to pre-set rules, which maximized variation in each set. Figure 1 shows an example of the profiles the participants saw on their computer screen. The question above is "Which course matches most with your idea of quality? Rank the courses according to your preferences". On the left the nine characteristics are shown. The respondents had to rank the vocational courses using the bottom four blocks with the options from 1 (the best) to 4 (the worst). Figure 1. Example of 4 profiles the participants faced on the screen.[In appendix]

To identify the impact the course characteristics on the choices of students in the conjoint task we used rank ordered logistic regression. This model interprets the 4x4 rankings assigned to the courses by our respondents as a rank ordering of choices out of a given choice set. After the conjoint task, students had to value quality aspects on a 10 point scale, in which 5 indicated 'I find this very important', 0 'neutral', and -5 'I'd rather not have this'. In the survey 37 aspects were valued, including the nine aspects that were selected for the conjoint task. Findings In the study 334 students from administrative studies, building and construction studies, and social pedagogic studies were surveyed. They completed the survey in the classroom. 56% of the students were male. The results of the both the survey and the conjoint task are seen in table 1. In the survey, teacher quality and diploma result scored highest, with a mean score of 4,05 and 3,89. The second column represents the outcomes of the conjoint task. The coefficients indicate the weight that the four participants groups placed on each of the nine quality aspects when ranking the courses.

In the conjoint task diploma result was the most important characteristic (.25) directly followed by structure (.24). Schooling hours and guiding hours in workplace learning were of minor importance for the students. The three aspects with the highest scores in the survey, teacher quality, diploma result and employers' satisfaction, are also highly valued (over .20) in the conjoint task. Furthermore, schooling hours appeared to be the least important aspect for the students in both the survey and the conjoint task. There are, however, some striking differences between both outcomes. Civic education, that scored only 0,43 in the survey, appeared to have substantial influence on the choices made in the conjoint task (.19). For the aspect guidance in workplace learning it is the other way around; it had a high average score in the survey (3,73), whereas in the conjoint task it is completely overruled by the other aspects (.03). Figure 1 shows the differences between both methods in a bar chart. Figure 2. Bar Chart. The importance of nine course characteristics according to the students in a survey compared to a conjoint task.[In Appendix] In the final paper we will further explore the differences between both methods. We will compare the results of subgroups (divided according to gender, age, study field, personality traits) on both methods.

Theoretical & educational significance 1.

This study shows how conjoint can be applied to the subject of educational quality. It explains the different steps of the conjoint study: the selection of aspects, the number of aspects and vignettes, the (digital) programming of the study and the analyzing of the outcomes. 2. Conjoint analysis is a relatively new way to examine perceptions of education quality. This study shows the differences of the conjoint analyses with the more traditional survey.

PAPER PRESENTATION

A new approach to 'text quality'

Victoria Johansson, Lund University, Sweden; Asa Wengelin, Lund University, Sweden; Roger Johansson, Lund University, Sweden

This paper is an approach to discuss the complicated measure of text quality – what do we mean by it, and what to we measure? We present a method for training reviewers to evaluate texts, and we investigate the text quality in a data

set consisting of 84 expository texts, produced in ScriptLog, by four groups: 1. University students without reading and writing difficulties (RWD), 2. University students with RWD, 3. 15-year-olds without RWD, 4. 15-year-olds with RWD.

After a training process involving both holistic and analytic methods, the reviewers evaluated the data set with unusually high interreliability (Cronbach's $\alpha = .917$). Not surprisingly, the texts by the adults without RWD were ranked the highest, followed by adults with RWD, 15-year-olds without RWD and 15-year-olds with RWD.

Further, we compared the text quality between adults and 15-year-olds without RWD, using writing speed and text length as co-variables. The results show that the quality evaluations are not dependent on either. This opens up for some new interpretations, since text quality has usually correlated with text length.

It is important that teachers or researchers, using increased text quality as evidence for development of any kind define what is meant by this notion.

In writing research, the importance of various writing process, as well as the written product is often related to text quality. Typically, text quality is related to various sets of text characteristics, e.g. text length, production rate, lexical measures, or the writer's age or schooling, and often increased text quality is seen as an important outcome of e.g. an intervention (cf. e.g. Rijlaarsdam et al, 2008). However, it is not always discussed what is meant by text quality, or how it is measured.

This paper is an approach a) to discuss the complicated measure of text quality, b) to present a method for training reviewers to evaluate texts, and c) to investigate the text quality in a data set consisting of 84 expository texts, produced using a keystroke-logging program (ScriptLog) by four different groups: 1. University students without any reading and writing difficulties (RWD), 2. University students with RWD, 3. 15-year-olds without any RWD, 4. 15-year-olds with RWD.

We engaged three reviewers (with a background including at least a master exam with linguistics; only one of them had worked as a teacher). Their task was to agree on a scale to use for judging text quality, and thereafter to identify properties, characteristic for each grade in the scale. Prior to the evaluation of the data set in our investigation, the three reviewers were trained on several sets of texts of the same type (e.g. expositorys) written by different age-groups (ranging from age 13 to adult university students; however no texts in the training data were produced by persons with RWD). In the first stage, their task was to evaluate texts on holistic grounds. The second stage was to group the rated texts, and agree on a scale to use, based on the grouping of the text. This led to a four-grade scale. The third stage was then to agree on text properties typical for each grade, and to select one or two model texts from each grade. The fourth stage was to train on a set of texts grading them using the model texts and the criteria for each text. In the fifth, and final stage, they graded the data set that we investigate in this study. The reliability between the reviewers proved to be high (Cronbach's $\alpha = .917$). This is notable, since e.g. Lofqvist (1990) report that a correlation around .70 will be considered a high agreement between teachers' judgements of student papers. The high interreliability in our study is thus a sign of that the method of working with both holistic and analytic methods to rate text quality can increase the certainty of how texts are evaluated.

When we relate the quality ratings to the four groups of writers in the data set we were interested in, we find that the texts written by the adults without RWD have the highest quality, followed by the adults with RWD. Thereafter follow the 15-year-olds without RWD and the group with the lowest quality is the 15-year-olds with RWD. This is not an unexpected result, considering the age differences between the groups, and the difficulties with text production that are typical for the groups with reading and writing difficulties. The question is whether this approach to measure text quality would have been the same if we e.g. had compared groups that were more similar in age, education or writing ability. Another question is whether the use of a more fine-graded scale would have led to a different grading.

Further, we compared the text quality between adults and 15-year-olds without RWD, using writing speed (e.g. median transitions between keystrokes within a word) and text length (e.g. number of keystrokes in the final texts) as co-variables. The results show that the quality evaluations are not dependent on text length or writing speed. This opens up for some new interpretations, since we know from other studies (e.g. Grandin & Lindskog) that text length (and thus also the ability to produce much text fast) is usually strongly correlated with text quality.

It is important to continue to discuss the notion of text quality, what is meant by it, and what contributes to an increased quality, in the light of recent changes in the educational system. For instance, in Swedish schools, a new set of additional national testing is proposed. How could children's writing development be discussed and judged if there are no reliable methods of measuring text quality? If 'text quality' is used for proving the developmental

outcome in any way, it is finally of equal importance for every researcher who uses the notion of text quality to clarify exactly what is meant by it.

PAPER PRESENTATION

Predicting Adolescent Truancy – Individual Judgments and Classroom Factors

Christine Saelzer, Education (IfE), Germany

Only little is known about the association of classroom characteristics with adolescent truancy. An unresolved critical question is whether high achievement standards, high workload, and high pace do protect against or increase adolescent truancy. In this study, self-reports from 3,500 Swiss middle and high school students in 202 classes (in 28 schools) were used to predict truancy. The multilevel latent covariate approach (MLC) implemented in Mplus was implemented to specify hierarchical models. These models served to differentiate between the student and the classroom level. It was found that high achievement standards were associated with a lower truancy rate at both the student and the classroom level, whereas a high pace during lessons was associated with more truancy. At the student level, the perception of low workload was an additional predictor of high truancy.

Predicting Adolescent Truancy –

Individual Judgments and Classroom Factors Research Topics and Objectives

Truancy is known to be an important predictor of premature school dropout (Rumberger, 2000). Skipping lessons is seen mainly as an individual student's behavior within an institutional context (Claes, Hooghe & Reeskens, 2009; Rothman, 2001). Focusing at the individual level, students who truant are often thought of as being academically weak and over-challenged at school (Fogelman, Tibbenham & Lambert, 1980; Tyerman, 1986). On the other hand, there is a reasonable argument that truancy may also be linked to high academic potential (Rumberger, 1987; Voss, 1966).

According to Walberg and Ahlgren (1970), learning outcomes represent a function of three distinct construct domains including aptitudinal variables, instructional variables, and environmental variables. Key to this claim is that environmental variables explain variance in learning outcomes over and above the amount of variance explained by instructional and ability variables. This paper applies Walberg and Ahlgren's theory to truancy and thus bridges a gap in truancy research by taking into account two aspects: (a) classrooms as learning contexts and (b) predictors of truancy. The focus is given to students' workload, pressure to perform, and pace during lessons. Two research questions are focused on: How can individual characteristics explain truant behavior? And how are classroom characteristics related to truancy?

Data and MethodsSample

Participants consisted of a total of 3491 Swiss seventh to ninth graders (n = 1142 grade 7, n = 1314 grade 8, n = 1089 grade 9) in 202 classes in 28 schools and their teachers and principals.

Instruments

Truancy was measured by a weighted frequency index consisting of seven items which focus on skipping single lessons, half and whole school days as well as several days in a row. Students' background factors were collected including gender, grade level, grades, class repetition, nationality, school level, and SES ([HISEI]) as well as individual and family-related scales. School characteristics were measured using structural criteria (e.g. school size, geographic situation) and students' and teachers' opinions concerning processes and classroom climate issues. Most of the scales were adapted from Eder's (1998) school study.

Analyses

For this analysis, the multilevel latent covariate approach (MLC) implemented in Mplus was adopted, which takes the unreliability of the group mean into account when estimating the contextual effect. The group average is thus treated as a latent variable. A nested multilevel model was specified using Mplus 5.2 (Muthén & Muthén, 1998-2007) in order to predict truancy from individual covariates, individual student judgments and aggregated class level (latent) covariates.

Results and Conclusions

Table 1

Most strikingly, in model 3, both pressure to perform and pace during lessons were significant predictors of truancy ($b = -.09$; $b = .12$) at the individual level and were associated with truant behavior when used as latent covariates at the class level (pressure to perform: $b = -.28$; pace during lessons: $b = .25$). Explained variance was low at the individual level (6%) and intermediate at the class level (35%). It was thus verified that shared classroom perceptions mattered for a student's decision to play truant.

Educational and Scientific Importance of the Study

Truancy is still seen as a minor problem by teachers and principals, but it is likely to become a major social problem during the next few years. The importance of truancy as a step towards school dropout is of immense social importance given the costs of students disconnecting themselves from the educational process. Understanding how truancy is related to classroom characteristics and how individuals respond to these features is useful in finding effective levers to prevent and deal with truancy as an unwanted student behavioral pattern. The level of perceived challenge is, both at the individual and the contextual level, a possible lever to prevent truancy.

PAPER PRESENTATION

Schooling and students' well being: a review of qualitative studies

Mara Westling Allodi, Stockholm University, Sweden

A systematic literature review of qualitative studies on the experiences and perceptions of school of Swedish children and adolescents was performed after literature searches in international and national databases. A narrative synthesis of 38 studies is presented focusing on the relationship between schooling and students' well being and mental health. Four themes were identified: general experiences (emotions, self-concept, choices); protective experiences (activities, participation, supportive relationships); risk experiences (tests, stress, school failure, negative evaluations, learning difficulties, lack of interest, negative relationships with teachers and peers); specific individual risks (disability, stigma, family problems, abuse, addiction, body image). The results are discussed in relation to developmental theories, special educational practices and current evaluation practices. The methodology of systematic review of qualitative studies applied in the field of educational research is discussed.

People's experiences and perceptions that are collected with non-experimental and qualitative studies can make a valuable contribution to an understanding of the meanings of processes and of relationships between phenomena. The object of this study was the relationships between educational experiences and students' well being and mental health. The methodologies of systematic review of qualitative research have been applied to a review of qualitative studies on Swedish children and adolescent's experiences of mental health and well being at school. The review was conducted as a part of a systematic review of research on "School, learning and mental health" performed by appointment of the Swedish Royal Academy of Sciences. The motives for doing a review of studies reporting children's and adolescents views on these matters was the ethical consideration to consider children and adolescents as subjects, having a right to express their views in matters that affect them; and the need to take account of the specific Swedish social and educational context through the experiences of the students that actively take part of it.

The aim of the review was to gather testimonies that can give indications of the experiences of mental health and well being of students in the Swedish educational system. Literature searches in several research databases with international and national publications were performed during spring 2009. A systematic screening of titles and abstracts was done on 527 references; 107 references were then screened in full text and 38 reports were judged to meet the inclusion criteria, requiring the presence of reports of children or adolescents' views, and that both aspects

of mental health and of educational factors were treated in the study. The studies included were written by authors from fifteen Universities; they consisted of doctoral dissertations, academic papers, peer-reviewed articles and reports from agencies and organisation, representing the disciplines of science of education, disability studies, psychology, public health, youth studies, social work and interdisciplinary. The studies included in the review collected the students' views by mean of individual interviews, focus group interviews, observations, texts, phone conversations, internet messages, surveys and drawings. The results from the studies that were relevant for the aims of the review are structured in four themes: general views (well being, emotions, self-concept, stress, choices); protective experiences (activities, achievement, enjoyment, mastery, relationships, participation); risk situations (tests, school failure, academic expectations, lack of meaning, lack of adaptation, conformism, alienation, relationships, victimization, exclusion); individual risk (disability, special educational settings, stigma, family problems, abuse, addiction, mental illness, body image).

The results are presented in a narrative synthesis, giving a particular weight to the direct and indirect report of children's and adolescents' own views. The theme general views is represented by sex studies. The adolescents defined mental health as emotional experiences, seen both as internal feelings and as relational feelings. Family, friends and educational environments as social and physical environments were perceived as determinants of mental health. A great number of feelings were related to school. The students expressed what characterize a healthy school environment and also that harassment and rejection at school, performance stress, worries about grades and future prospects could be threats against self-worth and self-esteem, while teachers that do not care could generate negative experiences. Various kind of stress could be described and various strategies to resist stressful situations: for instance emotional support, safety and involvement.

The educational environments can be an arena for social, cognitive and emotional experiences, relationships and accomplishments that are enriching the individuals and increase their well being. General structural characteristics of the educational environments may also affect well being in different directions: performance, evaluation and feedback, freedom of choice and responsibility for the future may be perceived as a burden. The protective experiences were described in nine studies that emphasised the protective role of supporting relationships with teachers and friends. Caring relationships with the teacher involve their instructional skills, their beliefs in the students' potentials, and their firmness in keeping helping the students, never giving up their efforts.

The relationships with peers are important for the students' well being and even for their commitment to school work. A relationship with caring staff at school could be a decisive turning point for students with family troubles. Success and mastery experienced at school can make the students feel empowered and more competent. The learning environment could be also experienced as a healthy heaven, a safe place filled with activities, that make you feel purposeful and engaged. Risk experiences in school was the fourth theme, represented by 25 studies. School difficulties and special educational interventions could be perceived as stigmatizing and contributing to embarrassment, lowered status or simply to an undesired separation from the company of peers, and sometimes also to harassments.

The competition, the pressure to get good grades experienced in certain groups could cause performance anxiety, concentration difficulties and psychosomatic symptoms. The social life of the group can be very deprived and unhappy for isolated and rejected students. Conflicts with the teachers are identified as contributing to lowered interest and motivation in school work, but also detached and indifferent behaviours may affect motivation and self-confidence negatively. The theme of specific and individual risks emerged in nine studies. Among students that experienced learning disability (dyslexia) secondary emotional problems had been common. Having a disability that influences the social behaviour may increase the risk to be victimized by peers. The students reported that the victimizations caused school difficulties, sickness, absenteeism and depression. Other social problems (family conflicts, abuse, addiction, refugee status) could also make the students more easily exposed to negative experiences at school.

Some reflections: The studies reporting views of younger children on the matters of this review were less well represented. The negative experiences may be expressed in rather cautious terms by younger children. The experiences of the students change when they grow older, go through developmental processes and encounter different educational situations. Several developmental trajectories can be identified. The systematic review of qualitative studies is a valuable methodological approach that can be applied in the field of special educational needs.

PAPER PRESENTATION

Success at adult education: The situation of 16 to 18 year-old students with special needs

Nadia Rousseau, Université du Québec à Trois-Rivières, Canada; Karen Tetreault, Université du Québec à Trois-Rivières, Canada; Ghislain Samson, Université du Québec à Trois-Rivières, Canada; Sylvie Frechette, Université du Québec à Trois-Rivières, Canada

Many students with special needs leave high school before getting a diploma but reconnect with school through adult education. However, very few studies examine the situations experienced by these students. Therefore, this study aims to document the factors explaining why youths with special needs register in adult education programs at the age of 16, and to describe and analyse the school experiences of these students until they leave adult education with or without diploma. A sample of 165 youths with special needs, registered in an adult education program, answered a questionnaire outlining their past, present and expected situation as students. Also 45 of them accepted to participate in focus groups. 59 youths who left the adult education participated in phone interviews discussing their adult student experience and their expectations about the future. Factors explaining the shift from youth to adult education are presented in order of significance. Students report a very positive perception of their school experience at the adult education. Recommendations are made to maintain this positive perception of adult education.

Introduction

Many teenagers abandon school before getting a high school diploma. In 2007-2008, 25.7% of Quebec teenagers were not enrolled in school and had not completed high school (MELS, 2009). They are unlikely to find a job in this complex society without the minimum credentials required in the job market. An important decrease in available jobs for youths without a high school diploma has been observed in the past years (Vultur, 2003).

Many youths reconnect with school through adult education. A significant increase of registration has been observed. Indeed, the number of students enrolled in adult education has increased from 128,200 in 1999-2000 to 158,793 in 2005-2006 (CSE, 2008). Many of them are students with special needs. Unfortunately, very few Canadian or Quebec studies examine the situations experienced by youths with special needs enrolled in adult programs. Therefore, it is advisable to examine the matter.

Objectives:

1. Document the factors explaining why youths with special needs register in adult education programs at the age of 16
2. Describe and analyse the school experiences of these students until they leave adult education with or without diploma.

Theoretical framework

Students that drop out of general education give the following reasons: lack of motivation, academic reasons, personal or family related issues, hoping to earn a living or have a job, their training perceived as completed, wanting to continue their schooling elsewhere, and repeated academic failures. (Potvin et al 2004). These reasons are associated with a number of challenging characteristics listed in several studies relating to dropouts : male gender, unproductive coping strategies, low self-esteem, poor social skills, negative perception of school, academic difficulties (especially in writing and reading), lack of motivation, behaviour problems (Fortin, Potvin & Royer, 2000), and negative school experiences (Rousseau, 2005). Finally, negative class atmosphere, negative teacher-students relationship and negative teachers' attitudes towards students with special needs (Potvin, 2005) are also associated with dropping-out. Many dropouts will register to the adult education in order to get a first diploma.

Methodology

A microethnographic analysis of case studies is conducted.

a) Participants and procedure

First objective

The sample is composed of 165 youths with special needs in high school and registered in an adult education program in autumn 2007. They answer a questionnaire containing mainly metaphors (see Steinhoff and Owens, 1989) outlining their past, present and expected situation as students. Also 45 of them participate in focus groups.

Second objective

59 youths of the above sample that left the adult program with or without a diploma also participate in a twenty-minute phone interview on their adult student experience and their expectations about their future.

b) Data source

Two independent coders conduct a qualitative network approach of analysis that implies an inductive coding. The Cohen's Kappa coefficient of inter-rater agreement is 0.82. Frequencies are calculated in terms of proportion of meaning units in interviews.

Findings and discussion

According to frequency accounts, factors explaining the shift from youth to adult education are presented in order of significance in three broad themes: negative high school experiences, possibility of getting credits or a diploma, individual students' characteristics. Factors associated specifically with adult education are fulfillment of distal (getting a job) and proximal (getting a diploma) objectives. Factors associated with school are individual support, respect of individual learning pace, less stress and anxiety, and hope of success. Factors that explain leaving adult education without certification are the following: employment and persistence of school problems.

The participating youths with special needs left high school for adult education because they do not like school. The negative feelings are stronger with those in special education classes. When leaving adult education, they all have, without exception, a very positive perception of their school experience, which represents a complete turnover. Students report working at their own pace in their books. Individual progress is monitored without references to the group. Moreover, positive feedback is given frequently and without prejudice. Unlike common belief, these students are persevering.

Conclusion and educational significance of the study

An increasing number of high school students who experience academic difficulties switch to adult education to get a high school diploma or the credits required for professional training. Throughout their schooling, they persist to overcome obstacles and progress at their own pace. Recommendations are made to maintain this positive perception of adult education.

PAPER PRESENTATION

Can preschool education prevent the incidence of later emotional and behavioural difficulties?

Pamela Sammons, University of Oxford, United Kingdom; Yvonne Anders , University of Bamberg, Germany; Kathy Sylva, University of Oxford, United Kingdom; Edward Melhuish, University of London , United Kingdom; Iram Siraj-Blatchford, Institute of Education - University of London, United Kingdom; Brenda Taggart, University of London, United Kingdom

Drawing on a large data set collected as part of the Effective Provision of Preschool and Primary Education 3-11 Project (EPPE 3-11) this paper looks at children identified as showing special educational needs in England at age 10. The present study investigates which child, family and home predict primary teachers' identification of children's SEN status in relation to emotional and behavioural difficulties at age 10 using logistic regression models. Further, the analyses explore whether children's earlier preschool experience is related to later incidence of SEN. The sample consists of 2509 EPPE3-11 children. 8.3 % of the children were identified by their teachers as showing SEN related to emotional or behavioural problems. Early health problems or behavioural problems, having been a premature child, low maternal education, self employment of the mother, low socioeconomic status and eligibility for free school meals show to be risk factors for the identification of SEN at age 10. Also, boys have a higher risk than girls whereas child age has a protective impact. Analyses further showed that the quality of preschool attended still was significantly

associated with SEN identification, even when other background factors were controlled. The results of the present study underline the continuing effect of preschool quality as a factor that has a specific role in reducing the likelihood of later emotional and behavioural problems. High quality preschool may be viewed as an effective intervention for enhancing resilience in young children.

Aims

More than 30 years ago the Warnock Report (Department of Education and Science, 1978) suggested that about 20% of children would at some stage in their school career experience special needs of some kind. There has been much debate about this figure, which was largely based on teachers' estimates, but it still reflects current levels of SEN identification in England (e.g. Croll and Moses, 2003). The early identification of SEN in primary school is considered one important prerequisite for children to reach their full potential (Davie, 1996). But rather than relying solely on strategies implemented in primary school, it may be more effective to investigate what influences children's development at an earlier age (in preschool). Preschool education programs which may promote better adjustment to school and school readiness (e.g. Magnuson et al., 2004; Sammons et al., 2008; Sylva et al., 2010) might therefore be hypothesised to be a means to help protect children from later being identified as having some form of SEN while they move through primary and secondary school. Only a few studies have investigated longer-term benefits of preschool education so far and very little attention has been paid to the question of whether preschool has particular benefits with respect to children with SEN or at risk of developing SEN (Anders et al., 2010; Taggart et al., 2006).

Drawing on a large data set collected as part of the Effective Provision of Preschool and Primary Education 3-11 Project (EPPE 3-11), - a major longitudinal study of preschool and primary school influences on children's developmental outcomes - this paper investigates children identified as showing special educational needs in England and explores the factors that help predict SEN status at age 10. The present study investigates which child, family and home factors predict primary teachers' identification of children's SEN status in relation to emotional and behavioural difficulties at age 10. Further, the analyses explore whether children's earlier preschool experience is still related to later incidence of SEN.

Methodology

Sample

All data are drawn from EPPE3-11, which followed children's cognitive and social/behavioural development between the ages of 3 and 11 in England and was funded by the Department of Children, Schools and Families (DCSF). The project collected a wide range of data on over 3000 children, their background and the preschool settings they attended. At each assessment of the longitudinal investigation, primary teachers completed a child social behavioural profile for each EPPE child and reported details of any SEN. This investigation uses the child profiles completed at the end of Year 5 (age 10). The sample for this study consists of 2509 EPPE3-11 children with a valid profile.

Measures

Outcome measure

Teacher reported on present SEN in the child profiles. The current analyses focus on special needs related to emotional and behavioural difficulties.

Predictors

Child factors included gender, English as additional language (EAL), age in months, ethnic group, birth weight, early behavioural problems, number of early health problems and number of early developmental problems as reported by the parents in preschool interviews, premature child and number of siblings.

Family factors included family structure, parents' employment status, parental education, family salary at time of preschool education, family SES and child eligibility for FSM (a proxy measure for low income).

Parent-child activities and routines during the preschool years which provide an indication of aspects of the early years home learning environment (HLE), such as reading to the child, listening to the child read, teaching songs and nursery rhymes etc, were aggregated to a scale measure of the quality of HLE (Melhuish et al., 2008).

Preschool measures: The duration of preschool attendance and the quality (based on environment ratings using ECERS-R and ECERS-E) and effectiveness of the preschool centre were regarded as potentially protective factors and tested as potential protective factors.

Statistical analysis

First, all child, family and home characteristics were tested as potential risk or protective factors for SEN. Stepwise analyses were conducted and only significant variables were retained in the models. Subsequently, the impact of indicators of preschool education was tested individually in logistic regression models controlling for all statistically significant variables retained in the background model. Standard errors adjusted for the multilevel structure of the data were estimated.

Findings

8.3 % of the children were identified by their teachers as showing SEN related to emotional or behavioural problems. Early health problems, behavioural problems in the early years, having been a premature child, low maternal education, self employment of the mother, low socioeconomic status and eligibility for free school meals show to be risk factors for the identification of SEN at age 10. Also, boys have a higher risk than girls whereas child age has a protective impact with older children in the sample being less likely identified as SEN. The quality of HLE is not significantly related to SEN identification. With respect to the influence of preschool experience, analyses revealed that the most basic indicator – preschool attendance versus no preschool – was not found to be significantly related to SEN identification when other background variables were controlled. The same holds for duration of preschool attendance and preschool centre effectiveness. In contrast the quality of preschool attended still was significantly associated with SEN identification, even when other background factors were controlled.

Theoretical and educational significance of the research

The results of the present study suggest that a range of preventive strategies that support children's development in the early years may improve 'school readiness' and therefore reduce the number of children who may be at risk of developing SEN in later years. An important point concerns the continuing effect of preschool quality as a factor that has a specific role in reducing the likelihood of later emotional and behavioural problems. High quality preschool may be viewed as an effective intervention for enhancing resilience in young children. The findings of the study are highly relevant to educational policy-making and the politics of change and improvement.

PAPER PRESENTATION

PowerPoint Does Not Make Us Stupid – But Extensive Slides Impair Recall of Oral Information!

Christof Wecker, University of Munich, Germany

This study investigated whether information presented on slides is more easily recalled than information presented orally, whether information presented orally is recalled more easily if concise slides are presented than if extensive slides are presented, whether concise and extensive slides are superior to purely oral presentation overall and whether any such effect of the presentation mode can be explained by differences in cognitive load. A field study with a one-factorial design with the conditions no slides, concise slides and excessive slides was conducted in tutorials about literature search and supply. Cognitive load as well as recall of information presented orally and information presented on slides were measured separately in all three conditions. The results show no general negative effect of slides with respect to the recall of orally presented information, but a superiority of concise slides compared to extensive slides with respect to orally presented information and compared to no slides with respect to overall recall of information. Information presented on slides is recalled more easily than orally presented information. Differences in cognitive load can be ruled out as explanations for any of these effects. Given these findings it seems advisable to keep presentations concise, but more research is needed in order to delineate the optimal amount and kinds of content on slides.

Presentation software has become ubiquitous in educational institutions. However a fear that "PowerPoint makes us stupid" (Gralla, 2010) has been voiced. Research evidence about the effects of the use and of design features of slides on cognitive learning outcomes is sparse. In one study a negative effect of a PowerPoint lecture compared to a traditional lecture was found with respect to the recall of information that was presented exclusively orally, with recall for oral information being as low in the condition with electronic slides as in a condition that did not receive any instruction on the topic (Savoy, Proctor & Salvendy, 2009). One potential explanation for this finding would be that the extensive use of slides might place to excessive demands on learners' cognitive resources. Another explanation could be that an extensive use of slides might induce the impression that only information presented on slides is important.

The present study aims to contribute to a broader research base about these issues and to provide some constraints for potential explanations for effects on recall of orally presented information. In particular, it addresses the following research questions: (1) How does the presentation of information on slides vs. purely oral presentation affect the recall of information? (2) How do concise vs. extensive slides affect the recall of information presented only orally and information presented on slides? (3) How does the presentation of information without slides, with concise slides and with extensive slides affect the overall recall of information? (4) Can differences in recall of information between presentation modes be due to differences in cognitive load?

Method Instructional setting.

The study was conducted in tutorials in which skills in searching and obtaining literature were taught. These started with a presentation about the scientific publication system and basics of literature research and supply, which was followed by a quiz that served as a posttest.Design. Three conditions were compared in a one-factorial design: No slides, concise slides and extensive slides. Four tutorial groups were nested within each condition.Independent variables. Content was constant across conditions. In the condition without slides all information in the presentation was given orally. In the conditions with slides the same information was presented orally, but in the condition with concise slides key points were listed on projected slides during some parts of the presentation, whereas in the condition with extensive slides also detailed information and key statements were projected on slides throughout the presentation. All slides contained a maximum of eight lines or six bullet points.

Dependent variables.

Recall of information was measured by 18 multiple choice items. One third of them covered information that was presented orally in all three conditions, information that was presented on slides in the condition with extensive slides, and information that was presented on slides in both conditions with slides, respectively. To equate these subtests, scores were z-standardized using the means and standard deviations from the condition in which all three kinds of information had been presented orally (no slides). Then two equally weighted scores were formed for recall of information presented only orally and for recall of information presented on slides separately for each condition.Cognitive load was measured by a single Likert type item with a nine-point answering scale.Participants. The sample comprised 294 freshers (86 % female, 14 % male) in a degree program in education from two subsequent years. Results (1) Recall of information presented on slides in the conditions with slides was higher than (i) recall of the same information in the condition without slides, $F(1; 282) = 14.48$; $p = .05$, and than (ii) recall of information presented only orally in the same conditions, $F(1; 181) = 43.78$; $p = .20$.(2) While there were no differences between concise and extensive slides with respect to the recall of information presented on slides, $F(1; 181) = 4.36$; $p = .02$. Although recall of orally presented information in the condition with concise slides was descriptively higher than in the condition without slides, these conditions did not differ significantly.(3) When recall for information presented only orally and for information presented on slides were weighted equally and combined to an overall indicator of recall of information, the three conditions differed in this respect, $F(2; 282) = 3.24$; $p = .02$. While concise slides were superior to no slides with respect to overall recall of information, $F(1; 191) = 5.53$; $p = .03$, the corresponding difference between extensive slides and no slides could not be secured against chance, $F(1; 192) = 1.47$; $n. s.$ (4) Cognitive load was generally moderate and did not differ between the three conditions, $F(2; 275) = 1.58$; $n. s.$

Discussion

A general negative effect of slides on recall of orally presented information as suggested by Savoy et al. (2009) could not be found. Instead, a positive effect of concise vs. extensive slides with respect to orally presented information was demonstrated. This effect cannot be explained by excessive demands on learners' cognitive resources.Presenting information on slides has an advantage with respect to the recall of these particular pieces of information. However, in many cases it seems unfeasible to put all the information one wants to convey on slides. Some information will almost certainly need to be presented orally. When equal value is attached to information irrespective of its presentation mode, concise slides appear superior to purely oral presentation whereas extensive slides do not. Therefore it seems advisable to keep slides concise. Future research has to delineate the boundaries of "conciseness".

PAPER PRESENTATION

Demonstration of Procedures in Face-to-Face Instruction: Effect of Animated Steps in Worked Examples

Christof Wecker, University of Munich, Germany

This paper deals with the question how worked examples for procedures should be demonstrated in face-to-face instructional situations. A plausible way of transferring the findings from research on worked examples to face-to-face instruction would be the use of presentation software. In particular, the requirement of making intermediary results transparent could be achieved by using animation functionalities for the stepwise presentation of intermediary results. The present study investigates whether such an animated stepwise presentation has a positive effect on procedure acquisition compared to a static presentation of the whole solution path.

A within-subjects design was implemented in a one-year university course about empirical research methods in two subsequent years: One of two procedures was demonstrated with animated stepwise presentation of intermediary results, whereas the other was demonstrated with a static presentation of the whole solution path. The order of the manipulation was counterbalanced. Procedure acquisition was measured in the regular examinations at the end of each term. The scores were z-standardized topic-wise in order to allow for within-subject comparisons of the two presentation modes. A significant positive effect of animated stepwise presentation of intermediary results compared to static presentation of the whole solution path was found, which was specific for the procedures in focus. This effect is remarkable given that it was obtained in a field study within a regular course where outcomes were measured several weeks after manipulation. In practice, intermediate steps should be presented stepwise using animation functionalities, which once was common in the age of the blackboard.

In many learning settings the acquisition of procedures such as performing statistical tests is a main goal of instruction. A central source for the acquisition of a procedure is the study of worked examples, i. e. the induction of the procedure based on the trace of intermediary results of the solution steps performed during its application (VanLehn, 1990): During the study of worked examples, the current knowledge of the procedure is applied to each intermediary result. Thereby, the subsequent intermediary result is either predicted or explained (anticipatory reasoning and principle-based explanation, cf. Renkl, 1997). An important prerequisite for this mechanism of procedure acquisition is specified by the so-called "show-work principle" (VanLehn, 1990): All intermediary results need to be transparent. Furthermore, step-wise presentation of intermediary results has been found to foster learning (Renkl & Atkinson, 2002). In face-to-face instructional settings, presenting the types of worked examples used in laboratory research often would appear somewhat strange. Instead, the more natural and common way of presenting worked examples is an instructor providing a demonstration of the procedure (cognitive modeling).

In fact, [o]ne could argue that studying worked examples is a type of observational learning" (van Gog & Rummel, 2010, p. 156). Therefore, the research literature on worked examples can be regarded as basic research that needs to be transferred to face-to-face demonstrations in practical application settings (Atkinson, Derry, Renkl, Wortham, 2000). A plausible way of transferring the findings from research on worked examples to face-to-face instruction would be the use of presentation software (e. g. PowerPoint) that has become ubiquitous anyway. In particular, the requirement of making intermediary results transparent could be achieved by using the animation functionalities of this kind of software for stepwise presentation.

The present study investigates whether such an animated stepwise presentation has a positive effect on procedure acquisition compared to a static presentation of the whole solution path. Method Instructional setting and content. The study was conducted as a field study in the context of a one-year university course about empirical research methods in two subsequent years during the winter and summer terms. Design and manipulation of the independent variable. A within-subjects design was implemented: Of two procedures (winter term: Cohen's kappa, summer term: t-test for independent samples), in each year one was demonstrated with animated stepwise presentation of intermediary results, whereas the other was demonstrated with a static presentation of the whole solution path. The order of the manipulation was counterbalanced across the two topics in the two years without changes in content or amount of accompanying verbal explanations.

Dependent variables.

Procedure acquisition was measured by calculation tasks in the regular examinations at the end of each term. In both cases, the occurrence of the steps of the procedure in the solutions was coded and counted (winter: Cronbach's $\alpha = .85$, summer: Cronbach's $\alpha = .90$). Furthermore, the unspecific learning outcomes (for the other topics of the course) were measured in these examination by means of 21 and 16 multiple choice items, respectively (winter: Cronbach's $\alpha = .63$, summer: Cronbach's $\alpha = .65$). Both measures were z-standardized using the means and standard deviations for the respective topic to allow for within-subjects comparison between the two manipulated conditions. Participants. The sample comprised 324 students from the lecture who participated in it for the first time and took both examinations in the same year. They were on average 21.4 years old ($SD = 3.2$); of them 88 % were female and 12 % were male.

Results

The z-standardized scores for procedure acquisition were higher for the topic covered with animated stepwise presentation of intermediary results than for the topic introduced with static presentation of the whole solution path was implemented, $t(323) = 2.25$, $p = .01$, $d = 0.12$. To rule out the possibility that this difference might be due to variations between terms confounded with the manipulation, the unspecific learning outcomes were compared in the same way. The z-standardized scores for this variable from the terms in which animated stepwise presentation of

intermediary results with respect to the particular topics chosen was implemented were not higher than the z-standardized scores from the terms in which static presentation of the whole solution path was implemented, $t(323) = -1.83$, n. s. Rather, the descriptive results tended in the opposite direction.

Discussion

In line with research on worked examples (Renkl & Atkinson, 2002), these findings indicate that animated stepwise presentation of intermediary results is more effective for procedure acquisition than static presentation of the whole solution path when demonstrating a procedure. In particular, potential confounding that might occur in a field setting using intact courses could be ruled out by means of the within-subjects design and the test for the specificity of the effect for the topics selected for manipulation. The effect on procedure acquisition is remarkable in spite of its low magnitude given that it was obtained in the context of a field study within a regular university course where the learning outcomes were measured several weeks after a rather small-scale manipulation. For instructional practice it might be concluded that when using presentation software for the demonstration of procedures, intermediate steps should be presented stepwise using the animation functionalities of the software. This was actually the typical way of presentation in the age of the blackboard, but in the age of slides it requires additional effort during preparation.

PAPER PRESENTATION

The Mere Exposure to a Problem Prepares Teacher Students for Learning

Inga Glogger, Institute of Psychology, Germany; Lars Holzapfel, Educational University of Freiburg, Germany;
Elmar Offenwanger, University of Freiburg, Germany; Rolf Schwonke, University of Freiburg, Germany; Matthias Nuckles, University of Freiburg, Germany; Alexander Renkl, University of Freiburg, Germany

There are approaches that try to optimize receptive forms of learning and direct forms of instruction by problem-oriented activities (e.g., Schmidt et al., 1989; Schwartz & Bransford, 1998). Such approaches typically use generative group activities that are quite time consuming. These activities are thought to generate useful forms of prior knowledge. Simply knowing about target problems might, however, already sufficiently prepare for learning from direct instruction, as the goal of learning and the application context becomes salient. In an experimental pretest-posttest design, 89 student teachers learned about assessing learning strategies in students' learning journals by a computer-based learning environment. The problem-first group were shown an authentic problem (evaluating learning journals and giving feedback) prior to a "receptive" learning phase and they worked on the problem after the learning phase. The problem-after group received the problem subsequent to the learning phase and then worked on it. The open-ended questions of the posttest were coded for identification of learning strategies and their quality and for suggestions to students for improving strategies (i.e., feedback). Providing the problem first enhanced learning in terms of identifying learning strategies and their quality. Surprisingly, suggestions for improving learning strategies were made more often by the problem-after group, even though they did not identify strategies and their quality as well as the problem-first group. Hence, receiving an authentic problem prior to learning prepared teacher students to providing feedback that was based on specific observation rather than sparsely founded suggestions.

Aims of the study.

There are approaches that try to optimize receptive forms of learning and direct forms of instruction by problem-oriented activities (e.g., Schmidt, De Volder, DeGrave, Moust, & Patel, 1989; Schwartz & Bransford, 1998). These approaches typically use generative group activities that should lead to forms of prior knowledge that allows for subsequent elaborative processes. For example, Schmidt et al. activated prior knowledge by letting students discuss explanations for a problem central to the learning domain. There are little attempts to systematically study which features of the work on the problems are crucial. Does it actually require solving the problem? Attempts to solve the problem let learners encounter lacks of understanding or knowledge which is thought to be productive (Kapur, 2008, "productive failure"). Simply knowing about an authentic problem might, however, also hint to knowledge deficits. Knowing an authentic problem makes the goal for learning and the application context more salient. If knowing about a problem already suffices to prepare for learning from direct instruction, this option would be more time efficient.

In a previous study, teacher students learned about learning journals and how to diagnose learning strategies in such journals. By writing learning journals, students are encouraged to use learning strategies such as elaboration, organisation, and metacognitive strategies. For example, they could explain how a new concept relates to something they already knew (elaboration strategy). In order to apply learning journals as a method to foster learning strategies in students, teachers have to be able to identify learning strategies, their quality, and formulate useful feedback. Therefore, as an authentic starting problem, student teachers received learning journals of students. They were asked to find learning strategies and criteria for evaluating them. They showed more transfer than a control group that received explanations instead. In the present study, which was part of the research program "Bildungsforschung" ("Educational Research") of the Baden-Württemberg Stiftung, student teachers only knew about the authentic problem (i.e., evaluating and providing feedback on students' learning journal), but they worked on it after learning. We expected that getting to know an authentic problem prior to learning enhances teacher students' diagnosis and feedback skills with respect to learning strategies.

Methods.

Eighty-nine student teachers (71 female, 18 male) from two equivalent seminars at a German University of Education participated in the study (title of the seminars: "Selected topics of mathematics instruction"). Two weeks prior to the intervention, they all worked on a pretest during their seminar. The pretest assessed diagnosis skills regarding learning strategies by three open questions. At the intervention, participants were randomly assigned to two conditions: (a) they received an authentic problem prior to learning with a computer-based learning environment and had 5 minutes to familiarize themselves with the problem (problem-first group, $n = 42$); (b) they received the same problem after learning (problem-after group, $n = 47$). The problem consisted of learning journal entries and a description of a situation ("Here you see two learning journal entries of two students. Your challenge is the identification of learning strategies and the formulation of a feedback to the students. Use the information from the learning environment. Before you start the learning environment, we would like to ask you to read the learning journal entries in detail (5 minutes)."). All participants learned in the computer-based learning environment for 30 minutes. In the learning environment, the diagnosis of elaboration strategies in learning journals was taught. Providing feedback was not specifically taught. After learning, the problem-first group had 10 minutes to solve the problem, that is, to identify learning strategies in the learning journals and to write feedback to the students. The problem-after group now received the problem, read it carefully (5 minutes) and worked on it for 10 minutes, that is, time-on-task was equal across groups. The open-ended questions of the posttest were coded by two independent raters ($ICCs > .80$). Learning outcome scores were (1) the number of sections coded as "identify and feedback learning strategies and their quality" and (2) the number of sections coded as "suggestions for improving learning strategies".

Results.

Teacher students who first familiarized themselves to the authentic problem achieved higher scores in identify ($F(1, 87) = 4.91, p = .029, \eta^2 = .05$). Suggestions, however, were made more often by the problem-after group ($F(1, 87) = 14.24, p = .001, \eta^2 = .14$). Prior knowledge was not significantly related to the learning outcome scores.

Theoretical and educational significance. Research on preparation to learn from direct forms of instruction used time-consuming instructional methods. Results of this study suggest that adult learners such as student teachers, however, can be prepared by the mere exposure to a problem taken from their professional context. The phase of (un)productive failure while struggling with a problem might not be necessary for all kinds of learners.

Unexpectedly, the problem-after group gave more suggestions to students how to improve their learning strategies even though they were less successful than the problem-first group in identifying learning strategies and explaining why the learning strategies were suboptimal. However, well-grounded specific and, thereby, helpful (Shute, 2008) suggestions can scarcely be made without detailed identification of learning strategies and their quality. We will reanalyse the suggestions in order to test if the problem-after group's suggestions were of lower quality than the suggestions of the problem-first group. In summary, receiving an authentic problem prior to learning prepared teacher students to learn and transfer their knowledge to giving feedback that was based on specific observation.

PAPER PRESENTATION

Expository Instruction before Inquiry Learning: Fostering Understanding of “Undiscoverable” Theories

Alexander Rachel, University of Munich, Germany; Christof Wecker, University of Munich, Germany; Eva Heran-Dorr, University of Bamberg, Germany; Christine Waltner, University of Munich, Germany; Hartmut Wiesner, University of Munich, Germany; Frank Fischer, Universität München, Germany

Some scientific theories that students are supposed to learn through inquiry learning involve assumptions about unobservable theoretical entities and relations among them. This study investigated whether prior expository instruction and summary expository instruction can foster the understanding of these theories. In an experimental study with a 2x2-factorial design 604 high school students from 23 classes participated in an inquiry unit about magnetism. Prior expository instruction fostered the understanding of the explanatory theory both in an immediate and a delayed posttest. Summaries produced an effect on understanding of the explanatory theory only in an immediate, but not in a delayed posttest. The findings suggest that prior expository instruction can provide learners with explanatory theories they can apply to phenomena observed during their inquiry activities and thereby foster the understanding of such explanatory theories.

One of the main goals of science education is to foster the understanding of scientific theories that can explain observable phenomena. Inquiry learning is regarded as functional for accomplishing this goal (de Jong, 2006). However, explanatory theories in science that students are supposed to learn often go beyond functional relationships among observable variables that can be discovered by observation in a straightforward way. For example, in phenomena related to magnetism, (theoretical) molecular magnets cannot be observed directly. Accordingly, the learners' hypothesis space (Klahr & Dunbar, 1988) will hardly contain assumptions about them, and they have little chance to discover them on their own. This suggests expository instruction about possible explanatory theories as an approach to foster theoretical understanding during inquiry learning. In principle, expository instruction can be provided prior to inquiry activities, but the same content can also be presented in a summary afterwards.

In the former case, learners could use these theories to explain the phenomena they encounter during inquiry activities, which could help them develop a robust understanding of them. In the latter case, however, this use of the theories is not possible: Without the opportunity to use them to make sense of the phenomena observed, learners may be less likely to build up a robust understanding of them. To test these assumptions, we conducted an empirical study to investigate the effects of prior expository instruction and summary expository instruction on the acquisition of understanding of scientific theories. We hypothesized that prior expository instruction improves understanding of scientific theories compared to no prior expository instruction in a test immediately after the learning phase as well as several weeks later. We further expected that summary expository instruction improves understanding of scientific theories compared to no summary expository instruction only in a test immediately after the learning phase, but not several weeks later.

Methods and data sources

Participants. The participants in this study were 604 German high school students from 23 7th grade classes (60 % female, 40 % male; age: $M = 12.66$, $SD = 0.59$). **Design.** Five to six intact classes were randomly assigned to each condition of a 2x2-factorial design with prior expository instruction (without/with) and summary expository instruction (without/with) as independent variables. **Procedure and learning environment.** Whole classes of students first completed a 10 minute pretest. Then they worked on an inquiry unit about magnetism for 100 minutes. In all conditions the students conducted hands-on experiments in dyads at up to eleven learning stations. They completed an immediate 20 minute posttest and about two months later a 20 minute delayed posttest in their classrooms.

Independent variables.

In the conditions with prior expository instruction, first a 25-minute introduction to the theoretical background of magnetism was provided by a teacher. No such introduction was given in the conditions without prior expository instruction. In the conditions with summary expository instruction a 25-minute teacher-led wrap-up phase about the same topics as in prior expository instruction took place afterwards, while there was no such phase in the conditions without summary expository instruction. **Dependent variable.** Understanding of the scientific theory of magnetism was measured by means of 16 multiple-choice and true-false items (immediate posttest $\alpha = .71$; delayed posttest $\alpha = .74$). A test for knowledge about functional relations among observable variables associated with magnetism was used as the pretest (13 items, $\alpha = .62$).

Statistical analysis.

Data were analyzed by means of single ANCOVAs with the respective posttest measure as the dependent variable, prior expository instruction and summary expository instruction as independent variables, class as a random factor nested within the cells of the design and the pretest measure for knowledge about functional relations among observable variables as a covariate. The significance level was set to 5 %. Results A main effect of prior expository instruction in favour of the conditions with prior expository instruction compared to the ones without prior expository instruction could be detected in the immediate posttest, $F(1; 19.14) = 12.39$; $p = .002$; partial $\eta^2 = .05$. An analogous main effect of prior expository instruction was found in the delayed posttest, $F(1; 19.37) = 10.87$; $p = .004$; partial $\eta^2 = .03$. Furthermore, a main effect of summary expository instruction in favour of the conditions with summary expository instruction compared to the ones without summary expository instruction was found in the immediate posttest, $F(1; 19.12) = ; p = .001$; partial $\eta^2 = .06$. However, this effect disappeared at the delayed posttest, $F(1; 19.38) = n. s.$ In both posttests, no significant interactions were found.

Discussion

These findings provide evidence for our argument that understanding of scientific theories that involve unobservable variables is less likely to be attained by inquiry activities without further support. Rather, learners benefit substantially by being introduced to the theories developed by scientists. The finding that a summary of the same content as provided by prior expository instruction did not produce a lasting effect on the understanding of scientific theory suggests that the effect of prior expository instruction is not simply a matter of being told the right answers. An explanation could be that prior expository instruction about theories that cover phenomena observed during hands-on experimentation can lead to the application of these theories during inquiry activities, thereby yielding deeper theoretical understanding. Overall, the study supports the argument that elements of direct instruction might play an important role in inquiry learning (cf. Klahr & Nigam, 2004), while still highlighting the importance of phases of inquiry in which learners can apply the theories to be learned. Teachers implementing inquiry learning would be well advised to reflect about the chances their students actually have to find out by inquiry what they are supposed to learn, and provide targeted support.

PAPER PRESENTATION

Interpersonal teacher behaviour: lesson associations with classroom social climate

Tim Mainhard, Utrecht University, Netherlands; Mieke Brekelmans, Utrecht University, Netherlands; Theo Wubbels, Utrecht University, Netherlands

The present study investigated whether the classroom social climate varies between lessons. Specifically, the within- and across-lesson associations of coercive and supportive teacher behaviour incidents with the classroom social climate were studied. Participants in the study were 48 Dutch secondary school teachers and their classes, that is, 1208 students. Multilevel process analyses showed that supportive behaviour incidents correlated with a positive social climate during the current lesson and the lesson a week later in terms of teacher interpersonal Affiliation. Supportive behaviour incidents did not, however, correlate with social climate in terms of teacher interpersonal Control. Coercive behaviour incidents correlated with disrupted teacher Affiliation during the current lesson and the lesson a week later, but did not virtually correlate to increased levels of a teacher's Control in the classroom.

How students perceive the classroom social climate, and especially the way students perceive their teachers interpersonally, is strongly related to student achievement and well-being (Davis, 2003; Wentzel 2002; Wubbels, Brekelmans, den Brok, & van Tartwijk, 2006). The more warm and supportive a teacher is, the more students report a sense of belonging and being engaged (Freeman, Anderman, & Jensen, 2007). On the other hand, if teachers are acting offensive and coercive learning is negatively affected, and students report more psychological and somatic complaints (Sava, 2002).

The aim of the present study is to examine how incidents of coercive and supportive teacher behaviour are associated with the variability of the classroom social climate teachers create. Studies which have investigated changes of the classroom climate (Mainhard, Brekelmans, Wubbels, & den Brok, 2010; Patrick, Anderman, Ryan, Edelin, & Midgley, 2001) have largely done so over rather extended periods of time (e.g., several months), thereby ignoring lesson-to-lesson variability. The present adds to the existing body of knowledge on classroom social climates by investigating these associations within (i.e., during a lesson) and across lessons; specifically, what is the association of coercive and

supportive behaviour of a teacher with the classroom social climate one or two weeks later? Incidents of teacher coercion and supportive teacher behaviour may change classroom social climate temporarily or permanently.

Classroom Climate and teacher behaviour

In the present study, the social climate is conceived as the quality of social relations in classrooms. Collective students' perceptions of the teacher Control and Affiliation are utilized as an indicator of the climate. Building on a phenomenological point of view, students are considered as the most appropriate informants of their learning environment (c.f., Lýdtke, Robitzsch, Trautwein, & Kunter, 2009). Teachers with relative more Control and Affiliation provide, in terms of students motivation and learning outcomes, more effective classrooms (Brekelmans, Sleegers, & Fraser, 2000). The student Questionnaire on Teacher Interaction (QTI, Wubbels et al., 2006) was used to tap students' perceptions teacher Control and Affiliation (respectively: $\alpha = .80$ and $.93$; ICC1 = $.44$ and $.52$, ICC2 = $.93$ and $.95$).

Actions to gain control that students perceive as coercive negatively affect the social climate and student learning (Lewis (2001). Coercive discipline includes sarcasm, yelling in anger, embarrassing students, and punishment. On the other hand, using appropriate humour, providing clear and structured instruction, or undertaking activities students think are fun are factors that support a positive classroom social climate. A Teacher Behaviour Observation Checklist (TBOC) was developed, to collect student observations of teacher behaviour incidents (coercive: $\alpha = .81$, ICC1 = $.58$, ICC2 = $.92$; supportive: $\alpha = .71$, ICC1 = $.53$, ICC2 = $.91$).

Hypotheses

In classrooms with more incidents of coercive teacher behaviour students perceive less Affiliation; teachers might gain Control because students comply with the teacher's display of power (Hypothesis 1).

Incidents of supportive behaviour positively correlate with students' perceptions of a teacher's Affiliation, but are also beneficial to the teacher's Control (Hypothesis 2).

Method

Participants and Procedure

48 Dutch secondary school teachers (26 females) and one of their classroom groups (1208 students, age $M = 14.09$, $SD = 1.47$). Teachers were asked to administered questionnaires on 9.31 ($SD = 2.35$) occasions during 4 month (i.e., 447 individual classroom lessons in total). Half of the students completed the QTI and the other students the TBOC. Thus, each time, a student focused on either teacher behaviour incidents or teacher Control and Affiliation to yield some independency in the applied measures.

Results

Multilevel process analysis was employed (van Doorn et al., 2008), which relates two or more simultaneously assessed concepts across time. This analysis is similar to multilevel modelling employing time varying covariates but without including a designated time variable as a predictor. Results are summarized in Table 1.

Discussion

Hypothesis 1

Frequently using coercive behaviour was associated with significantly lower teacher Affiliation. It immediately disrupted the social climate, and was associated with less Affiliation a week later. The use of coercive behaviour was associated with somewhat more Control in class, but acting coercively in two lessons in consecutive weeks occurred to counterbalance these associations.

Hypothesis 2

Frequent supportive behaviour was associated with more teacher Affiliation during the current lesson as was supportive behaviour one week earlier, but to a lesser extent. More frequent supportive behaviour however was hardly associated with teacher Control.

There were no differences found between classrooms in the associations between teacher behaviour and the social climate (i.e., random slopes). This suggests that the processes described here are comparable across classrooms.

Practical implications

Coercive teacher behaviour is very unlikely to go together with greater Control in the classroom. Teachers who engage in coercive behaviour may deliberately sacrifice Affiliation because they believe they will re-establish or consolidate their Control in the classroom. The present study shows that this assumption is not justified. Teachers should use small rather than intense corrections, behave as unaggressive as possible (Evertson & Weinstein, 2006), and should apply increased intensity of disciplinary actions only for intensified disruptive student behaviour (Cr   ton et al., 1989).

Regarding supportive behaviour, although the effects we found were not substantial, we have shown that supportive behaviour pays off immediately and is an investment for the near future as well.

PAPER PRESENTATION

Dialogic interaction among primary pupils in a wiki-environment in science

Judith Kleine Staarman, University of Exeter, United Kingdom; Manoli Pifarre Turmo, University of Lleida, Spain

This paper describes the analysis of the collaborative process of a primary pupils' writing task with the aid of a Wiki environment. Students worked and contributed to the wiki in pairs. The aim of the project was to explore how a wiki may be used to support primary school pupils' collaborative interaction and to shed light on the complex process of collaboration and interaction, both in and around the Wiki environment.

Our study illustrates some of the challenges and the difficulties that students had to face in order to write a text collaboratively with a Wiki. We argue that students need to develop an intersubjective orientation towards others participants' perspectives, to be able to co-construct knowledge about a topic. For this purpose, the project utilised a "Thinking Together" – type approach to help students to develop an intersubjective orientation towards one another and to support the creation of a 'dialogic space' to co-construct new understanding.

We present our focus for the analysis of face-to-face students' interaction in order to contribute in the Wiki environment, which is based on a dialogic approach to collaboration. Our results illustrate how the thinking together approach became embedded in the Wiki environment and how in the context of a science project, it enabled the collaborative writing of a joint informative text about the science topic under investigation.

Our aim for this paper was to find out how, in a Wiki environment, students develop and maintain shared understanding of a science topic, and how students are taking each other's perspective into account. We also aimed to examine how the wiki environment itself may or may not support students in this process. To this end, we designed, implemented and evaluated a science project in which primary students used a Wiki environment, with the specific aim of establishing and supporting collaborative interaction, while engaging in a collaborative writing task. Students worked in pairs and also made their wiki contributions as pairs.

Our theoretical background is grounded in socio-cultural theory, which states that social interaction lies at the heart of all learning processes. From our perspective, participation in a collaborative activity requires that participants establish and maintain what Rogoff (1990) and Wertsch (1991) have termed intersubjectivity.

To enable and support collaborative learning, there are a number of particular relevant characteristics of wikis. First, wiki software enables the collaborative editing of texts and these texts are then available to the whole community of users. This means that the joint collaborative process and product is visible to all participants. Secondly, the wiki software allows two separate but related collaborative processes to happen simultaneously. The actual wiki content is written collaboratively on one page, while a tab leads to another page, in which participants may negotiate the actual content of the wiki. Thirdly, the collaborative writing process in a wiki environment is asynchronous, mediated and indirect, which gives participants the opportunity to reflect on what they read and write to respond/reply to their partners. And fourthly, all revisions to the wiki page are kept in the wiki history, enabling users to trace the development of the wiki and reflect on the changes in the collaborative work.

Although these features are characteristics of wiki design that may enhance the collaborative processes, it remains unclear which pedagogical approach could contribute most to successful collaborative learning processes using wikis and what difficulties and needs primary students would require in order to participate in the Web 2.0 global knowledge era.

The study took place in Lleida, Spain, in an urban primary school. Twenty-five 9-10 year old pupils participated in the study. Students worked together in pairs in the wiki environment to create a joint informative text about a science topic, together with 2 other pairs. We analyzed in depth the data collected during the seven wiki sessions. We video-taped, transcribed and analyzed face-to-face pairs' interaction while working in the wiki environment.

In this paper, we aim to answer the following research questions:

1. What type of peer's interaction occurs when they are working in a wiki environment? What features of dialogue are they using?
2. How does the face-to-face interaction of pupils support the interaction in the wiki-environment and the creation of a joint collaborative text.

3. What is the relationship between the pairs' collaborative communication and thinking as evidenced in their talk and their contributions in the wiki environment?

Our analysis approach has strong links with a methodological framework called Sociocultural Discourse Analysis (Mercer, 2005). The first stage of the analysis involved characterizing the type of interaction of students in and around the Wiki. The second stage of the analysis process consisted of searching for the presence of key words that may indicate reasoning and collaboration. For this reason, we used a computer-based concordance analysis programme (Wordsmith Tools).

For our analysis approach, we adopted a dialogic approach to studying the interaction of the students, and aimed to characterise the interaction process in terms of the students' intersubjective orientation. We based our analysis on the characterisation of talk in terms of Disputational, Cumulative and Exploratory, as proposed by Mercer and colleagues (Mercer, Littleton and Wegerif, 2004). We argue that a dialogic approach such as this is needed to analyse interaction in a complex environment such as the one utilised in the current study, to be able to take into account the collaborative dimension of computer-supported collaborative learning.

Our data showed many episodes in which students presented a Disputational or more Cumulative orientation. The presence of these kinds of students' orientations could partially be explained in relation to the purposes of the task, it also indicates that the technology itself does not guarantee effective collaborative processes. It is therefore necessary to design an instructional approach that prepares students to use the wiki effectively and to develop students' awareness about thinking and working together in web 2.0 technologies. This result is in line with many voices that highlight students need a shift to a more participatory and collaborative culture of literacy practices (Wei-Ying, Hyo-Jeong & Seng-Chee, 2010). This shift needs also deep changes in the pedagogical practices that design the conditions to develop students' competences that eLearning 2.0 technologies require.

In contrast, our study also found episodes in which students presented a more Exploratory orientation. In the paper we will discuss what characteristics of the pedagogic design of the wiki environment used in our study might support students' joint interaction processes. Briefly, we stand out the next four. Firstly, the students' preparation to collaborate in a wiki environment using the "Thinking Together" approach was fruitful. Students used explicitly many of the features of the program in their collaborative talk. Secondly, every pair presented their own ideas in an initial text in the wiki environment, which was helpful in giving a 'voice' to all members of the group from the beginning of the collaborative work as it enabled all the pairs to be orientated to each other's ideas from the start. Thirdly, the students were all the time working with an artefact that was created as the product of their active participation. This may have encouraged users to examine others' opinions more closely, take them into consideration and increase their knowledge more deeply. Fourthly, the asynchronous nature of the collaborative processes in the wiki seems to have supported co-reflective processes about others' ideas, thoughts, arguments and information, which, in turn, lead to reconstruction and reorganization of experience.

PAPER PRESENTATION

Doing instructions. Exploring instructions in multilingual classroom interaction

Oliver St John, Orebro university, Sweden, Sweden, Sangeeta Bagga-Gupta, University of Orebro, Sweden

Doing instructions. Exploring instructions in multilingual classroom interaction

The aim of this study is to explore what might distinguish instructions from other kinds of classroom interaction in different classroom settings. Data is taken from video recordings of entire lessons in English, Home Economics, French and Maths as part of ethnographic fieldwork at an international secondary school in Sweden. CA analytic procedures have been adopted and developed. A complementary source of data is ethnographic field notes.

Preliminary findings suggest that instructions exhibit distinct features which participants orient to as instructions while relating them structurally to lessons as a whole. In doing instructions, teachers routinely mark their beginnings with 'openings' (e.g. calling the class to attention), sequence a variety of components (e.g. invoking past lesson activity) and conduct recurrent ways of bringing them to a close (e.g. giving a summary). Data makes evident certain kinds of boundary markers framing instructions as well as reinforced discourse, measured pace and the prominence of kinetic and gestural synchronized signals during such activity. A comparison of doing instructions across subjects suggests that the learning of any subject is, to a significant degree, language learning.

The pedagogic significance of such studies is to encourage investment in instructions as not simply communication for cueing other learning tasks, but as platforms for supporting task-related language learning, student engagement, the

negotiation of common purpose, cohesion between different (parts of) lessons, the creation of meaningful entry points, etc. In short, an environment for co-constructing meaning and understanding for tasks.

Doing instructions. Exploring instructions in multilingual classroom interaction

The 's' on the end of 'instruction' indicates the distinction made in teaching methodology arenas between explaining subject content (instruction) and explaining what to do (giving instructions) (e.g. Kerry and Wilding, 2004). 'Instruction' has often been equated with learning (Säljö, 2005:13) while 'giving instructions' has been viewed as prior or incidental to learning per se, as an activity whose value is attached to the greater cause it serves. While the view that the main purpose of instructions is to prepare the way for forthcoming learning activity has some validity, it masks the complexity of the relationship between giving instructions and other teaching routines and activities that structure classroom lessons (see Richards & Lockhart, 1996). Views of learning as integral to social practice (Lave & Wenger, 1991), as participation and acquisition (Sfard, 1998) and as interaction (Firth & Wagner, 1997; 2007) challenge an assumed distinction between a non-learning preliminary and learning proper as untenable.

The aim of this study is to explore what might distinguish instructions from other kinds of classroom interaction, such as transitions or teacher-presented instruction, in different classroom settings. Aspects which observations in this study have suggested may be relevant to the distinctive identity of 'giving instructions' include discursive composition, boundary markers, techniques used by participants to make meanings clear and constraints on or opportunities for interaction.

This study is part of a larger analysis of lesson phases using video documentation of eighth-grade lessons recorded during ethnographic fieldwork at an international secondary school in Sweden. Video data for the study has been selected from sixteen English, Home Economics, French and Maths lessons. In pursuit of an emic perspective, CA analytic procedures have been adopted and developed by amplifying CA transcript conventions in order to widen the aperture on some of the finely-tuned visually-mediated communicative moves configuring classroom interaction. This multi-track transcription system aims to make available for analysis not only speech, but the printed, written language, bodily conduct and positions in relation to artefacts and other environmental resources in the classroom (see Bagga-Gupta & St John, 2010, in preparation). As a complement to this fine-grained micro view, ethnographic field notes serve as a bridge to possible broader significations in the analysis.

Preliminary findings suggest that instructions exhibit distinct features which participants orient to as instructions while relating them structurally to lessons as a whole. In doing instructions, teachers routinely mark their beginnings with 'openings' when they call the class to attention, announce an imminent task or preview what the 'instructions' are intended to explain or achieve. After beginning, teachers sequence a variety of components including invoking past lesson activity, use of artefacts such as books and whiteboards, categorizing or labelling tasks, directives in steps or stages, prospectively projected sample utterances to illustrate specific activity, examples of task-related choices the students are to make and task assessment criteria. The data also indicates that teachers conduct recurrent ways of bringing instructions to a close, such as giving a summary, managing role distribution or delivering a directive to begin the task.

Data makes evident teacher use of oral expressions (e.g. ok) body movements (e.g. claps) and orientations to classroom artefacts (e.g. books) as boundary markers between instructions and other activities. Talk tends to be well reinforced by paraphrases, double-layered in some cases, while the pace tends to be more measured and the use of synchronized kinetic and gestural signals is a prominent part of the concerted communicative action.

Indeed it is evident that the internal structure of instructions bears many of the features related to the organization of a whole lesson. A picture of task instructions as a miniature model of a lesson suggests that learning has just as much chance to thrive during the doing of instructions as it might in any other component part of a lesson. Cross-subject comparisons of doing instructions showcase that the way language is used in classrooms provides a basis for relating lessons along language continua rather than separating some as 'language' lessons and others in terms of non-language learning lessons. Since the different subjects and disciplines of school are constituted by and generate their own vocabularies and conceptual lexical labels, the learning of any subject is, to a significant degree, language learning.

The pedagogic significance of such studies is to encourage investment in doing instructions as not simply communication for cueing other learning tasks, but as a platform for supporting task-related language learning, student engagement, the negotiation of common purpose, cohesion between different (parts of) lessons, the creation of meaningful entry points, etc. In short, an environment for co-constructing meaning and understanding for tasks. Such an investment will make better sense if giving instructions is viewed not as a set of directions or step-by-step

guide, for example, on how to assemble a piece of furniture or operate an appliance, but as one of the steps integral to and inseparable from the process of realizing all the steps.

PAPER PRESENTATION

Instructional Explanations When Introducing the Pythagorean Theorem: A Case Study

Daniela Jimenez, German Institute for International Educational Research, Germany; Eckhard Klieme, Deutsches Institut für Intern. Pädagogische Forschung, Germany

Instructional Explanations in mathematics lessons remain a common practise and a typical discourse form though mathematics education has gone through dramatic changes in the last decades. The role of explanations seems to be particularly important when students are learning a new content, because explanations are a mean of conveying mathematical knowledge (Perry, 2000).

The aim of the present study is to characterize effective instructional explanations in videotaped mathematics lessons when introducing the Pythagorean Theorem. The case study was carried out in the context of a broader study including tests of mathematical understanding taken to the students immediately before and after the videotaped lesson unit. The 3 classes examined here were selected according to their learning outcomes under control of their previous knowledge. The results suggest that effective instructional explanations are based on concrete graphic support, showing flexibility in rewording and linking with previous knowledge. Besides, they include concrete applications of the Theorem and examples of its usefulness in everyday life. Even though these findings don't allow generalization, they could suggest that effective instructional explanations contribute to instructional quality.

Background and Aim of the Study One of the most important shifts in mathematics learning and instruction in the last decades has taken place in the conception of the subject matter, changing from a perspective of mathematics as composed of concepts and skills to be learned, to a new one emphasising the mathematical modelling of the reality (De Corte, 2004). This shift has had natural implications on classroom processes, and changed instructional settings and practises. In that landscape instructional explanations are an interesting topic, since they remain being a typical form of classroom discourse, especially when new contents are introduced to the students (Perry, 2000). Instructional explanations can be defined as pedagogical actions in response to implicit or explicit questions provided by teachers or students (Leinhardt, 2001). Their main purpose is the understanding of a portion of subject matter and can be accomplished in different ways, including diverse degrees and sorts of interaction between teacher and one or more students (Kiel, 1999). This means that instructional explanations can appear in several contexts and also take different shapes according with the instructional setting in which they occur.

On one hand instructional explanations have been conceived as a critical issue in understanding mathematical concepts since they are an important communication form of mathematical knowledge (e.g., Perry, 2000). Additionally, it has been argued, that since explanations are a form of oral communication, they offer the teacher the possibility to monitor the students' understanding and provide, if necessary, additional information or discuss possible misunderstandings immediately (Duffy et al., 1986). In contrast to that, Wittwer & Renkl (2008) indicate that explanations are often unnecessary, since they don't really promote understanding. A possible underlying reason is that while explanations occur, the learner assumes a passive role only listening to the teacher, instead of engaging actively in his own learning process. To sum up, there is agreement about considering instructional explanations as a frequent issue within lessons, but there are contradictory positions about whether and how they contribute to promote understanding. We would like to argue that whether instructional explanations promote understanding or

not depends rather on elements of the way how explanations take place than to their frequency or duration. Consequently, the only possibility to assess whether instructional explanations are effective or not is regarding carefully the context in which they occur.

The present paper aims to shed light in aspects related to success and failure of instructional explanations in mathematics lessons when introducing the Pythagorean Theorem. More specifically following research questions will be examined, namely, what characterizes instructional explanations in lessons in which a high promotion of mathematical understanding takes places compared to lessons in which a low promotion of mathematical understanding occurs? Method The data source is the Chilean implementation of the core-design of the study "Quality of instruction, learning and mathematical understanding" designed and carried out originally in Switzerland and Germany (2000-2006) by the German Institute for International Educational Research and the University of Zurich. The complete Chilean sample consists of 21 mathematics teachers of 7th grade classes and their respective 784 students, which participated in the investigation along one school year. In every class 3 consecutive lessons about the introduction of the Pythagorean Theorem were videotaped. Tests of mathematical understanding were taken immediately before and after the videotaped lesson unit. 3 of those teachers were chosen in order to carry out the present case study, according with the results of the post-test (under control of the pre-test). The analyses for the case study were based on the theoretical phases of the videotaped lessons and their respective transcripts. They included following dimensions of the instructional explanations, (1) use of graphic support, (2) explanations are repeated/modified, (3) Pupils' participation and contribution to explanations, (4) check for understanding, (5) link with previous knowledge, (6) abstraction and usefulness of the Pythagorean Theorem. Results The findings show differences in most of the dimension analyzed. Effective explanations about the Pythagorean Theorem were supported by hands-on activities, not only performed by the pupils, but also by the teacher or shared with the whole class. Besides, explanations' repetitions include often new information and there's some evidence of flexibility by rewording and going in depth. The teacher continuously checks for understanding while explaining and links the new contents with previous knowledge, not only mentioning it when a step is missing, but also using it as context to embed the new contents. Finally, effective explanations about the Pythagorean Theorem include concrete applications and examples of its usefulness in everyday life. In contrast to that, less effective explanations include graphic support, but just as context and not as a concrete tool. Repetitions occur frequently, tend to be rigid and don't incorporate new information. The teacher checks for understanding only few times along the lesson and often implicitly. New contents were linked with previous knowledge strictly when needed, for example to solve an exercise, but not really clarifying which is the link and why it is necessary. Only few or none concrete applications of the Pythagorean Theorem were presented and its usefulness was limited to mathematical contexts. It's interesting to note, that there were no differences regarding the participation opportunities given to the pupils, mainly answering dichotomous questions or only with one word.

Discussion

It is possible to characterize effective instructional explanations and distinguish them from less effective ones, regarding to what extent they promote mathematical understanding. In other words, even if we don't aim to assume that the improvement in learning outcomes is only attributable to the explanations examined here, these findings could suggest that effective instructional explanations contribute to instructional quality. These finding were obtained in a case study and don't allow generalization, besides they refer to an introductory unit in one curricular content, facts that allow a thorough examination. However, it would be interesting to investigate to what extent such characteristics can be applied to other teaching contents or whether it is possible to define features that allow their valid and reliable measure in bigger samples..

PAPER PRESENTATION

Experienced and non-experienced e-tutors in Europe: Differences in supporting online collaboration
Birgitta Kopp, Ludwig-Maximilians-University, Germany; Maria Cristina Matteucci, University of Bologna, Italy;
Carlo Tomasetto, University of Bologna, Italy

In this study, we investigated differences between experienced and non-experienced European e-tutors in their support of online collaboration in practice. Therefore, we developed a questionnaire European e-tutors had to fill in to evaluate specific collaborative activities and to answer yes/no-questions regarding their intervention to support these collaborative activities. In respect of these collaborative activities, we distinguished between cognitive and social activities which are relevant for effective online collaboration.

Overall, we received answers of 78 e-learning experiences from 17 different European countries. Cluster analysis was conducted to determine groups of e-tutors who answered similar regarding the response type across the various categories of support activities. To validate the cluster solution, we compared the resulting two clusters on the basis

of the experience of e-tutors. The results indicate that e-tutors with experience evaluate relevant cognitive activities more important for collaboration than e-tutors without experience. Furthermore, e-tutors with experience intervene more often to foster cognitive and social activities. These findings show the importance of expertise in e-tutoring: It seems that e-tutors with experience consider the importance of specific cognitive activities for effective online collaboration and that they also are more familiar in detecting dysfunctional social phenomena and in adequately intervening to avoid such phenomena. Therefore, for daily practice it seems to be necessary to train e-tutors in sensitizing them to the problems and pitfalls of online collaboration.

Objectives

This study investigates how experienced and non-experienced e-tutors differ in supporting collaborative online learning in practice. E-tutors received a questionnaire evaluating specific online activities and answering yes/no-questions whether they practically gave online support for these specific activities in their e-learning experiences.

Theoretical framework

E-tutors are very important for the support of their learners, because virtual collaboration is often more demanding for learners as they mostly have no experience with this way of learning. E-tutors are defined according to their main function, which is to supervise and support learners.

When we look at the support of e-tutors, the question is which collaborative activities they specifically foster. There are especially cognitive and social activities important for collaboration. Cognitive activities are knowledge exchange, online discussion, argumentation, collaborative problem solving, and considering different perspectives. Regarding social activities, the focus is on the motivation of the group members, interpersonal interaction, social influence processes and information processing.

Regarding the daily practice of e-tutors, the question arises how e-tutors support collaborative online learning. As research on the topic of expertise shows that experts differ from individuals without expertise in their way how they deal with problems, the question remains whether such differences in problem-handling are true for e-tutorial support in collaborative online learning.

Research question

Do experienced and non-experienced e-tutors differ in supporting online collaboration? As experienced e-tutors already know how collaboration in virtual learning environments functions, the assumption is that experienced e-tutors differ in their support from non-experienced e-tutors in that way that experienced e-tutors support collaborative online learning to a greater extent than non-experienced e-tutors.

Method

Sample

The sample included seventy-eight e-learning experiences from 17 different European countries. All e-tutors completed an online questionnaire regarding their e-learning experiences with collaborative learning. Participants were instructed to complete one questionnaire for each e-learning course.

Design of the Study

The study was a survey for e-tutors regarding their experiences in providing and supporting virtual collaboration which took place in July 2007. All e-tutors received access to an online questionnaire in their language and were asked to answer this questionnaire for every e-learning experience they offered.

Data sources

The online questionnaire which was developed for this purpose included two main dimensions: cognitive activities and social activities. Regarding the cognitive aspects of collaboration, the questionnaire included five main activities: knowledge exchange, online discussion, argumentation, collaborative problem solving, and considering different perspectives. To gain deeper insights into these activities, the questionnaire asked e-tutors whether they intervened to foster the specific collaborative activity and if yes, how they intervened and if no, why they did not intervene.

Based on theoretical assumptions, social activities were evaluated mainly according to four processes: motivation of the group members, interpersonal interaction, social influencing factors and information processing. Regarding motivational aspects, two dimensions were considered, namely different group goals (2 items) and dysfunctional competition. Interpersonal interaction included phenomena such as dysfunctional interpersonal conflicts, balanced participation, and diffusion/lack of responsibility. Social influencing factors are ignoring minorities and putting pressure on group members. Information processing included the following: superficial discussion to avoid conflicts and addressing the e-tutor rather than group members (2 items). In the questionnaire again, e-tutors were first asked

whether they intervened to avoid a dysfunctional phenomenon. If they answered yes, they were asked how they intervened, and if no, why they did not intervene.

Data analyses

We used the TwoStep cluster methodology to explore the data. The algorithm selected the optimal number of clusters based on either the Schwarz Bayesian Information Criterion (BIC) or the Akaike Information Criterion (AIC). Once clusters were established, we used separate t-tests and chi-square tests on variable(s) not used to form the clusters to test the validity of the cluster solution. We compared the clusters based on their response type across the various categories of support activities in terms of past experience of e-tutors, feedback practices and intervention rate.

Results

The cluster analysis identified two clusters whose stability was ascertained until 75 % of the sample size. Using a theoretically meaningful distinction, we report the data on the cognitive and on the social activities. Cluster 1 (n= 51; 65.4%) comprised e-tutors who evaluated cognitive activities more important (mean between 4.90 and 5.47) than e-tutors included in cluster 2 (n =24; 30.8%) (mean between 4.08 and 4.83). Furthermore, e-tutors of cluster 1 intervened between 40 and 48 times to foster cognitive activities in online collaboration while e-tutors of cluster 2 intervened only 8 to 14 times. Regarding social activities, according to Chi-Square-Tests again e-tutors of cluster 1 intervened in 9 of 11 times significantly more often than e-tutors of cluster 2.

Validity of the two cluster solutions was evaluated by testing group differences on variables that were theoretically or empirically related to each cluster. In particular we used as cluster validation items concerning the past experience of e-tutors in designing and realizing online courses. We expected e-tutors with experience to be over-represented in cluster 1, which was confirmed by a chi-square analysis. The great majority of e-tutors with past experience in designing and realizing e-learning courses belonged to cluster 1, $\chi^2(1, n = 75) = 11.75, p$

Discussion

Cluster analysis has shown that our sample of e-tutors significantly differ in evaluating the importance ascribed and in intervention rate concerning specific cognitive activities which are relevant for online collaboration. Subsequent analyses confirm that e-tutors who intervened more frequently in respect of fostering cognitive and social activities in virtual collaboration are those with past experience. Even though, overall the intervention rate for social activities is much lower than for cognitive activities (overall less than 50 per cent), e-tutors with experience are more able to detect dysfunctional phenomena and thus support their learners in working effectively together.

Educational significance

This study shows that experience in supporting e-learning groups is an essential precondition for evaluating relevant collaborative activities higher and in adequately intervening for fostering the interaction between group members. As this study asked e-tutors concerning their daily practice, it seems essential to train e-tutors in considering and detecting specific dysfunctional phenomena which may otherwise inhibit effective group work.

PAPER PRESENTATION

Scaffolding self-regulated learning: implications for the design of CBLEs

Anneline Devolder, Ghent University, Belgium; Johan van Braak, Ghent University, Belgium; Jo Tondeur, Ugent, Belgium

Research has shown that in order to learn effectively in computer-based learning environments (CBLEs), students need to show sufficient self-regulated learning skills (SRL). Unfortunately, not many students possess these necessary skills, so support needs to be provided towards the students when learning in these environments. A specific type of support we focus upon in this study are scaffolds. Scaffolds are technology-mediated systems that support the learners when performing a task (Sharma & Hannafin, 2007). In the field of scaffolding, little conceptual clarity exists. Moreover, it was shown that some specific scaffolds are only effective for some specific processes of SRL (Schraw, 2007). The aim of this study was to create an overview that makes it possible to compare the effectiveness of the different scaffolding types in support of the different processes of SRL. Therefore, we extended a review study in search of which specific scaffolds are proven to be effective in supporting SRL processes when gaining scientific knowledge. In order to support educational practice in the decisional process of choosing the right scaffolds, the results of this study are presented in an integrated framework of SRL.

FrameworkComputer-based learning environments (CBLEs) are becoming ubiquitous and more extensively used in education [1]. CBLEs comprise systemic features (e.g. open-ended in structure, non-linear) that offer new possibilities for learning and instruction like direct visualization and manipulation of complex topics [6]. In order to learn effectively with CBLEs, learners will need to show skilful engagement which can be captured as self-regulated learning

(SRL) [15]. Students are self-regulated to the degree that they are metacognitively, motivationally, and behaviourally active participants in their own learning process [16]. Unfortunately, many students do not possess the necessary SRL-skills [3]. Therefore, students need to be supported when learning with CBLEs. Research has shown that scaffolds can give the necessary support to students lacking SRL-skills [1]. Recently, scaffolding is being described as "...the provision of technology-mediated support to learners as they engage in a specific learning task" [12, p.29]. Studies have shown that different types of scaffolds provide effective support for different processes of SRL [4]. This means that when CBLEs are being developed, the types of scaffolds will need to be selected with care. Purpose & Method In order to support educational practice in this decision making process, the aim of our study is to synthesize and schematize research results on the effects of scaffolding on the processes of SRL when learning in CBLEs. To fulfil this purpose, a systematic literature review was conducted [8]. Some general criteria were set to mark out our search (e.g. studies published since 2000). Second, inclusion and exclusion criteria were defined. According to these criteria, the database Web of Science was searched through using terms like scaffold*AND self-regulated learning/self-regulat*. This search resulted in 24 articles. To present these results clearly, they were placed in an integrated framework of SRL [5] that is designed based on some central models of SRL as well as more current research relating the specific context of CBLEs towards these central models [e.g. 9,2,14].

Results

The results of this are presented in Table 1. Table 1. An integrated framework for effective scaffolds in support of processes of self-regulated learning (p: primary education; s: secondary education, h: higher education) Cognition Motivation Behaviour Phase 1: Task definition & Planning Guiding questions (h) Concept-mapping task (s,h) Preset goal hierarchy & goal Description (s) 'Plan ahead' prompts (s) Searching features (p) High-order questions (h) Phase 2: Monitoring Diagrams (h) Hints & cognitive feedback (p) Self explanation prompts, reason-justification prompts, cues (s) Written question prompts (s) Guiding questions (h) Phase 3: Control Metacognitive feedback & Strategy prompt (h) Concept-map template (p) Spoken advice (prompts) (s,h) Generating prompts (s) Processing prompts (s) Worked-out examples (s) Organization feature (s) (headings and written) Question prompts (s) Organization feature (s), Collaboration features (p), Maintenance features (p) Self-explanation prompt & Worked-out example (u) Spoken advice (h) Worked-out examples (s) Saving/viewing features (p) Concept-map (h) Strategic prompts & Graphic advance organizers (h) Phase 4: Reaction & reflection 'Look back' prompts (h) From the 24 retrieved studies, 16 of them proved that the use of certain scaffolds were effective when gaining scientific knowledge. Most of the studies examined scaffolds that support processes of cognitive regulation.

Results indicate that especially prompts are effective scaffolds for this area. Little effective scaffolds were found in the area of motivation and behaviour. The area of context in this framework was deleted, because no effective scaffolds were found. Another remarkable finding is that a small amount of these studies focuses on primary education, although this is a category of students possessing the least SRL-skills. As it can be seen in the framework and is confirmed by the literature, some scaffolds provide effective support for multiple processes of self-regulated learning [10]. Conclusion On the basis of the discussed theoretical framework and method, we were able to list up the effective scaffolds influencing self-regulatory skills of students when learning in CBLEs. In the presentation, we will focus on the meaning of these scaffolds towards the design of future CBLEs while bringing personal characteristics (e.g. prior knowledge) and contextual characteristics (e.g. task, peers) into account.

PAPER PRESENTATION

Understanding the online information seeking practices of young people

Rebecca Eynon, University of Oxford , United Kingdom

As the Internet and other new technologies become embedded within the lives of young people there is a growing interest in the extent to which new technologies can enhance informal and formal learning. Effective online information seeking forms a key part of many of these potential learning opportunities. Using nationally representative survey data of 1000 young people, this paper aims to add to existing research by providing empirical data on how and why young people in Britain use the Internet for information seeking outside formal educational settings for homework and everyday life. Using path analysis, this paper will provide an overview of the ways young people are using the Internet for information seeking and examine the individual (e.g. age and gender), skill and contextual factors (e.g. parent, school and friends use of technology) that help to explain this behaviour. It is hoped that these findings may assist in the development of policies and practice to support young people to make the most effective use of the Internet for information seeking as part of their learning in a global networked society.

As the Internet and other new technologies become increasingly embedded within the lives of young people there is a growing interest in the extent to which new technologies can enhance informal and formal learning opportunities (e.g. Becta, 2008). Effective online information seeking forms a key part of many of these potential opportunities both to support formal education (e.g. for homework) and to support informal learning through everyday life information seeking (ELIS) (Savolainen, 1995).

While relatively little is known about how and why young people access information online in their daily lives for these purposes, it is likely that there is significant diversity in what, how and why young people search for information online.

This paper aims to add to existing research by providing empirical data on how and why young people in Britain use the Internet for information seeking outside formal educational settings for homework and ELIS. The data is based on a nationally representative face to face survey of 1000 young people in Britain aged 8, 12, 14 and 17-19. The survey was conducted between December 2008 and January 2009 utilising a stratified sampling strategy. The survey formed part of the Learner and their Context study, commissioned by Becta, which explored young people's views and experiences of new technologies outside school and was designed to inform the UK's Harnessing Technology Strategy. Using path analysis, this paper will provide an overview of the ways young people are using the Internet for information seeking and examine the factors that help to explain this behaviour. Drawing upon the learning ecology approach (Barron, 2006) and in line with a range of theoretical frameworks that stress the importance of understanding both individual and environmental factors when exploring Internet use (e.g. LaRose et al., 2001; McHale et al., 2009) this paper will examine the importance of: 1) individual factors, specifically, age and gender (Livingstone and Helper, 2007), socio economic factors and quality of access (Facer, Furlong, Furlong, and Sutherland, 2003); 2) networks of support, specifically, peer use of technology (Ito et al., 2008), parental engagement / regulation (Livingstone and Bober, 2005) and the school environment; and 3) skills and confidence, that is, self concept in

learning new things and confidence in online information seeking skills (Broos and Roe, 2006). Each of these three areas are hypothesised to contribute (both directly and indirectly) to online information seeking. The overarching research question for this study is: what are the direct and indirect effects of individual and contextual factors on online information seeking for homework and everyday life?

The initial analysis demonstrates that parent's involvement in their child's uses of technology and school uses of the Internet have no direct effect on online information seeking either for homework or everyday life. However, they do have a direct effect on learner self-concept and / or online information seeking ability which are of key importance in understanding both kinds of online information seeking analysed here. Furthermore, individual characteristics which reflect basic factors of digital inclusion (such as home access to the Internet and / or socio economic status) continue to play an important role in understanding online information seeking for homework and / or everyday life. The findings indicate that there is a need for researchers to explore both offline factors (e.g. SES and learner self concept) as well as online factors in understanding Internet use; and highlights the opportunities open to educators to support young people more in using the Internet for information seeking. It is hoped that these findings may assist in the development of policies and practice to support young people to make the most effective use of the Internet for information seeking as part of their learning in a global networked society.

PAPER PRESENTATION

Effects of constructivist teacher-led digital platform on learning achievement

Rosen Vigal, University of Haifa / Time To Know, Israel

This study explores the effects of a constructivist teacher-led one-to-one computing learning environment on elementary schools students' achievement in Mathematics and English Language Arts (ELA). The subjects were 59 4th grade students, who joined a Time To Know year-long program in Dallas, Texas and 68 4th grade students who learned in traditional settings. Findings indicated that learning with Time To Know program significantly enhanced students Mathematics and ELA achievements and contributed to development of Mathematics reasoning skills. In addition, the study showed that Time To Know program narrowed the gap between the low and high achievement students, as well as significantly promoted the academic outcomes of at-risk students, compared to the traditional settings. Overall, the findings indicated that intertwining digital content that is aligned with state standards and a constructivist-oriented teacher-led platform, enables a significant empowerment of teaching and learning processes.

Over past decade, there has been a growing interest in one-to-one laptop technology initiatives, whereby the teachers and the students have full access to a technology-rich learning environment (Bebbel, 2007; Gulek, & Demirtas, 2005; Jaillet, 2004; Lei & Zhao, 2008; O'Dwyer et al., 2008; Shapley et al., 2009; Silvernail & Gritter, 2005; Weston & Bain, 2010; Zucker & Light, 2009). The current study explores the effects of teaching and learning in the Time To Know program on Mathematics and ELA achievement of 4th grade students, compared to learning in more traditional setting.

Time To Know's teaching and learning environment is designed with a social-constructivist teacher-led approach to learning and teaching (Fosnot, 2005; Prawat & Folden, 1994; Roschelle, Pea, Hoadley, Gordin & Means, 2000; Von Glasersfeld, 1995). The program consists of five main components (Walters, Dede & Richard, 2009; Weiss & Bordelon, 2010): (a) Infrastructure: one-to-one laptop environment with a workstation for the teacher; (b) Interactive year-long core curriculum: Recommended sequences of interactive learning activities that are aligned with state standards. Teachers can modify these sequences by uploading their own "best practice" materials directly into the lesson flow; (c) Digital Teaching Platform (DTP): A platform that enables the teacher to conduct or plan a lesson, and to receive formative and summative assessment reports for data-driven instruction; (d) The platform also enables teachers to create their own content and adjust the recommended ready-made interactive learning activities to their teaching needs.; (e) Pedagogical support: Every teacher who joins the program takes part in comprehensive professional learning and ongoing guidance from an instructional coach.

The study addressed the following questions regarding the effects of the Time To Know program:

1. What is the impact of Time To Know program on reading, writing and Mathematics academic achievements, as measured by Texas Assessment of Knowledge Skills (TAKS) tests, compared to the traditional settings?
2. What is the impact of Time To Know program on academic achievements of at-risk students, compared to the traditional settings?
3. Do Time To Know students demonstrate greater Mathematics reasoning skills than control students?
4. Do lower performing Time To Know and control students (based on previous year TAKS scores) differ from higher performing students on Mathematics reasoning skills?

The study was based on the quantitative methodology using a quasi-experimental design (participation or non-participation in the Time To Know program). Pretest data were collected before the onset (April, 2009) of a Time To Know program, while post-test data were collected near the completion of the year-long school program (April, 2010). The study participants were 4th grade male and female students from four elementary schools from the Dallas-area district. Gender distribution was close to even. Two experimental schools were selected on the basis of two criteria: their participation in the Time To Know program and the same demographic background. Two control schools were purposively sampled to "match" the two Time To Know schools on the basis of known demographics (e.g., neighborhood characteristics, teacher characteristics, student characteristics). In all, there were 127 students who participated in the pre- and post-test data collection (59 experimental and 68 control students).

The instruments comprised on Mathematics, Reading and Writing and an adopted Mathematics reasoning test (HersHKovitz, in preparation). Mathematical reasoning refers to the ability to analyze mathematical situations and construct logical arguments (Francisco, & Maher, 2005; Stiff, & Curcio, 1999; Yackel, & Hanna, 2003). The Mathematics reasoning test was based on open-ended questions related to graphs and tables theme in 4th grade Texas curriculum that was taught in both the control and Time To Know classes.

The results indicated that participation in Time To Know (T2K) program contributed significantly to 4th grade students' academic outcomes in reading, writing and Mathematics, as measured by TAKS standardized tests. After controlling for gender, at-risk status, and 2009 reading TAKS scores (ANCOVA), the Time To Know students ($M=657.2$, $SD=88.3$) significantly outperformed the control students ($M=602.9$, $SD=104.4$) on the 2010 reading TAKS, $F(4, 95)=10.8$, p Time To Know students ($M=656.7$, $SD=83.0$) scored significantly higher than the control students ($M=625.1$, $SD=91.4$) on the Mathematics TAKS test, even after controlling for previous years TAKS scores (ANCOVA), gender, and at-risk status, $F(4,95)=6.5$, p

Although not significant, a trend was found in the context of at-risk students, showing that at-risk and non-at-risk students in the Time To Know classrooms score similarly. Whereas, in the control classrooms, the at-risk students Mathematics score much lower than the non at-risk population.

After controlling for students' third grade math TAKS scores, gender and at-risk status (ANCOVA), there was a statistically significant difference between the Time To Know and control students in the context of Mathematics reasoning (see Figure 9). Time To Know students ($M=35.7$, $SD=8.1$) far out-performed the control students ($M=24.3$, $SD=11.3$) on the Mathematics reasoning assessment overall ($F(4,95)=5.7$, p

Overall, the findings of the current study are showing the high potential of one-to-one computing learning environments, in which a comprehensive digital curriculum is combined with a constructivist-oriented teacher-led platform. Further research is recommended to examine qualitatively changes in teaching and learning practices underlie the effects of Time To Know program on academic outcomes, as well as the possible affective processes (i.e.

engagement, motivation, self-regulated learning). In addition, given the relatively small sample, it is essential to conduct large-scale studies to examine the effects of comprehensive one-to-one laptop learning environments.

PAPER PRESENTATION

Effects of computer-based interventions to enhance the development of mental number representations

Andreas Obersteiner, Technische Universität München, Germany; Stefan Ufer, University of Munich, Germany;

Kristina Reiss, Technische Universität München, Germany

Cognitive psychological and neuropsychological research suggests two core cognitive systems of number processing, namely an object-file system for the exact representation of discrete objects and an analogue magnitude system allowing an approximate representation of quantities. In an intervention study we explored whether an exact or an approximate approach for fostering students' development of mental number representations was more successful. N=46 second grade students were tested in basic number processing (e.g., number comparison) before and after seven computer-based intervention sessions. During the intervention students played one of two versions of a number game, requiring exact or approximate number processing. Results show that both the exact and the approximate condition led to improvements of basic number processing, without significant differences between these conditions. Process data revealed that both games were suitable for the students and did not differ in difficulty.

Theoretical background and aims

Cognitive psychological and neuropsychological research suggests that number processing relies on two "core systems" (Feigenson, Dehaene & Spelke, 2004), namely an object-file system for the exact representation of single objects and an analogue magnitude system for an approximate representation of quantities. Both systems seem to be innate and are responsible for early number learning. To enhance learning, mathematics education theories support the use of two kinds of manipulative materials representing exact numerosities using symmetric structures (e.g., a pegboard with two rows of ten pegs each) or analogue quantities (e.g., an empty number line). There is, however, no empirical evidence for the assumption that the use of such number representations has an effect on the development of students' mental representations. The aim of our study is to explore whether an intervention using specific external number representations leads to improvements in basic number processing tasks, whether differential effects can be found for specific tasks, and whether computer games are an appropriate method for such an intervention.

Methods

In an intervention study with N=46 second grade students (mean age: 7;2 years) we used two different computer games (see Obersteiner, Ufer & Reiss, 2010). Both games were based on the "Number Race" (Wilson, Dehaene, Pinel, Revkin, Cohen & Cohen, 2006), an adaptive software with the aim of enhancing "number sense". The two games were identical with respect to the overall conception. Depending on the level, the player had to solve number comparison tasks, calculation tasks, or number identification tasks with increasing task difficulty and time pressure. After each task, the player had to move his character on a game board by clicking on each square separately ("counting strategy") or by clicking on the end square directly. However, the games differed in the way tasks were presented to the player. In the exact version numerosities were presented in symmetric structures and the tasks required exact number processing (e.g., exact calculation), while in the approximate version numerosities were presented without structures and the tasks required approximate number processing (e.g., approximate calculation). During the game, process data such as successful runs and number of clicks were logged. Before and after seven intervention sessions (30 minutes each) the students took a computer-based test of basic number processing (dot enumeration of structured and unstructured sets, number comparison, magnitude comparison, magnitude estimation, approximate calculation). Response times and accuracy rates were measured. Data from 3 students were excluded from further analysis due to absence in more than one intervention session.

Preliminary results

Both versions of the intervention program were suitable for the students and did not differ in general difficulty, as indicated by an equal mean number of games won by the students (22.1 for the exact version, 23.2 for the approximate version; $t(41)=-1.04$; $p=0.30$). Overall, students improved their number processing skills as indicated by reduced response times in all tasks of the post-test as compared to the pre-test. An analysis of variance with repeated measures showed that neither the differences between the two intervention groups nor the interaction terms with group reached significance for any task ($p \geq 0.053$ for group differences, $p \geq 0.108$ for interactions). Process data such as the number of clicks used to move the character on the game board revealed that students in the exact condition were more successful in directly clicking on the correct square as compared to students in the approximate condition (79% vs. 46% successful direct clicks; $t(41)=8.08$; $p<0.001$). This may reflect the successful use of structures by students in the exact condition.

Discussion

The two computer games were comparable in overall difficulty. They were an appropriate method to be used in an intervention study with an experimental design. Both games had positive effects on second grade students' number processing abilities. However, as the present experiment was basically carried out to test the computer games, there was no control group, so that we do not know how specific these effects were. First results did not reveal group differences, indicating that both the exact and the approximate approach can be used to foster students' number processing abilities. In the present study, we have tested a relatively small sample. After further developing the computer games we will test intervention effects in a larger sample of first grade students. So far, we have analysed differential effects on the group level only. In further analysis we will explore how individual factors such as working memory or visuo-spatial abilities may have influenced students' test performances and their success during the intervention. A better understanding of such relations could help to develop individually tailored training for each individual student and is therefore of high relevance for mathematics education.

PAPER PRESENTATION

Students' use of tools in an undergraduate course: in search of tool-use patterns

Jan Elen, Katholieke Universiteit Leuven, Belgium; Geraldine Clarebout, Katholieke Universiteit Leuven, Belgium; Griet Lust, Katholieke Universiteit Leuven, Belgium

Research in controlled settings has revealed that students' tool-use behavior is a complex self-regulated behavior that cannot be taken for granted (Azevedo, 2004). It remains however unclear if these results are replicated in an ecological setting characterized by learning tasks integrated into the natural flow of the study, enough time to learn to use the tools and with long-time retention measurements (Grabinger, 2008). This contribution focuses on students' tool-use in an ecological setting. An undergraduate course was selected as object of research because despite the popularity of blended courses, as an integration of course management systems into the traditional constellation, there is little insight in how students behave in those environments. More specifically, the study investigates how students use the whole toolset at their disposal, whether user-profiles can be found and what the effects of students' tool-use on performance are. Cluster analysis reveals three distinct tool-use patterns or user profiles: the no-users, the intensive users and the incoherent users. Results from multiple analyses of variance reveal that those tool-use patterns affect the performance significantly. The results indicate that despite the benefits of blended learning environments as illustrated in literature, not all students seem to profit from the opportunities that are provided. Similar as in controlled settings, the results seem to indicate that students' tool-use cannot be taken for granted. Hence, they call for more research into the influencing variables, student-and context related, and the performance effects.

Research in controlled settings (e.g. review Aleven et al, 2003) underlines the fact that adaptive tool-use, as using tools in accordance with perceived learning needs, is a self-regulated activity that cannot be taken for granted (Azevedo, 2005). However, most of the research is done in a controlled setting characterized by non-embedded learning tasks and a focus on short-time learning effects (Grabinger, 2008). It remains unclear whether these results are replicated in an ecological setting. The current study puts the tool-use research in an ecological setting and more specific in an undergraduate blended course where learning is supported by various combinations of classical face-to-face initiatives (e.g. lectures, learning sessions) and digital devices as provided through the CMS (e.g. exercises, practice quiz, discussion board). Despite the fact that students, in most cases, have control in using these tools, there is little insight in how students' deal with this learner control i.e. how they use the tools and how that affects their performance.

First evidence in the Elis, Marcus and Taylor (2003) study indicates that coherently using the total tool-set cannot be taken for granted. Students were unsure of how to approach the online tools in ways that are likely to maximize the learning benefits in blended experiences. With respect to students' use of CMS tools, different studies reveal that students differ in how they approach a specific CMS tool (e.g. Grabe & Christopherson, 2005) or multiple CMS tools (e.g. Hoskins & Van Hooff, 2005) and this affects their performance for the course. The studies are however focused on one or multiple CMS tools without investigating how students use the tools all together, i.e. tool-use patterns.

The current study investigates students' tool-use in a blended undergraduate course. Based on evidence regarding students' use of CMS tools, it is expected that tool-use differences will exist and similar with evidence in controlled settings (e.g. Jiang, Elen & Clarebout, 2009) they will reflect distinct tool-use patterns among students. At least three tool-use patterns are expected: the no-users, the incoherent users and the intensive users.

Method

The sample

The study runs in a first year undergraduate course at the department of 'Educational Sciences' at the Katholieke Universiteit Leuven. It contains 91% of the course-participants ($n=159$). There are 152 women and 8 men. Most of the students were 18 years (72.3%).

The undergraduate course: toolset

Additional to the lectures, a CMS was provided and a team of support staff was at students' disposal. The support staff organized three learning support sessions and a feedback session that students could use voluntarily. The CMS was designed using Blackboard. The access and the use of the learning environment were under control of the student.

The tool-use behavior was captured through log-files. Table 1 presents the tools and the log indicators that were used in this study.

Indicators of learning

Students' course performance was assessed by an exam (consisting of factual items, comprehension items and application items) and an assignment for which students had to argue about an educational proposition.

Results

Students' tool-use behavior: tool-use patterns

K-means cluster analysis in Matlab was performed. K-means cluster solutions with two to ten clusters were fitted using 1000 restarts (for a discussion of the use of K-means cluster analysis, see Steinley, 2003). On the basis of a scree-test, the three-cluster solution was selected as optimal solution since a clear demarcation point is visible after three clusters.

One-way analysis of variance reveals that all the tool-use variables have a significant impact in defining the three clusters, $p = .000$. Post-hoc comparisons are illustrated in figure 1. As the figure illustrates, those three clusters represent different tool-use behavior among students, characterized by different tool-choices and distinct intensity in using them.

Fig 1. Tool-use patterns

Learning effects of the tool-use patterns

Multiple analysis of variance reveal a main effect of students' tool-use behavior on the five performance indicators, $F(5,150) = .139$, $p = .005$. More specific, students' tool-use behavior influences their total course grade, $F(2,154) = 5.056$, $p = .007$, and their assignment score, $F(2, 154) = 7.767$, $p = .001$. As for the assignment score, students in cluster 3, $M = .09$, $SD = .96$, and in cluster 2, $M = .31$, $SD = .78$, outperform students in cluster 1, $M = -.41$, $SD = .94$. For the total course grade, a significant difference exists between students in cluster 1 and cluster 2. Students in cluster 2, $M = .29$, $SD = .89$ outperform students in cluster 1, $M = -.25$, $SD = .81$.

Discussion and conclusion

In line with our expectations, three usage patterns were found. Students in cluster 1 reflect no users, they did not use the available face-to-face and CMS tools. Students in cluster 2 are intensive users, they used all the available tools. Students in cluster 3 are incoherent users, they used the face-to-face tools, the course material outlines and the learning support. The two latter CMS tools have a clear link with the face-to-face context. The outline notes referred to the face-to-face lectures and the learning support referred to the learning support sessions.

A significant difference was found between the no-users and the other patterns in performance on the assignment and on the total course grade. Surprisingly, no significant differences were found between intensive and incoherent users. This result raises questions with respect to the functionality of some CMS tools, the consistency in the intensive users group, possible mediating variables and possible influencing student variables.

PAPER PRESENTATION

Where's the math? Locations of mathematical activity in classes with handheld technologies

This presentation will examine the locations of mathematical activity in classrooms where handheld digital technologies are used. By drawing on Actor-Network theory, it will discuss the interactions between humans and materials within the sociotechnical networks of mathematics classrooms as they form in relation to Texas Instruments' TI-Nspire™ graphing calculator. The findings indicate that while many individual elements and connections exist within classroom sociotechnical networks, they operate as a complex interconnected whole. In particular, they suggest that the ways technologies are configured in mathematics classrooms have a profound effect on the mathematical practices within them but also suggest that this is far from a one-way phenomenon.

In this presentation, I will examine the locations of mathematical activity in classrooms where handheld digital technologies are used. By drawing on Actor-Network theory, I will discuss the interactions between humans and materials within the sociotechnical networks of mathematics classrooms as they form in relation to Texas Instruments' TI-Nspire™ graphing calculator. TI-Nspire™ and related technologies are broadly advocated in curriculum documents and guidelines for teachers (Ontario Ministry of Education, 2005; Qualifications and Curriculum Authority, 2007). In addition, a growing body of mathematics education research suggests that these technologies help learners make connections with and between mathematical concepts and enrich their mathematical thinking (Kaput & Schorr, 2008). Given this support for the use of digital handheld technologies, it is important to unpack the ways they change the geography of mathematical activity in classrooms. In this presentation, I will address these changes by examining the role of TI-Nspire™ as a location of mathematical activity in relation to other materials, teachers and students.

Theoretical Perspective

As a theoretical perspective, I draw on Shaffer and Clinton's approach to understanding the relationship between digital technology and learners in mathematics classrooms (2006). In particular, following their lead I draw on the Activity-Theory concept of learning as activity that always involves cultural tools. This notion suggests that understanding the mediation of tools including technologies is vital to understanding learning itself (Saljo, Eklund & Makitalo, 2006). While Activity-Theory foregrounds the important role of tools in human activity, it considers technologies and humans to have an asymmetrical relationship. In this relationship, humans are assumed to act as agents and technologies are not (Shaffer and Clinton, 2006). This assumption may obscure the important role that particularly complex digital technologies such as TI-Nspire™ can have in mathematical learning. To address this issue, I turn to Actor-Network theory to conceptualize the relationships between humans and technology as part of social networks of humans and non-humans all mediating each other's activity (Latour, 2007). Within these sociotechnical networks the relationship between actors, both human and non-human, are conceptualised in reciprocal terms offering the notion that when interacting the capacity to act cannot be located in either party but instead emerges from their interaction (Latour, 2007). Together the combination of Actor-Network theory and Activity-Theory provide a useful perspective for examining the mediation of mathematical learning within networks of humans and materials.

Method

I observed two ninth grade mathematics classes in the Canadian province of Ontario, spending a week video recording in each classroom. Augmenting this, I conducted a series of recorded interviews with the teachers that began with an in-depth session focused on their experiences teaching with technology. Continuing the interviews, the teachers participated in a retrospective debriefing interview following each observed class. In addition, I interviewed two students from each classroom about their experiences with TI-Nspire™.

Following data collection, all video-recordings, interview transcripts and collected artefacts were examined using Interaction Analysis (Jordan & Henderson, 1995) as an analytic approach to describing the complex activities and interactions within the networks of mathematical activity. As a tool for performing this analysis, the qualitative data analysis software Transana was used. This powerful and flexible software supported a detailed examination and interlinking of all collected data, including video, in a single environment.

Findings

The findings that I will present show the complex ways that the introduction of a digital handheld technology such as TI-Nspire™ changes the geography of mathematical activity in classrooms. They speak to the relationships between TI-Nspire™, teachers, students, and a wide range of materials such as the computer lab, paper/pencil, the blackboard, and interactive whiteboards. All these materials served as locations of individual and shared mathematical activity in the two observed classrooms. While no material replaced any of the others with the introduction of TI-Nspire™, the

networks of humans and materials in each classroom reconfigured in different ways that supported different mathematical activity.

While many individual elements and connections exist within classroom sociotechnical networks, the findings of this study indicate that they operate as a complex interconnected whole. In the two observed classrooms, it was particularly evident that the effects of the teachers' decisions to include TI-Nspire™ as part of their instructional practices were not limited to, for instance, the local relationship between student and handheld technology while completing an activity. They were instead extremely broad, influencing practices as diverse as the use of the computer lab and whole-class discussion of homework. The findings of this study suggest, that the ways technologies are arranged in mathematics classrooms have a profound effect on the mathematical practices within them but also suggest that this is far from a one-way phenomenon. While teachers have enormous influence through their choices of what technological arrangements to use, the technologies themselves along with other elements of the classroom geography mediate these configurations and are highly interrelated.

PAPER PRESENTATION

The Adoption of Technology Innovations

Charalambos Vrasidas, CARDET - University of Nicosia , Cyprus; Christiana Aravi, CARDET, Cyprus; Katerina Theodoriodu, CARDET, Cyprus; Petros Panaou, UNIC - CARDET, Cyprus; Anastasia Economou, CPI, Cyprus; Ireneos Pattis, UNIC - CARDET, Cyprus

The adoption of innovations and technology in teaching and learning has been studied extensively. This paper presents findings from 3 year program that focused on the development of case studies of the use of ICT in the classroom and results from large-scale evaluations of technology initiatives in Cyprus public schools. A large-scale survey was conducted and 30 case studies were developed in order to examine the use of ICT by teachers, the effectiveness of teacher professional development and the challenges faced by practicing teachers with respect to the integration of Information and Communication Technologies (ICT) in the curricula. This paper discusses findings from the large scale survey and enriches the findings with qualitative data from the ethnographic case studies to illustrate insights on effective practices of ICT adoption in Cyprus education.

Introduction

Attempts to integrate technology in education provoke a variety of responses from teachers that range from enthusiasm and skepticism to fear and uncertainty. A long history of technology use in education reveals that the first reaction is to use new technology in the same traditional ways as the old technology. Old curricula and pedagogical approaches should be reformed, and if necessary replaced, to take advantage of the affordances of the new media.

Context

During the last two years, we were involved in two large scale evaluations of the Cyprus Education system and 5 developmental research programs supported by the Republic of Cyprus, EU Structural Funds, and the European Commission. The focus of these projects was on the adoption of ICT by K12 teachers and the effectiveness of existing professional development programs offered. One of the key issues that came out was the importance of both formal and informal ways for teacher lifelong learning, and the role that online environments can play to support them. In

this paper, we present the summary of findings from evaluation work conducted to investigate the adoption of ICT in Cyprus public schools. This paper discusses findings from the large scale survey and enriches the findings with qualitative data from the ethnographic case studies to illustrate insights on effective practices of ICT integration in Cyprus education.

Research Methods

Participants

For the ethnographic case studies part of the projects, a total of 30 K12 schools participated (10 high schools, 20 primary schools). From each school we had one teacher as a case study. Each teacher and his/her class comprised of one case study in a variety of subjects. Teachers were chosen by the Ministry of Education based on the following criteria: teachers must have participated in some of the professional development programs, represent all counties of Cyprus (geographical distribution), and they must have expressed interest to participate in the case studies.

Setting and Procedures

The project research team that investigated and evaluated the case studies was led by the international Research Center CARDET. A total of 55 researchers were involved in the research. In order to achieve homogeneity and ensure consistency in data collection and analysis, four half-day workshops were held during which all researchers received appropriate training. The evaluation work span a period of 20 months.

Research/Evaluation Questions

The study investigated a series of questions. For the purpose of this paper we focus on the following:

1. What factors affect teachers' efforts in technology integration?
2. How do teachers use ICT?
3. What barriers do teachers face in using technology in the classroom?

Data Collection, Instruments and Analysis

Data for this project were collected and analyzed using both quantitative and qualitative methods. Data were collected from the following sources:

- . Pre-interviews conducted with each teacher on the planning process for the unit to be implemented and the teacher expectations
- . Observations of at least ten lessons implemented by each teacher, which integrated technology in the classroom over a period of 6 weeks.
- . Teacher self-reflective journals
- . A teacher post-interview
- . Interview with each teacher's technology advisor
- . Interviews with at least 3 students from each case (selected with the help of the teacher)
- . Student pre and post-tests.
- . A large scale survey administered to K12 school teachers.

For the purpose of this paper, we focus on the findings from the large scale survey. The main objective of the survey was to analyze how teachers use technology in the classroom and what challenges they face. In the discussion below, we enrich the findings of the survey, with qualitative data from the 30 case studies. In order to develop the 8-page instrument for the survey, we relied heavily on the findings from the qualitative data (e.g. interviews and observations). In addition, we reviewed other instruments, and consulted with experts in the field. A first draft instrument was developed and pilot-tested with 10 teachers and 4 experts. Following the pilot, we finalized the instrument and administered it to a sample of 1051 teachers using stratified sampling procedures. The total population of primary school teachers in Cyprus, during 2008-2009 was 4150. We ensured that all counties and regions of Cyprus were represented from both rural and urban settings. The response rate of the questionnaire was 50.5% (531 out of 1051).

Data Analysis

During data analysis, we followed the inductive and deductive stages used in interpretive and case study research. After we collected and organized all the data, we read through the data three times and generated assertions. Once we generated assertions from the data as a whole, we entered the deductive stage. In this stage, we engaged in detailed examination of the data corpus and looked for data to confirm or disconfirm our assertions. Moreover, statistical analysis of quantitative data included tables and diagrams, whereas authentic excerpts were extracted from the qualitative data.

Results

Even though the authors have studied all research questions related to this study, this section discusses only findings on the factors that affect teachers' efforts in technology integration and the challenges they face. The findings presented in this paper shed light to the complexities of integrating ICT in teaching and learning. The research reported is the first of its kind conducted in the Cyprus context. Findings reveal that teachers are willing to integrate technology into their teaching practices. However, even though they realize the benefits of ICT integration, a lot of teachers today seem resistant to integrating technologies. This is due to several factors that were revealed through the findings, such as lack of time, the ill-structured design of the school curriculum, and lack of infrastructure

PAPER PRESENTATION

Depiction of Theme in Graphics: Its Influence in Expository Text

Robert Danielson, California State University, Chico, United States; Neil Schwartz, California State University, United States; Stefan Krause, University of Koblenz-Landau, Germany; Marie Lippmann, University of Dresden, Germany; Sevil Gonen, California State University, Chico, United States; Maryam Fallahi, California State University, Chico, United States; Steven Caldwell, California State University, Chico, United States

It is well documented that when graphics are paired with textual material, recall is enhanced. However, not all graphics operate in a similar fashion. Previous research has indicated that decorative graphics provide little to the overall understanding of textual material, while representative graphics help learners construct a cognitive model of text content. Recently, decorative graphics have been found to be more effective than previously thought. Graphics which highlight the underlying themes present in a narrative, yield comprehension that is comparatively deep. This effect has been found both immediately after reading and one week later. In the present investigation, 80 volunteers read an expository text about the conflict in Darfur in the presence of a graphic depicting either the text theme of civil war or genocide, or they saw a graphic depicting the geographic region of the conflict, or no graphic at all. Results showed that the graphics, when they are metaphors of the underlying text themes, greatly enhance recall of the text when compared to either the non-thematic graphic or no graphic at all. Results are discussed in terms of the way decorative graphics can be used to influence deep learning.

Examples of text paired with graphics are prolific throughout textbooks and the web. It is well understood that when the two appear together, performance is consistently better than text alone (Carney & Levin, 2002; Schnotz, 2002; Schnotz & Bannert, 2003; Mayer, 2003; Mayer, Hagerty, & Mayer, 2005; Lewalter, 2003). However, not all types of graphics function in the same way, and specific text-graphic combinations lead to different performance outcomes. Schnotz & Bannert (2003) demonstrated that unique graphics, paired with identical texts, create different mental representations of textual information, and poorly selected graphics interfere with mental model construction (Schnotz & Bannert, 2003). Furthermore, some graphics are less reliable in their effect on learning from text, particularly when employed to decorate a page. Levin, Anglin, and Carney (1987), in a meta-analytic review, found moderate to strong effect sizes for graphics employed to inform text by representing all or part of text content, but weak to non-existent effect sizes for graphics used for decoration.

We contend that graphics used to adorn text serve more than a simple decorative function. Instead, they convey information about the theme of a text and influence a learner's cognitive interaction with a passage (Schwartz, Battinich, Lieb & Mortensen, 2008; Schwartz, Lieb, Battinich & Kuinke, 2007). Schwartz & Collins (2008) demonstrated that decorative graphics are capable of activating the prior knowledge of learners in idiosyncratic but reliably predictable ways. Mortensen & Schwartz (2009) found that thematically-related decorative graphics increased recall of both literal details and deeper level themes embedded in text-- immediately after reading the text two weeks later.

Unfortunately, Mortensen & Schwartz (2009) found effects with a narrative passage that, because of its ambiguous nature, may have contributed to the influence of the graphics. They also failed to test the effects against a non-thematic graphic condition. This investigation focused on expository text-- more common in textbooks and media, and tested the graphics against a non-thematic graphic condition.

Methodology

Design

The design was a 4 Metaphorical Graphic Theme (Genocide vs. Civil War vs. Geographic Location vs. None) x 3 Passage Theme Type (Genocide vs. Civil War vs. Neutral) fixed ANOVA, with repeated measures on the passage theme variable.

Participants

Eighty undergraduate volunteers (mean age = 23) were randomly assigned to experimental conditions in equivalent proportions of gender.

Materials

Experimental passage. The experimental passage was an 839-word expository text describing the current conflict in Darfur, written to reveal two socio-political themes— civil war and genocide. Overall, the passage contained a total of 80 idea units—40 neutral, 20 civil war, and 20 genocide. Neutral idea units provided contextual background of the conflict, geographic information, and a historical timeline. Civil war idea units consisted of rebel groups uniting against a corrupt government for representation. Genocide idea units consisted of a planned extermination or removal of a group of individuals. To ensure idea units were properly assigned to their corresponding themes, sentences were randomly ordered, rated by a group of 40 undergraduates, and factor analyzed for the identification of evoked themes and emotional valiance. Outliers were removed, and the passage was reconstructed as a cohesive unit.

Experimental graphics. Three metaphorical graphics were designed. The first graphic was a topographical representation of the region. The graphic depicting Civil War graphic consisted of two lions of similar color and size engaged in combat. The graphic depicting Genocide consisted of two lions of similar color and size devouring a third lion of a dissimilar color and size. Graphics were normed by a separate group of 40 undergraduates to ensure they elucidated the intended metaphor without evoking the alternate metaphors. (See Figure 1).

Experimental Website. An experimental website was designed to display the materials. The website consisted of 15 hypermedia pages; informed consent, general instructions, an essay prompt, and a demographic questionnaire. Prior knowledge of the conflict was assessed by embedding a 7-point Likert scale into the demographic questionnaire.

Procedure

Participants navigated the experimental website with the experimental text presented on the right half of the screen while one of three graphics (or no graphic) were randomly presented on the left. Participants were allotted six and a half minutes to comprehend both the text and the graphic. Participants were then allotted 15 minutes to write an essay containing as much information as they could remember, including any thoughts, feelings, or reactions to the text.

Data Source

Measures of comprehension were derived by scoring the essays for the number of three types of idea units— passage-neutral material and material related to the genocide and civil war themes. Two graduate students scored half the protocols in each between-subject group, and redundantly scored 20% of the total. Inter-rater reliability was $r = .90$.

Findings

Neutral-passage idea units recalled were analyzed across Metaphorical Graphic Theme (Genocide, Civil War, Location, No graphic) in a univariate ANOVA. Results yielded a significant effect between graphic conditions, $F(3, 76) = 3.495$, $p = .02$. Post hoc Tukey tests revealed neutral passage recall was highest ($M = 6.4$, $SD = 3.68$) in the presence of the metaphorical graphic depicting the theme of genocide. By contrast, recall was significantly reduced when the graphics contained no metaphor for theme (location, $M = 3.65$, $SD = 2.65$), and no graphic at all ($M = 3.68$, $SD = 2.63$). No relation was found between prior knowledge of the conflict and number of idea units recalled. (See Figure 2).

Theoretical and educational significance

These findings support Mortensen & Schwartz (2009), revealing that thematically related graphics increase recall of both deeper level themes and literal details from text. The results support those found by Mortensen & Schwartz (2009), but underscore the presence of the effect with expository text and test it against a thematically unrelated and absent-graphic condition. It is important to note that Mortensen & Schwartz (2009) found the largest effects when learners returned two weeks after reading. Delay condition data and the extent to which recalled is mediated by critical thinking skills will be presented and explained using the model proposed by Schnotz and colleagues (2003).

PAPER PRESENTATION

What do players have to say about informal learning through games?

Ioanna Iacovides, The Open University, United Kingdom; James Aczel, The Open University, United Kingdom; Eileen Scanlon, OU, United Kingdom; Will Woods, The Open University, United Kingdom

It has been suggested that digital games can be powerful learning environments that encourage active and critical learning, including participation within "affinity groups" and "semiotic domains" (Gee, 2004). However, there is still a need to provide further empirical evidence to substantiate these claims, especially if educators want to try to replicate people's enthusiasm for games within a formal educational context. By addressing the question "How do players describe learning in the context of gaming?" this study seeks to further our understanding of how and what people learn informally through playing games by first examining the player perspective. A set of learning categories, based on a series of email interviews with a range of adult games players, is identified along with some themes to consider in relation to players' views on learning within this context. The findings indicate the importance of considering more than just what occurs during play, because, for example, players often consult external resources for advice about what to do in the game world. It is also pertinent to note players' ideas about value and transfer of learning across contexts. The research raises questions about the completeness and applicability of these learning categories, and about how these categories relate to motivations for playing games and engagement during play.

PAPER PRESENTATIONS

Aligning Instruction to Individual Learning Needs in Adaptive Hypertext Learning Environments

Eniko Bezdan, Open University, Netherlands; Liesbeth Kester, Open University of the Netherlands, Netherlands; Paul A. Kirschner, Open Universiteit, Netherlands

Educational hypertext research on the effectiveness of pre-structured, static hypertext learning environments have greatly enhanced our understanding of how pre-structured hypertext environments affect navigation and learning outcomes. In particular, the effect of different types of graphic organizers have been extensively studied in the past two decades. In the meantime, however, the focus of hypertext and hypermedia design have moved on toward the development of ever more sophisticated adaptive techniques, yet empirical data about the cognitive effects of adaptive hypertext/hypermedia have been slow coming. The scarcity of research regarding the cognitive consequences of adaptive hypertext/hypermedia is somewhat surprising, as it has the potential to bring one of the longest standing ambitions in education one step closer: being able to provide instruction which is finely tuned to the learning needs of the individual learner. Knowledge accumulated about the learning effects of static hypertext environments, along with the results of studies about learner versus system control for task selection are examined, in order to outline possible future directions for adaptive hypertext/hypermedia research in an educational context.

When speaking of hypertext/hypermedia, the most basic kind of classification that can be made is between static and dynamic/adaptive. In static, more traditional, hypertext the sequencing of hyperlinks is fixed and the text content of the nodes remains unchanged. As the degree of interconnectedness via hyperlinks and the placement of hyperlinks between nodes determine the structure of hypertext (e.g., linear, hierarchical, network/semantic), navigation aids called spatial maps, graphical browsers or graphical organizers, depicting this structure of hyperlinks and nodes, are frequently used as a way of tackling the problem of disorientation (McDonald & Stevenson, 1998). Not surprisingly, one of the main themes of hypertext research in an educational context has been to examine the effects of different types of graphic organizers and its effects on navigation and learning outcomes (DeStefano & LeFevre, 2007).

Besides differences regarding their structure (e.g. linear, hierarchical, network), graphical organizers can also be divided into interactive and static. In the case of interactive organizers, the hypertext structure as defined by its hyperlinks, and the structure depicted in a graphic organizer need not be the same, as indeed they often are not. This is for example the case when nodes can be accessed directly by clicking on the concepts in the organizer. Once arrived at a textual node, there is only the option clicking on the back-button which leads back to the graphical organizer (e.g., Amadiou et al., 2009; Potelle & Rouet, 2003). Thus, a graphical organizer of this sort is not intended to describe the structure of the hypertext itself, as the lines drawn between the concepts in the graphical organizer do not

correspond with the actual hyperlinks of the document. Consequently, it is almost certainly not the act of navigation (i.e. navigation here simply means clicking on concept in the organizer) which enhances learning, but the repeated viewing a representation of the relationships between the important concepts and of a knowledge domain.

Although in appearance similar to the interactive organizers described above, static graphic organizers usually have a different function. Static organizers can be a way of depicting the exact hyperlink structure of the hypertext document, as was the case in the study conducted by McDonald en Stevenson (1998). By visualising all possible pathways through the document, graphic organizers of this kind are navigation aids which could be said to convey a certain kind of spatial information. Thus, these are spatial maps which show how to get from a one text node to another, as well as the relative distance of textual nodes to each other as defined by the number intermediate steps between them. What still remains unclear is, however, to what extent graphic organizers showing possible navigation paths engage same cognitive processes as graphic organisers in which the linkages (i.e. lines between concepts) do not correspond with the actual hyperlinks in the document. Besides the open questions remaining with regard to static hypertext, the cognitive effects of more complex, adaptive hypertext are largely unexplored. Today's learners encounter adaptivity on a daily bases when they for example use a search engine to browse the internet. Search engines make use of sophisticated algorithms analysing individual search histories in real time to select the hits in response of a search query, thereby adapting content presentation to the individual user. Yet, the widespread exposure to adaptive hypertext and hypermedia of the student population has so far sparked surprisingly little interest in educational research. Usability and user satisfaction studies are being carried out by the developers of adaptive hypertext/hypermedia, who come for the most part from the field of information and computers sciences. However, very little attention is paid in these studies to cognitive effects and learning outcomes (Brusilovsky, 2003).

The cognitive effects of adaptivity are being studied, however, in the specific context of adaptive task selection. Adaptations on task selection often focus on the degree of freedom the learner gets over task selection. The most common classification regarding the locus of control for the adaptations distinguishes between system controlled adaptation, user controlled adaptation, and shared control by the system and the learner (Corbalan, Kester, & Van Merriënboer, 2009). It could be argued that studies focusing on adaptive task selection, although mostly presented in hypertext/hypermedia format, are not representative of the hypertext/hypermedia that are typically encountered when browsing the web. Nevertheless, insights gained from these studies are still relevant for hypertext/hypermedia in a broader sense, as different levels of system and learner control can be incorporated and made adaptable in diverse hypertext/hypermedia formats. Utilising effectively the possibilities of adaptive hypertext and hypermedia could be the key to truly customising instruction to individual learning needs. But in order to do so, it is necessary to gain a better understanding about the extent the structural characteristics of navigation aids (e.g., graphic organizers) and hypertext structure as defined by its hyperlinks have differential effects on cognitive processes in the course of learning. Additionally, varying the locus of control in adaptive task selection is a good starting point to explore how shifting the control from the system to the learner and vice versa affects learning outcomes. There is also still much to be learnt about the possible objects of adaptive control, as the structure, content and the form and type of navigation aids in hypertext/hypermedia can all be made adaptable in a great number of ways. The focus of this paper is, therefore, to explore how adaptations regarding structure, content and navigability might interact with variations in the locus of control of these adaptations.

Effects of Drawing and Diagram Selection on Learning from Multiple Representations in Biology

Carla Firetto, Pennsylvania State University, United States

Peggy Van Meter, The Pennsylvania State University, United States

Active processing of diagrams embedded in science text improves student learning. This study tests two manipulations intended to improve learners' processing of diagrams. All participants read a biology text that contained 25 diagrams. 7 of these 25 diagrams were removed in both active processing conditions. In the first of these, the Draw condition, participants constructed their own drawings to replace the missing diagrams. In the Select condition, participants selected the correct diagram from amongst a set of alternatives. These two conditions were compared to conditions in which participants studied the materials with all diagrams provided and a text only control. Learning outcomes were evaluated on a multiple-choice posttest that was divided into two subtests. One subtest tested knowledge that corresponded to content related to the 7 missing diagrams. The second subtest tested knowledge taken from other areas of the instructional material. Results show that participants who constructed drawings scored significantly higher on the correspondent subtest than did participants who studied either the text only or the text with the provided diagrams. There were no differences between the selection condition and the provided diagram condition on this subtest nor were there differences between drawing and selection. On the subtest with non-correspondent items, all three conditions that received diagrams scored significantly higher than did participants in the text only condition. There were no differences found between these three conditions on this non-correspondent subtest, however.

Student-generated drawing is a strategy in which learners draw to depict instructional text (Van Meter & Garner, 2005). Although this strategy has been shown to increase learning (Van Meter, Aleksic, Schwartz, & Garner, 2006), other studies have failed to show strategy benefits (Leutner, Leopold, & Sumfleth, 2009). This study tests the drawing strategy by comparing learning outcomes for students who draw to those who were either provided diagrams or were forced to actively process provided diagrams. Forced processing was operationalized by requiring participants to select a correct diagram from amongst alternatives (Zhang & Linn, 2010).

Research hypotheses include:

Participants who actively process diagrams will acquire more knowledge than will participants who do not actively process diagrams.

Participants who construct drawings will acquire more knowledge than will participants who select diagrams.

The benefits of active diagram processing will be found on subtests that assess both correspondent and non-correspondent knowledge.

High prior knowledge participants will benefit from active processing of diagrams to a greater degree than will participants with lower prior knowledge.

Methods

Participants and Design

106 Educational Psychology students were randomly assigned to conditions. Conditions were text only (Text), text and provided diagrams (Provided), selection (Select), and drawing (Draw).

Materials

Instructional Materials. Participants studied a paper booklet describing muscle physiology. The text contained 1,780 words and 25 diagrams. Diagrams either depicted structures or were sequenced to depict processes.

Condition Manipulations. Participants in the Text condition studied booklets containing only text. In the Provided condition, booklets contained text and all diagrams were provided. Participants in the Select condition received booklets in which seven diagrams were removed. At these locations, participants selected the correct diagram from amongst a set of alternative diagrams. Missing diagrams were dispersed throughout the instructional material. Participants in the Draw condition also received booklets with missing diagrams. Booklets in this condition contained blank space and participants drew a diagram depicting the contents of the accompanying text.

Pretest and Posttest Measures.

Participants completed a pretest assessing prior biology knowledge.

The posttest was a multiple-choice test. This test was divided into two subtests. The first tested knowledge corresponding to the content that participants either selected or drew. The second tested knowledge taken from other areas of the instructional material. There were 17 correspondent items (C) and 25 non-correspondent items (NC). The alpha coefficient for the full test was .77.

Procedures.

Participants completed experimental sessions in a computer lab. Sessions were randomly assigned to condition. The experimenter explained instructions for each condition. Participants in the Select and Draw conditions were told of the missing diagrams and of the selection or drawing task, respectively. Participants completed the demographic survey, pretest, and posttest online; instructional materials were on paper.

Results

An extreme-groups split on the prior knowledge variable divided participants into high and low prior knowledge groups. 91 participants remained following this split.

Condition effects on the posttest variables were tested in a 2 (prior knowledge) X 4 (condition) MANOVA. The interaction between prior knowledge and condition was nonsignificant. Main effects for both prior knowledge and condition were significant; $F = 7.36$, $p\&\eta^2 = .15$; $F = 6.16$, $p\&\eta^2 = .18$, respectively. Univariate tests revealed a significant main effect of prior knowledge for both NC and C subtests; $F = 11.09$, $p\&\eta^2 = .12$, $F = 10.52$, $p\&\eta^2 = .11$. High knowledge participants scored higher on both subtests than did low knowledge participants.

There was also a significant main effect of condition found for both NC and C items; $F = 5.84$, $p\&\eta^2 = .17$; $F = 10.23$, $p\&\eta^2 = .27$. Tukey's HSD comparisons revealed that the pattern of these effects differed across the two subtests. For the NC subtest, the Provided, Select, and Draw groups all scored significantly higher than did the Text group. There were no significant differences across any of the three groups that received diagrams along with text.

On the C subtest, each group that received diagrams again obtained higher scores than did participants in the Text condition. There were also differences amongst these three groups. The difference between Select and Draw was not significant, but students who drew did score significantly higher than participants in either the Text or Provided conditions. Participants in the Select condition did not obtain significantly higher C scores than did participants in the Provided condition.

Discussion

This study demonstrated that the drawing strategy can be effectively embedded into lengthy instructional materials. Participants in the Draw condition were required to construct 7 of the 25 total diagrams. We believe that the construction of some, but not all, diagrams was important to the success of the strategy. First, the diagrams that were available to Draw participants provided a necessary form of support (Van Meter & Garner, 2005) by illustrating key structures and spatial relations. Second, providing some diagrams may have reduced the cognitive load associated with the drawing strategy (cf. Leuntner et al., 2009). The differential pattern of performance on NC and C items suggests that the benefits of drawing are local. Drawing did show an advantage when the subtest assessed knowledge directly related to drawn content. When non-correspondent knowledge was tested, however, Draw participants did not obtain higher scores than did Provided participants.

This study also demonstrated that active processing of the diagrams alone, through the selection task, did not improve learning (Van Meter et al., 2006). It is possible, however, that the selection task was not sufficiently complex to support learning (Zhang & Linn, 2010).

We are currently analyzing qualitative characteristics of constructed drawings. Once this coding is complete, we will examine relationships between these characteristics and learning outcomes.

PAPER PRESENTATION

The role of teacher characteristics in promoting student engagement

Jolien van Uden, ROC van Twente/ Twente University, Netherlands; Henk Ritzen, Applied University Edith Stein, Netherlands; Jules Pieters, University of Twente, Netherlands

In this research the relationship between teacher characteristics, like their motives to become a teacher, their self-efficacy beliefs, competences and interpersonal teaching style, are examined in relation with student engagement. Disengagement is an important risk factor in the process of dropping out. Three types of engagement are being distinguished: behavioural, emotional and cognitive engagement. The relation between all three types of student engagement, and teacher characteristics are explored during a survey in vocational education and training centres in the Netherlands (VET Colleges). This survey consists of a teacher and a student questionnaire. The results of both questionnaires will be combined, so the engagement of the students can be linked to the characteristics of their teachers. The first student results show a relation between student engagement and interpersonal teaching styles. The results of the complete datasets are examined during the spring and will be presented at the Earli 14th Bienial Conference.

Theoretical framework Student drop-out is a hot item in the Netherlands (Researchcentrum voor Onderwijs en Arbeidsmarkt, 2009). From a pedagogical perspective drop-out is the result of a long term process of disengagement

and withdrawal of a student from education. This process of disengagement starts during the early years of education (pre-school and primary education) and could result in dropping out of school in higher and vocational education (Dynarski, Clarke, Cobb, Finn, Rumberger & Smink, 2008; Hammond, Linton, Smink & Drew, 2007). Drop-out is not the result of one single factor, research confirms that different factors influence the decision to drop-out. These risk-factors are interrelated, interact with each other and have a cumulative effect on the decision to quit school (Dynarski et al, 2008). Among the important factors that influence drop-out of school is student engagement (Appleton, Christenson & Furlong, 2008; Fredricks, Blumenfeld & Paris, 2004). The expectation is that if student engagement has increased and other risk factors are offset by prevention activities or special student care programs like mentoring and individual coaching programs, the drop-out rate will decline. In this research we focus on what the teacher can do to improve student engagement. The concept of engagement is a multidimensional construct consisting of three components (Appleton et al., 2008, p.370):-

Behavioral engagement: a student is behavioral engaged if he participates in the lesson. The student is on time, concentrates on the assignments given, puts effort into these assignments and undertakes action if possible.-
Emotional engagement: a student is emotional engaged if he is enthusiastic about school. He is interested in going to school, he can identify himself with school and demonstrates a positive learning attitude. –

Cognitive engagement: a student is cognitive engaged if he understands the importance of his education. He is able to formulate his own learning goals, disposes of self-regulating abilities and the extent to which he wants to put effort in receiving good learning results. According to Hattie (2003) the teacher accounts for 30 percent of the variance in the school success of students. The abilities of the student himself account for 50 percent of the variance. Other aspects, family, school and peers, explain five till ten percent of the variance. If school success is explained for 30 percent by the role of the teacher, could that mean that the teacher would have the same impact on student engagement? A lot of research has been conducted to examine the relationship between drop-out and engagement (e.g. Archambault, Janosz, Fallu & Pagani, 2009; Finn, 1989; Klem & Connell, 2004) while almost no research has been done to examine the way teachers can influence the engagement of students. In this research we examine what teachers can do to improve the engagement of students in lower educational tracks (assistant training level 1 and basic vocational training level 2). In this inquiry the teacher characteristics are limited to: The motives to become a teacher: A person can choose to become a teacher based on extrinsic, intrinsic and altruistic motives (e.g. Pop & Turner, 2009; Richardson & Watt, 2006). Which motives are important in stimulating student engagement? Competences: Teachers can develop three types of knowledge and competences: subject knowledge, didactical knowledge and pedagogical knowledge (e.g. Beijaard, Verloop & Vermunt, 2000; Borko, 2004; Darling-Hammond & Bransford, 2005). Which competences are related to higher student engagement of students in vocational education level 1 and 2? Personal characteristics: Literature suggests that students in the lower educational tracks are in need of social-emotional competent teachers. Interested, warm and careful teachers can make the difference in case of students at risk of dropping out (Jennings & Greenberg, 2008; Pianta & Allen, 2008).

A large amount of self-efficacy is related to educational innovation, good class management, offering suitable learning activities and taking responsibilities for students in need of special care. Furthermore teacher self-efficacy is associated with student's motivation and self-esteem and more positive attitudes towards school (Caprara, Barbaranelli, Steca & Malone, 2006). The motives to become a teacher, the competences and personal characteristics will probably result in specific behaviour in the class in interaction with the students. Wubbels, Créêton and Hooyman (1985) have adapted the 'Rose of Leary' for educational interaction. They call this adapted model 'Model for interpersonal behaviour' (MITB). This model distinguishes two dimensions: the amount of influence and the amount of proximity. A higher score on both dimensions correlates with better cognitive and affective results (e.g. Den Brok, Brekelmans & Wubbels, 2006; Van Petegem, Aelterman, Van Keer & Rosseel, 2008). We examine whether these results also apply for student engagement.

Research design

In this research we examine which teacher characteristics influence student engagement. Little research is done with respect to this subject, therefore we decided to start an explorative survey. This survey consists of two questionnaires, one for teachers and one for students. The student questionnaire is used to measure the student engagement (all three components) and will be correlated with the results of the teachers. We ask the teachers and students to fill in a short version of the questionnaire on teacher interaction (QTI) (Wubbels, Créêton & Hooyman, 1985). Besides the QTI teachers answer questions about their motives, competences and the mentioned personal characteristics. All teacher questionnaires will be linked to the results of their students. One completed teacher questionnaire needs at least ten completed student questionnaires to be included in the analysis. Results Several institutions of vocational education participate in the survey at this moment. The first student results (N = 370) show a relation between student engagement and the interpersonal teacher style (table 1). In the beginning of 2011 we will be able to analyze the teacher questionnaires in combination with the student questionnaires. We will present the results of those

analyses at the Earli Conference in Exeter and answer the question which teacher motives, competences and personal characteristics.

PAPER PRESENTATION

Science and technology education for the future: needs of future employees
Professional Development, Science Education, Vocational education

Liesbeth Baartman, Eindhoven University of Technology, Netherlands

Koen Gravemeijer, Eindhoven School of Education, Netherlands

Technological developments and computerisation influence many jobs. The goal of this study is to identify to what extent employees need an increased and/or different understanding of science and technology to function in their jobs than is currently taught in schools. Whereas previous research tended to focus on very general skills (e.g., problem solving, communication) or long detailed lists of content knowledge, the focus of this study is on competences such as modelling and visualising. Companies most influenced by technological developments were selected in cooperation with National Centres of Expertise on vocational education. They were asked in which companies (1) more and/or different scientific and technological competences, and (2) creativity and flexibility are required. We focused on jobs at the level of senior secondary vocational education, as these jobs are most prone to being outsourced or taken over by computers. Employees working in the different companies were asked what knowledge and skills they use during their work, for example when working with machines and computers. Preliminary results show the influence of technological developments on almost all jobs. Required knowledge and skills are for example: data-analysis, the use of graphs and thinking beyond one's own job. The need for flexibility, creativity and insight in 'black boxes' seems to depend on the level of education.

Theory and aims The increased use of information- and communication technology and the influence of scientific and technological developments have caused many countries to redefine the key competences for adequately functioning professionals. This study specifically focuses on the needs of future employees: what competences in the domains of science and technology do they need to function adequately in their jobs, now and the future? Previous studies tend to focus on very general skills such as problem solving and communication (e.g., Holbrook & Rannikmae, 2007), which do not provide any specification of what should be taught. Other studies provide long and detailed lists of content to be taught in schools (e.g., AAAS, 1993). These lists run the risk of quickly becoming outdated as the amount of technical information is doubling every two years (Binkley et al., 2010). This begs the question whether we can identify competences that are general in the sense that we may expect them to stay valuable for a long time, but at the same time not too general to offer directions for curricula. This study tries to answer this question by interviewing employees in companies that are subject to technological developments. In the literature, two domains provide input to this study. First, a number of studies focus on 21st century-skills, lifelong learning competences, or key skills. For example, Binkley et al. (2010) analysed curriculum and assessment frameworks around the world, and identified ten competences, including creativity, critical thinking and ICT literacy. Voogt and Pareja-Roblin (2010) and Dede (2009) reviewed different reports about 21st century skills, generally relying on private/business initiatives. These reports mention skills such as communication, ICT literacy, social awareness, and creativity. Problematic is, however, that explicit links to educational levels are missing and the educational community hardly participates in this debate. These reports thus provide little direction with regard to the content of education. Second, we reviewed the literature about knowledge and skills used in the workplace. Here, hardly any studies exist on the use of science and technology at the workplace. There are, however, studies on mathematics that are general enough to be useful for science and technology as well (e.g., Bakker et al., 2006; Pozzi et al., 1998). These studies show the importance of: (1) knowing what processes are 'hidden' in computers or machines, and (2) analysing relationships between variables, based on quantitative data.

Data and Methods **Participants** The context of this study was vocational education in the Netherlands, preparing students for a job at levels ranging from assistant worker to middle management. This middle-level job was chosen, as it is likely to be most affected by technological changes, while employees are not specifically educated in this domain (Levi & Murnane, 2005). To identify companies most influenced by technological developments, interviews were conducted with National Centres of Expertise, who develop national qualification profiles for the different branches. Six interviews were conducted with representatives from: animal and plant care, car mechanics, audician/optician, graphical design, commercials/presentation, and nursing/care. Seven interviews were conducted with employees of these branches: a farmer using robots, employees of Ford cars, a company developing logistical systems, an ICT desk, an outsourcing company, and an audician. In November/December 2010, more interviews will be conducted in different branches, and nursing specifically. **Interviews** Representatives of the branches were asked to describe developments with regard to: (1) the amount of science and technology, (2) the content of science and technology, and (3) flexibility and creativity needed to function on the job. Depending on their

function, the employees were asked:- what kind of machines and computer programs they work with;- if they need to know the 'invisible processes' inside;- how they are trained to work with new machines and computers;- what they do in case of an unexpected outcome or problem. All participants were asked to describe job situations in which scientific and technological knowledge and skills are used. Preliminary results Full results, including the remaining interviews and more examples from concrete job situations, are presented at the conference. - Required knowledge and skills: most employees need some basic knowledge of science and technology. For example, audicians need knowledge of the auditory organs. - Flexibility and creativity: at lower levels, employees are not expected to suggest improvements or solve non-standard problems. An exception is 'defence/tank' mechanics. They need to know the exact working of tank engines, enabling creativity in emergencies. - Insight in black boxes: opinions seem to differ here. In general, employees can work with machines without knowing 'what is going on inside'. For example, graphical designer can use software to make sketches without knowing how colours mix. Theoretical and educational significance Most jobs seem to be influenced by computerisation and technology, leading to changed requirements in terms of knowledge and skills, creativity and insight in black boxes. The identification of these changed requirements could guide curriculum adaptations, better preparing young people for their future jobs. More research seems warranted on the use of science and technology at the workplace (following studies on mathematics). This study is a first step in this direction. Using a Personal Development Plan for different purposes and its influence on learning & performance
Assessment methods, Assessment of Competence, Professional Development

Simon Beusaert, Maastricht University, Netherlands

Mien Segers, Maastricht University, Netherlands

Wim Gijselaers, Maastricht University, Netherlands

Today, organizations are increasingly implementing assessment tools such as Personal Development Plans. Although the true power of the tool lies in supporting the employee's continuing professional development, organizations implement the tool for various different purposes, professional development purposes on the one hand and certification/selection/accountability purposes on the other (Smith & Tillema, 2001). The study presented here aims at a better understanding of how the purpose of the Personal Development Plan (PDP), as perceived by the employee, influences the extent to which s/he undertakes learning activities and consequently leads to improved performance. Data were collected from 286 employees working in a regional Dutch tax office and 81 experts from an international organization that is specialized in medical technology (n=367). Data were analyzed by conducting hierarchical regression analyses. Results indicate that perceiving the PDP either as a learning and development tool or as a certification and selection tool, positively predicts the undertaking of learning activities and the employee's performance. Follow-up regression analysis indicated that the most powerful predictor of undertaking learning activities and a high-quality performance is the extent to which employees perceive PDPs as serving learning and development purposes. The results of this study suggest that if an organization wants their employees to learn by undertaking learning activities and in turn perform better, the tool should in the first place be introduced and used as a learning and development tool.

1. Aim Today, organizations are increasingly implementing assessment tools such as Personal Development Plans (PDPs) to stimulate employees to intentionally undertake learning activities and in turn improve workplace performance (London, 1997; van de Wiel, Szegedi, & Weggeman, 2004). In general a PDP can be described as an assessment tool embedded in a larger assessment cycle of development and performance interviews; used to gather and document information about the competencies the employee worked on and is planning to further develop (Beusaert et al., 2010). It is argued that although there is a trend towards using the tool for performance appraisal

(summative assessment), the power of the tool lies in supporting employees' professional development (formative assessment) (Darling-Hammond & Snyder, 2000; Smith & Tillema, 2003). Some authors even wonder whether a single assessment format such as a PDP can serve different purposes at the same time (Dochy & McDowell, 1997; Wolf & Dietz, 1998). For example, different authors question whether PDPs can be discussed in development interviews as well as in appraisal interviews, conducted by one and the same supervisor (e.g. Beck, Livne & Bear, 2005; Wolf & Dietz, 1998). When using the tool for both purposes at the same time, the purpose of the tool as well as the guidelines and the structure are not always clear (Smith & Tillema, 2003). In this respect, it is argued that one of the quality standards of assessment is making the purpose of the assessment clear (e.g. Tillema, 2003), especially in the case of PDPs because of the potential differences in content of and approach to the tool (Arter & Spandel, 1991). When it is not clear what the PDP strives toward, this jeopardizes the quality of the assessment practice. Employees' self-protection and fear of underachieving may lead to the collection of unauthentic evidence and the construction of invalid PDPs, instead of PDPs that openly reflect on the employee's learning and development (Smith & Tillema, 1998, 2001). On the contrary, other authors believe that information gathered during the learning or development process can be very useful for summative evaluation (e.g. Snyder, Pippincott & Bower, 1998). Despite the many arguments elaborated upon in literature, there is hardly any evidence on the effect of implementing PDPs for different purposes. The study presented here aims to contribute to a better understanding of how the purpose of the PDP, as perceived by the employee, influences the extent to which s/he undertakes learning activities and in turn, leads to improved performance. Based on the aforementioned literature, the following hypotheses are formulated: H1. Perceiving the PDP as a (organizational and individual) learning and development tool predicts the employee's undertaking of learning activities and the employee's performance significantly positive. H2. Perceiving the PDP as a selection and certification tool predicts neither the employee's undertaking of learning activities, nor the employee's performance significantly positive. H3. In the case both learning/development and certification/selection goals are taken into account, perceiving the PDP as a learning and development tool is the most powerful predictor of the employee's undertaking of learning activities.

2. Method Two organizations participated in the research. Participants are 286 employees (response rate 20%) of a regional Dutch tax office and 81 employees (response rate of 41%) from an international organization that is specialized in medical technology. For an overview of the different measures, example items, and Cronbach's alphas, we refer to Table 1. Data analysis was done by calculating descriptives and conducting correlational and regression analyses. Table 1 Overview of the different scales and their descriptives

Scale	N	Alpha	Example items
The perceived nature of the goals			Indicate on a Likert scale going from 1 to 5 in which way your organization is striving for the following goals by implementing PDPs:
Personal learning and development goals	3.89		Stimulate reflection or learning.
Organizational learning and development goals	4.88		Stimulating collaboration with colleagues.
Certification and selection goals	4.76		To delivering evidence to my supervisor.
Outcome variables			
Undertaking learning activities	6.90		Because of using a PDP I look up things in books, journal or on the internet.
Performance	6.97		Since I am using a PDP and have related meetings, the quality of my work improved.

3. Findings The correlational analysis indicate that the three different goal components correlate significantly positive with Undertaking learning activities and Performance. To examine the independent effect of the three perceived goals components on the employee's undertaking of learning activities and performance, three hierarchical regression analyses were executed. The findings indicate that personal as well as organizational learning and development goals predict the employee's undertaking of learning activities ($b = .18$; $p = .020$; $p < .05$) and performance ($b = .35$; $p = .033$; $p < .05$) significantly positive, which confirm Hypothesis 1. In contrast to our expectations, the Certification and selection goals also predict the undertaking of learning activities ($b = .14$; $p = .014$; $p < .05$) and the employee's performance ($b = .29$; $p = .029$; $p < .05$) significantly positive, which is not in line with Hypothesis 2. However, in order to determine which goal component is the most powerful predictor of the employee's undertaking of learning activities and performance, we conducted subsequently hierarchical regression analyses. The results show that organizational learning and development goals is the most powerful predictor of undertaking learning activities ($b = .14$; $p = .014$; $p < .05$). Next, the performance of an employee is more likely to improve because of the PDP if s/he perceives the assessment tool as a learning and development tool (personal: $b = .17$; $p = .017$; $p < .05$) and not as a certification and selection tool (not significant).

4. Theoretical and educational significance of the research Theoretical significance. To our understanding this is the first quantitative study that researches the influences of the different perceived purposes of the PDP on the undertaking learning activities and performance in an organizational context.

Practical significance. This study has implications for human resource development in organizations. First, in order to stimulate employees to undertake learning activities and improve their performances by using a PDP, introducing and using the PDP as a tool for learning and development is the most effective. Second, this research leads to the question: How to balance between certification and selection purposes on the one hand and learning and development purposes on the other, knowing that learning and development purposes are stronger predictors of undertaking learning activities and performance? First, keep learning and development interviews separate from performance interviews and have them conducted by a different person. Second, make a distinction between the criteria used for discussing the PDP during the learning and development interviews and the criteria used during performance interviews.

Exploring new horizons: teacher professional development through networked learning
Continuing professional development in Teachers, Professional Development, Social interaction

Daniel Van Amersfoort, Open University, Netherlands

Monique Korenhof, Open University, Netherlands

Nienke Moolenaar, University of Twente, Netherlands

Maarten De Laat, Open University, Netherlands

In educational practice and policy, teachers' professional development initiatives are catering to the notion that teacher learning is situated in a dynamic social context. One way in which teacher learning is shaped in practice is through networked learning. However, empirical evidence of networked learning as a means of teachers' professional development is scarce. The aim of the study was to examine teachers' perceptions of, and experiences with, networked learning to explore core concepts of teachers' networked learning in primary education. This article reports on an exploratory case study among primary school teachers of ten learning networks in two school districts in the Netherlands. We used constant comparative analysis in combination with an input-process-output approach to code the transcribed interviews on teachers' perceptions of networked learning. Findings indicated that teachers' perspectives on, and experiences with networked learning can be attributed to five main aspects referring to pre-conditions for networked learning (input), four main aspects related to the process of networked learning, and five main aspects pointing at output of teacher networked learning. Moreover, we found evidence of feedback loops connecting the input, process, and output stages. Insights from this study provide meaningful understanding of teachers' professional development through networked learning and the factors that constrain and support teachers' networked learning in daily practice. It is through these networked learning experiences that teachers' professional development will permeate teachers' daily practice and, ultimately, improve instructional practice.

PAPER PRESENTATION

Languaging and identities in the construction and organization of 'Swedish for immigrants'.

Jenny Rosen, University of Dalarna, University of Orebro, Sweden; Sangeeta Bagga-Gupta, University of Orebro, Sweden

This study draws upon ongoing research in Project-KIK, Categorization of Identities and Communication. Project-KIK is interested in social practices in a tailored education for adult immigrants in Sweden and the discourses framing it. The theoretical framework employed approaches language policies in terms of a dialectical relationship between the policies (macro level) and the learning that takes place in the language classroom (micro level). Our empirical material consists of audio- and video recordings of everyday interactions at an institutional arena constituted under the name of "Swedish for immigrants (Sfi)".

Our preliminary analyses illustrate among other issues, how multilingualism and monolingualism in Sweden are reflected in and negotiated through everyday interaction and the social practices in classroom settings. By highlighting empirical examples from two separate language learning classrooms, we discuss how different learning environments are created in relation to how teachers and students negotiate their understandings of languages and identities. The understanding of Swedish as the principal and only language used for communication in this institutional setting is challenged by the multilingual languaging practices that the students employ. As a result, different opportunities for the students (both in terms of learning as well as constructing and negotiating identities), are constituted.

The study presented here draws upon the ongoing work in project-KIK, Categorization of Identities and Communication. Project-KIK is interested in both the social practices and the discourses that frame a tailored education for adult immigrants in Sweden. It focuses on conceptualizations and the "doing" of languages and identities in the specific institutionalized arena that emerged in the post-world war II period with the intention of teaching Swedish language to adult immigrants in the nation-state of Sweden.

Research concerned with the language situation of adult immigrants in different European national contexts is not uncommonly founded upon an understanding of languages in terms of being standardized, static and with defined (often national) boundaries. For example, there is an established body of literature that focuses on language policy and politics at the societal (or macro) level, with an emphasis on the legal rights and policies in different nation states. Our interest in languages lies in their dynamic and fluid nature and embraces the theoretical perspective found in dialogism (e.g., Linell 1998, 2009). This entails that our approach to language policies is both multidimensional and complex.

The theoretical framework employed in the study that is presented here approaches language policies in terms of a dialectical relationship between policy (macro level) and the learning that takes place in the language classroom (micro level). The study presented here explores how policies regarding languages are reflected in the organization of language learning for adults. More specifically, we focus upon issues of multilingualism and monolingualism and show how these are oriented towards in the mundane, everyday social practices in classroom settings. The Swedish Language Act from 2009, maintains that 'Swedish is the principal language in Sweden', and that 'all residents of Sweden are to be given the opportunity to learn, develop and use Swedish'. The Act furthermore decrees that persons with "a different mother tongue" are to be 'given the opportunity to develop and use their mother tongue'. The tension between Swedish as the principle language on the one hand, and a recognition of multilingualism on the other, and which is reflected in such central policy documents, comes also alive in the language learning classroom.

Using empirical examples from our ongoing study, we show how questions regarding the status of Swedish and multilingualism are not only issues of debate on a macro level, but are (i) reflected in and (ii) discussed by the members of the language learning classroom and (iii) shape languaging activities there. KIK-project encompasses approximately 85 hours of audio and video materials and ethnographic field notes from five different classroom settings at an institutional arena that is called "Swedish for immigrants (Sfi)". Members in the typical Sfi classroom include 10-20 adult immigrants with diverse linguistic experiences and cultural resources. A variety of monolingual Swedish language textual materials are used in these classroom settings. The diversity of the students in the classroom with regards to their educational and linguistic experiences is understood, in the specific institutional setting of 'Swedish for immigrants', as a challenge for the organization of learning and instruction. In this presentation, we juxtapose empirical examples from two different types of classrooms: in the first, the institutional categorization of the students is done in terms of "limited educational background". Most of these students have at the time of the field study been enrolled in the educational program for one semester. In the second classroom, the students are categorized in terms of "long educational background" and the students in the project classroom had been enrolled from a period of a couple of weeks to approximately one year.

Through our analyses, we discuss how different learning environments are created following how teachers and students negotiate their understandings of languages and identities in the classroom. The understanding of Swedish as the principal and only language used for communication in this institutional setting is contrasted with more multilingual languaging practices that the students employ. Our analysis raises issues regarding different types of

opportunities for the learning of Swedish as well as the ways in which identities are constructed and negotiated in the two different settings. In an environment, in which students multilingual resources are acknowledged and seen as a tool in the institutional target language learning, students are also given the opportunity to constitute a multilingual identity in their new country of residence. In contrast, when the students' use of their linguistic resources is subverted, students use resources to challenge the "Swedish only norm", rather than focusing on the language learning. Empirical examples will be used to illustrate these tensions.

PAPER PRESENTATION

Teachers' Mutual Understanding - A Systematic Analysis of Talk with Two Approaches

Inger Osterlund, Abo Akademi University, Finland; Varpu Tissari, University of Helsinki, Finland

Mutual understanding among teachers has an impact on development of school and students' success. The present study highlights the complexity in dialogues which signify the use of different approaches when analysing the data. The aim is to analyse teachers' mutual understanding during meetings by using different methods of analysis. This micro educational study on social interaction, analyse video records from teacher meetings, which are part of the data from two larger case studies. The first case study examines the multi-professional cooperation of an elementary school teacher and a subject teacher whilst they are planning a field visit to a nature school. The second case study investigates changes of codes in the collegial talk of secondary school teachers at a formal teacher meeting. Theoretically, the selected excerpts are examined from the sociocultural theories of learning, and from the sociolinguistic perspective. Methodologically, the excerpts are scrutinized by analysis of communicative functions, and according to the multimodal analysis. The results from the multimodal analysis point out a few utterances to the situated meaning that are accepted but not heard, or tolerated. The analysis of communicative function provides further insight on the thematically different communicative functions embedded in the interaction of teachers participating at the meeting. The results provide a diversity that indicates how a systematic outlining of the data varies. Thus, the study may stimulate networking of teachers both in virtual and face-to-face interaction.

Mutual understanding among teachers and between teachers and other professionals cooperating has an impact on development of school and students' success (Little, 2010; 1990; Willman, 2001; Fullan, 2002; Hargreaves, 2003). The ways in which such mutual understanding is constructed during teachers' talk vary and depend on which entries are chosen to explore talk.

In this micro educational study on social interaction, the authors analyse video records the teacher meetings, which are part of the data examined in two larger case studies (Yin, 2003). The first case study examines the multi-professional cooperation of an elementary school teacher and a subject teacher whilst they are planning a field visit to a nature school, in which the latter is working as a nature school teacher. The second case study examines changes of codes (Bernstein, 1990; Bourdieu & Passeron, 1990; Goffman, 1981; Goffman, 2000; ; Grenfell & Kelly, 1999; Lemke, 2007; Moore, 2006; Schiffirin, Tannen, & Hamilton, 2001; Tannen, 1998; Tannen, 2005) in the collegial cooperation of secondary school teachers at a formal teacher meeting.

The aim is to explore and analyse the construction of mutual understanding of teachers participating in the meetings, by using different perspectives and analysis methods. The objectives are to examine the teachers' talk in order to understand how teachers orchestrate their interaction with each other, and to analyse the obstacles and opportunities in such situations.

A sequence of the video data from both of the case studies is analysed by exploring the interaction and talk of teachers. Theoretically, the selected excerpts from the data from both case studies are examined from two perspectives. The first perspective draws on the sociocultural theories of learning (Packer & Goicoechea, 2000), and the second perspective draws on the sociolinguistic perspective using Bourdieu (Bourdieu & Nice, 1986) and with an interactional input from Gumperz (Schiffirin, 1994; Schiffirin, Tannen, & Hamilton, 2001) through Tannen (1989; 1998; 2005).

Methodologically, the excerpts from the data from both of the case studies are scrutinized by the analysis of communicative functions, and according to the multimodal analysis. The former sheds light on the thematic nature of interaction, and also on its moment-by-moment construction in the ongoing interactions (Kumpulainen & Wray, 2002; Kovalainen & Kumpulainen, 2005; Kovalainen, & Kumpulainen, 2007). The latter refers to the problematic in breaking up interaction into separate modes. This problem is overcome by looking at all the modes together at the same time, and examining how the modes interact in a small scale of data for a later exploration in the larger scale of data. (Jewitt, 2009; Bezemer & Jewitt 2010.)

The research questions are the following: 1. How mutual understanding is constructed during teachers' talk? 2. What may be the obstacles and opportunities for analyzing the talk with different methods of analysis?

The preliminary results from the multimodal analysis point out that the informing part of the meetings is dominating. However, when teachers' talk is addressed and when they form spaces for negotiations with arguments, the mutual understanding is shaped by cultural codes and quick changes of codes. A few utterances are left unnoticed which draws attention to the situated meaning as accepted but not heard, or as tolerated. The communicative functions provide insight on the thematically different communicative functions embedded in the interaction of teachers participating at the meeting. Both analysis methods are influenced by the debate of social relations in communicative practices that are in nature more for bringing in positive than negative influences.

Firstly, the results relate to the social capital and trustful networks within heterogeneous groups where both weak and strong ties (Coleman, 1990) are essential for mutual understanding. Secondly, non-verbal communication influence in the negotiations (Auer & Di Luzio, 1992; Duranti & Goodwin, 1992; Mercer, 2000; Tannen, 1989; Norris, 2004), and in the effort of finding a solution that is accepted or at least tolerated by the members (Firth, 1995; Naquin & Kurtzberg, 2009). Though the dialogues and utterances in the examples are chosen to explain the main objective of mutual awareness, it is impossible to generalize. Every speech event and utterance is strongly attached to the spatial and the contextual settings that are unique and will never occur again.

As a conclusion, the results of the analysis from different perspectives provide a diversity of systematically outlining the data. Therefore, the potential of teachers' talk and social interaction highlight differences either in the cultural sense, as different cultural codes, or in the subject, as differences in ontology and epistemology, even if the focus is the same. It is of significance to go beyond oneself, and extend the understanding even if the mutual understanding is not reached but only tolerated. Finally, the analysis in this study highlights the complexity in dialogues and multipart talk which signify the importance of the different approaches and data.

The paper argues for the essential to approach a problem, which is multifaceted, from different standpoints. The key elements (namely, talk, artefacts, gazes, gestures, etc.) in critical situations are paving the way to move forward. Therefore, the data is analysed first in a small scale, and later on in a large scale. Finally, the paper focuses on the critical situations in talk that may change overtime and space, to stimulate cooperation and networking of teachers both in virtual and face-to-face interaction.

PAPER PRESENTATION

"What's a Fourth? What's a Fifth? What's the Point?": Constructing Definitions in Scientific Inquiry

Leslie Atkins, California State University, Chico, United States; Irene Salter, CSU, Chico, United States

In a class for preservice teachers, undergraduate students observed and attempted to explain complex phenomena related to light and color. In doing so, they frequently invented terms which were negotiated and refined by the class, and some became precise, stable, and useful terminology. These include invented terms (e.g., "the seconds" and "kooshing") and everyday terms (e.g., "focus"). In this paper we provide an analysis of the evolution of one of these terms, "the seconds," and how demands of intersubjectivity, together with theory, observation, and utility, shape the evolution of the definition. In the analysis, we see not only improvements in students' understanding of light, but a shift towards academic discourse registers and a nuanced understanding of the role of definitions in science

Objectives

A debate regarding the definition of a "personal epistemology" recently appeared in the Journal of the Learning Sciences as Sandoval (2009) argued that clarity of definition is necessary for theoretical progress, while Elby (2009) countered that theoretical progress must precede the definition. "The scope of personal epistemology should not be decided entirely a priori," Elby claims, "it is more productive not to converge on a definition until further empirical and theoretical progress points us toward the best way to 'cut up [nature] ... along its natural joints'" (p. 64). We point this out not to make a statement regarding personal epistemology, but definitions. Many curricula take a "front end" approach: students are given precise definitions and they use these to enable progress on understanding key ideas. An alternative is an "iterative" approach: allow for students' inquiry to make theoretical and empirical progress before definitions reach scientific precision. There is little work, however, on how we might facilitate student inquiry to promote this iterative process, or even what such iteration might look like. The paper will describe the evolution of the definition ("the seconds") that undergraduate students constructed in a course on scientific inquiry, and addresses the question of how and why this term changes over time. We will argue that, through the communicative need to agree on a definition, theory and experiment are advanced, and students develop a shared understanding of

characteristics of light, constructing a nuanced and scientific definition that balances pragmatic constraints with theoretical ideas.

Framework and methods

Two theoretical perspectives guide our interpretation of student ideas: idealized cognitive models and knowledge-in-pieces. Idealized cognitive models were introduced by Lakoff (1990), arguing that categories arise from cognitive models that carve out a space for terms. Such models vary in size and stability; they may be constructed on the fly (Barsalou 1983) and still maintain the structure characteristic of common categories. When analyzing student terminology and the stories that provide boundaries to those terms, we take a knowledge-in-pieces framework (diSessa 1988), interpreting utterances not as evidence of beliefs but stories constructed in the moment and sensitive to context. In approaching the question of how the terminology is shaped by student inquiry, we employ Interaction Analysis (Jordan and Henderson 1995) and recent work on intersubjectivity (Nathan, Eilam et al. 2007). Transcripts are analyzed for evidence of repairs (Schegloff 1992), and how such repairs modify participants' initial descriptions. Data comes from a course, Scientific Inquiry, for undergraduate preservice elementary teachers. Every class session is videotaped, and digital copies of student work are kept, and our analysis focuses on identify events that cause shifts in terminology (here, the term is the "seconds").

Data

In the second week of the course, there are two competing ideas to explain the observation of "fuzziness" on the edge of a spot of light (Fig. 1): light "bends" around corners or "bounces" along walls. In a small-group conversation, Amanda terms these bounced rays "the seconds." The following day the whole class works to understand Amanda's idea. Below, we provide a few critical turns in the discussion of "the seconds" that foster evolution of the term. 4. Allie: [Fig. 2]...Whites are the firsts— they all get reflected...— pinks are the seconds... each time it hits a wall you add one, pretty simply. 5. Breanna: It's gonna get dimmer and dimmer...That's why we were talking about how it matters if it's a second or third or fourth. Because every time it hits something it's going to get dimmer. Other students disagree with their diagram and, by turn 30, students have noted several differences in their diagrams of "seconds," with one student (Dee) pressing for representational conventions. In time, her request is recast not as mere convention, and students identify empirical and theoretical work required to clarify the term: 31. Breanna: I don't think it matters what it hits off of as long as it hits off of something then it should be called a second. And if it hits something twice, it's a third...40. Allie: ...the mirror makes a huge difference because the the mirror does not act like a wall. It reflects much differently. ... 52. Dee: So I guess the real question is: 'when it hits the mirror is any of the light absorbed.' Because to me the definition of a second is 'when it hits something, some of the light is absorbed so not all of it is coming back out.' ...60. Steven: I think it's going to be extremely hard to differentiate what's a second, what's a third... what's the point? Might as well just break it down to 'primary light' and 'secondary light.' Like anything secondary and after will be obvious. ...We must have some agreement on definitions in order to communicate effectively, but the terminology must also agree with something useful - a 'carving at the joints' of things we wish to understand. Steven argues that distinguishing seconds from thirds is pointless for our activity: we can understand the "fuzzy edge" as being caused by light that bounced, regardless of how many times.

These interactions drive empirical investigations, which then inform the iterative development of the definition of the term, "the seconds." To create terminology, as Lakoff suggests, is to model: to construct a story that carves out relevant objects that are given names. The stories may be constructed on the fly, with terms that are provisional and contextual. These stories, however, have an audience, and the need to establish intersubjectivity with this audience drives the modification of stories; the group artifacts serve to drive stability of the stories, and, concomitantly, the terminology develops "hard edges." Over time, this interaction creates terminology that is increasingly stable, precise and clear.

This proposal highlights students' initial steps at constructing and refining terminology; a final paper will include a more complete story of the terminology that students ultimately constructed, the interplay of experiment and theory that, together with interactions, led to the final definition, and a more detailed description of methodology.

PAPER PRESENTATION

Newcomers' Learning in Communities of Practice

Julia Eberle, Ludwig-Maximilians-University Munich, Germany; Karsten Stegmann, Universtiy of Landau, Germany; Frank Fischer, Universitat Munchen, Germany

Learning in communities of practice is mainly informal without explicit learning goals. Newcomers start as peripheral members and become active members as their "community knowledge" grows. This process of newcomer's learning in communities of practice is only vaguely described as legitimate peripheral participation and hardly studied

empirically. Thereby, it is hard for communities to support newcomers learning process: knowledge on effective means how to facilitate the integration of newcomers is lacking. Approaches from group research on socialisation tactics may fill the gap. Therefore, we investigated to what extent group size, time, and different socialisation tactics as an addition to the process of legitimate peripheral participation are related to the integration of newcomers in communities of practice. A correlation study on 16 German student associations with overall 223 members was conducted using social network surveys to measure the level of integration. In interviews with experienced community members, data about tactics to foster the integration of newcomers were collected. Five socialisation tactics could be identified. In a HLM analyses two of them (positive welcoming strategies and accessibility of knowledge) showed to be significantly related to the level of integration. In this model also group size was included, which was negatively related to the level of integration, while the factor time itself played no important role. Therefore, we assume that combining the concept of communities of practice and legitimate peripheral participation with theories from group research is a promising approach for a better understanding of the learning process of newcomers in communities of practice.

Learning by working on a shared topic with a group of people, like on an open source software project, is mainly informal and explicit learning goals can hardly be defined. Groups of people who work together on a topic for some time have been conceptualised as communities of practice (CoP). Barab and Duffy (2000) define a CoP as an interdependent system that puts the individual into a larger context and provides meaning for being and acting, based on a common cultural and historical heritage of shared goals, understandings and practices among the members. Newcomers who are integrated in a CoP undergo a complex process of learning and enculturation that shapes their identity as an active member of a larger system. Lave and Wenger (1991) describe this process as legitimate peripheral participation (LPP), which seems mostly to be a matter of time that a newcomer spends in the CoP. However, this concept is so far not very well empirically investigated. Promising approaches to expand the understanding of the LPP process can be found in group research. Regarding socialisation of new employees in work groups, socialisation tactics have been found influential means (Saks, Uggerslev, & Fassina, 2006). Levine and Moreland (1991) collected important tactics, used by work groups to foster the socialization process of the newcomers; e.g. encapsulation describes activities in which older group members encourage newcomers to spend their time for the CoP and with its members. Positive welcoming strategies as another example are used, when groups try to welcome newcomers in a friendly way. In addition to this, group size has been shown to influence individual thinking and behaviour in (work) groups, e.g. voluntary turn-over rates (Hausknecht, Trevor, & Howard, 2009). This leads to the assumption that the size of a CoP could also influence integration processes of newcomers. So far it is unclear what factors structure, support or hinder the LPP process of newcomers in CoPs. We assume that the learning process is not only a matter of time, but that specific socialisation tactics are used by CoPs that shape this learning process.

Research Question

To what extent can group size, time, and the use of socialization tactics predict the integration of newcomers in CoPs? Method 223 members of 16 student associations from the University of Munich participated in this study. They were chosen as an example for CoPs as they fulfil all three criteria defining a CoP mentioned above: they are an interdependent group with a shared cosmology and a reproduction cycle. The level of the members' integration in their CoP at a certain point in time was computed for every newcomer, based on data of a social network survey. In this survey all members were asked to indicate how intensively they had worked with each of the other members during the last three months. Additionally a semi-structured interview was conducted with an experienced senior member of every student association. In this interview participants were asked how their CoP had proceeded to integrate newcomers and were then asked about the socialisation tactics described by Levine and Moreland (1991). Via a content analysis a value for the use of the found integration mechanisms was then achieved for every CoP. An exploratory stepwise multi-level regression analysis (HLM) including the individual and the CoP level was applied to test the research question.

Results

Five socialisation tactics were found that the CoP members reported to use to foster the integration process of their newcomers: supporting legitimate peripheral participation, positive welcoming strategies, accessibility of community knowledge, encapsulation, and providing information about the CoP to potential newcomers before their entry. To explore which of those aspects are actually relevant to the process of newcomer integration the found tactics and the group size were step-wise included into a multi-level regression model which in the beginning only included time to predict the level of integration. In the final model the level of integration was negatively predicted by group size ($\beta = -0.139$) and positively predicted by positive welcoming strategies ($\beta = 0.716$). Time alone had no significant effect ($\beta = 0.025$), while it predicted the level of integration negatively in combination with positive welcoming strategies ($\beta = -0.118$) and positively in combination with accessibility of knowledge ($\beta =$

0.047). In short, newcomers are better integrated in smaller groups. They are integrated faster if the groups focus on knowledge access strategies. However, the explanation of the influence of welcoming strategies is more difficult: newcomers in groups that use this strategy are better integrated in general, but slower compared to groups that put less effort in positive welcoming strategies.

Conclusions

Our results provide evidence that combining the idea of LPP and theories from group research is a promising approach to a differentiated understanding of the underlying mechanisms of learning processes in CoPs. Five socialisation tactics have been identified in this study and for two of them a significant relation to the learning process in CoPs have been proved. This implies that it seems possible for community members to actively shape the learning process of newcomers and that not every tactic applied and widely used is really effective for learning.

Meta-cognition

"I didn't expect to feel like this" – Affect management and perseverance in doctoral candidature

Robert Cantwell, University of Newcastle, Australia; Janene Budd, University of Newcastle, Australia, Australia;

Jill Scevak, University of Newcastle, Australia

"I didn't expect to feel like this" – Affect management and perseverance in doctoral candidature Janene Budd, Jill Scevak, and Robert Cantwell University of Newcastle, Australia A growing body of research has documented the affective, or emotional, demands associated with PhD candidature, which may include coping with social isolation and the fear of negative evaluation by significant others, such as supervisors, peers, or family, and dealing with uncertainty and intellectual change. Unfortunately, there has been a lack of research attention regarding how these affective experiences are interpreted and managed at the level of the individual PhD student, and the impact of this on persevering with doctoral candidature. To explore this issue, the results from the first phase of a large scale, mixed-methods longitudinal study investigating the metacognitive and affective profiles of over 1200 PhD students from across Australia are presented, and complemented with the results of a small-scale qualitative study of PhD students who were experiencing a 'crisis of persistence', and considering termination of candidature. Together, these findings suggest that although an affective response to the personal changes associated with the transformational nature of higher level intellectual development may be expected in doctoral study, misinterpreting this affective experience can have potentially serious consequences in terms of perseverance with PhD candidature, ranging from unnecessary attrition to suicidal ideation. The results of the two studies will be discussed in terms of the implications for doctoral pedagogy. In particular, we discuss the importance of, and strategies for, helping students to more comprehensively understand and manage the affective experiences associated with doctoral learning, and identify areas requiring further research.

"I didn't expect to feel like this" – Affect management and perseverance in doctoral candidature Janene Budd, Jill Scevak, and Robert Cantwell University of Newcastle, Australia Various aspects of doctoral candidature have attracted much research attention since the recognition of the high attrition and slow completion rates that occur across institutions internationally. The background to this paper is the growing body of research documenting the affective, or emotional, demands associated with PhD candidature, which may include coping with social isolation and the fear of negative evaluation by significant others, such as supervisors, peers, or family, and dealing with uncertainty and intellectual change. Although it is generally agreed that intellectual development is expected to occur during the doctoral research process (e.g. Batchelor & Di Napoli, 2006; King & Kitchener, 2002), Stevens-Long and Barner (2006) have noted that the management of affective experiences accompanying intellectual development in higher education has been largely ignored in the literature. More importantly, there is a lack of understanding of how these affective experiences are interpreted and managed at the level of the individual PhD student, and the impact of this on progressing through doctoral candidature. To address this issue, an ongoing, large-scale, mixed-methods design study

is investigating the affective and metacognitive profiles of over 1200 PhD students from universities across Australia, to provide both cross-sectional and longitudinal data regarding the management of affect during candidature. The study is underpinned by a constructivist learning theory framework, and assumes that there will be individual differences in the application or experience of a variety of metacognitive, affective, and personality factors as students seek to manage the intellectual and other demands of doctoral learning.

The study consists of three components: 1) comprehensive online surveys assessing metacognition, affect and personality, along with demographic and candidature data, conducted at baseline and with a 12 month follow-up, 2) brief online 'journey tracking' surveys conducted monthly for 12 months, and 3) two series of telephone or email interviews. The focus of this paper is an exploration of individual differences in 'perseverance' as a personality trait, based on the initial stages of data collection. While dispositional perseverance was one of many factors assessed in the baseline survey, during the first series of telephone and email interviews for the study it was also identified by the majority of interviewees as a personal quality or characteristic that is central to success in PhD candidature. As a measure of dispositional 'perseverance and passion for long-term goals', the Short Grit Scale (Duckworth and Quinn, 2009), was employed to examine how self-reported perseverance might be related to various demographic or candidature factors, as well as to a number of different measures of metacognition and affect.

The baseline survey data indicated that mean perseverance scores for participants in this study were relatively high compared to the populations of 'high achievers' studied by Duckworth and colleagues (2007, 2009). Consistent with Duckworth, Peterson, Matthews and Kelly's (2007) findings with the original Grit scale, was the positive trend, evident via ANOVA and Scheffe analysis, between perseverance and age. There were no significant differences associated with stage of candidature. Strong and significant positive correlations were found between perseverance and a number of metacognitive measures, most notably with indicators of a student's sense of hope, agency and self-efficacy. To further investigate the responses to the Grit questionnaire, this paper draws on the findings of a small-scale qualitative study undertaken to explore and describe how PhD students discuss the experience of what could be termed a "crisis of perseverance" – a time of intense uncertainty and distress regarding whether or not to persist with the PhD (Budd, Scevak, and Cantwell, 2010). In an approach enabling a more immediate insight into this experience than that offered by retrospective reflections from attrited PhD students, and enhanced ecological validity through the preservation of participant anonymity, a number of public domain online forum discussions for PhD students were analysed to learn more about the factors at play at the time when quitting was considered.

An analytical approach based on grounded theory (Corbin & Strauss, 2008) was used. The findings of the public forum study identified that, at least for these students, uncertainty about their ability or willingness to persevere with the PhD was often associated with a sense of disappointment that the student's expectations of the PhD and of themselves as PhD students were either unmet or mismatched. Many observed in themselves a change from confident and successful graduate, to depressed, lonely, and uncertain PhD student. There was a dissonance between their expected and actual affective experience of themselves as PhD students, an uncertainty about what this meant, and a waning of motivation. Clearly, the students' decisions about perseverance in doctoral study were closely related to their interpretation of the affect associated with the PhD process. Further, these findings suggest that while such affective dissonance may be a common experience among PhD students, it is not well understood. For example, while this type of affective response and personal change may be associated with the transformational nature of higher level intellectual development usually expected in doctoral study, a lack of awareness of this possibility may result in the interpretation of this experience as indicating a lack of personal ability or suitability for the PhD process. The latter certainly appeared to be the assumption on which many students' discussion comments were based.

Analysis of these online discussions highlighted how misinterpreting this affective dissonance can have potentially serious consequences in terms of perseverance with PhD candidature, ranging from unnecessary attrition to suicidal ideation. The results of the two studies will be discussed in terms of the implications for doctoral pedagogy. In particular, we discuss the importance of, and strategies for, helping students to more comprehensively understand and manage the affective experiences associated with doctoral learning, and identify areas requiring further research.

PAPER PRESENTATION

Creating metacognitive environments in primary Religious Education lessons

Shirley Larkin, University of Exeter, United Kingdom

This paper focuses on the RE-flect project. RE-flect was a collaborative mixed methodology research project designed to create metacognitive learning environments in primary year 5 classrooms. Participants were 10 state run primary schools from one UK local education authority area. In total 10 teachers and 250 pupils age 9-10 years took part in the year long project. The aims of the project were to develop activities to enable pupils in RE year 5 primary classrooms

to reflect on and consider their own ontological positions in relation to others; create metacognitively-oriented classroom environments and improve attainment in RE support teachers in developing their own metacognition in order to reflect on their own ontological positions.

The project draws on theories of metacognition and metacognitively oriented learning environments. The paper provides findings from the quantitative pre and post test measures of attainment in RE and from a scale, REMOS designed to measure pupils' perceptions of their learning environment. An illustrative case study of one school in the project suggests the systemic and local obstacles teachers and pupils face in creating metacognitive environments in religious education lessons.

This paper describes a year long collaborative project between a team of university researchers and ten primary school teachers. The project, RE-flect, was designed to create metacognitive environments in year 5 primary religious education lessons. The guidelines for Religious Education in English Schools: Non-statutory Guidance 2010 (DCSF, 2010) are challenging, suggesting that RE should cover a wide range of goals from provoking questions about the meaning and purpose of life and what it means to be human; to encouraging pupils to explore their own beliefs as well as contributing to community cohesion by promoting tolerance. School inspectors and professional inter-faith groups have criticised the provision of RE in primary schools (Ofsted, 2007). In particular it was found that pupils do not gain a secure conceptual framework within which to fit their learning and teachers lack confidence in teaching a subject in which they are not specialists. It has been suggested that pupils cannot engage with others without first understanding their own beliefs and values ((Inter Faith Foundation, 2006). Without developing the skills to reflect on their own thinking pupils often view RE as simply a "matter of opinion" (Freathy & Aylward, 2010) and thus oversimplify the nuances of difference within faiths as well as the complexity of identity and culture more generally. Baumfield has suggested that the study of pedagogy in RE is "underdeveloped" (Baumfield, 2010). This paper argues that there needs to be a shift in emphasis away from research on content (Hayward, 2006; Rymarz, 2007) or the extent to which the representation of religious traditions may be considered truly authentic (Everington, 1996; Greaves, 1998) or representative (Jackson, 2004; Nesbitt, 2004) towards an emphasis on the pupils' "response, thinking and critical self-awareness" (van der Zee, Hermans, & Aarnoutse, 2006). The RE-flect project seeks to address these specific issues through supporting teachers in creating metacognitive environments.

Metacognition

Metacognition can be defined as everything we know and believe about our own and others' cognitive processes and the regulation and control of our own thinking (Flavell, 1979). Flavell suggested metacognition enables us to "make wise and thoughtful life decisions" (ibid pg910). This project views metacognition as enabling self understanding through a reflection on one's own thinking, beliefs, epistemological stance and values. In this way, metacognition prioritises knowledge of self before engagement with the other. Research indicates that it is not enough to train teachers to facilitate metacognition (Zohar, 2006). Teachers need to develop their own metacognition (Duffy, Miller, Parsons, & Meloth, 2009). It is plausible that some of the difficulties encountered by non-specialist teachers of RE are linked to a lack of metacognition.

This project aimed to provide teachers with a framework for developing activities, pedagogy and classroom environments to support the development of metacognition. There is a focus on metacognitive orientation. Metacognitive orientation refers to the extent to which psychosocial conditions that are known to enhance pupils' metacognition are evident within classrooms. The characteristics of metacognitively-oriented learning environments (Thomas, 2003; Thomas & Mee, 2005) suggest that the beliefs and practices of the communities within which students learn to learn and reason strongly influence their metacognition; that specific language plays a key role in relation to communication regarding thinking and learning processes to and between pupils, and that pupils require particular encouragement if they are to reflect on, critique and possibly alter their thinking processes.

Participants

250 pupils aged 9-10 years in 10 different state run primary schools from one UK education authority
10 teachers with a responsibility for teaching religious education in these schools.

Research Aims to:

develop activities to enable pupils in RE year 5 primary classrooms to reflect on and consider their own ontological positions in relation to others; create metacognitively-oriented classroom environments and improve attainment in RE support teachers in developing their own metacognition in order to reflect on their own ontological positions.

Methodology

This is a collaborative project with a mixed methodology design. Pre and post quantitative measures are illuminated by qualitative data collected during the project. Individual case studies of classes within the project provide detail of the classroom practices developed during the project.

Data Collection and Analysis related to the above aims

1. Pupils create "world view profiles" during the project – analysed qualitatively with a focus on ability to express thinking; ability to reflect on ideas and sophistication of ideas expressed
2. Pre, predicted and post level of attainment in RE using standard UK assessment Pre and post scores on REMOS a scale developed to measure pupils' perceptions of the metacognitive orientation of their classroom environment Pre and post semi-structured interviews with 6 focus children in each class 3x10 semi-participant classroom observations, including video capture of the lesson and activities - data analysed qualitatively using NVIVO and related to a theoretical framework of metacognition
3. 3 methods of developing teacher metacognition – repertory grids, reflective diaries and on-line discussion - data analysed using content analysis, concordance analysis and discourse analysis

EthicsBERA ethical guidelines were adhered to. Special consideration was given to ethical issues surrounding using reflective diaries as data and to supporting participants through the processes of producing repertory grids and reflecting on thinking.

Findings

The paper presents headline findings from the pre and post measures along with an illustrative case study which illuminates the way teachers and pupils worked together to create metacognitive environments in one RE classrooms. Preliminary data is showing that teachers face a number of system level challenges to creating such environments, these are connected to UK policy on religious education in primary schools and to wider educational factors such as whole school attainment targets. The project ends in July 2011 when the quantitative data will be available.

Discussion and ImplicationsThe paper will discuss the findings in relation to theories of metacognition and the creation of metacognitive environments. Implications for teacher development will be drawn and suggestions for future research made. It is not possible to detail these implications until the project ends.

PAPER PRESENTATION

Rethinking the scope of Metacognition: a multi-dimensional account

Robert Cantwell, University of Newcastle, Australia; Jill Scevak, University of Newcastle, Australia; Sid Bourke, University of Newcastle, Australia; Krystyna Cholowski, University of Newcastle, Australia

In this paper, we report on a study of metacognition in PhD students, examining the possibility that identified individual differences may well reflect variations at an epistemic rather than componential level. Following Veenman et al. (2006), we speculate that the scope of metacognitive knowledge includes more than strategic regulation. We suggest metacognitive knowledge also provides a higher order, multi-dimensional dispositional framework that guides the affective, intellectual and contingency appraisals individuals must make in generating regulatory decisions.

263 PhD students completed measures relating to the management of intellectual, affective and contingency demands in candidature. A two-step cluster analysis discriminated two groups differing significantly across all measures. Factor analysis identified three dimensions to the responses: "Coping" with the intellectual, affective and contingency response demands of learning; "Naivety" in conceptualising the intellectual demands coupled with a diminished sense of competence and commitment; and "Disengagement", through diminished understanding of the intellectual demands combined with an abrogation of responsibility for progress. Third, analysis of variance indicated that Cluster 1 members more highly Coping, Cluster 2 members more highly on Naivety and Disengagement.

We interpret these results as evidence of the multi-dimensional nature of metacognitive knowledge. The differences in the strength and direction of affiliation with the three factors (Coping, Naivety and Disengagement) by the two groups suggest differences in the qualities of the active metacognitive knowledge base driving engagement with the doctoral task. Such differences in epistemic metacognitive frameworks have the potential to provide explanations of problematic candidature and inform developments in supervisor pedagogy.

Traditionally, metacognitive research has focused on self-regulatory capacities and their relationships to planning, monitoring and evaluative behaviours. More recently, research has begun to extend the remit of metacognition in learning to minimally acknowledge the relationships between regulatory decision-making and other, perhaps more general, domains of individual differences. Veenman et al., (2006) gave impetus to this process by identifying the need to examine metacognition in the context of other individual differences, although they did not extend this to suggest a more general unified metacognitive construct to account for individual differences in learning. Nonetheless, there has

been some movement in extending the scope of explanation of effective metacognitive activity. A recent special issue of the journal "Metacognition & Learning" (April, 2010), for example, considered the relationships between epistemology and metacognition. For many of the contributors, the link between epistemic beliefs and metacognitive behaviours was emphasised, giving rise to at least some degree of a recognition of the potential mutuality between epistemological and metacognitive beliefs (see Mason et al, 2010; Richter & Schmid, 2010; Muis & Franco, 2010; Bromme, Pieschl & Stahl, 2010). It is our position that this observed link represents only one of many potential associations between domains of individual differences and regulatory behaviour (see Veenman et al. 2006) and that the aggregate of these potential associations may provide evidence of a more generalisable model of metacognition that explicitly acknowledges the interdependence of a multitude of potential sources of individual differences in explaining how specific regulatory decisions are derived and acted upon.

In this paper, we report on a study of metacognition in PhD students. We see the PhD as a useful medium through which the nature of metacognition can be explored. The PhD is first and foremost difficult, requiring candidates to manage intellectual tasks ranging from the basic technical through to those requiring mastery of quite high levels of complexity and abstractness. The PhD also requires completion of a multitude of (related) tasks over an extended time period. Thus the regulatory demands of the PhD exist at many levels, and require maintenance over an extended period of time. Moreover, the PhD is not only about regulation of intellectual activity: it also involves the regulation of affective responses which over time will be as many and varied as evident in the intellectual demands. Finally, as a function of both difficulty and extended time, the PhD also involves the ongoing management of the potential challenges and difficulties in candidature: how the student responds to contingency is also an issue of regulation.

In this study, 263 PhD students completed a battery of instruments relating to the management of intellectual demands (Need for Cognition, Metacognitive Awareness, Epistemological Beliefs), affective demands (Efficacy, Coping) and contingency demands (Volition, Responsibility, Procrastination) of candidature. The analysis focused on three questions: a) whether, as an elite cohort, doctoral students could nonetheless be discriminated on the basis of responses to these questionnaires, b) whether there was an underlying dimensionality to the responses to the questionnaires, and c) whether identified groupings within the cohort differed in their level of affiliation with identified dimensions in the responses. In relation to the first question, a two-step cluster analysis identified two clusters differing significantly across all measures. In relation to the second question, factor analysis identified three dimensions to the responses: "Coping" with the intellectual, affective and contingency response demands of learning; "Naivety" in conceptualising the intellectual demands coupled with a diminished sense of competence and commitment; and "Disengagement", through diminished understanding of the intellectual demands combined with an abrogation of responsibility for progress. In relation to the third question, analysis of variance indicated that Cluster 1 members identified more closely with the Coping factor, while Cluster 2 members identified more closely with the Naivety and Disengagement factors.

We interpret these results as providing evidence for the possibility of a multi-dimensional account of metacognitive knowledge. In the first instance, the cluster analysis provided evidence of heterogeneity within the doctoral cohort. Because the differences between the cluster groups were both significant and spread across all measures, and because these differences were consistently in the appropriate direction, we concluded that the students comprising Cluster 1 had a broader and more strongly internalised base upon which to generate appropriate regulatory interventions. That is, this group likely had, at an epistemic level, a more functional metacognitive framework with which to manage the intellectual, affective and contingency demands of candidature, a framework that included not only the basic self-regulatory skills of conventional descriptions of metacognition, but also the broader epistemological, efficacy, coping and volitional dimensions that provide the conditions for effective regulation to occur. The results of the factor analysis and subsequent ANOVAs gave support to this interpretation. The differences in the strength and direction of affiliation with the three factors (Coping, Naivety and Disengagement) by the two cluster groups suggests differences in the qualities of the active metacognitive knowledge base driving engagement with the doctoral task. Such differences in epistemic metacognitive frameworks, we argue, have the potential to provide explanations of problematic candidature and inform potential developments in supervisor pedagogy.

PAPER PRESENTATION

A New Framework for the Conceptualization of Epistemic Cognition

Clark Chinn, Rutgers University, United States; Luke Buckland, Rutgers NJ, United States; Ala Samarapungavan, Purdue University, United States

In previous work (Authors et al., 2010a, 2010b) we have considered how ideas prevalent in the philosophical literatures of analytic epistemology and the philosophy of science might be used to extend and improve educational research on epistemic cognition. Research on epistemic cognition examines cognitions, especially beliefs, about knowledge and the conditions and processes of attaining knowledge (e.g. Hofer and Pintrich, 1997). Our expanded

framework for models of epistemic cognition includes five categories: (1) epistemic aims and their interactions with non-epistemic aims, (2) the structure of knowledge, (3) the certainty, sources, and justification of knowledge, (4) epistemic virtues and obligations, and (5) the reliable processes by which knowledge is achieved. These categories capture many epistemic topics and concepts that feature in the philosophical literatures, but which have not yet featured in extant educational research. In this paper we further elaborate the framework, and provide a more detailed analysis of how philosophers have elaborated on the topics within these five categories. We also develop systematic analyses of the ways in which educational researchers' conceptualizations of epistemic topics diverge from those of philosophers. We argue that an expansion of the dimensions of models of epistemic cognition provides psychologists and educators with rich theoretical resources that can better explain students' thinking and learning.

A New Framework for the Conceptualization of Epistemic Cognition

Goals

Epistemic cognition refers to cognitions about topics such as knowledge and how people come to attain knowledge. The most prominent framework for conceptualizing epistemic beliefs in current educational research derives from the landmark work of Hofer and Pintrich (1997) which characterizes these cognitions in terms of four dimensions: (1) the degree to which knowledge is viewed as simple versus complex, (2) the degree of certainty of knowledge, (3) the sources of knowing, and (4) the justification of knowing. In this paper we aim to expand on this seminal framework by drawing on philosophical work to identify additional topics that educational researchers could investigate.

Method

We have extensively reviewed two philosophical literatures that discuss epistemological topics: analytic epistemology and the philosophy of science. We analyzed epistemological topics and subtopics covered in 150 significant contemporary philosophical books as well as numerous articles from prominent philosophical journals. From these sources, we developed a list of significant topics related to epistemic cognition. As a result of our analyses, we argue that epistemic cognition should be viewed in a more expansive manner than educational researchers have done. We argue specifically that important topics for researchers of epistemic cognition fall into at least five distinct categories, which we briefly describe below.

A Philosophically-Grounded Framework for Conceptualizing Epistemic Cognition

In previous work (Authors et al., 2010a, 2010b), we have provided a broad overview of the five categories of epistemic topics. In the paper for EARLI, we will provide a much more detailed analysis of how philosophers have elaborated on the topics within these five categories, and we will provide a new, systematic analysis of the differences in the frameworks of educational researchers, on the one hand, and philosophers, on the other. Given the space limitations of this proposal, we can here provide only a brief introduction to topics in these five categories. In our paper and presentation, we will provide elaborated analyses of important topics within each of these categories as well as a detailed analysis of the ways in which educators' conceptualizations of epistemic topics diverge from those of philosophers. We will argue that philosophical work suggests many new issues that could be productively addressed in future educational research. The five categories are as follows:

1. Epistemic aims and their interactions with non-epistemic aims. Philosophers have extensively investigated different kinds of epistemic aims (e.g., acquiring true beliefs, avoiding false beliefs, developing powerful explanations, and so on). They have asked what kinds of knowledge people value and thus what epistemic aims they adopt (e.g., do people seek knowledge for its own sake, or knowledge because it is useful in helping them achieving other aims such as wealth or happiness). We will summarize a broad range of issues relating to epistemic aims that philosophers have viewed as important to understanding epistemic cognition. We argue that educators have seldom addressed what epistemic aims students adopt or what their beliefs are about what kinds of aims should be adopted.

2. Structure of knowledge. Current psychological and educational research on epistemic cognition has addressed the complexity versus simplicity of knowledge. Philosophical work suggests the need to investigate more than just this one aspect of the structure of knowledge. As one of many examples we will provide, EC researchers could also examine the degree to which knowledge is viewed as universal (i.e., knowledge applies very broadly) versus contextually (i.e., knowledge is very specific to particular situations).

3. The certainty, sources, and justification of knowledge. Our third category encompasses the certainty, sources, and justification of knowledge. (We include certainty within this category because philosophers treat certainty as a function of the strength of the justification of knowledge, so that degree of certainty is closely tied to strength of justifications.) These are categories that have been explored by many educators. However, philosophers identify many specific issues within these broad categories that have been unexplored by psychologists and educators.

4. The ethics of knowledge: epistemic virtues and obligations. Epistemologists extensively investigate epistemic virtues such as intellectual honesty, intellectual courage and open-mindedness. They also address issues of

epistemic obligations—an example of this is the extent to which one is obligated to seek out information on different kinds of questions, such as the extent to which one is obligated to have a certain level of economic knowledge when voting on economic issues. EC researchers have addressed a few epistemic virtues, especially open-mindedness. Philosophical research suggests many other virtues that could be investigated, and we will present a taxonomy of these virtues. Philosophical research also suggests new avenues of research on epistemic obligations, which have not yet been investigated by psychologists or educators.

5. Reliable and unreliable processes for achieving knowledge. Epistemologists and philosophers of science intensively study processes by which knowledge is reliably produced. For philosophers who focus on these reliable processes, a belief is justified (roughly speaking) if it results from a reliable belief-forming process (or set of processes). Philosophers who address these processes ask questions about the conditions under which different processes do and do not promote knowledge. For example, philosophers may ask questions such as these about social processes of knowledge production in the mass media: What media processes promote societal knowledge, and which do not? Under what conditions do particular media processes (such as televised debates between experts) promote knowledge? Under what conditions do such debates promote knowledge in society, and under what conditions do they not? We think that there is little research by EC researchers on students' beliefs about reliable and unreliable processes for achieving any epistemic aims, including true beliefs. We will present an analysis of the many types of reliable processes that philosophers have examined as important to epistemic cognition.

In this proposal, we have provided a brief overview of our philosophically-grounded framework for epistemic cognition. In the full paper, we elaborate on the specific issues that philosophers have addressed, and we show by expanding the issues included under epistemic cognition, psychologists and educators will gain theoretical resources that can better explain students thinking and learning. We will show how this framework can be applied in educational research.

PAPER PRESENTATION

Young Children's Experiences through Transition between Preschool and Primary School in Chile

Daniela Jadue Roa, University of Cambridge, United Kingdom; David Whitebread, University of Cambridge, United Kingdom

Full Title: Young Children's Experiences through Transition between Preschool and Primary School in Chile and its Relation with their Developing Resilience and Sense of Agency. Abstract: This paper discusses the preliminary findings of an ongoing PhD research in its last phase. This research was carried out in a State school in Santiago de Chile, with 16 young children aged 5 to 6 years during their transition between preschool and primary school. The research design is a multiple-case study within a bio-ecological perspective (Bronfenbrenner, 2005) and therefore, data was gathered from children, their parents and their practitioners. Video-recording, photograph interviews (book-making and poster-making), were carried out with children; the 'Children's Independent Learning Development (CHILD 3-5)' Checklist (Whitebread, Coltman, Anderson, Mehta, & Pino-Pasternak, 2005) was applied by practitioners and semi-structured interviews supported by a questionnaire (Dockett & Perry, 2000a, 2000b, 2000c, 2000d) were carried out with practitioners and parents or caregivers. The purpose of this study is to explore the transition process that Chilean young children experience between preschool and primary school and its relation with their developing resilience (Cefai, 2008; Dunlop, 2003c) and sense of agency along this period (Bandura, 1982, 1993; Bruner, 1996). This study was organized in two phases (before and after transition) and it was developed between September 2009 and August 2010.

The present study was inspired by the proposal of 'The Mosaic Approach' (Clark, 2005; Clark & Moss, 2001); by the research carried out in Australia by Dockett's and Perry's (2007) the 'Starting School Research Project'; and by Dunlop's (2003a, 2003b, 2003c) research study carried out in Scotland. Accordingly, the present study aims to explore young children's experiences in the context of an early transition between preschool and primary school in Chile, and how these experiences relate to their developing resilience and sense of agency within an educational context. Hence, this research intends to answer the following research questions:

Main question: How do young children's experiences of transition between preschool & primary school in Chile relate to their developing resilience and sense of agency?

- Further questions:
- a) How do young children experience transition between preschool & primary school in Chile?
 - b) How do parents experience young children's transition between preschool & primary school in Chile?
 - c) How do practitioners experience transition between preschool & primary school in Chile?
 - d) How do young children's resilience and sense of agency develop during their transition between preschool & primary school in Chile?

To answer these questions, the research was designed with a multiple case study approach within a bio-ecological perspective (Bronfenbrenner, 2005). Taking this into account the research methods are child-centred and seek to gather young children's perspectives on their own experiences. Therefore, visual and participatory methods such as photography, video recording, book-making and poster-making were used (Clark, 2005; Clark & Moss, 2001, 2005; Jones, 2004; Veale, 2005). In addition, and with the aim of acknowledging the social constructivist perspective of the research design proposed, data was also gathered from adults involved with the young children participating on this study. Practitioners used the 'Children's Independent Learning Development (CHILD 3-5)' Checklist (Whitebread, et al., 2005) to assess young children's self-regulatory skills; and practitioners and parents or caregivers participated in semi-structured interviews guided by the Questionnaire developed by Dockett & Perry in their 'Starting School Research Project' (Dockett & Perry, 2000a, 2000b, 2000c, 2000d). In other words, this design aims to acknowledge young children's voices and agency through their learning and developmental processes. Young children's voices are reflected in this research project by the recognition of their agency and by the inclusion of them as valid informants and active participants in research concerning their experiences (Cousins, 1999; UNICEF, 1989). Taking into account that the school year in Chile goes from March to December and the characteristics of the study, the data collection process was organised in 2 phases: (1) Phase One, from September 2009 till December 2009; and (2) Phase two, from March 2010 till August 2010.

Phase one considered a familiarisation time, video-recording of classroom activities (with a special focus in the classroom interactions); the application of the 'Children's Independent Learning Development (CHILD 3-5)' checklist (Whitebread, et al., 2005); photographs interviews with the book-making activity; and semi-structured interviews with adults participants. The purpose of selecting the book-making session as the first photograph interview was to help young children to engage with the researcher and to help them being confident to share their experiences and reflections on kindergarten. During Phase two the same data collection process was repeated, however, photograph interviews involved the poster-making activity. The purpose of doing a poster in this second phase is to help young children with reflecting about things that have changed in first grade. They are invited to think about what young children need to know about primary school, and to discuss why; also what can schools, teachers and families do to help children who are starting primary school (Margetts, 2006). All these questions are also explored with adults involved in the semi-structured interviews carried out with them.

The data analysis has had as a main purpose the co-construction of meaning with young children's perspectives and adults involved in their experiences. Therefore, data has been coded grounded in what the data reveals and supported with the theoretical framework presented for the present study. Two main coding schemes have been developed: one regarding young children's perspectives on transition; and a second one related with their expressions of resilience and developing sense of agency. In order to ensure that during this process the focus is young children's voices and the construction of meaning, the following principles for listening to young children developed by Clark and Moss (2001, 2005) have been acknowledged: . 'it is an active process of communication involving hearing, interpreting and constructing meanings . Not limited to the spoken word . A necessary stage in participation in daily routines . Participation in wider decision-making processes' (Clark & Moss 2005, p. 8) In sum, this paper invites to a discussion about preliminary findings of young children experiences in their transition and their demonstrated resilience and sense of agency. Present findings can be discussed in the light of the outcomes of previous research carried out in the field and its contributions to further research in this context are considered. Lastly, this paper aims to reflect upon the contributions of visual methods in participatory research with young children, their effectiveness in helping the researcher to listen to young children's perspectives and, particularly, young children's perspectives in the context of an early transition in Chile.

Young Children's Perceptions of the Nature and Functioning of Artifacts with Adaptive Behaviour

David Mioduser, Tel Aviv University, Israel; Asi Kuperman, Tel-Aviv University, Israel

This study examines the effect of experimenting with advanced-robotic technological systems on young children's perceptions of the Nature and functioning of controlled artifacts with adaptive behavior. 10 kindergarten children performed a series of explanatory and programming tasks of increasing complexity, in terms of the expected robot's adaptive behavior. The research questions focused on: (a) children's perceptions of behaving artifacts, whether these reflect a psychological/behavioral or a technological/functional perspective, and (b) children's ability to program behaving artifacts focusing on the representational structures used for expressing the robot's behavior (e.g., scripts or rules) and on the troubleshooting processes (debugging). Findings are indicative of young children's (both "explainers" and "programmers") ability to conceptualize the robot's behavior using a technological perspective. As well, the results convincingly show "programmers" ability to construct complex robot behaviors. Moreover, we observed children's ability to use generalizable, a-temporal and abstract representations of the desired behaviors (e.g., rules), seemingly a serious challenge for kindergarten children according to existing literature. It seems that the interaction between the concrete (the physical robot and its actual functioning) and the abstract (the symbolic interface for constructing and debugging the control program) supported children's performance at sophisticated cognitive levels.

Kindergarten Children's Perceptions of the Nature and Functioning of Artifacts with Adaptive Behavior David Mioduser, Asi Kuperman Tel-Aviv University Children are exposed nowadays from a very young age to controlled technological systems. A visit to the nearest supermarket introduces them to automatic doors, barcode readers or controlled conveyor belts. Many toys they play with are programmable? and at home they interact with complex devices such as controlled appliances, mobile phones and computers. In recent years, children from a kindergarten in central Israel have been exposed to experiences with simple robots as part of the implementation of a curriculum focused on technological thinking. The curriculum has been developed upon the idea that technological thinking integrated into the kindergarten's culture will stimulate the children's curiosity and will support, and even demand, the use of high-order thinking, analytic capabilities, abstraction and problem solving, laying out the road to meaningful knowledge building processes. Such technological-thinking related skills are not part usually of the curriculum in kindergartens.

This study examines the influence of experimenting with advanced-robotic technological systems on children's perceptions of the Nature and functioning of controlled artifacts with adaptive behavior. The main goal was to explore how kindergarten children perceive and program the behavior of an adaptive robot.

Method

The population included 10 kindergarten children aged 5-6 (chosen randomly from a group of 25). Data was collected using observations and interviews. A qualitative research paradigm was chosen for the study, due to the small sample. Two types of tasks were implemented: (a) explanatory tasks in which children were requested to describe and explain the observed behavior of a robot, and (b) programming tasks of a robot's adaptive behavior. The tasks were built as a progression of increasing complexity, defined by the number of program components (e.g., rules, routines) required for generating the robot's behavior. The programming environment, "RoboGan", was developed for kindergarten children. It is icon-based, enabling to define the control rules in intuitive manner not requiring reading or writing code. The research questions addressed in this presentation focus on: (a) children's perceptions of behaving artifacts: whether these reflect a psychological/behavioral or a technological/functional perspective. (b) children's ability to program behaving artifacts, focusing on the representational structures used for expressing the robot's behavior (e.g., scripts or rules) and on the troubleshooting processes (debugging).

Findings

On children's perception of the robot's behavior Findings indicate that the children referred unevenly to the robot as a behaving artifact from psychological/behavioral and technological/functional perspectives. The utilization of anthropomorphisms (as indicator of a psychological perspective) was not dominant, compared to usage of technological language (Figure 1). When used, it was mostly due to the linkage made by the children to the task's underlying story, thereby recurring to the usage of anthropomorphisms, e.g.: "walking on the bridge", "careful not to bump into an obstacle", "getting the goal". In contrast, the technological perspective, and the usage of technological language, was dominant. This finding emphasizes the children's ability (both "explainers" and "programmers") to conceptualize the robot as functioning artifact. Figure 1: Children's perception of the robot's behavior as a function of task complexity A decrease in the use of anthropomorphisms as the task's complexity increases was observed both amongst the 'explainers' and the 'programmers'. This indicates that in more complex tasks children describe what they see or do in more "professional" terms. Thus for complex behaviors, anthropomorphism is not sufficient - when children understand the connection between the task, the robot and the interface, they perceive the robot from a technological/functional perspective. This indicates also children's ability to establish the linkage between the robot as concrete artifact and the programming environment as abstract or symbolic space. This abstraction is evident in the

children's explanations, in their analysis of the robot's behavior and in the capabilities they exhibit in the programming process.

On children's ability to program the robot's adaptive behavior Among alternative constructs used for representing a device's behavior, in this study we focused on three: episode (description of a one-time event), script (a sequence of events in a temporary structure and re-usable as routine) and rule (general and a-temporal construct, using condition/action terms such as "if... then..."). Findings indicate that children were able to use all three constructs, as required by the programming tasks (Figure 2). Usage of rules indicates the ability of kindergarten children to generalize and use a-temporal abstract representations, something seemingly beyond the capabilities of kindergarten children according to existing literature. Additional support to this claim in the findings is the relatively low usage of episodic descriptions. The programmers seldom used concrete terms for describing the robot's behavior, and were inclined to use the more complex structures (i.e scripts and rules). Figure 2: The robot's behavior representation as a function of task complexity

Regarding troubleshooting and problem solving, different strategies were used by the children until satisfactory completion of the task was reached, e.g. deleting the whole program and starting over, or replacing one command at a time till the expected behavior was observed. In summary, technological thinking entails an important, interesting and unique experience which has the potential to contribute to young children's conceptual understanding, problem solving and learning of complex phenomena in the everyday environment. Kindergarten children are at a stage in which their curiosity is at its peak. They ask, examine and try to discover the world in which they live in, hence meaningful authentic and relevant experience leads to learning. The tasks they were exposed to were real: they were required to learn and to use their acquired knowledge to fulfill tasks in the real world: programming a functioning artifact in the real world. These conclusions encourage the need for further studies focusing on implementation of technological thinking in the kindergarten curriculum as well as on additional questions beyond the scope of this study, e.g. the importance of adult mediation, mental models developing from these experiences, educational tools which may be developed following the study's findings, and naturally, the collaborative learning taking place in technological thinking-based group activity.

PAPER PRESENTATIONS

Teacher's talk about toddler's early literacy experiences at preschool

Sara Hvit, Jonkoping University, Sweden; Polly Bjork-Willen, Linkoping University, Sweden

Early literacy experiences are important parts of toddler's literacy development at preschool. The importance of children's literacy is also emphasized in the new Swedish preschool curriculum. Kress (1997) points out, that a literary sign is a combination of meaning and form, and that the meaning making should be seen in a social and cultural context as well as an activity. From this point of view young children's literacy does not consist of reading and writing only. It also includes all visual information that communicates to the children in their everyday world. The present paper aims to explore how teacher teams at 10 diverse preschools during focus group interviews, talk about and discuss toddler's literacy experiences. Detailed analyses of the interviews are made. The analyses show that three main areas of toddlers' literacy are highlighted in the talk; 1) toddlers' own manifestation of literacy, 2) how to work with toddlers' literacy, and 3) what characterizes the literacy environment. However, the majority of the teams were not used to verbalize and openly discuss toddlers' literacy and its implication on the preschool practice. The latter finding is a challenge for the teacher education and the implementation of the new curriculum.

Aim and theoretical background. In Sweden most children begin preschool at the age of one, and 80 % of the children between one to three years old go to preschool for education and care on a daily basis (Skolverket, 2009). Hence, the way the curriculum is implemented is of great importance for the children's learning and development, particularly when the youngest children aged one to three (named toddlers in the present paper) are concerned. In the new curriculum for the Swedish preschool there are clarifications in the area of language and communication. Language and communication are described as inextricably connected with children's identity and understanding of self and others (Ministry of Education, 2010). Furthermore the curriculum calls attention to the fact that language environment in preschools should offer children opportunities to explore and use written language. The conclusion drawn from the curriculum outline above is that the expectations laid on the preschool teachers' way of realizing a 'good' language environment are very high.

The focus of this paper is to investigate the language environment for toddlers at preschool, and the study takes its theoretical starting point from Barton's (2007) ecological view of literacy. It also uses a multimodal approach of children's meaning making in different modes (Kress, 1997, 2010). Consequently, to understand toddlers' intentions in literacy events, it is important to pay attention to their verbal as well as non verbal way of expressing themselves and

to create meaning (Lökken, 2006, 2009). More specifically the aim is to explore how literacy is talked about and discussed by teacher teams working with toddlers.

Method

In the present study focus group interviews with ten teacher teams are analyzed in detail with respect to the teachers talk about literacy events with toddlers. Each team was interviewed at two distant occasions, hence the data includes in total 20 interviews. The interviews originate from a larger corpus of interview data and this in turn is a part of a comprehensive study that investigates preschool as a context for children's language development at 60 preschools, being equally distributed over three communities in Sweden. As the literacy of toddlers is the focus of the present study, only interviews with teams working solely with toddlers were selected. The interviews were transcribed, and a collection of sequences including the teachers' talk and discussions about literacy and literacy events were selected for the analysis. Transcriptions were prepared using conversation analytic notations (cf Hutchby & Wooffitt, 1998). The sequences of talk were analyzed in detail with a participant-oriented perspective on interactional conduct (Schegloff, 1999). All names of persons and places have been changed to preserve participants' anonymity.

Preliminary findings

Preliminary findings indicate that literacy is defined and discussed in most varying ways between the teams, but also within a team. To verbally express what signifies toddlers' literacy seemed to be an unusual issue for many of the teams. Although, the areas that gradually became emphasized were 1) toddlers' own manifestation of literacy, 2) how to work with toddlers' literacy and 3) what characterizes the literacy environments. When literacy was described from the perspective of the child, a common description in the interviews were how toddlers use books, and how obvious it is that toddlers identify themselves as readers as well as writers. For example it was described how the children read for each other and for the dolls, and that they turn the pages and sounds like reading. The toddlers also encourage their listeners to be really quiet and listen carefully (c.f. Björk-Willén & Cromdal, 2009). However, most of the teams declare that they oppose to teach toddlers reading and writing. They preferred methods that are embedded in everyday practice, and that literacy should be highlighted in situ, for instance asking a child "do you want to read for me or do you want me to read?", or "what are you writing?". One of the teachers points out that "the physical language environment in total aims to learn them (the children) to read and write, but we do not coach them to read and write". The environment and the pedagogic material are not referred to as an isolated unit, but the connection between physical aspects of the environment, language and teaching attitudes are often discussed in the interviews. So is the kind of artifacts and its locations that are used to improve toddlers' literacy.

Theoretical and educational significance of the research

The teachers' talk and discussions about toddlers' literacy strengthens the way of viewing toddlers style (i.e. Lökken, 2006, 2009) and their manifesto of literacy (Björklund, 2008). The discussions about the language environment also have a clear multimodal approach to small children's literacy (see Kress, 2010). However, the teacher's talk about toddlers' literacy was unreflecting and based more on experiences than theory. The talk also derives from a play based rather than a teaching view of toddlers' early literacy.

PAPER PRESENTATION

Early development of self-regulation and the use of communicative signs in educative interactions

From a socio-cultural approach, the role of language as a tool to support the self-regulation (SR) of physical and cognitive activity has been widely studied, yet there is little evidence on the role of pre-linguistic semiotic systems in the early development of self-regulatory skills. By extending Vygotsky's hypothesis on the development of SR to a pre-linguistic level, the purpose of the study is to analyze the transition from other-regulation to SR through mediated activity. We observed four children longitudinally at 11, 13 and 15 months old in triadic interaction (child-adult-object) with one of their parents. The object for the interaction was a toy which conventional use requires the understanding of rules, the execution of successive sequences of actions and the use of a hammer as an instrument. We coded for parents' use semiotic utterances to scaffold the object's conventional uses to their children, (i.e. verbal utterances, demonstrations, ostensive signs, pointing gestures, etc), and for children's use of signs related to their activity (ostensive gestures, pointing gestures, vocalizations). Parents used complex semiotic mediators during the interaction, and children engaged in progressively more complex conventional uses of the object over time. We identified 44 events in which children used pre-linguistic signs with a self-regulatory function (4, 4 and 36 at 11, 13 and 15 months old respectively). We analyzed and classified these events according to their semiotic modality and their function. We present qualitative observations that illustrate these categories.

A global networked society means fast changes that demand for the ability to adapt to new circumstances. Supporting children to become self-regulated independent learners is probably one of the most important goals of education in this context. During the last decades, the awareness of the importance of quality Early Years Education especially during the 0-3 period has increased. From a vygotskian perspective, the role of language as a tool to support self-regulation (SR) has been widely studied (on children older than 3 years old, Winsler, 2009)) and numerous educative tools have proven to effectively promote SR. However, there is little evidence on the role that pre-linguistic semiotic systems might play in the early development of self-regulatory skills (i.e. Rodríguez & Palacios, 2007, Valloton, 2008, Delgado, Gómez y Sarriá, 2009).

This study aims to address this gap in the literature. We aim to understand when and how do children start using semiotic tools with a self-regulatory purpose. Understanding the early development of SR and it's relation with non-linguistic semiotic tools, has great implications for early years education. The questions of the study are: (1) what kind of communicative semiotic tools do parents use to regulate the children's behavior? (2) Do children use similar communicative semiotic tools (ostensive gestures, pointing gestures, vocalizations) to regulate their action, either directed towards the adult, or to themselves?

Four infants and one of their parents were videotaped at their homes while interacting with a complex object during five minutes. The object of the interaction is described in Basilio & Rodríguez (in press) It is a wooden toy with different parts: a box with three holes on the top, three balls that fit in the holes, but they do not fall inside the box unless they are pushed down. There is a hammer to hit the balls and push them down and make them fall. The bottom of the box is inclined so the balls exit through a hole in one side of the box (Figure 1). Parents were told to "Play with their babies as they would normally do".

We conducted a microgenetic analysis of interactions from a semiotic-pragmatic perspective of development and objects (Rodriguez and Moro, 1999). We coded for parents use semiotic utterances to scaffold the object's conventional uses to their children, (verbal utterances, demonstrations, ostensive signs, pointing gestures, symbolic gestures), and for children's use of signs related to their activity (ostensive gestures, pointing gestures, vocalizations). We identified 44 events in which children used pre-linguistic signs with a self-regulatory function (4, 4 and 36 at 11, 13 and 15 months old respectively). We analyzed and classified these events according to their semiotic modality and their function. We present qualitative observations that illustrate these categories. We describe the categories used to characterize these behaviours (both, used in previous studies and developed in this study) and we analyze observations that illustrate them. The following is an example.

Observation 4. duration: 28 seconds.

C1 (Child 1, girl) 15 months old; A (Adult, father)

Indexical sign, Ostensive gesture and vocalization; requesting specific help to the adult.

C1 hammers the balls that she has placed in the holes previously. A encourages her action saying "Very good, very good, very good, another one, come on!". C1 hammers over the box, but does not aim at any specific ball, so she just manages to introduce partially the three of them, but none of them would fall inside the box. C1 stops hammering and tries to take out one of the balls. A grabs the child's hand holding the hammer and says "it's about to fall, it's about to fall. Once again, once again, hit it one more time", directing her arm so that the hammer is over a ball, and making the movement up and down, like hammering but not hitting the ball. Then A, holds N1's arm higher and says "come on,

you hit it!" letting her arm go, so when it falls it hits the ball with the hammer and makes the ball fall into the box. A celebrates saying "Good!". After this immediate demonstration. N1 takes the ball from the exit hole, she places it again and hammers three times, but doesn't manage to hit the ball. A says "Come on, hit it harder". Then C1, points at the ball with the hammer, she looks at her father's hand and still holding the hammer, she shows him her wrist and vocalizes "hmm", requesting for his help to hammer. A grabs her hand and says "Do you want me to help you? Come on" and guides her hand hammering with her until the ball falls into the box.

In this observation the child has the goal of hammering the ball, but she is not succeeding. After trying by herself, she asks the father to help her. She manages to communicate him what she wants without words, using an indexical sign (when she points toward the ball using the hammer) an ostensive sign (when she shows her wrist with her hand holding the hammer) and a vocalization. The father understands her intention and helps her, so she succeeded in her goal. This behaviour indicates that the girl, as young as 15 months old is capable of: - holding a goal in mind, - she understands the sequences of actions necessary to complete the goal, - she knows that her father can help her, - and she communicates effectively what she wants. In this case, she is not yet capable of achieving the complete use of the object but herself, but instead of giving up and do something else, or instead of giving the hammer to the father for him to do it, she keeps the hammer, and request for help in the specific part of the action where she has difficulties. We conclude that sensitive microgenetic analysis of triadic interactions allows to evidence that children develop self-regulatory skills even before they learn to use language, non-verbal communicative tools also fulfil a self-regulatory function from early in life.

PAPER PRESENTATION

Antecedents and consequences of initial and sustained interest during a learning task

Anna Tapola, University of Helsinki, Finland; Marjaana Veermans, University of Turku, Finland; Markku Niemivirta, University of Helsinki, Finland

In two related studies, the change in students' on-task interest was examined as a function of individual and task characteristics. Elementary school students worked in two groups with a different simulation task type to learn the basics of electricity. Students' personal goal orientations and interest in math and science were measured before the task. Pre- and post-tests were used for measuring relevant content knowledge on the subject. On-task interest was recorded repeatedly in different phases of the task. The results of Study 1 (n=52) were tested for replication and extended with measures on students' self-reported use of motivational regulation strategies in Study 2 (n=120). Repeated measures ANOVA and partial least squares method were used for analysing the data. The role of task characteristics in students' on-task interest was reflected in the results showing, first, that the general level changes in on-task interest were different in the two simulation task groups. Second, the learning outcomes seemed partly to depend on the changes in students' on-task interest, in favour of the task group where an increase in on-task interest was observed. On the other hand, students' initial interest at the beginning of the task depended on their individual characteristics. Time sequenced on-task interest ratings also strongly predicted one another, regardless of the task condition. Students' self-reported tendency to use motivational regulation strategies was related to their on-task interest throughout the task. Discussion focuses on the importance of acknowledging both individual and situational factors in the development of students' on-task interest.

Summary

Introduction

In order to cope with a learning task, students need a sufficient level of initial motivation to get started, as well as maintained motivation to perform it (Sansone & Thoman, 2005). To better understand the formation of this 'motivational chain', integrated knowledge on the factors affecting students' motivational state at the very beginning and during the learning task is needed. The separate roles of various antecedents and consequences of motivational states have been studied within different research traditions. However, there have been only a few attempts to integrate distinct motivational constructs from different theoretical frameworks (Harackiewicz et al., 2008). Also studies that would have examined the dynamic changes of motivation over the course of a learning task are scarce. ObjectivesConsequently, two related studies were conducted to address these shortcomings. Central concepts of goal orientation and interest theory were used to study the dynamics, as well as the antecedents and consequences of students' on-task interest during a learning task. More specifically, we wanted to know 1) how students' on-task interest change in the course of a learning task, 2) how students' individual and task characteristics affect students' on-task interest, and 3) which factors predict students' learning outcome measure.

Method

In order to examine the role of task characteristics, a condition comparison was created. Elementary school students (10 to 12 years old) worked either with a semi-concrete or concreteness fading simulation task to learn the basics of electricity. Before the simulation task, students' personal goal orientations and subject-specific interest in math and science were measured. Taking into account the dynamic nature of on-task interest (Ainley & Hidi, 2002), repeated measures in different phases of the task were used. Students' prior knowledge on the subject (pre-test) was measured before, and learning outcomes (post-test) one day after the simulation task. The change in students' on-task interest was analysed using repeated measures of ANOVA. Partial least squares (PLS) path modeling was used to examine the effects of antecedents and consequences of on-task interest.

Results

In Study 1 (n=52), the simulation task condition had an effect on the way students' on-task interest changed during the learning task. Students' level of interest increased among those who were working with the semi-concrete simulation type, while a decrease in interest was found in concreteness fading condition. However, students' initial on-task interest was dependent on their interest in science and math, which, on their part, mediated the effects of mastery-intrinsic and avoidance orientation on initial on-task interest. It was also found that independently of the task condition, the effects of time sequenced interest measures on one another were notably strong. Further, our results gave indications that the changes in students' motivational state were reflected in their learning outcome measure after the task. At the group level, students who experienced an increase in their interest during the task also performed better in the post-test. In Study 2 (n=120) the same design was replicated with slightly revised methodology and a larger sample. We also wanted to gain more knowledge of the factors related to the development of students' interest during the task. It has been suggested that students' tendency to use motivational regulation strategies affect whether the initial level of motivation will be sustained (Wolters, 2003). We used a modified questionnaire developed by Wolters (1999) to measure students' self-reported use of motivational regulation strategies after the learning task. Thus, we were able to examine students' on-task interest also from the perspective of their self-regulatory tendencies.

The preliminary results of the Study 2 indicated that, as in Study 1, there was an increase in students' level of on-task interest in the semi-concrete simulation condition. In the concreteness fading condition, on-task interest maintained at the same level throughout the task. The effect of mastery-intrinsic orientation, mediated by students' interest in math and science, on initial on-task interest was replicated. Like in Study 1, repeated on-task interest measures strongly predicted one another. Students' tendency to use motivational regulation strategies was related to their personal goal orientations (except avoidance orientation) as well as on-task interest measures.[1]

Conclusions

Although acknowledged in theory, there is a lack of empirical studies concerning the changes in motivational states during a learning task. The results of the two studies reported here illustrated the dynamic nature of students' on-task interest. The differences found in the two task conditions showed, first, that besides maintaining students' interest, task characteristics may have the potential to even enhance it. Second, although the level of students' interest was rather high in both conditions throughout the task, it was the positive change that seemed to matter when considering students' learning outcomes. While the general level changes could partly be attributable to the differences in task conditions, the results showed that students entered the task situation with different motivational backgrounds which affected the level of their initial on-task interest. The importance of the initial interest at the beginning of the task was highlighted in its predictive effect on subsequent interests during the task. Further, as shown in Study 2, students who reported having used motivational regulation strategies more often during the learning episode were also more interested throughout the task. The results of the studies speak in favour of acknowledging individual factors that affect, not only the initial level but also the maintenance of students' transient motivational states. Consequently, besides considering the "interestingness of the environment", the influence of students' motivational background should be taken into account in study designs as well as in practical implications.

PAPER PRESENTATION

Motivational approaches to the study of theology in relation to theology students study path

Laura Hirsto, University of Helsinki, Finland

The aim in this study is to explore the relationships between motivational approaches to the study of theology and theology students' curricular choices during their study path. Relationships were explored through follow-up data. During their first year, they completed a questionnaire which included motives for studying theology. On the third and fifth year they were asked to respond to questions concerning their curriculum choices. There are empirical indications that spirituality is one of the determinants of career behavior (Lips-Wiersma, 2002): it influences career purpose, sense-making and coherence. Duffy and Blustein (2005) argue that individuals who have a strong spiritual relationship with a higher power and are religious through intrinsic motivation tend to be more confident in their ability to make career decisions and are more open to exploring a variety of career options. The theological studies provided an interesting context to investigate religious and spiritual aspects of motivation, for those aspects usually are more detectable in choices of theology students compared to university students in other fields. According to preliminary results, certainty of curriculum choice, curriculum choices and reasons given to them were significantly related to the motivational approaches for the study of theology reported in the beginning of university studies. However, the pattern was different when third and fifth year relationships were compared.

AimsThe aim in this study is to explore the relationships between motivational approaches to the study of theology and theology students' curricular choices during their study path. Vocational psychologists have conducted a great deal of research into the effect of contextual variables on career development, but have yet to explore adequately the role of spirituality and religiousness (Duffy & Blustein, 2005, p. 431-432). Theoretically, religious questions are intertwined in the personal worldviews (cf. Hirsto, 2001) and values of students and affect motivational constructs. Spirituality and religiousness can provide people with an ultimate sense of purpose (Emmons, 1999; McIntosh, 1995). There are also empirical indications that spirituality is one of the determinants of career behavior (Lips-Wiersma, 2002): it influences career purpose, sense-making and coherence. Duffy and Blustein (2005) argue that individuals who have a strong spiritual relationship with a higher power and are religious through intrinsic motivation tend to be more confident in their ability to make career decisions and are more open to exploring a variety of career options.

The theological studies provide an interesting context to investigate religious and spiritual aspects of motivation for those aspects usually are more detectable in choices of theology students compared to university students in other fields. Faculties of theology in Finland offer a general theological education and the education required to become a teacher of religion, as well as qualifications for students wishing to become pastors in the Evangelical-Lutheran church. It could be assumed that more students in these faculties than in higher education in general have some sort of spiritual motivations for their study. However, the teaching at these faculties is non-confessional and students come from various Christian spiritual traditions. Studies on motives for studying theology have produced some classifications: a spiritual calling, the instrumental approach, the scientific approach, self-fulfilment, a helping orientation, being assured of a place to study, and other people's influence (Niemelä, 1999; Baylis, Cargas, Hartley, Rowland, Sabri, Stavrakopoulou and Wyatt, 2004). The relationships with motivational approaches and curricular choices will be explored through the following questions: How are the motives in the beginning of the theological studies related to a) certainty of curriculum choice b) curriculum choices, and c) reasons given for the choices in the third and the fifth year of university studies?

Methodology

This is a follow-up study among theology students. During their first year, they completed a questionnaire which included motives for studying theology. On the third and fifth year they were asked to respond to questions concerning their curriculum choices. The response rates were 70.4 % in the first year, 41.8 % in the third year and 25.9 % in the fifth year. Missing data-analysis will be reported in this presentation.

Findings

In the beginning of the university studies similar factors of motivational approaches were found compared to earlier research (c.f. Hirsto & Tirri, 2009). Of the third year students, 79.9 % reported to be certain of their choice of the curriculum, while in the fifth year 85.7 % were certain. The distribution of the choices in third and fifth year represented very well the distribution of the graduating Masters' of Theology. According to preliminary analysis, experienced spiritual calling is related to the certainty of curriculum choice in the third year of the university studies

($t=2,540$, p In addition to certainty of curriculum choice, also the actual curriculum choices were investigated in relation to motives to start to study theology. Of the motivational approaches in the beginning of the university studies, spiritual calling, a helping orientation, assuring a place to study, other people's influence were significantly related to the curriculum choices students had made in the third year of their theological studies. Also, uncertainty of career choice was significantly related to curriculum choices. In the fifth year spiritual calling and a helping orientation in the beginning of the theology studies were related to curriculum choices in the fifth study-year. Also, in the fifth year, uncertainty of career choice in the beginning of the studies was related to curriculum choices. The contents of the reasons students gave for their curriculum choices were qualitatively analysed and classified. Top level categories were named: calling or certainty, exclusion and other. However, the nature of the explanation differed according to curriculum choices, which students had made. Therefore, the relationships of these curriculum choice bound explanations were investigated further. This revealed interesting significant relationships and variety of the motivational approaches of the students following different curriculum paths. The study path of religion teachers and pastors seems to be somewhat coherent, but students' in general theological education curriculum seems to have more or less dissonant approach to their studies.

Theoretical and educational significance of the research

This study sheds light to university students study paths in a specific context of theological education. The findings will be discussed in terms of the theoretical background, self-regulation (e.g. Pintrich, 2004; Zimmerman, 2002; Boekaerts & Cascallar, 2006) and curriculum development. Through this empirical starting point, implications are discussed also in terms of more general academic education. This research contributes to the understanding of how motivational approaches in the beginning of university studies may affect the choices later in the study-path. It seems that spiritual calling, which, in case of other curriculum choices except that of becoming a pastor, seem to take a form of unquestioned certainty, plays an important role in certainty of choices during university studies. More generally, results also suggest that there are students trying to progress in their university studies, but who may not have a very clear vision of their goals. If this lack of perspective is persistent, which it seems to be according to these results, this phenomena would need more intensive elaboration in developing higher education curricula.

PAPER PRESENTATION

Achievement Goals Over Time: How Changes in Mastery and Performance-Approach Predict Deep Knowledge

Daniel Belenky, University of Pittsburgh, United States; Timothy Nokes, University of Pittsburgh, United States; Matthew Bernacki, University of Pittsburgh, United States

The current study examines two factors that are critical to understanding the role of achievement goals in classroom learning; how goals change over time and the relation between those goals and what is learned. Students' achievement goals were measured in relation to three exams completed during a Cognitive Psychology lecture course ($N = 154$). The exams included items that assessed different kinds of knowledge including factual, conceptual, and application based understanding. Performance on the initial exam was predicted by student performance-approach goals, while performance on the third exam was predicted by mastery-approach goals. Moreover, a positive change in mastery-approach goals from Exam 1 to Exam 3 led to increased performance on the third exam, while a positive change in performance-approach goals led to decreased performance. This effect was driven by an advantage for mastery-approach goals on the application-based items. These results indicated that mastery-approach goals may be particularly important for the development of deeper forms of understanding, and that movement towards such goals over the course of a semester may be a pedagogically important aim for instructors.

The relationship between achievement goal orientations and academic performance is mixed (see Linnenbrink-Garcia, Patall, & Tyson, 2008). In some cases, mastery goals predict achievement, while in others, performance goals are better predictors. In the current study, we focus on two factors that may be contributing to the conflicting findings in the literature; the type of knowledge being measured on achievement tests, and how goals change over time. Specifically, we analyzed exam items, differentiating between fact-based, concept-based, or application-based questions. We test the hypothesis that advantages observed for performance-approach goals reflect performance on items that assess a fact-based understanding, while advantages for mastery-approach goals reflect deeper forms of understanding as measured by concept- and application-based items (see Harackiewicz, Barron, Pintrich, Elliot, & Thrash, 2002). Furthermore, we examined how achievement goals change over the course of a semester, and how these changes influence exam performance.

Methodology:

Participants were students in a Cognitive Psychology course at the University of Pittsburgh ($N = 154$). Students completed questionnaires at four time points throughout the semester; on the first day, before the first exam (5 weeks in), before the second exam (9 weeks), and before the third exam (14 weeks). Questionnaires assessed a range

of motivational and self-regulatory variables. For the purposes of this paper, we focus on achievement goals and their relationship to exam performance. We measured mastery-approach, performance-approach, and performance-avoidance goals using three 7-point Likert scale items for each construct (1 = Strongly Disagree, 7 = Strongly Agree) from the Achievement Goal Questionnaire – Revised (Elliot & Murayama, 2008).

For each multiple-choice exam, the percentage of total items correct was calculated to measure overall performance. The items on each exam were analyzed and coded into sub-categories of fact-based, concept-based, or application-based items by two raters ($r = 0.94$, $n = 125$, $p < .05$). Fact-based items assessed the direct recognition of information from the course, concept-based items required students to reason with concepts and theories covered in the course, and application-based items required students to apply knowledge to a given scenario or analyze given information in light of particular concepts or theories.

Findings:

Mean values for each goal score at the first and third exam are given in Table 1. Each construct showed a decrease in endorsement of these goals across time points.

To analyze the effect of achievement goals on Exam 1 performance, the three achievement goal constructs were entered as predictors into a linear regression predicting exam scores. Overall performance was not predicted by any achievement goal. However, when examining the subscales, we found that performance-approach was a marginal predictor of factual and applied item performance ($B = .27$, $p = .07$ and $B = .28$, $p = .06$, respectively), performance-avoidance goals negatively predicted performance on the applied items ($B = -.31$, $p < .05$), and mastery-approach goals did not predict any subscales. In contrast to the first exam, mastery-approach goals predicted performance on the third exam ($B = .25$, $p < .05$). When looking at subscales, mastery-approach predicted performance for factual and applied ($B = .26$, $p < .05$ and $B = .31$, $p < .05$, respectively) and was marginally predictive of performance on conceptual items ($B = .16$, $p = .10$). Neither performance goal was predictive of subscale scores at Exam 3.

The effect of mastery-approach at the third exam is particularly interesting in light of the fact that, as a whole, the class reported less mastery-approach goals at the third exam than at the first (see Table 1). To examine the effect of this change on an individual basis, we calculated a difference score for each student by subtracting goals at Exam 1 from goals at Exam 3. This resulted in a “change score” value for mastery-approach, performance-approach, and performance-avoidance goals. A negative change score indicates that the student decreased in their endorsement of that particular goal. These change scores were entered into a regression predicting performance on Exam 3. Mastery-approach change scores positively predicted exam performance ($B = .23$, $p < .05$), while performance-approach change scores negatively predicted exam performance ($B = -.24$, $p = .05$). Looking at the subscales, we see that performance on applied items is positively predicted by changes in mastery-approach goals ($B = .33$, $p < .05$), but marginally negatively predicted by changes in performance-approach goals ($B = -.22$, $p = .08$). Increases in mastery-approach goals promoted deep understanding, while increases in performance-approach goals inhibited the development of such understanding.

Summary:

Exam 1 performance was positively predicted by performance-approach goals but not mastery-approach goals. However, at Exam 3, mastery-approach goals positively predicted performance whereas performance-approach goals did not. Furthermore, changes in these goals over time predicted exam performance. Students who became more mastery-oriented had higher Exam 3 scores, while those who became more performance-approach oriented had lower scores. These changes were especially strong for the applied items that required a deeper understanding of the material.

Theoretical and Educational Significance:

In order to shed light on inconsistent findings in the literature on the relationship between achievement goals and achievement we focused on how student goals change over time and the types of measures used to assess achievement. We found that an increase in mastery-approach goals over time leads to better performance on measures of deeper understanding. In contrast, increases in performance-approach goals were associated with lower performance on such measures. Focusing attention on variation of achievement goals across time and context may improve our conceptualization of how achievement goals positively influence students, and how educators can maximize these benefits.

PAPER PRESENTATION

Longitudinal relationships between achievement goal orientations, well-being and educational choice

Markku Niemivirta, University of Helsinki, Finland; Katariina Salmela-Aro, Helsinki Collegium for Advanced Studies, Finland; Heta Tuominen-Soini, University of Helsinki, Finland

The purpose of this study was to examine the developmental characteristics of secondary school students' achievement goal orientations, and, especially, the relative benefits of adopting either mastery vs. performance-focused goal orientations in terms of students' subjective well-being. The participants were of 549 students secondary school students of whom 176 (42% females) chose the vocational track and 373 (52% females) chose the general academic track after the ninth grade. The design included four measurement points, two before and two after the transition from lower secondary to upper secondary education. All students completed a questionnaire with scales assessing achievement goal orientations, self-esteem, depressive symptoms, and satisfaction with educational choices. Latent growth curves were estimated for each type of achievement goal orientation. Later ratings of self-esteem, depressive symptoms, and satisfaction were regressed on the trajectories of change in achievement goal orientations, while controlling for the effects prior level of self-esteem, frequency of depressive symptoms, and school performance. The results showed some systematic changes in achievement goal orientations over time, which, to some extent, were moderated by the educational context. Changes in achievement goal orientations independently influenced the students' later well-being. The patterning predictive effects showed that positive changes mastery tendencies were related to parallel changes in well-being, whereas increases in performance-focused tendencies, especially in performance-avoidance orientation, were associated with decreases in well-being. The findings of this study contribute to our understanding of the long-term changes in students' academic motivation during the transition from lower secondary to upper secondary education.

Achievement goal orientations refer to individuals' tendencies to strive for certain outcomes and to favor some types of goals over some others. Much of the recent research on achievement goal orientations has focused on their achievement-related antecedents and outcomes (for a review, see Kaplan & Maehr, 2007). Fairly little attention has been paid on the developmental aspects of different orientations and how changes over time in them relate to some personal factors other than achievement, such as subjective well-being. Quite lively debate has also focused on the relative benefits of adopting either mastery tendencies (i.e., striving for gain in competence) vs. performance-related tendencies (i.e., striving for the demonstration of competence), although the criteria for evaluating such adaptiveness have mostly revolved around achievement-related indicators (Midgley, Kaplan, & Middleton, 2001). The main objective of this study was thus to contribute to the current discussions by examining the developmental characteristics of secondary school students' achievement goal orientations, and, especially, whether the striving for some types of goals in the long run proves to be more beneficial in terms of subjective well-being than striving for some other types of goals.

The few studies available addressing the linkage between achievement goal orientations and well-being suggest that tendencies reflecting the strive for self-improvement and growth (i.e., mastery focus) are related to more adaptive socio-emotional functioning and more positive self-evaluations, whereas the tendency to validate and demonstrate one's personal qualities (i.e., performance focus) is associated with adjustment problems and socio-emotional vulnerability (e.g., Sideridis, 2005; Tuominen-Soini, Salmela-Aro, & Niemivirta, 2008). In this study, we expected to find similar relationships between achievement goal orientations and subjective well-being in a longitudinal setting. That is, we assumed that changes over time in different types of achievement goal orientations were predictive of later well-being in such a way that increases in mastery-focused tendencies were associated with higher well-being, and increases in performance-focused tendencies were related to lower future well-being.

The participants were of 549 students secondary school students of whom 176 (42% females) chose the vocational track and 373 (52% females) chose the general academic track after the ninth grade. The design included four measurement points, two before and two after the transition from lower secondary to upper secondary education. All students completed a questionnaire with scales assessing different achievement goal orientations (e.g., mastery, performance-approach, and performance-avoidance orientations) and two important aspects of general well-being, self-esteem and depressive symptoms. Also, students' ratings reflecting their satisfaction with their educational choices were assessed at time 4. Within the structural equation modeling framework, latent growth curves were

estimated for each type of achievement goal orientation. Later ratings of self-esteem, depressive symptoms, and satisfaction were regressed on the trajectories of change in achievement goal orientations, while controlling for the effects prior level of self-esteem, frequency of depressive symptoms, and school performance.

The results showed an increase in mastery goal orientation over time, whereas no change was detected in performance-approach and performance-avoidance orientations. The trajectories of change were moderated by educational track so that stronger increase in both mastery and performance-approach tendencies were evident for vocational students. When examining the predictive effects of growth trajectories of achievement goal orientations on well-being, the results showed that later self-esteem was predicted by lower initial level of performance-avoidance orientation as well as by increases in mastery orientation and decreases in performance-avoidance orientation. Depressive symptoms were influenced by both prior school performance and increases performance-avoidance orientation. The initial level of mastery orientation as well as increases in mastery orientation and decreases in performance-avoidance orientation had an effect on students' satisfaction with their educational choices.

The findings of this study suggest some systematic changes in achievement goal orientations over time, which, to some extent, are moderated by the educational context (i.e., educational track). Changes in achievement goal orientations also seem to independently influence the students' later well-being. The patterning predictive effects further show that positive changes mastery tendencies appear to be related to parallel changes in well-being, whereas increases in performance-focused tendencies, especially in performance-avoidance orientation seem to contribute to decreases in well-being. The findings of this study add to understanding of the long-term changes in students' academic motivation during the transition from lower secondary to upper secondary education. The results also importantly contribute to the recent debate on the benefits of adopting either mastery-focused or performance-focused achievement goal orientations in school settings.

PAPER PRESENTATION

Mathematics with eyes wide shut: Facing challenges and overcoming barriers

Claudia Ventura, Faculdade de Ciencias e Tecnologia da Universidade Nova de Lisboa, Portugal; Nuno Santos, Escola Secundaria de D. Dinis, Lisboa, Portugal; Margarida Cesar, Universidade de Lisboa, Instituto de Educacao, Portugal

In Portugal, students categorised as presenting Special Educational Needs attend mainstream classes (ME, 2008). Mathematics presents high levels of rejection and low achievement (Céêsar, 2009). Considering mathematics knowledge as socially constructed, giving a meaning is an essential step to access mathematical tools (Vygotsky, 1934/1962). Representing mathematical objects is a barrier blind students experience. Braille writing specific features must be considered when teachers talk about mathematics in classes including blind students (Santos & Céêsar, 2007). They need a thick descriptive discourse and language adapted to Braille writing. In a mainstream classroom teachers must consider the blind student(s) and the non-impaired students, facilitating all students' participation. Communication plays an essential role in students' mathematical knowledge appropriation (Sfard, 2001). Collaborative work can be used as a mediator of students' learning (Céêsar, 2009). This study belongs to the Interaction and Knowledge project whose aims were to study and promote collaborative work in formal educational scenarios. We assume an interpretative approach and an action-research design. The main participants are the students (N=190) from classes including blind students (N=11), two teacher/researchers and a psychologist. The data collection instruments are: observation, questionnaires, documents, informal conversations and students' protocols. Inductive categories emerged from the content analysis (Hamido & Céêsar, 2009). We analyse some examples of students' solving strategies and social interactions illuminating teachers' role in blind students' learning process and the particularities of mathematics Braille. They also illustrate the importance of the communicative processes due to the use of mathematical Braille, particularly differences among blind and non-blind students.

The Salamanca Statement (UNESCO, 1994) symbolises a rupture: changing from the integration into the inclusion paradigm. In the integration paradigm, schools and society looked for students' normalization. After the Salamanca

Statement students' characteristics are respected and teachers try to potentiate them (Céêsar & Ainscow, 2006). In the Portuguese curriculum mathematics is a compulsory subject until the 9th grade (14/15-year-olds). It is one of the most selective, as many jobs and university courses ask mathematics as a condition to be admitted (Céêsar, 2009). Failing in this subject puts students' school path and professional life at risk. Mathematics is one of the subjects that more often contribute to early school dropouts. Therefore, it is crucial to promote all students' access to mathematics achievement, particularly blind ones. Mathematics uses abstraction, an ability that is more difficult to develop when students use a symbolic system (Braille) different from the one used by non-impaired students. This is a barrier blind students need to overcome in order to mobilize/develop their mathematical abilities and competencies (Santos & Céêsar, 2007). Communication is also very important to a blind student because s/he does not have access to the information captured through sight. Thus, we need alternative forms of communication that can surpass this problem. A mathematics teacher of a mainstream class with blind student(s) must adapt his/her practices to each student, including the blind one(s). A way to include every student in the mathematical activities is through the promotion of peer social interactions. Social interactions play an important role in students' socio-cognitive and emotional development (Vygotsky (1934/1962) and in giving students a voice (Wertsch, 1991). Collaborative work in mathematics classes is a way to promote peer and dialogical social interactions (Céêsar, 2009). The problem that originated this research was the difficult inclusion process experienced by many blind students in a mainstream mathematics class. We aim to understand the sort of communication that is established between mathematics teachers and blind students included in mainstream classes, the adaptations that can be observed in the practices developed by teachers and the interactive patterns between students (blinds and non-blind).

The research questions we address are:

- (1) Which are the facilities and the difficulties that blind students experience to have access to the cultural mathematical tools?
- (2) What can be done to facilitate their access to them?

This study is part of Interaction and Knowledge (IK) project. Its main aims were to study and to promote collaborative work in formal educational scenarios, contributing to a more inclusive and intercultural education (Hamido & Céêsar, 2009). This research project lasted 12 years (1994/95 to 2005/06), included 69 mathematics teachers and more than 600 mathematics classes. We focus in those attended by blind students (N=11) included in mainstream schools. We assume an interpretative approach (Denzin, 2002) and developed action-research projects (Mason, 2002). The participants were these blind students (7th to 12th grades – 12 to 18 years old), their classmates (N=190), their mathematics teachers, a psychologist and significant others (colleagues, friends, families, other educational agents).

During the first week of the school year (September), students answered to a questionnaire, a task inspired in projective techniques and an instrument to evaluate abilities and competencies. They also answered two other questionnaires in the begging of the second term (January) and the end of the school year (June). Participant observation (registered in teacher/researchers' diaries, audio/video taped, photos), informal conversation, documents and students' protocols were collected during all school year. Data treatment and analysis is based in a narrative content analysis (Clandinin & Connelly, 1998) from which inductive categories emerged (Céêsar, 2009) illuminating empirical evidence.

We analyse some examples that illuminate teachers' adaptations to practices and to the communication with blind students. We also present some examples of solving strategies and mathematical thinking, discussing the particularities of the Braille writing. This analysis illuminated that there were complements of verbal information to respect the blind students' characteristics. Some complementary information was presented through movement, touch and materials adapted to befit their needs. But teachers also performed some adaptations to the tasks to allow the blind students to participate in the same mathematical activities as their peers. Thus, the results illuminate how dialogical social interactions can contribute to a more inclusive mathematics education and facilitate blind students' access to the cultural tools of mathematics.

PAPER PRESENTATION

The relationship between naming-speed and spelling in dyslexia

Erlin van Genuchten, Knowledge Media Research Center, Germany; P. C-H. Cheng, School of Informatics, University of Sussex, United Kingdom; Paul A. Kirschner, Open Universiteit, Netherlands; Paul Leseman, Utrecht University, Netherlands

Literature about dyslexia proposes two competing theories. The phonological deficit theory holds that people with dyslexia have problems with their phonological representations, whereas the double deficit theory holds that people with dyslexia show an additional naming-speed deficit that is claimed to be equally important in causing reading problems. Research on the relationship between naming-speed and reading has shown that reading problems are related to the commonalities between phonological processing and naming-speed, which supports the phonological deficit theory. However, research on the relationship between naming-speed and spelling has shown that naming-speed remains a significant predictor for spelling when phonological problems are controlled, which supports the double deficit theory. A problem with studies relating naming-speed to spelling is that they use the standard naming-speed test used in reading research. In this test, individuals have to verbally name letters, instead of presenting them graphically. Also, this test does not distinguish between information processing speed and pronunciation speed. To this end, we implemented an adapted naming-speed test — measuring the speed of retrieving a letter from memory during writing — to investigate the relationship between naming-speed and spelling. The results confirm previous findings that naming-speed and spelling are unrelated. Our findings imply that future studies should use adapted naming-speed tests to shed light on why the phonological deficit theory explains the relationship between naming-speed and reading and the double deficit theory the relationship between naming-speed and spelling.

Literature about dyslexia proposes two competing theories. One, the phonological deficit theory, holds that people with dyslexia have problems with their phonological representations affecting performance on any task requiring phonological processing (Pennington, Cardoso-Martins, Green, & Lefly, 2001). The other, the double deficit theory, holds that people with dyslexia show an additional naming-speed deficit that is claimed to be equally important in causing reading problems (Vaessen, Gerretsen, & Blomert, 2009).

The phonological deficit is defined as difficulties in storing and/or retrieving words and in processing information in working memory, whereas the naming-speed deficit is defined as the inability to rapidly retrieve phonological codes from memory (Vellutino, Fletcher, Snowling, & Scanlon, 2004). Although many studies have shown that people with dyslexia indeed have phonological processing problems (e.g., Pennington et al.), it is still unclear whether naming-speed is a separate problem or a problem caused by phonological processing weaknesses.

Research on the relationship between naming-speed and reading has shown that reading problems are related to the commonalities between phonological processing and naming-speed (e.g., Schatschneider, Carlson, Francis, Foorman, & Fletcher, 2002), which supports the phonological deficit theory. However, research on the relationship between naming-speed and spelling has shown that naming-speed remains a significant predictor for spelling when phonological problems are controlled (e.g., Savage, Pillay, & Melidona, 2008), which supports the double deficit theory. A problem with studies relating naming-speed to spelling is that they use the standard naming-speed test used in reading research. This test measures the time individuals take to encode and verbally name a series of letters (Denckla & Rudel, 1976). In contrast, letters are decoded and presented graphically during writing. Another problem is

that the time needed to utter the name of a letter is included in the measured time. However, as people with dyslexia have problems with rapid naming, it is more relevant to examine how long they take to retrieve a letter name from memory. To this end, we implemented an adapted naming-speed test—measuring the speed of retrieving a letter from memory during writing—to reinvestigate the relationship between naming-speed and spelling. MethodParticipants were 95 Dutch children ($M_{age} = 8.28$ years, $SD = .64$), namely 29 grade 3 children with dyslexia (DYS), 33 grade 3 chronologically age matched (CA) children without dyslexia, and 33 grade 2 reading age matched children (RA) without dyslexia. Children wrote four types of sentences ($N = 24$) from memory. In familiar sentences (e.g., Have go hungry), syntactic, semantic, and phonologic support facilitated remembering. In jumbled sentences, syntactic support was removed by presenting words in random order (e.g., You the dog). In sentences containing language-like non-words (e.g., Rummer hoat barden), semantic support was removed by presenting non-existing words that sounded Dutch.

Finally, in sentences containing language-unlike non-words (e.g., Knuk greupeg), phonological support was removed by presenting non-existing words that did not sound Dutch. Children also wrote their first names, which served as a writing baseline. To evoke pauses between letters, children wrote sentences on a piece of paper attached to a graphics tablet containing horizontal rows of rectangles. They wrote one letter in each rectangle (Figure 1). Naming-speed was measured as pause lengths by gauging the time that the pen was lifted from the paper between writing two consecutive letters.

Figure 1. Example sentence. After the experiment, we counted the number of phonological spelling errors. These errors were marked when a word sounded completely different than the stimulus (e.g., 'knuf' instead of 'knuk'). Results We predicted naming-speed or the number of phonological spelling errors with type of sentence, group and writing baseline simultaneously in a regression analysis. This analysis revealed that CA children exhibited shorter pause lengths and made fewer phonological spelling errors than RA and DYS children. RA and DYS children did not differ in pause lengths; however DYS children made more spelling errors than RA children. A second regression analysis testing whether pause length mediated the effect of group on spelling errors yielded no significant results.

Discussion

The double deficit theory was confirmed by two findings. First, DYS children lagged behind in their spelling development compared with their peers; this disadvantage was clearer for phonological processing than for naming-speed problems. This supports the double deficit theory as a similar pattern would be expected for similar deficits. Second, the finding that naming-speed did not mediate the effect of group on spelling errors also confirmed that the naming-speed and phonological processing deficits are independent. These results are in line with previous studies on the relationship between naming-speed and spelling. These findings imply that future studies should use adapted naming-speed tests?measuring time to retrieve a name from memory instead of total performance time?to shed light on why the phonological deficit theory explains the relationship between naming-speed and reading and the double deficit theory the relationship between naming-speed and spelling.

PAPER PRESENTATION

Dyslectic trainee teachers' views of their educational trajectory and their future vocational role

Lena Ivarsson, Mid Sweden University, Sweden; Ulla Damber, Mid Sweden University, Sweden

The objectives of this study was to explore how Swedish dyslectic trainee teachers view their past educational trajectory, their present studying situation, their adjustment to university studies, and their future vocational role. To get an inside perspective of the students' perceptions, in-depth interviews were chosen as method of inquiry. As the conditions for dyslectic students in school have changed according to different policy documents over time a life history perspective was employed in the interviews. This was made in order to get a full description both of the individual experiences and the conditions provided by the school environment. Even though all ten students have a diagnosis of dyslexia, a majority of them were not diagnosed until they were in upper secondary school or even at the university. One major finding was that no extra support was given until the diagnoses were made. The students perceived that their university studies required rigorous planning and lots of time, and they claimed that the compensatory support they had been given was crucial to them to meet the academic demands. In describing their Future Time Perspective the students emphasized their ability to understand and help children with special needs. This was a major driving force for them to apply to become trainee teachers. A major implication of these findings is that dyslectic children are not identified so that remedial assistance can be brought in as early as possible. Secondly, these students' capacities and strengths should earn more attention both in practice and research.

The overarching objectives of this study were to explore how Swedish dyslectic trainee teachers view their past educational trajectory, their present studying situation, their adjustment to university studies, and their future vocational role. The study was conducted in Sweden at a small university, predominantly carrying out distance education. A substantial part of the student body has a working-class background. The informants, all women, were varying in age from twenty to fifty. The distribution of the sexes reflects the fact that the majority of the trainee students are women. To get an inside perspective of the students' perceptions, in-depth interviews were chosen as method of inquiry. The student counselor, who was the contact person for dyslectic students, distributed invitations to the students to participate in the study. This procedure was chosen to guarantee the students' anonymity in case they rejected the invitation. In order to get a picture of the compensatory support the students were offered at the university, the student counselor was also interviewed. The theoretical framework is based on a social cultural view of the individual and his/her learning (Wertsch, del Rio, & Alvarez, 1995).

We aimed to employ a broad perspective on the students' life situations, including their social, cultural, and historical background, and not only their clinical background. The social, cultural, and historical perspective also encompasses the view of learning employed in the study. As the conditions for dyslectic students in school have changed according to different policy documents over time, a life history perspective was employed in the interviews (Goodson, 1994), together with a Future Time Perspective (FTP), as FTP is an important predictor of school investment and academic success (Peetsma, 2000). A simplified version of the Zimbardo time perspective inventory was employed in the student interviews (Zimbardo & Boyd, 1999). The life history perspective was chosen in order to get an extended description both of the individual experiences and the conditions provided by the school environment. Even though all ten students have a diagnosis of dyslexia, a majority of them were not diagnosed until they were in upper secondary school or even at the university. In Sweden children are seldom diagnosed with dyslexia in elementary school. It seems like the students were able to handle the rather simple texts, often fictional, used in early reading instruction. In the students' narratives it is clear that the problems with reading got more apparent when they encountered more abstract and complex non-fictional texts in upper secondary school and, above all, at the university level.

Most students were diagnosed with dyslexia as upper secondary school students or as university students. The student narratives revealed that the need for support was clearly manifested in upper secondary school, but no support was offered. One major finding was that no extra support was given until the diagnoses were made. Even those students, who had an earlier diagnosis, were dependent on the help each individual teacher could or would offer. Some students reported that their self-esteem suffered a lot as they linked their reading problems to a view of themselves as "being stupid". In particular, for those students, the diagnosis of dyslexia was a relief. At university level the students perceived that their studies required rigorous planning, a lot of time, and many hours of reading. They claimed that the compensatory support they had been given, was crucial to them to meet the academic demands. The compensatory actions will be described in the presentation. In describing their Future Time Perspective the students emphasized their ability to understand and help children with special needs. This was a major driving force for them to apply to become trainee teachers. Firstly, a major implication of these findings is that dyslectic children are not identified so that remedial assistance can be set in as early as possible. Secondly, it is obvious that the condition of dyslexia, in these students, is not only linked to the problems associated with reading, but also to a strong Future Time Perspective and ability to large investments in their studies. Our conclusion is that these students' capacities and strengths should earn more attention both in practice and research.

PAPER PRESENTATION

Academic self concept in children with special educational needs attending different school types

Dietmar Grube, University of Oldenburg, Germany; Lieselotte Scheewe, University of Bremen, Germany; Julia Nicklaussen, Carl-von-Ossietzky Universität Oldenburg, Germany; Susanne Mayer, Carl von Ossietzky Universität Oldenburg, Germany

Some children with a mild intellectual disability or with socio-emotional problems visit classes at special schools, some others are integrated within classes in regular elementary schools. The academic self-concept is an important variable for life-long learning. From the theoretical view of the big-fish-little-pond-effect (Marsh, 1987) lower self-concept scores can be predicted in children that are integrated in classes at regular schools than in children instructed in special classes.

The present study is aimed at testing this hypothesis. Self-concept and other school related variables were collected from 13 children attending special classes and from 13 children attending regular classes. All children had been diagnosed as needing special educational help. The children attending schools in the rural regions of Germany were matched for age (about 9 years) and sex. For reasons of statistical control individual reading, arithmetic and working memory were assessed. Each child completed a questionnaire regarding emotional and social school experience ("Fragebogen zur Erfassung emotionaler und sozialer Schulerfahrungen", FEES 1-2; Rauer & Schuck, 2004). The groups of children differed significantly regarding academic self-concept, attitude toward school and enjoyment to learning with children educated in special classes showing more advantageous values than children integrated within regular elementary schools. An analysis of covariance showed that the significant differences were saved after controlling cognitive variables.

Findings

Show that self-concept of children with special needs is at risk if the children are schooled within regular schools. A disadvantageous self-concept seems to reduce the attitude toward school and the enjoyment to learning.

Children who fail to profit from regular instruction at school in the long term may be categorized as children with special educational needs. Some children with a mild intellectual disability or with socio-emotional problems visit classes at special schools, some others are integrated within classes in regular elementary schools. In former times, special classes were arranged in order to give special instruction to children with special needs and in order to save them from learning standards they can't reach. Nowadays, directed by the Convention on the Rights of Persons with Disabilities (2006), more and more children with special needs receive their special education while attending regular schools.

Children with special educational needs should be encouraged regarding both, cognitive and socio-emotional aspects. On the socio-emotional side, the academic self-concept is an important variable. In this theoretical context the well known big-fish-little-pond-effect (Marsh, 1987) predicts a disadvantageous self-concept in children with classmates whose mean capability is much higher than their own. Therefore one could predict lower self-concept scores in children that are integrated in classes at regular schools than in children instructed in special classes. On the other side, teachers of regular classes that integrate children with special needs should be well trained and prepared to be conscious of the big-fish-little-pond effect and to fight against it. From this point of view one should predict no differences between the two groups of children educated in different contexts.

The present study is aimed at investigating the self-concept of children with special educational needs attending special classes compared to children attending classes in regular schools. Self-concept and other school related variables were collected from 13 children attending special classes (four girls, nine boys, mean age = 9;0 years, SD = 0;3) and from 13 children attending regular classes (four girls, nine boys, mean age = 9;1 years, SD = 0;4). All children had been diagnosed as needing special educational help. The children attending schools in the rural regions of Germany were matched for age and sex. For reasons of statistical control individual reading and arithmetical skills as well as working memory were assessed. Each child completed a questionnaire regarding emotional and social school experience ("Fragebogen zur Erfassung emotionaler und sozialer Schulerfahrungen", FEES 1-2; Rauer & Schuck, 2004) that gives information about the following seven variables: social integration, class climate, academic self-concept, attitude toward school, effort tendency, enjoyment to learning, feeling to be accepted.

Simple t-tests ($\alpha = .05$) did not show significant differences between both groups of children regarding reading and arithmetical skills and working memory. However the groups of children differed significantly regarding academic self-concept ($d = 1.04$), attitude toward school ($d = 0.92$) and enjoyment to learning ($d = 0.99$) with children educated in special classes showing more advantageous values than children integrated within regular elementary schools. For the other socio-emotional variables analyses did not show any significant differences. Because there were tendencies

toward better cognitive skills in children attending special classes an additional analysis of covariance was carried out. This analysis showed that the significant differences found for socio-emotional variables were also significant after controlling reading skills, arithmetical skills and working memory.

These findings show that the self-concept of children with special educational needs is at risk if the children are schooled within regular elementary schools. A disadvantageous self-concept seems to reduce the attitude toward school and the enjoyment to learning. Consequently, teachers instructing children with special needs within regular schools have to take the risk for the self-concept of the children into account. Educational research has to yield further knowledge and schools of education have to impart the knowledge about how to save the self-concept of students from being damaged by the context of more capable peers.

PAPER PRESENTATION

The role of text production processes in the development of understanding through writing

Veerle Baaijen, Center for Language and Cognition Groningen, Netherlands; David Galbraith, Staffordshire University, United Kingdom; Kees de Glopper, Faculty of Arts, University of Groningen, Netherlands

Writing is often used as a tool for learning in schools. Current theories of writing, however, have different conceptions of the processes responsible for its epistemic effects. The knowledge-transforming model (Bereiter and Scardamalia, 1987) attributes it to deliberate planning designed to satisfy rhetorical goals. By contrast, the dual-process model (Galbraith, 2009) claims that it depends on the spontaneous formulation of thought during dispositionally-guided text production. Two groups of writers - high self-monitors, whose writing is assumed to be directed towards rhetorical goals, and low self-monitors, whose writing is assumed to be dispositionally-guided - were asked to write an article for the university newspaper. Half the participants were asked to make an outline before writing (outline planning); the other half were asked to sum up their main point before writing (synthetic planning). All participants were asked to rate their understanding of the topic before and after writing, and, in order to assess the extent to which content was modified during text production, keystroke logs were collected. The results are broadly compatible with the dual-process model: (i) writers reported significantly more development of understanding after synthetic than after outline planned writing; (ii) low self-monitors writing synthetically planned text showed much higher levels of text modification during writing; (iii) developments of understanding within the synthetic planning condition were significantly related to the extent of text modification during writing. Alternative explanations for the findings, and their implications for designing school writing tasks, will be discussed.

Writing is often used as a tool for learning in schools. However, there are contrasting conceptions about what is responsible for the epistemic effect of writing. Problem solving models of writing (e.g. Bereiter and Scardamalia, 1987) attribute the development of understanding through writing to deliberate planning designed to satisfy rhetorical goals. By contrast, Galbraith (2009) claims that the development of understanding depends on the extent to which text production is dispositionally driven. This paper focuses on the fundamentally different role that these two theories attribute to text production processes. For the problem solving models of writing, text production is a passive process of translating thoughts into words, whereas the dual process model (Galbraith, 2009) suggests that text production is an active knowledge constituting process in its own right. 42 high self-monitors (whose writing is assumed to be directed towards rhetorical goals) and 42 low self-monitors (whose writing is assumed to be dispositionally driven) were asked to plan and write an article for the university newspaper. Half the participants were asked to make an outline before writing (planned text production) while the other half were asked to write down a single sentence summing up their overall opinion (non-planned text production). We used the latter as a control planning condition, which we defined as synthetic planning.

To assess the development of understanding, participants were asked to list ideas and to rate their understanding of the topic both before and after writing. To assess the extent to which content was modified during text production, keystroke logs were collected during writing (Leijten & Van Waes, 2006). In order to capture text production processes we used a simple indicator of content modification during text production, which we will label as the text modification index. The text modification index is the number of process words registered by Inputlog as a proportion of words in the final text. This index is taken as the extent to which text is modified during writing. Because only the dual process model attributes an active role to text production processes we will take the perspective of the dual process model to state the predictions. If the dual process model is right then the text modification index should be at a maximum when low self-monitors write synthetically planned texts, since it is assumed that low self-monitors' writing is dispositionally driven and that outline planning reduces the extent to which text production is spontaneous. Furthermore, if the dual process model is right, high levels of text modification should also be associated with increases in subjective understanding.

This experiment showed three important results. First, writers reported significantly more development of understanding after synthetic than after outline-planned writing. Secondly, low self-monitors writing synthetically planned text showed much higher levels of text modification during writing than the high self-monitors writing outline planned texts. Third, developments of understanding within the synthetic planning condition were significantly related to the extent of text modification during writing. Taken together, the latter two results suggest that dispositionally-driven (i.e. low self-monitors') writing leads to more modification of thought during text production than writing that is directed towards rhetorical goals (high self-monitors), and this is associated with the development of writers' subjective understanding. This effect is reduced when writing is outline planned. These results are, therefore, compatible with the main claims of Galbraith's dual process model. However, a key question that remains is the nature of the process by which text modification occurs during writing. Is it a consequence of the spontaneous formulation of thought in language, or of a more deliberate planning and rhetorical evaluation of sentences as they are produced? In order to examine this, a further, more detailed analysis of the key-stroke logging data is currently in progress. To date, this analysis has supported the assumption that the text modification index is a valid measure of differences in the number and nature of production and revision phases during writing. More detailed analyses of these findings will be reported in the paper, in addition to the data described above. These results have potentially important implications for the way that writing is taught in schools. Outline planning is one of the most common writing strategies taught in schools, and this is often accompanied by a focus on the rhetorical goals of different forms of writing. Our results suggest that, at least so far as learning is concerned, more exploratory, less structured forms of writing, may be equally important.

PAPER PRESENTATION

Bursts of written language production increase across the initial years of schooling

Rui Alexandre Alves, Universidade do Porto, Portugal; Ilda Jesus, Universidade do Porto, Portugal

Writers compose in bursts, that is, texts are produced by adding up stretches of words, which in adults have an average length of about nine words (Kaufer, Hayes, & Flower, 1986). How do writers progress to achieve this length? Do children readily start by adding up segments of about nine words? Likely not. Here we report a study conducted with Portuguese children that we set up to find if burst length develops throughout the initial four years of schooling. To test this, we formed groups of first, second, third, and fourth graders ($N = 166$). The children handwrote narratives (elicited by a cartoon like drawing) into a digitizing tablet that recorded pauses and bursts. Regarding pauses, we found that its duration decreased from 1st to 4th grade. Regarding bursts, we found a steady increase in burst length from 1st to 4th grade, the average burst size for the four groups were, respectively: 1.84, 3.53, 5.26, and 7.86 words. This result shows for the first time that burst length heightens during the initial years of schooling. Overall, across grades the picture that emerges from this study is one of writing becoming progressively more efficient, as reflected by decreasing pause duration, and increased burst length. These results are of educational relevance, because online measures of writing, such as pauses and bursts, can be thought as markers of writing efficiency, thus teaching us more about identifying and promoting writing skills in the initial years of schooling.

Writers compose in bursts, that is, texts are produced by adding up stretches of words, which in adults have an average length of about nine words (Kaufer, Hayes, & Flower, 1986). How do writers progress to achieve this length? Do children readily start by adding up segments of about nine words? Likely not, because several studies have already shown that in adults burst length is affected by several factors including domain expertise (Kaufer et al., 1986), language skill (Chenoweth & Hayes, 2001), available working memory capacity (Chenoweth & Hayes, 2003), and transcription skill (Alves, Castro, Sousa, & Stromqvist, 2007; Alves, Olive & Castro, 2010). Since many of these skills show developmental trends with age and schooling, it is likely that in children they might contribute to a steady progression of burst length. Nevertheless, bursts of written language production have been seldom studied in children (but see, Alves, Branco, Castro, & Olive, in press), and this topic is unexplored. Here we report a study conducted with Portuguese children that we set up to find if burst length develops throughout the initial four years of schooling.

The first scientific report that writers compose in bursts was made by Kaufer et al. (1986). They compared expert to novice writers, and showed that the experts had larger bursts and wrote generally better texts. For many years this topic of research was overlooked, but has recently seen a handful of studies. Chenoweth and Hayes (2001) compared undergraduates writing two texts, one in their native language (L1), the other in their second language (L2). As predicted, they found that writers were more fluent and had larger bursts in L1 than in L2. Also in a sample of adult writers, Chenoweth and Hayes (2003) have further shown that reducing verbal working memory capacity by articulatory suppression (saying "tap, tap, tap..." to a metronome) decreased both writing fluency and burst length. Two recent studies by Alves and colleagues have argued that automatizing transcription leads to larger bursts. Alves et al. (2007) asked low and high skilled typists to compose written narratives from a set of pictures. They found that the later group used larger bursts. In an experiment, Alves et al. (2010), randomly assigned undergraduates to one of four

conditions resulting from the crossing of output modality (handwriting vs. typing) and transcription skill (low vs. high). They have shown that, irrespective of modality, the high skilled groups composed in larger bursts.

All the skills just discussed have typical progresses during the first years of schooling, thus it is reasonable to expect that they might contribute to more efficient bursts from first to fourth grade. To test this, we formed groups of first, second, third, and fourth graders. The mean ages, size of the groups and gender distributions were, respectively, as follows: M = 6.4 years old, n = 30, 20 girls; M = 7.5 years old, n = 47, 20 girls; M = 8.4 years old, n = 48, 24 girls; and M = 9.5 years old, n = 41, 24 girls. These groups were asked to write a narrative from a simple line drawing depicting a child strolling with a balloon. The children handwrote the stories into a digitizing tablet, that was controlled by an E-Prime script programmed to measure pauses and bursts of language production.

Two-way Gender X Grade ANOVAs were computed on the means of pause duration and burst length. Regarding pause duration, main effects of both gender, $F(1, 158) = 5.42, p < .05, \eta^2 = .03$, and grade, $F(3, 158) = 7.71, p < .01, \eta^2 = .13$, were found. No interaction was found in this analysis. Girls made shorter pauses than boys. Pause duration decreased from 1st to 4th grades, which is compatible with more efficient composing processes. Regarding burst length, main effects of gender $F(1, 158) = 7.70, p < .01, \eta^2 = .05$, and grade, $F(3, 158) = 40.15, p < .01, \eta^2 = .43$, were found. Also, the interaction between gender and grade was significant, $F(3, 158) = 4.22, p < .01, \eta^2 = .07$. While there were no gender differences in the initial two years of schooling, girls in the 3rd and 4th grade showed larger bursts than boys. A similar gender advantage has been reported before in fourth graders (Alves et al., in press), and seems to be accounted by an early advantage of girls in transcription skills (Berninger & Fuller, 1992). As expected, a steady increase was found in burst length from 1st to 4th grade, the average burst size for the four groups were, respectively: 1.84, 3.53, 5.26, and 7.86 words. This result shows for the first time that burst length increases during the first years of schooling. Overall, across grades the picture that emerges from this study is one of writing becoming progressively more efficient, as reflected in decreasing pause duration, and increasing burst length. These results are of educational relevance, because online measures of writing, such as the one studied here, can be thought as markers of writing efficiency, thus teaching us more about identifying and promoting writing skills in the initial years of schooling.

PAPER PRESENTATION

Instruction as Mediated Practice: a critical analysis of an intervention study

Susan Jones, Exeter University, United Kingdom; Debra Myhill, Exeter University, United Kingdom

Abstract

This paper will present qualitative findings from a nationally-funded study measuring the impact of contextualized grammar teaching. This study was designed in response to calls for a Randomised Control Trial to establish 'if grammar teaching works', but the trial itself was embedded within a qualitative framework. The focus of this paper is the qualitative data, including teacher interviews and observation data. Both the observations and the interviews were coded using a grounded approach employing NVIVO software to facilitate the coding process. The RCT revealed a positive effect of 1.53 for those classes being taught explicit grammar. However the classroom observations and interviews with the teachers reveal that the pedagogic materials used in the intervention were mediated differently by different teachers and key themes informing these differences were linguistic subject knowledge and beliefs about

the value of explicit grammar teaching. This presentation seeks to show the different and nuanced ways in which an intervention shown to be effective, is realised in the classroom context.

Introduction

The study from which this data is drawn aimed to measure the impact of contextualized grammar teaching. The term 'contextualized' was used to indicate that grammar features were taught at the point of writing, as a set of linguistic choices the students might employ for purposeful rhetorical reasons. The research took place against a contested background regarding the value of explicit teaching of grammar (Gordon 2005). As a consequence of this debate there had been calls for a Randomised Control Trial to establish empirically 'if grammar teaching works' (Andrews et al 2006). This study employed an RCT but embedded the trial within a qualitative framework. It is this qualitative data that reveals that while there was a positive effect for those classes being taught explicit grammar, the pedagogic materials were mediated differently by different teachers. Thus it is argued that a simple 'what works' approach to educational research misrepresents the complexity of classroom contexts; the aim here is to reveal some of this complexity through a presentation of the findings from the teacher interviews and classroom observations.

Methodology

32 schools were recruited and randomly assigned to intervention and comparison groups. Both groups were taught three types of writing, Fictional Narrative, Argument, and Poetry Writing, through the year, employing schemes of work designed by the research team. In both conditions the learning focus, period of study, resources and learning objectives were the same; however, the intervention group received detailed lesson plans and a day's training in their use and a pedagogic rationale for the teaching. This rationale was informed by a view of grammar teaching that promoted the exercise of informed choices regarding the multiple possibilities of linguistic expression, rather than the teaching of grammar knowledge for its own sake. The comparison group received medium term plans but no pedagogic support or training and taught in their usual manner. Both groups completed pre and post test writing assessments which were scored by an independent organization responsible for marking the National Key Stage tests in the UK. However informed by a belief that 'to undertake a trial of an educational or social intervention without an embedded qualitative process evaluation would be to treat the intervention as a black box, with no information on how it worked, how it could be improved, or what the crucial components of the intervention were.' Moore, Graham and Diamond (2003) the RCT was embedded within a qualitative design. The qualitative data included teacher and student interviews, observation data and examples of student writing. Contextual data relating to individual teachers such as length of service, academic background and linguistic subject knowledge, together with the demographics of the schools were also collected.

Findings

The headline findings of the study indicated a positive effect size of 1.53 for the intervention group. However, the RCT does not provide a simple answer to the question 'does grammar teaching work.' Embedded within the data are the complexities of the classroom context and the differential ways by which the schemes of work were taught and understood. Both the observations and the interview analysis reveal teachers adapting the schemes of work to accommodate either the teachers' own practice and approach, or to avoid areas that challenged their own subject knowledge. In the interviews the teachers frequently air their own concerns about their lack of linguistic subject knowledge. The teachers also reveal their own beliefs about students' ability to engage with grammatical concepts and the pedagogic decisions that resulted from these beliefs. More positively however, there are also examples of teachers being surprised by unexpected outcomes, experimenting with linguistic possibilities and making connections between the schemes of work and pedagogic practice.

Conclusion

While the headline findings indicate the efficacy of contextualized grammar teaching, the qualitative data reveals that this is mediated in different ways by different teachers. The effectiveness of the teacher is informed by a complex set of understandings and skills of which subject knowledge is only part of the equation (Phelps and Shilling 2004). Schulman (1986) speaks of pedagogic content knowledge as the integration of subject knowledge with pedagogy such that the teacher needs to translate what they know into a form that can be taught to others. What is revealed in this data is the struggle to make this translation. At the same time teaching as a profession is the focus of competing discourses whereby both what is taught and how it is taught is a contested agenda frequently aired in professional, research and social contexts. The place of grammar; the role of the teacher and the purpose of writing instruction have all been subject to significant pedagogic shifts. This ranges from progressive approaches to a more prescriptive skills-based curriculum and more recently, attempts to reduce centralised strategy making, returning autonomy to teachers and schools. This shifting pattern and the tensions created are also articulated by these teachers and visible in their pedagogic decision making. This presentation seeks to show the different and nuanced ways in which an intervention shown to be effective, is realised in the classroom context.

PAPER PRESENTATION

A new perspective into writing regulation: Regulation Episodes in expert research article writing

Anna Inesta, ESADE Business School, Spain; Montserrat Castello, Universitat Ramon Llull, Spain

The present study tests a new unit of analysis, the Regulation Episode, with the objective of identifying patterns in the writing regulation activities implemented by 2 expert writers while producing a research article in Spanish as their L1 in ecological conditions. Qualitative analysis of video-recorded writing sessions (Writer 1: 660 hours in 11 writing sessions; Writer 2: 1016 hours in 12 writing sessions), all produced drafts (Writer 1: 14; Writer 2: 13) and writing diaries (Writer 1: 11; Writer 2: 15) showed that Regulation Episodes took place along the writing processes. Two morphological factors were found to characterize Regulation Episodes: explicitness/implicitness (whether or not Episodes appeared after writers' challenge declaration) and continuity/discontinuity (whether or not Episodes required more than one session to solve the challenge). Also, explicit Episodes focused on molar challenges while implicit episodes focused on local, especially those related to the construction of their authorial voice.

We understand by Regulation Episode the sequences of actions that authors strategically implement with the objective of solving a difficulty or challenge identified during the writing process. We expected that this unit of analysis would allow us to approach the regulation of a challenging task such as research article (RA) writing in a comprehensive way and find meaningful writing strategy patterns in ecological conditions.

Participants were two experienced researchers in the field of psychology, who decided to write a RA in Spanish as their academic writing L1[1] in co-authorship conditions. For the purpose of research, Writer 1 and Writer 2 accepted to work separately on the whole article to compare their versions and negotiate a joined one for submission. Writer 1 devoted 660 hours distributed in 11 sessions to write the RA while Writer 2 devoted 1016 hours distributed in 12 writing sessions.

Two independent judges participated in the categorization of the data at two different levels of analysis. Macro-level analysis involved distinguishing the objectives, challenges, solutions as declared in the writing diaries participants were asked to fill in for every writing session, as well as in the process and retrospective interviews. Micro-level analysis, on the other hand, involved analyzing the transcripts of the researchers' video-recorded writing activity (for each of the writing sessions) to identify the actions implemented while working on the RA as well as infer the intentionality underlying these actions.

Results obtained through macro-analysis confirmed the existence of Explicit REs in the writing process of both participants, which were found to be either continuous (challenge and solutions are cited and implemented in one same writing session) or discontinuous (challenge and solutions are cited and implemented in different writing sessions). Finally, micro-level analysis showed evidence of intentional challenge resolution that had not been explicitly identified by the writers. We considered this to be evidence of implicit Regulation Episodes, which we defined as those sequences of actions of at least 10 bursts[2], some of which are aimed at reformulating or adjusting various elements of the sentence, showing an intention to address a challenge, despite not having made any explicit reference to it during the writing process. Examples of these two kinds of Regulation Episodes will be shown in the session.

[1] In the context of the study there are two official languages, Spanish and Catalan, and while the writers considered Catalan to be their first language, they considered Spanish to be their first language for academic writing purposes.

[2] We use the unit of burst in the same way as Chenoweth & Hayes (2001, 2003) or Beare & Bourdages (2007).

PAPER PRESENTATION

Professional Development through Reflection. A Video and Interview based Analysis.

Corinne Wyss, Educational University Zurich, Switzerland

The conventional Universities of Teacher Education in Switzerland, as well as in the surrounding countries are in a changing phase. Teacher education is part of a critical and controversial discussion and new methods and criteria for teacher education are being looked for. With the definition of standards, the quality of teacher education and the teaching competencies of the students should be secured.

One outcome of these discussions about teacher education and professional career is the image of the teacher as "reflective practitioner". The reflecting competency of a teacher is assumed to be an important factor for professional learning and development. Further more, it is the basis for teaching progression and qualitative instruction. But, there is little known about the reflecting competency of teachers and their reflecting practices.

This study tries to find some evidence by questioning novice and expert teachers with different methods and instruments. The analysis is proceeding on the basis of videotaped lessons which are taken at the beginning and at the end of the job entry phase. The longitudinal study reveals how the reflecting competencies are changing in the first year on the job. The coeval study identifies differences between the novice teachers and the expert teachers.

Affiliation

This paper is written within a national project of the Universities of Teachers Education of St. Gallen and Zürich called "Assessing Standards of Teaching Competency in Initial Teacher Training and in the Job Entry Phase".

PAPER PRESENTATION

Reflecting on Reasoning by Studying Videos

Carolyn Maher, Rutgers University, United States; Cindy Hmelo-Silver, Rutgers University, United States; Marjory Palius, Rutgers University, United States; Robert Sigley, Rutgers University, United States

This study examines the features identified by teachers studying videos of children's mathematical reasoning in an online environment. Analysis of small group discourse about the videos indicate that teachers related the video to their own and classmates problem solving, identified connections to other videos, indicated the enjoyment of studying the videos, and related the videos to opportunities to improve their own teaching. Also, teachers made key connections of the videos to assigned and non-assigned readings. Significant findings are (1) that the video offered a context to discuss the undiscovered potential for reasoning in children and (2) that assigned and other readings were introduced by teachers to support the ideas that were offered.

Aims:

When learning is viewed as a process in a social context, it is crucial to consider ways in which technology influences how students engage in building new knowledge (Collins & Halverson, 2009; Peters & Slotta, 2010). Researchers have argued that technology can serve as cognitive and metacognitive tools that extend classroom experiences beyond the physical classroom to enable learning in virtual spaces (Azevedo, 2005; Lajoie & Derry, 1993). The view that such tools can change the nature of teaching and learning as students enable new forms of activity requires study. It is important to understand how learners develop and deepen their understanding through interactions with each other and with computer tools. Asynchronous discussions offer opportunities to students to be more reflective than they might be in face-to-face groups that call for immediate feedback. They also provide instructors a window into the development and extension of knowledge, offering formative assessment and facilitation of multiple groups (Andriessen, 2006; Bonk et al., 1998). It is claimed that student reflection about their learning is essential in order think about the broader contexts in which they might apply their knowledge (Etkina et al., 2010; Salomon & Perkins, 1989). Opportunities to reflect and revisit ideas, and discuss them within a community of learners, have shown to be especially powerful in the development of mathematical reasoning (XXX, 2010). Blending asynchronous online discussion with access to electronic resources, particularly videos, suggests a potent model for catalyzing learning among mathematics teachers.

The Study:

This research examines online discussions of groups of teachers enrolled in a technology-enriched, hybrid course in mathematics education. A goal for the instructional intervention is that teachers learn to recognize children's reasoning as presented on video clips that come from a seminal collection on children reasoning in mathematics being preserved for worldwide accessibility. Setting/intervention: The intervention model involves studying videos of students across K-12 grades as they engage in cognitively challenging mathematical tasks and providing explanations of children's justifications for their solutions. We analyze online discussion within a course management system, where four groups of about 6-7 teachers engage in conversation about their mathematical problem solving. The data source include postings from a group of seven students, over a three day period, coded for Unit 8, five weeks into the strand. Full paper data will be expanded to all four groups.

Research Questions:

The questions that guide the study are: (1) How, if at all, does discussion of studying of videos contribute to knowledge of children's reasoning; and (2) What are indicators of contributing factors? Data Source: A unit over two weeks involved teacher problem solving in class, and online discussions about a video and related readings. The video involved 5 tenth graders, working in groups of two and three working on the following problem: How many different block towers can be built selecting from three colors of blocks such that the towers have at least one of each color? For the online portion, teachers were asked to describe tenth grader Romina's solution to the problem, indicate whether it is convincing and why or why not. They also were asked to compare Romina's solution strategy with those that emerged in class, and to comment on how explaining and justifying contribute to learning mathematics.

Results:

Data emerging from online discussion were coded with time stamp and for initial (I) and response (R) posts. The categories that evolved from the assignment related the videos to: problem solving (VP), value of the video (VA), examples of student reasoning (VR), and examples from the literature (VL). Teacher postings about connections of the readings to practice were also coded (RP). Studying video proved to be a strong catalyst, with 76% of the reasoning related the video and 24% related to the paper. Teacher comments reflected acknowledgement of Romina's proof as correct, clever, convincing, elegant, impressive, similar/different than that of their/other class members, to the way other members of their class solved it, similarity in notation, cleverness in notation, personally insightful, brilliantly represented, etc. The full paper will elaborate on these results, reporting on all four groups and blending quantitative analysis with qualitative evidence in the form of examples of postings made by the teachers.

Implications:

Understanding what a knowledge community looks like in practice is important for advancing our understanding of how to create and facilitate collaborative knowledge building on line and how carefully selected videos made available globally can enhance collaborative learning. Attention to student reasoning is an important aspect of mathematics teaching that can be enhanced through studying videos and thinking deeply about them.

PAPER PRESENTATION

Adaptive Teaching Strategies in German Primary Schools

Jasmin Warwas, German Institute for International Educational Research (DIPF), Germany; Andju Sara Labuhn, German Institute for International Educational Research, Germany; Silke Hertel, German Institute for Internat.Educational Resarch, Germany; Eckhard Klieme, Deutsches Institut fur Intern. Padagogische Forschung, Germany; Marcus Hasselhorn, DIPF, Germany

Dealing with students' heterogeneity and providing individual support to students in classroom instruction are key to teachers' work in every day school life, and are important demands of educational policy. To reach this goal, teachers can make use of several adaptive teaching strategies such as individualised worksheets and expert groups. When investigating classroom practices, teachers' beliefs play a major role. The aim of our study is to investigate what adaptive strategies teachers use, and which role both the heterogeneity of students and the teachers' beliefs play for their use. Teachers in German primary schools (N=26) reported their use of adaptive teaching strategies and their constructivist beliefs. To measure heterogeneity, we assessed the variability of grade level 3 students' (N=469)

competencies in reading comprehension and mathematics in each class. Using linear regression analyses, we could not confirm a relationship between the heterogeneity of students' competencies and the self-reported use of adaptive teaching strategies. Furthermore, teachers holding a constructivist view reported a more frequent use of individualised worksheets, but they did not report to prefer expert groups. Additionally, we found significant interaction effects between the teachers' constructivist view and the heterogeneity of students' competencies regarding the self-reported use of adaptive teaching strategies. The present study reveals important implications for the development of intervention studies designed to provide individual support to students, and for implementing adaptive teaching strategies in teachers' classroom instruction.

Dealing with students' heterogeneity and providing individual support to students in classroom instruction are key to teachers' work in every day school life, and are important demands of educational policy. To this end, Corno and Snow (1986) defined adaptive teaching as "teaching that arranges environmental conditions to fit learners' individual differences" (p. 621). To reach this goal, teachers can make use of several adaptive teaching strategies such as individualised worksheets and expert groups. The former emphasise students' individual learning strategies and are quite popular in German classroom instruction. The latter is a cooperative learning method assigning students to "expert" roles, as the Jigsaw method does (Aronson et al., 1978). A large body of research shows cooperative learning methods to be effective for dealing with heterogeneity and fostering the students' achievement (e.g. Cohen, 1994; Johnson, Johnson, & Stanne, 2000). When investigating classroom practices, teachers' beliefs play a major role. Here, a direct transmission view is contrasted with a constructivist view (see Peterson, Fennema, Carpenter, & Loef, 1989; Staub & Stern, 2002). According to a direct transmission view, teachers are transmitters of knowledge. Within a constructivist framework, students are active constructors of knowledge and teachers support students' self-regulated learning strategies. Therefore, the aim of our study is to investigate what adaptive strategies teachers use, and which role both the heterogeneity of students and the teachers' beliefs play for the use of these strategies.

Hypotheses:

We hypothesize that (1) teachers use individualised worksheets as an adaptive teaching strategy in primary schools more frequently than expert groups, (2) teachers use adaptive teaching strategies particularly in classes with high heterogeneity, (3) teachers with a constructivist view use adaptive teaching strategies more frequently, and (4) teachers with a constructivist view use adaptive teaching strategies more often when they are teaching in classes with high heterogeneity.

Methods:

Teachers (N = 26) in German primary schools completed a questionnaire about their adaptive teaching strategies (e.g. 'How often do you use expert groups as an adaptive teaching strategy in your current classroom instruction?' 1 = never to 4 = in every lesson) and their beliefs (e.g. 'Students should create new ideas on their own and use individual learning strategies.' 1 = I disagree to 4 = I totally agree; three-item scale measuring a constructivist view; Cronbach's alpha = .80). Teachers were predominantly female (89%) and about a half of them had professional experience of more than ten years. Furthermore, we assessed their students' (N = 469) competencies in reading comprehension and mathematics using German standardized diagnostic instruments, such as Wuerzburg Silent Reading Test (Kuespert & Schneider, 1998) and German Mathematics Test (Hasselhorn, Marx, & Schneider, 2004). About half of these students in grade level 3 were female (52%) with a mean age of 8,8 years. To assess heterogeneity, we used the variability of students' competencies in reading comprehension and mathematics in each class. We conducted pairwise comparisons of the self-reported use of two adaptive teaching strategies: individualised worksheets and expert groups. Using stepwise multiple linear regression analyses, we tested main and interaction effects of (a) the heterogeneity of students' competencies for each class, and (b) the teachers' beliefs on the use of these strategies.

Results:

In line with our first hypothesis, a comparison of mean values revealed that teachers reported they used individualised worksheets more often than expert groups ($t(1,24) = 4.63$, $p < .05$, $R^2 F(2,22) = 7.55$, $p < .05$, $R^2 F(2,22) = 7.04$, $p < .05$, $R^2 F(3,21) > 6.95$, $p < .05$, $R^2 = .50$) or in mathematics ($F(3,21) > 10.70$, $p < .05$, $R^2 = .61$). Regarding the self-reported use of expert groups, we found a significant interaction effect between teachers' beliefs and heterogeneity of students' reading comprehension ($F(3,21) = 3.18$, $p < .05$, $R^2 = .31$), whereas the interaction between teachers' beliefs and heterogeneity of students' competencies in mathematics did not reach significance ($F(3,21) = 1.99$, $p = .15$, $R^2 = .22$). However, the significant regression weight for the interaction term ($b = 0.41$, $SE = 0.29$, $p < .05$).

Conclusion and further discussion:

In our study, the heterogeneity of students' competencies within classes was not directly related to the self-reported use of adaptive teaching strategies. However, heterogeneity in a classroom can stem from different reasons and can

also be assessed in other ways, such as socioeconomic background or migration status. Also, the direction of the effects found in our explorative study should be confirmed in longitudinal studies. Furthermore, previous research shows social learning arrangements such as expert groups to be a teaching strategy dealing with students' heterogeneity as well as fostering the students' achievement. Nevertheless, this adaptive teaching strategy is quite rarely used in German primary school classroom instruction. Most likely, teachers report to use this strategy when holding a constructivist view and facing the challenge of teaching students with comparatively heterogeneous competencies. In this study, we aimed to investigate the relationship between self-reported teaching strategies and beliefs, and the heterogeneity of students' competencies. For implementing adaptive teaching strategies in teachers' work in every day school life, it is necessary to examine the teachers' current practices. Thus, the present study reveals important implications for the development of intervention studies designed to provide individual support to students.

PAPER PRESENTATION

Effects of experience and kind of information in making achievement judgments in schools

Assessment of Competence, Cognitive Skills, Continuing professional development in Teachers; Julia Herfordt-Stopel, University of Luxembourg, Luxembourg; Sabine Krolak-Schwerdt, University of Luxembourg, Luxembourg

In a series of experiments, judgment biases and their formation in teachers' assessment of students' performance were investigated. These experiments focused on specific student attributes which, in general, should not influence the achievement assessment, e.g. socioeconomic status or migration background. Previous experiments have provided evidence that experienced teachers are less influenced by these characteristics, especially when the accountability for their decision is high (cf. Krolak-Schwerdt & Rummer, 2005). The difference between experienced and inexperienced teachers might be that they process students' characteristics in a different way. The ability of experienced teachers to ignore irrelevant student characteristics was the focus of three experiments involving different types of participants representing different career levels (experienced teachers as experts, student teachers as novices, and students as laypersons). In these experiments, a special paradigm (Mouselab; cf. Payne, Schkade, & Bettman, 1986) was used. The Mouselab paradigm makes it possible to specify which information is retrieved in what order and which information is ignored when participants search for information about students. The kind of student information which was retrieved in our experiments differed among the three groups. Experts preferred information on achievement characteristics, whereas laymen and novices favored information more connected to person evaluations in daily life. Furthermore the reproduction of the students' attributes was more correct for experienced teachers when the accountability for their judgment was high, than for laymen or novices. For the laymen, no such differences could be shown, whereas, the effects for novices were inconclusive.

Theoretical background Assessment of students is an important task for teachers. However, this assessment may be influenced by student attributes that are not achievement characteristics, such as migration background or socioeconomic background. Until now, it is not known which kind of information (grades, information about solved tasks, additional personal information, etc.) is integrated in what way into judgments. The continuum-model (Fiske & Neuberg, 1990) may help in modeling such judgments. The continuum-model distinguishes two kinds of judgment strategies.

The first strategy is the category based strategy. In this strategy, an activated category (e.g. one based on socioeconomic background or migration background) is used to judge a student. To apply the category based strategy, only low cognitive and motivational effort is needed. For this reason, the category based strategy is used for most judgments, especially when the accountability for the judgment is low. When the accountability for a judgment is high, the second strategy, the attribute based strategy, is used. In this strategy, any available information about the student is integrated into a judgment. This strategy requires much more cognitive effort but leads to less biased judgments. Beyond this, previous research has provided evidence that experienced teachers are less affected by these additional characteristics than inexperienced teachers (Krolak-Schwerdt & Rummer, 2005). This supports the assumption that certain level of expertise is needed to switch between the two strategies (Krolak-Schwerdt & Rummer, 2005), and suggests that not only the amount of information used for the judgment differs with differing levels of expertise, but also the kind of information used.

Methods

In a series of three experiments, the study tested how experts (experienced teachers), novices (student teachers), and laymen (students) search and discern information about students. For these experiments, a special paradigm, Mouselab (cf. Payne, Schkade, & Bettman, 1986) was used. By using Mouselab, it was possible to measure which kind of information (grades, sample tasks, additional information like manners or social behavior) was used to evaluate

students. In Mouselab, it is not only possible to record which information is read by the participants but also the length of time and order in which information is viewed. In these experiments, half of the participants were instructed to form an impression (low accountability) while half were asked to predict the future development of a specific student (high accountability). After the instruction, participants read information about students presented in form of the Mouselab paradigm. After they were informed about a student, the participants had to give a description of that student. Furthermore, the novices took part in a special condition involving retrospective thinking aloud. Research questions and hypotheses

When the goal impression formation is activated, experts encode the student information in a category based manner. Therefore, their reproductions are biased by the activated category and they should produce more inferences. The processing data (Mouselab data) should show that participants retrieve less information under the impression formation goal. In contrast, when the goal for the experts is to give a prognosis of the students' academic development, they should integrate all information about the student in an attribute based manner. In this case, experts are expected to produce much more correct reproductions and fewer inferences. The processing data should show that experts search for more information when accountability is high.

For laymen, we expect no effects of the induced goal, because the continuum-model would predict that they are not able to switch between the two different goals. Furthermore, we believe that not only information processing itself, but also the kind of information used differs between experts and laymen. Experts should retrieve more information associated with achievement, as they are trained to do, whereas laymen should concentrate more on additional information resembling that used in daily life. For the novices, no concrete research questions were formulated. Their judgment process was only observed in an explorative manner.

Results

Concerning the recognition data, experts made more correct reproductions when they worked under the instruction to give a prediction (high accountability). Furthermore, experts made more inferences when they reported their first impression of a certain student (low accountability). For the laymen, no such differences could be shown. The novices showed no effect for the correct reproductions. However, they showed a marginally significant effect for inferences in the same direction as experts. Concerning the information which was used for judgment (Mouselab data), experts revealed a preference for information related to a students' achievement, while novices and laymen preferred information more connected to daily life (e.g. manners).

Discussion

This series of experiments gives evidence that experience is a crucial factor in making achievement judgments. For laymen and experts (experienced teachers) the expected effects on memory could be shown. Furthermore, these experiments support the assumption that information processing between experts and laymen is different and that the two groups base their judgments on different kinds of information. In summary, these results indicate the progression from laymen to experts and give important insight into the search and processing of student achievement information. On a further level, these results may help in developing training programs for student teachers. A very important point which is suggested by these experiments is that student teachers must be trained to concentrate on the important information (achievement information) and to screen out other information (migration background).

PAPER PRESENTATION

Assessing ck, pck- and pk-components of prospective teachers' diagnostic competence

Claudia von Aufschnaiter, Institute of Physics Education, Germany

Among the competences outlined to be relevant for pre- and in-service teachers, assessment and diagnosis is frequently mentioned. Teachers need to be able to identify students' conceptions and their learning outcomes and

they have to monitor students' learning trajectories in order to design instruction accordingly. Even though such diagnostic competence plays an important role in teachers' professional knowledge it is yet rarely explicitly addressed in educational research. Using the distinction between content knowledge (CK), pedagogical content knowledge (PCK) and pedagogical knowledge (PK) we have set up a model to describe diagnostic competence. The model serves as a framework for both, the development of a pre-service curriculum that establishes this competence and the evaluation of prospective teachers' professional competences. Research reported focuses on first results for CK, PCK, and PK which were gathered on prospective teachers of science and mathematics. These prospective teachers demonstrate middle or high knowledge of science content and science methods but show difficulties in diagnosing students' competences. Furthermore, no interrelation was identified between assumed moderating factors, such as attitudes or reported motivation, and the prospective teachers' PK.

Theoretical Framework and Research Aims

During the last couple of years, an increasing number of research projects have addressed teacher profession. Shulman's distinction between subject matter/content knowledge (CK), pedagogical content knowledge (PCK), and pedagogical knowledge (PK) (e.g., Shulman, 1987, see also Park & Oliver, 2008) is often used to describe teachers' professional knowledge. Even though knowledge about students' learning and methods by which this knowledge can be achieved are considered to be important aspects of professional competences, typically these are not addressed in detail in current research projects. In particular, a coherent model to describe diagnostic competence on which the design and evaluation of curricula in teacher education can be built can hardly be found in current frameworks. In order to establish and evaluate prospective teachers' diagnostic competence at university level, we have developed a framework aiming to model subject-matter related diagnostic competence (Figure 1). The framework draws on Shulman's distinction and identifies facets of (subject-matter) diagnostic competence in all three areas (CK, PCK, PK). These facets are either a prerequisite of assessment (such as content specific knowledge about the topic/subject that is to be diagnosed) or refer to the methods and results of diagnosis (such as questionnaires to assess students' prior conceptions). Furthermore, we have included competences which refer to making use of methods and results of assessment for the design of instruction. For each facet, several standards are developed which describe related competences.[Figure 1. Model for diagnostic competence]In our project, the model serves as a heuristic for two research aims. First, it informs us about the design of a curriculum which aims to establish prospective teachers' diagnostic competence. Second, the model provides the frame of reference for assessing prospective teachers' competences and the development of these competences during university training.

Procedure, Sample and Methods

The project lasts for four years (10/2008-09/2012) and comprises two cohorts of prospective teachers (at the beginning typically about 20 years old) who are monitored through their university education (which takes about 3-4 years). Cohort 1 has started in 2008, cohort 2 in 2009. All prospective teachers are included who have chosen either two sciences as subjects or a science subject and mathematics. The number of participants in each cohorts are calculated for each subject individually, numbers vary from roughly 50 (physics) to roughly 140 (biology). For educational psychology all prospective teachers are included who study for a teacher exam (N roughly 800 per cohort).In each subject and for educational psychology the prospective teachers' competences are assessed about once a year. Early in their education, the focus is on CK-components shifting slowly to increasing complex PCK-components; anchor items are included in all tests. Instruments are based on established questionnaires and tests used, for instance, in German research on teacher profession. Sample items for CK, related PCK and PK are presented in Figures 2a-c. Assessments in educational psychology also include items focusing on the assumed influencing factors (Figure 1). [Figures 2a-c. Sample items of CK-, PCK- and PK-tests aiming to assess diagnostic competence (based on Halloun et al., 1995; Riese, 2009)]In addition to summative assessments, formative assessments take place in physics and biology education. Here, the prospective teachers are videoed while working on CK- or PCK- tasks. Videos are then analyzed using surface and deep level coding procedures. These analyses have recently begun so that we cannot yet report sound results but will have those ready for the conference.

Results

During their first year of university education, our prospective teachers demonstrate similar subject matter learning difficulties than pupils do. However, the prospective teachers seem to have a good understanding of Nature of Science and science methods. Our hypothesis that a limited understanding of the content also limits the prospective teachers' ability to diagnose students' learning opportunities and difficulties seems to hold true for the majority of our population. However, some of the students (about 30%) either demonstrate high CK but low PCK or, more surprisingly, low CK and high PCK. It has to be stressed that these results are gained with relatively small sample sizes of physics students and without controlling that the level of difficulty for CK- and PCK-tests is similar. Our first analysis of participants' videos indicates that CK is important for PCK: For CK-tasks the prospective teachers rarely discuss PCK-aspects whereas for PCK-tasks a noticeable amount of time is spent on discussing the science content. The final grade

in school and gender have the largest impact on prospective teachers' PK but regression analysis indicates that moderating factors for CK are different than those for PK. Those prospective teachers who hold a higher tolerance regarding bad exams show less achievement. During one year, the prospective teachers' self-evaluation of their educational skills has significantly increased even though their educational training is at the beginning.

Conclusions and Implications

The project is novel in its emphasis on trying to model and identify diagnostic competence and its development in prospective teachers. It can be expected that the model itself and results gained in the project contribute to research on teacher profession. Even though the project is explorative in its nature, it can reveal as to whether prospective teachers will establish competences we consider to be relevant, how long such a process takes (even though it might become shorter with better learning opportunities) and what kind of learning difficulties prospective teachers encounter.

PAPER PRESENTATION

Surprising differences, hidden difficulties: findings from a teacher education pilot

Christopher Deneen, Hong Kong Institute of Education, Hong Kong; Ronnie Shroff, Hong Kong Institute of Education, Hong Kong

In the last several years, Hong Kong has undergone significant changes in quality assurance and enhancement at the tertiary level. Within this context, the Hong Kong Institute of Education, the region's largest teacher education provider has conducted an exploration of an outcome-based approach to course design, implementation and assessment within teacher education programs.

This paper reports findings from an institute-wide pilot study on OBL, implemented in 2009-2010. Pilot aims included trialing of teacher education course modifications across all undergraduate departments, analyzing and comparing students' and tutors' perceptions of the trial courses, identifying challenges within the trial process, generating evidence-based recommendations to the Institute for larger-scale implementation, and providing evidence-based findings towards to the larger teacher education community on issues of quality assurance and enhancement.

35 instructors and 672 students across 12 departments participated in the pilot. Survey, interview, focus group and related data were collected and analyzed using both quantitative analysis (item/factor scoring, ANOVA, factor analysis) and qualitative analysis (modified grounded theory). Findings include significant discrepancies between instructors' and students' perceptions of course design, assessment and implementation elements. Data analysis also revealed the significance of hidden barriers at multiple levels to change implementation. Theoretical and practical implications for institutions of teacher education contemplating or engaging in quality assurance and enhancement are discussed.

Context

In the last several years, Hong Kong has undergone significant changes in quality assurance and enhancement at the tertiary level (Kennedy, 2008; 2009). One manifestation of this has been the Hong Kong University Grants Committee's (UGC) suggestion that regional universities adopt an outcome-based learning (OBL) approach (Ewell, 2006). The Hong Kong Institute of Education is a tertiary institution serving over 7000 students. The principal focus of the Institute is teacher education. In 2007, the Institute began an exploration of OBL as a means to learner-centered quality assurance and enhancement. This paper reports on findings from the second institute-wide pilot study (Pilot II) on OBL, implemented in 2009-2010.

Aims

Five principal aims of Pilot II:

1. Within an OBL paradigm, enact a trial of teacher education course improvements across all undergraduate departments
2. Analyze and compare students' and instructors' perceptions of trial courses
3. Identify challenges within the trial process
4. Generate evidence-based recommendations to the Institute for larger scale implementation
5. Generate evidence-based findings that may inform the larger teacher education community on issues of quality assurance and enhancement

Methodology

Sample

35 instructors and 672 students participated across 12 departments.

Data collection

Two survey instruments were developed, an Instructor Survey Instrument and a Student Survey Instrument. Instruments were constructed from the same item matrix, which allowed for comparisons in response between instructors and students. Both instruments used a positively-loaded six-point scale (Lam & Klockars, 1982), and open-response items. Qualitative data was collected through instructor professional development sessions, instructor group sharing sessions, and student focus groups. Ethnographic interviewing techniques (Spradley, 1979) and Morgan's (1997) focus group protocols were utilized.

Data Analysis

Data was subjected to qualitative and quantitative analysis. Confirmatory Factor Analysis (CFA) was used on student survey data. CFA was not used with instructor survey data due to sample size restrictions. Analysis of mean, mode, standard deviation, was applied to both instructor and student survey data as well as ANOVA. Qualitative data was coded using a modified Grounded Theory technique (Strauss & Corbin, 1990).

Findings

Factor Analysis

CFA demonstrated the existence of five factors. Inter-correlation values and fit statistics indicated that respondents saw these factors as separate but related components of the pilot course:

1. Course Intended Learning Outcomes (CILOs)
2. Planning, design and alignment
3. Learning and teaching activities
4. Course assessment
5. Feasibility/Comparison

Findings from the fifth factor have been integrated into the discussion of the four course planning and implementation factors.

CILOs

Students evaluated this factor quite highly; CILO factor mean on the student survey was 4.31. Mean factor score on the instructor survey was 4.42, indicating strong parity between students' and instructors' evaluation of CILOs. This factor represents the area in which there was greatest course change as seen through analysis of professional development and sharing session data. Student-generated data reinforced the above findings; students perceived CILO-specific differences from other courses they had taken. Data indicated students placed a high value on outcomes that were practice-oriented.

Planning, design and alignment

This factor received positive ratings from both students and instructors. However, there were concerns as to whether this factor was conceptualized similarly by students and instructors. CFA analysis of the student survey revealed a strong (.97) inter-correlation between this factor and the factor, learning and teaching activities of the course." Fit statistics revealed that despite this inter-correlation, a model with separate factors was more viable. One hypothesis to explain this finding is that students viewed course planning and design differently than instructors. Qualitative and quantitative data from instructors support the hypothesis.

Learning and teaching activities

This factor received highest overall evaluation by students. Factor mean was 4.33. Qualitative data supports this positive impression. However, student ratings negatively correlate to year in degree program. This finding held across the first four factors but it was most pronounced within learning and teaching. One hypothesis is that students'

evaluative criteria become more refined as they progress in the degree program. This interpretation is supported by related research into variance in SET scores by student characteristic (Sailor, Worthen, & Shin, 1997).

Course assessment

Students evaluated this factor category lowest out of all four impact categories. Factor mean was 4.08. This factor category yielded the greatest variance between student and instructor evaluation. Assessment factor mean on the tutor survey was 4.82. Larger-scale analysis of data suggests that classroom assessment was the area of least change within Pilot II. Findings suggest this lack of change was due to multiple factors including administrative barriers and participating instructors' response to change initiatives.

The subset of instructors and students who did make/experience changes in course assessments experienced significantly different results. Open-ended survey responses as well as interview data yielded strong positive response from both groups.

Theoretical and educational significance

Pilot II had strong interaction with unanticipated context issues, such as institutional policy and procedures. Impact was especially pronounced in assessment findings. Attention within the paper is given to understanding these interactions and how findings could be of significance to institutions engaged in quality assurance and enhancement.

Understanding the significant aggregate gap between instructor and student evaluations of classroom assessment has theoretical significance in relation to an emerging field of inquiry: stakeholder conceptions of assessment (Brown, 2006; 2009; 2010). The subset of courses where there were changes to assessment produced significantly different results. The paper discusses theoretical implications and practical possibilities for fostering change in course assessment and addressing challenges to implementation and adoption.

Findings related to planning and teaching are of special significance to teacher education and the preparation of student teachers in the practice of course planning and teaching. Designing transparency into courses is discussed, both as a design element within teacher education courses and as a skill to be taught to student teachers.

The paper also discusses findings on teaching and learning in relation to strategizing student engagement according to progress within degree programs. Implications for teacher education program design are discussed, in terms of outcome development, course leveling, and course mapping/sequencing.

PAPER PRESENTATION

Personalisation in (Initial) Teacher Education

Christian Kraler, Teacher Education and School Research, Austria

Globalisation influences teacher education in Europe especially since the introduction of the Bologna process. This forces governments and universities to reform their teacher education programs. Competence-oriented programs imply the chance to plan initial teacher education outcome oriented and at the same time to increase the process specific flexibility for the course of education of individual students. Thus the idea is to develop a flexible curriculum matrix for a teacher education program with regard to the objective profession-specific course of education defined by competencies and the individual, personal course of education concerning choices, prevailing conditions and other biographical aspects.

In this talk the main findings of a study based on interviews with graduates of a competence oriented teacher education curriculum, a curriculum analysis and quantitative context data will be presented. The research question of the study is: "What are student based developmental tasks during a competence oriented teacher education program?" One result is that we do have two different only partially overlapping cultures of initial teacher education. Based on the concepts of developmental tasks and personalised learning we try to integrate the different approaches into the design of a flexible curricular matrix for initial teacher education with regard to the findings of the study and the existing literature.

One of the effects of the technology-based globalisation of markets is the current status of the individual. The logic behind this seems to be that everything is potentially available at any time for anybody. The responsibility is delegated to the individual. On the other hand, we find that institutions or governments control processes of all kinds increasingly by prescribing detailed structural and content-specific standards for the individual's actions. The same, at least in the German speaking countries, goes for educational systems and especially for teacher education. The modularisation of teacher education programs at universities initiated by the Bologna process (following the logic of global or continental markets) has led to more choice and flexibility for students. Yet on the curriculum level we now find a higher fragmentation of contents. This probably makes the essential profession-specific task of integrating the different elements of initial teacher education for both, the individual teacher student and teacher educators, more challenging than before.

On the other hand, the consequences of this global thinking can be a big chance for teacher education and in particular for the very specific, traditionally government controlled and inflexible teacher education systems in Austria and Germany. The changing framework forces governments and universities to reform their teacher education programs. Thus the internationalisation of teacher education and the necessary governmental reaction to the big international student assessments has led to the implementation of competence-oriented teacher education curricula. As the increasing research literature on this topic since the turn of the century shows, the definition of profession-specific competencies at least improves transparency regarding the efficacy of the teacher education system. Curricular competencies and Bologna modules would offer a profession-specific raster for the individual teacher education student. Carefully implemented, such curricula for teacher education imply the chance to plan initial teacher education in view of the outcome (what are minimum requirements for beginning teachers?) and at the same time increase the process-specific flexibility for the individual course of education. Students have more choices with regard to their individual strengths and weaknesses.

The study presented moves within this context. The underlying question is this: How can a competence-oriented university-based teacher education program be developed further into a profession-specific, personalised course of education?

The theoretical framework of our research into teacher education at the University of Innsbruck is threefold. The starting point is Kant's pedagogical question: How can I cultivate freedom under constraint? Based on this question we adapt Havighurst's concept of developmental tasks (cf. Trautmann 2004), the concept of the course of education (Meyer M. 2007) and put it in the context of personalised learning (Des 2006). The idea is that teachers need to experience successful ways of teaching for our changing society during their own professional education at university that implies personalised learning and an individual course of education. Taking into account institutional limits and reasonable common standards for beginning teachers a matrix of curricular modules and profession-specific competencies might lead to a flexible set of specific developmental tasks for students. Personalisation would imply that not all these tasks need to be taken on by every student and that the order must remain flexible.

The University of Innsbruck has implemented a competence-oriented, portfolio-supported teacher education program in 2000 (Kraler 2008). It is based on curricular developmental tasks for every academic year (e.g. 1st year: trial identification, self-assessment, shift in perspective from pupil to teacher, introduction & fit). After ten years of experience we get positive feedback from schools and school authorities. But at the same time an ongoing evaluation study has shown that the students view their education as too inflexible and rigid. The next logical step for program development was to systematise the feedback and the student experiences (Kraler 2009). So the central research question of the study is: What are student-based developmental tasks during a competence-oriented teacher education program? The objective, ultimately, is to develop a flexible curriculum matrix for our teacher education program with regard to the objective profession-specific course of education defined by competencies and the individual course of education concerning choices, prevailing conditions, etc. In the context of our personalised concept we used a qualitative approach and held 25 profession-specific biographical interviews, on a voluntary basis, with graduates of our teacher education program. The interviews covered questions from the origin of the idea of becoming a teacher, the school career, the experiences at university, familial and private influences, up to next steps after graduation. The average duration of the interviews was between 1h20min and 2 hours. In keeping with our gender distribution, there were 7 male and 18 female interviewees. In addition to the interviews we could analyse the portfolios of the interviewees and, as a quantitative element, take into account all the students' grades. The data analysis was done computer-supported (MaxQDA), using a combination of grounded theory, metaphor analysis and hierarchical content analysis. The grades contextual biographical data were analyzed with SPSS. We also analysed the curriculum (18 different subjects), focusing on the description of competencies.

The main findings are:

Prescribed program/curriculum-based developmental tasks: - Trial identification - Understanding fundamental ideas of the relevant subjects - Teaching internships to test out acquired competencies - Readjustment & amendment (based on the experiences from the internship) - Diploma certification
Student-based developmental tasks (interviews, portfolios): - Role allocation: growing into the role of the student - Relations: disengaging from the parental home, relationship/new friendships/old friendships sustained, students studying together - Dealing with frustration concerning course organisation and specific contents - Subject-specific socialisation (faculty culture) - Change of perspectives through periods spent abroad (especially when studying languages) - Earning money (subject-related, e.g. tutoring, or non-subject-related, often also just to get a change)
The last part of the presentation will deal with our first approaches to designing a flexible curricular matrix for initial teacher education based on the findings of the study mentioned.

PAPER PRESENTATION

Wisdom-related competence in teacher education - an adapted model of psychological wisdom research

Robin Stark, Saarland University, Germany; Miriam Hoffmann, Saarland University, Germany

Wisdom-related competence supports effective action in complex social situations as for example in an educational setting. Our concept of wisdom-related knowledge postulates 14 knowledge and attitude categories which constitute wisdom-related competence. We distinguish wisdom-relevant and wisdom-specific knowledge and attitude dimensions. In order to investigate the level of wisdom-related competence in teacher candidates, we generated complex scenarios situated in an educational context. 49 teacher candidates processed these scenarios in two different learning conditions: problem-based learning (n=24) and analysis of erroneous examples (n=25), plus a control group of n=9. In the pretest, we assessed "wisdom" through the three-dimensional Wisdom Scale (3d-WS) and the Self-Assessed Wisdom Scale (SAWS) and tolerance of complexity through the Tolerance of Complexity Scale. We performed a content analysis on the written answers of pre- and posttests using a specific coding manual and the software MaxQDA. Means were higher in the post- than in the pretest but still at only 35% (problem-based condition) resp. 36% (erroneous example condition) of the theoretical maximum. There were no significant differences between experimental conditions, but both experimental conditions outperformed the control group. A significant predicting factor for posttest achievement proved to be the prior level of wisdom-related competence as assessed in the pretest. Posttest total scores' correlations to the three additionally implemented scales missed statistical significance, whereas posttest scores of some wisdom-related dimensions correlated at least partially to the 3d-WS, SAWS and the Tolerance of Complexity Scale.

Aims: Based on the Berlin Wisdom Paradigm (e.g. Staudinger & Baltes, 1996a) and the Balance Theory of Wisdom (Sternberg, 2001), our model of wisdom-related competence distinguishes 14 wisdom-relevant and wisdom-specific knowledge and attitude dimensions (Hoffmann & Stark, 2009), the first being necessary, but not sufficient prerequisites for the development of wisdom whereas the latter describe aspects characteristic for people whose actions could be considered to be "wise".

We tried to reveal the level of wisdom-related competence in teacher students as we consider everyday school life as a highly complex and very dynamic working environment where dealing with wisdom can provide valuable "orientation knowledge" (Staudinger & Baltes, 1996a) in order to facilitate complex problem-solving.

We investigated whether wisdom-related competence can be fostered by a short scenario-based learning environment with either a problem-based learning approach or by processing erroneous examples.

In order to validate our wisdom model respectively our coding system, we compared the results of our assessment method to two existing wisdom scales (3dWS, Ardelt, 2003; and SAWS, Webster, 2003) and a scale for assessment of tolerance of complexity (Radant & Dalbert, 2006).

Methodology

Sample

Participants were teacher students (n=63, 40 female, 23 male), between 19 and 36 years old (M=22.13; SD=3.80), who during their studies underwent a practical training of five weeks. They all participated in the pre- and posttest; the two experimental groups worked with a learning environment in the problem-based learning (n=24) or the erroneous example (n=25) condition.

Scenarios

We developed four scenarios dealing with problematic situations in everyday school life. Two of them were used in the pre- and/or post tests, two only in the experimental conditions.

Problem-based learning vs. Learning from erroneous examples

In the problem-based learning condition, participants had to process a scenario and compare their own answer to a sample solution given by a fictitious psychologist.

In the erroneous example condition, the erroneous example consisted of a given answer by a fictitious laymen. This erroneous example had to be compared to the sample solution.

Coding manual

The coding manual comprises 14 categories (Hoffmann & Stark, 2009). Answers are coded according to their congruence with an ideal answer on a 7-point-scale.

Wisdom Scales

3d-WS: This scale by Ardelt (2003) consists of 39 items belonging to either the cognitive, affective or reflective subscale, each item is rated on 4- resp. 5-point Likert scales.

SAWS: The SAWS (Webster, 2003) comprises 40 items belonging to one of the five subscales "Experience", "Emotional Regulation", "Reminiscence/Reflection", "Humour" and "Openness" with a 6-point Likert scale.

Tolerance of Complexity Scale: This scale (Radant & Dalbert, 2006) assesses tolerance of complexity in three subscales ("Challenge", "Pressure" and "Necessity") of 20 items each on a 6-point Likert scale.

Findings

Concerning pretest performance and tolerance of complexity, learners of the three groups did not differ significantly. Total scenario scores (theor. max.: 98 points) in the posttest ranged from 21 to 56 points in the erroneous example condition ($M=35.72$; $SD=9.14$; 36% of theor. max.), from 14 to 49 points in the problem-based learning condition ($M=34.58$; $SD=10.81$; 35% of theor. max.), and from 17 to 35 points in the control group ($M=26.67$; $SD=5.96$; 27% of theor. max.). There were no significant differences between the two experimental groups. Both experimental groups clearly outperformed the control group. For all groups, pretest scores were strong predictors for posttest performance. There was no interaction between pretest scores and experimental condition. Correlations between posttest results and the Tolerance of Complexity Scale, 3d-WS and SAWS missed statistical relevance. Tolerance of Complexity correlated with "domain-specific background knowledge" ($r=.29$, $pr=.29$, $pr=.27$, $pr=.29$, $pr=.27$, $pr=.34$, $pr=.27$, $pr=.30$, p

Theoretical and educational relevance

On an abstract level, results indicate an existing deficit in teacher candidates concerning wisdom-related competence. More concretely, our results show that aspects of wisdom-related competence can be fostered effectively and economically by a scenario-based learning environment. Similar results can be achieved by problem-based learning and learning by erroneous examples. However, they also show that both approaches are not effective enough to develop wisdom-related competence. We suppose that in order to come closer to this goal, both approaches have to be implemented for a longer period. They should be combined with additional instructional support, e.g. innovative feedback methods. Based on findings by Staudinger & Baltes (1996b), we propose that these methods could be realized by implementing forms of cooperative learning (e. g., reciprocal teaching; Palincsar & Brown, 1984). The correlations between aspects of wisdom-related competence assessed by our coding procedure and the two wisdom scales can be interpreted in terms of first indicators for convergent validity.

PAPER PRESENTATION

An investigation into the analogies used for teaching the mole in secondary classrooms

Chemistry, Science Education, Secondary school

Su Chi Fang, The University of Melbourne, Australia; Christina Hart, The University of Melbourne, Australia;

David Clarke, University of Melbourne, Australia

The mole is a fundamental concept in chemistry. Using analogies when introducing the mole is common in textbooks. However, what type of analogies and how they are used in introducing the mole in classrooms needs to be investigated.

This paper is part of my PhD research program in which I intended to look into the reasons why the mole concept is difficult to be taught and learned by comparing two countries (Australia and Taiwan). Data included video records of the lessons and the chemistry teachers' and students' interviews. The aims of this paper are (1) to explore what are the analogies used to introduce the mole concept, and (2) to inquire into how these analogies play a role in helping learning the mole concept.

The findings showed that using analogies in introducing the mole was popular in secondary classrooms. The analogy of 'a dozen' was employed the most frequently. In addition, a second group of analogies like 'packages of rice' or 'trucks of oranges', and a third group related to chemical reactions were also used in classrooms. In fact, different analogies highlight different aspects of the mole concept. However, it seems that these analogies were used without making explicit the aspect they actually address. Moreover, the essence of the mole concept, that it depends on a proportional relationship, was not conveyed by these analogies. Suggestions about effectively using analogies in teaching the mole concept are also presented.

Using analogies in teaching and learning chemistry is deemed a powerful strategy because analogies provide a bridge connecting between the unfamiliar target concept and familiar analogy (Duit, 1991). Previous research has showed that generally in textbooks the mole concept was introduced with analogies, such as a dozen (Staver & Lumpe, 1993). However, what kinds of analogies are used and how they are used in teaching and learning in classrooms has not been previously explored. Therefore, the aims of this paper are (1) to identify what analogies are used to introduce the mole concept. (2) to inquire into the role these analogies may play in helping students' learning of the mole concept. This study is positioned as a classroom study, based on the perspective that learning science is not only a personal meaning making process but also a social interactive activity. Seven chemistry classrooms were participating in this study, including two year-8 and three year-10 classrooms in Taipei, and two year-11 classrooms in Victoria. Data generation included videotaping the lessons, teacher and student interviews. Analysis of the empirical data was based on a content analysis of the mole concept.

In these seven classrooms, a dozen was the most frequently used analogy in the lessons on the mole. The analogies could be categorised into three different groups: (1) The number group, (2) The mass group (3) The chemical reaction group. The number group includes analogies such as a dozen, a box etc, and they stress the point that the mole represents a number, 6×10^{23} . The analogies in this group suggest that it is possible to count and know exactly what the number is. The mass group comprises analogies like trucks of oranges and packages of rice. The mass group of analogies emphasized the situation where the number involved is huge, so 'weighing' is used as a strategy to quantify the amount. Therefore, within this context, 'weighing instead of counting' is the point and exactly how many there are is NOT important. The analogies in the chemical reaction group are not directly related to the mole concept, but implicitly involve the application of the mole in chemical reactions, for example, monkey and banana, and the process of baking a cake.

Teachers used one or more of these analogies at the time when they introduced the mole. However, it appeared that their students accepted the number group most readily. The number group of analogies seemed to be easier to grasp because the connections between the analogy 'dozen' and the target 'mole' are straightforward (Duit, 1991). In other words, it is simple to relate a number to the term, 'mole', just like we relate 12 to a dozen. In contrast, the connections between the analogy 'packages of rice' and the 'mole' were not explicit. Also whenever the mass group of analogies was presented, the teachers did not explicitly make the link with the mole. The teachers alluded to 'weighing instead of counting', but they did not explain how this strategy works with the mole in chemistry. Consequently, the students could not actually see the connection between these analogies and the mole and in interviews they did not refer to them as helpful for their learning. The third group of analogies seems to be more problematic because the analogies concern the ratio between reactants and products in chemical reactions and not the mole concept itself. This connection, again, was not made explicit and the students did not appear to find this type of analogy meaningful.

Nevertheless, these analogies used in the classrooms do not perfectly match the mole concept. They were limited in that they did not explain the proportional relationships between $12C$ and other elements. An activity that is more analogous to the use of the mole concept in chemistry will be provided. Two significant issues pertaining to how

teachers can use analogies more effectively in science teaching are discussed. First, the connection between the analogue and the target should be made as explicit as possible to the students. In other words, students' attention should be guided and directed to the intended way of using the analogy (Coll, 2006), otherwise students might see and interpret analogies in a different way from their teachers (Treagust & Harrison, 2006). Second, it is important that teachers discuss "the scope and limitations of an analogy" (Justi & Gilbert, 2006, p. 128) with students. For instance, in the case of mole, although 'a package of rice' is a promising analogy for students to learn the mole, the meaning it conveys is still limited, since this analogy cannot reflect the essence of the use of the mole in chemistry. Therefore, as Justi and Gilbert (2006, p. 129) suggested, teachers might adopt "discuss and guide" approach rather than "show and tell" when they teach with analogies.

PAPER PRESENTATION

A Practice of Science as Varied as the Members of the Science Classroom Community Culture and Education, Inquiry learning, Science Education

Michele Koomen, Gustavus Adolphus College, United States

This paper reports on a qualitative study of nine culturally, linguistically and academically diverse students as they studied insect biology and ecology in their inclusive seventh grade life science class. Three fundamental data collection methods of qualitative research (student observations, interviews and artifact analysis) framed the data collection portion of this study. Constant comparative and microanalysis frameworks for grounded theory were used to systematically analyze the data set resulting in a practice of science that is different for each of the nine youth: A practice of science that is fragile and tentative and tied with the language of science; a practice of science that is dutiful and pragmatic although absent in passion or curiosity, and a practice of science positions one student to be dis/abled. Implications of this study to the greater research community and insights for instructional practice and structure of learning opportunities for all students are discussed.

Aims/Purpose

Many, many science classrooms across the world represent our global society and as such are rich in diversity, language, culture and ability. The United States is no exception to this new normal where 20 percent of school-aged children have at least one parent who is an immigrant and 5 percent of the students were immigrants themselves with language minority students speak an amazing 400 + languages (Nieto, 2004). On top of the growing linguistic and cultural differences in the school age population, science classrooms increasingly are places where students with exceptionalities are mainstreamed (Hobbs & Westling, 2002) as a result of legislative initiatives such as the Individuals with Disabilities Education Act (IDEA, 1990) and subsequent amendments (IDEA, 2004). Science for all Americans (AAAS, 1989, 1993) call for egalitarian access to science education is based on beliefs that all youth can learn science. The theme of the 2011 EARLI conference is "Education for a Global Networked Society." If our science classrooms illustrate the richness of our global society, doesn't it make sense that we try to understand how some members of that global diversity contextualize and experience learning as we position ourselves to embrace education for a global networked society? This paper will describe a research study focused on learning for students from diverse backgrounds who have been underserved in the education system (Basu & Barton, 2007; Upadhyay, 2008).

Theoretical Frameworks
