Against this background empirical teacher education research is challenged. Evaluation designs and measurement instruments have to be developed, for example, in order to precisely examine the outcomes of teacher education on the basis of educational standards. However, a question hardly taken into account when discussing the output of teacher education is related to the diversity of student teachers when they start out to become a teacher: To what extent do they differ in domain-specific learning preconditions right at the beginning of their teacher education? Do such differences contribute to differential development in future teachers? Although there is research findings on future teachers' vocational interests upon entry into teacher education (cf., e.g., Klusmann et al., 2009; Ziegler, 2009) as well as on the biographical perspective of professionalization (e.g., Terhart et al., 1994), in-depth research on various elements of their "professional profile" they might already have as early as when entering teacher education does hardly exist. However, learning preconditions of future teachers has to be taken into account, for example, when designing a new teacher education curriculum or adequate evaluation designs.

Thus our presentation focuses on future teachers who just entered teacher education. The theoretical framework is a model of professional competencies (Baumert et al., 2010; Blömeke et al., 2010a, b), allowing us to differentiate elements of professional knowledge (such as general pedagogical knowledge) from affective-motivational characteristics (such as vocational interest and domain-specific self-efficacy). Teacher education research looking at future teachers who have nearly finished their teacher education shows cognitive as well as affective-motivational characteristics are substantially intercorrelated (e.g., Blömeke et al., 2010a, b). When looking at our target group of future teachers at the beginning of teacher education, we also assume interdependency of cognitive characteristics on the one side and affective-motivational characteristics on the other side, which, however, should then be loosely connected only. Apart from correlation analysis of quantitative measures, our research also intends to provide possible explanations using qualitative methods to reconstruct the biographical approach of teacher students and their first pedagogical experiences.

A sample of 56 future teachers is used who attend a new model program of educational opportunities to learn in teacher education at the University of Cologne ("Kölner Modellkolleg Bildungswissenschaften"). Having started in winter term 2009/2010, the model program offers a new curriculum closely aligned to teacher education standards (KMK, 2004) and orientated towards profession-related tasks (Artmann, Herzmann, Karduck & Käßig, 2010). The curriculum's content is structured according to the four core competencies proposed by the KMK (2004): educating ("Erziehen"), teaching ("Unterrichten"), assessing ("Beurteilen"), and innovating ("Innovieren"). Currently, the model program is applied to a small group of 56 teacher students only before it will be implemented in the BA/MA structure of teacher education programs beginning in winter term 2011/2012. Aiming at a standard-based assessment of teacher education, a range of evaluative measures is assigned to it providing in-depth information on its effectiveness and allowing the application and development of innovative measurement instruments. The inventory of standardized instruments includes the TEDS-M achievement test measuring pedagogical knowledge (Käßig et al., in press), domain-specific self-efficacy scales (Schulte et al., 2008), and vocational interest scales (Pohlmann & Möller, 2010). The qualitative instrument design includes portfolios documenting self-reflection and knowledge of teacher students.

First we will give an overview on the model program, including a depiction on its intended curriculum and the evaluation design. Secondly, first results from the first occasion of measurement on learning preconditions of future teachers are presented. Apart from descriptive statistics giving basic information, intercorrelations of various quantitative measures such as future teachers' pedagogical knowledge, vocational interest, domain-specific efficacy, and pedagogical experience future teachers have gained before starting their teacher education are reported. According to our assumptions, there are small correlations that we interpret as future teachers' beginning professionalization: For instance, future teachers' intrinsic vocational interest for pedagogy and their pedagogical self-efficacy positively intercorrelates with their pedagogical knowledge. However in general, cognitive and affective-motivational characteristics are loosely intercorrelated only ($|r|$). As a consequence, pedagogical implications for the design of adequate opportunities to learn dealing with diversity of future teacher students at the start of their teacher education will be discussed. We will present good practice examples from the model program at the University of Cologne we assume to be successful and have the potential to give new impulses for improving teacher education.

PAPER PRESENTATION

Developing Socially Just Teachers for Urban Schools

Joan Whipp, Marquette University, United States

Drawing from literature in moral philosophy, culturally relevant teaching, and justice-oriented teacher education, this paper reports on a study of 12 graduates of an urban teacher preparation program in the United States who are now teaching in urban schools. Using an interpretive cross case study design, the study followed these teachers from the end of their student teaching experience into their first year of teaching to investigate their developing perceptions of socially just teaching, how they were enacting those perceptions in teaching practice, and what pre-program, program, and on-the-job knowledge, experiences, and dispositions were contributing to that development. Data sources included surveys, student teaching evaluations, and interviews. Data analysis revealed that at the end of student teaching ten of these teachers held individualistic views of socially just teaching but by the end of their first year of urban teaching, four of those teachers were moving toward a more structural approach to socially just teaching. Program factors most related to the development of structurally-oriented orientations to socially just teaching practices were: 1) field experiences in urban schools and community agencies with culturally diverse populations; 2) course content that sparked moral responses and challenged previous thinking; and 3) mentors and instructors who modeled and explicitly talked about culturally relevant teaching practices. Non-program factors that

encouraged structural approaches to justice-oriented teaching were: 1) immersion experiences in urban and/or high-poverty communities; 2) first-hand experiences with discrimination ; and 3) targeted support from colleagues and administrators during the first year of teaching.

Throughout the world, students from low-income racial, ethnic, and immigrant minority groups often do not have the same educational and life opportunities as their middle class, ethnic majority peers. As a response, teacher educators have continually asked: What knowledge, skills, and dispositions should teachers have who are teaching for social justice by actively working to remove classroom and institutional barriers that keep all students from academic success? This and related questions are the focus of research that my colleagues and I have been conducting on our teacher education program which is intentionally designed to prepare teachers to teach in urban schools in the United States.

This paper reports findings of an empirical study of 12 graduates who are now teaching in schools serving large numbers of children living in poverty. Using an interpretive cross case study design, the study followed these teachers from the end of their student teaching experience into their first year of teaching to investigate their developing perceptions of socially just teaching, how they were enacting those perceptions in their teaching practice, and what pre-program, program, and on-the-job knowledge, experiences, and dispositions were contributing to that development. Philosophical perspectives on the moral nature of teaching (Dewey, 1933; Dotti, 2009; Freire, 1970; Hansen, 2001; Noddings, 1992; Sockett, 2009), research on culturally responsive teaching practices (Cochran-Smith, 2004; Ladson-Billings, 1994; Villegas & Lucas, 2002), and theory and research on justice-oriented teacher education (Chubbuck, 2008; 2010; Chubbuck & Zembylas 2008; Cochran-Smith, Shakman, Jong, Terrell, Barnatt & McQuillan, 2009; Villegas, 2007; Watson, Charner-Laird, Kirkpatrick, Szczesiul & Gordon, 2006; Zeichner & Flessner, 2009) offer insights regarding the knowledge, dispositions, and skills needed for socially just teaching.

This literature maintains that justice-oriented teacher education should include both individualistic and structural approaches. Individualistic approaches emphasize fairness and providing equal learning opportunities within classrooms for students who have been traditionally marginalized in schools. Individualistically-oriented teachers work hard to build on their students' cultural knowledge and everyday experiences. They set high expectations and consistently provide academic challenge and opportunities for higher order thinking for all students. Teachers with structural approaches to teaching for social justice do more. They see themselves responsible not only for the learning of all students in their classrooms but also for critically addressing structural inequities in their schools and communities that diminish their students' "learning and life chances" (Cochran-Smith, 2004). They work to change unfair policies in their schools and communities; and they teach in ways that challenge all students "to envision themselves as active citizens with the power to transform unjust structures" (Chubbuck, 2010).

This study posed the following questions:

- 1) What is the demographic, educational, professional and dispositional profile of a sample of students from an urban teacher education program who choose to teach in urban schools?
- 2) How did these teachers' perceptions of socially just teaching develop during their teacher education program and during their first year of teaching?
- 3) How are these teachers enacting these perceptions in their teaching practices?
- 4) What pre-program, program, and post-program factors appeared to influence these teachers' socially just perceptions and teaching practices?

Data sources included interviews, surveys, and student teaching evaluations. With the help of a research assistant and NVivo software, I used the frameworks of moral philosophy, culturally responsive teaching practices, and justice-oriented teacher education to code all data and develop case reports for each of the 12 teachers. Cross-case analysis of surveys, interviews and student teaching evaluations for these students as they left the program revealed that all 12 were remarkably similar in dispositions and background experiences. Specifically, compassion, responsibility toward individuals, openness, and reflectivity were the most frequently coded dispositional categories across cases. Also, ten of the 12 entered the program with significant pre-program cross-cultural experiences. Similar to other recent studies of graduates from programs focusing on social justice (Cochran-Smith, 2009), however, these data indicated that at the end of their program, ten of these 12 students saw justice-oriented teaching individualistically. Notably absent in their interviews was the "critical consciousness" that many have argued is an essential element in socially just and culturally responsive teaching. Only two, Sarah and Michael, offered any vision of justice-oriented teaching that included structural as well as individual elements. Interviews at the end of their first year of teaching, however, indicated that, in addition to Sarah and Michael, four other teachers were developing structural orientations to socially just teaching and enacting those perceptions in their work. One described her campaign to change her school's policies around unfair grouping and curricular practices for students with disabilities; another spoke about

trying to change school discipline policies that set low and inconsistent expectations for student behavior; another described her attempts to introduce more challenging curriculum and fairer assessment practices in her "whole school"; and the fourth described how she saw her teaching as "improving the lives of students" who "have...been left behind in the social network," which she was doing through home visits with parents and building awareness in her students of "injustices" in "their own neighborhood" and "ways that they can help to change that."

Comparative analyses of interviews and surveys at the end of student teaching and a year later highlighted both program and non-program factors that related to the development of structural orientations to justice-oriented teaching in this group of teachers.

Program factors included:

1) field experiences and student teaching in urban schools and community agencies with culturally diverse populations; 2) course content that sparked moral responses and challenged previous thinking; and 3) mentors and instructors who modeled and explicitly talked about culturally relevant teaching practices. Non-program factors before, during and after teacher preparation that seemed to encourage structural approaches to justice-oriented teaching were: 1) immersion experiences in urban and/or high-poverty communities prior to college entrance; 2) first-hand experiences with discrimination or prejudice; and 3) targeted support from colleagues and administrators during the first year of teaching. These factors suggest ways that teacher education programs can more strategically design curriculum, field experiences and mentoring to support the development of socially just teachers for urban schools.

PAPER PRESENTATION

What undergraduate and postgraduate student teachers learn about learning and teaching through PBL

Collaborative Learning, Initial Teacher Education (Pre service), Problem Solving
Rosalind Murray-Harvey, Flinders University, Australia

The abundant literature on PBL provides convincing arguments, some supporting and others questioning its effectiveness in achieving desired learning outcomes. In a teacher education program where careful attention was given to aligning PBL aims and assessment, quantitative and qualitative data on students' experience of PBL as learners and prospective teachers were analyzed to ascertain: (1) the extent to which PBL achieved its stated learning and instructional aims, and (2) whether learning through PBL was experienced differently for undergraduate and postgraduate pre-service teachers.

Quantitative data capturing four dimensions of learning competence: problem solving, communication skills, knowledge building, and intra/inter-personal development were obtained via a 19-item questionnaire from 122 students twice in the semester. Using the combined score of all four dimensions students reported significantly increased competence over the semester. For separated dimensions, postgraduate females reported significantly more communication skills competence and knowledge building.

NVivo qualitative analysis software supported mapping of students' final course papers (that included reflections on PBL for learning and teaching) for social, emotional and cognitive engagement indicators of learning through PBL.

Four areas of engagement with PBL emerged: emotional, cognitive, social (collaborative) and transformational providing insight into students' experience of PBL as learners and their understandings about teaching, including benefits of and barriers to effective collaborative learning. Importantly, transformational learning differentiated the postgraduates' from the undergraduates' experience. A key message for tutors is the need be explicit about the PBL learning process itself to fully support students' transition to this holistic yet unfamiliar and challenging way of learning.

Relevance

Claims for and against PBL continue to be debated in the literature; some focusing on learning processes and others on instructional practices. This warrants a closer look at learning through and teaching with PBL, certainly within teacher education. Pre-service teachers should be familiar with a range of instructional approaches, yet PBL is an unfamiliar learning environment for most, so including PBL in a teacher education program ideally serves two purposes – one that attends to processes involved in learning as a student; the other to pedagogy.

Theoretical and Educational Significance

This paper argues that claims about the effectiveness of PBL rely on that research sufficiently representing and reflecting PBL aims. The literature however, reveals a lack of congruence in the way research has addressed the nexus between PBL aims and outcomes, with more data gathered on easily measured (content knowledge), than other outcomes. Such uneven treatment leaves unanswered questions about the social and emotional (e.g. collaboration and motivation) dimensions of learning, cognitive engagement (e.g. critical thinking), or professionally relevant communication skills. The PBL literature acknowledges this alignment gap.

Studies of PBL effectiveness have largely concentrated on comparing PBL with non-PBL approaches. As well, studies have looked at differences among students from different disciplines. No published research has investigated the PBL experience for students who are undergraduates compared with postgraduates; a consideration for course delivery.

Aims and Method

This study aimed to map student learning through PBL with particular interest in examining cognitive, affective, and social dimensions of students' learning that have received less empirically-based PBL research attention, among them, higher-order thinking, motivation, communicating effectively and working collaboratively. The guiding research question was: In what ways does PBL contribute to students' learning about learning and teaching? In answering this question consideration was given to undergraduate and postgraduate students' perspectives as both learners and as prospective teachers.

Context

The reported study was undertaken at an Australian university, drawing on both quantitative and qualitative data provided by pre-service teachers about their experience of PBL. Postgraduate students were enrolled in separate classes to undergraduates but undertook a matched program of study. This provided an ideal opportunity to explore the two student groups' experiences of PBL.

Participants were students who consented to researchers using their course assignments for analysis. They provided background information on sex, age, previous learning using PBL, major area of degree study and work experience. Of the 122 students for whom data were available 36% were males (proportionally representative of the cohort). Ages ranged from 19-52 years (Mean 24.5 years; SD 6.81) with an average difference of 10 years between undergraduates and postgraduates. Six students indicated previous involvement with PBL.

Sources of data

The Learning Evaluation

Students submitted a mid-term written report on their PBL experience and an end-of-semester learning evaluation paper (used for qualitative data analysis in this study).

Critical thinking scores

A 5-point scale critical thinking rubric (Angeli, & Valanides, 2009) was used to rate two papers submitted by students: their mid-term report on the PBL experience following the first case study and the final paper, completed after the second case study (6 weeks apart). This enabled analysis of critical thinking scores between two points in time.

Students' self-assessment of PBL performance

After completing each PBL case study students self-assessed their learning performance across four areas: problem solving, communication skills, knowledge building, and interpersonal relationships using a 19-item questionnaire. Students were asked to rate "your current level of competence developed through your participation in the small group that you have worked in on this PBL case" along a 4-point scale: 4 = Highly Competent, 3 = Competent, 2 = Becoming competent, and 1 = Not competent. The instrument itself was examined using PAF to determine the coherence of the scales.

Findings

NVivo qualitative analysis software was used to search for terms and concepts indicative of cognitive, affective, and social engagement; dimensions of learning that are well explicated in the literature. Analysis sought to confirm, through a targeted search of students' evaluations rather than merely explore, student learning in relation to the stated aims of PBL.

Four main themes emerged, labeled as: emotional, collaborative, cognitive, and transformational; the latter two displaying some overlapping features but distinctive enough to warrant identification as separate themes. The notable

difference between postgraduate and undergraduates was in Transformational Learning. This theme identified itself through comments made mainly by postgraduate students who connected PBL to their wider life experience and its impact on changing conceptions about professional practice citing how PBL could be applied in teaching their students.

Absent from this proposal are specific statements students made about teaching and learning that are included in the full version of this paper. Importantly, critical thinking scores were used to guide selection of highly reflective and well considered, exemplary comments.

For all four dimensions of students' self-assessed tutorial performance there was significant improvement ($t(83) = -8.347$; $p = 0.000$, $ES = 0.87$) over the semester with no significant difference between undergraduates and postgraduates or between males and females although females' competence improved marginally more than males'.

The Assessment of Performance instrument proved to be a reasonably robust tool to assess four areas of PBL learning and enabled measurement of that learning over time. Refinement of this instrument should provide students and teachers of PBL with a reliable, valid tool to measure an inclusive range of PBL outcomes.

Using the Wilcoxon Signed Ranks test, Mean Critical Thinking scores for the first and second assignments for 24 students revealed a significant difference between the scores, indicative of higher critical thinking on the final papers ($z = -2.37$, $p < 0.05$, $ES = 0.48$); the increase accounted for mostly by postgraduate females' increased critical thinking scores.

What students reported about learning through PBL shows that this approach operates across cognitive, affective and social dimensions to provide a holistic learning experience. Furthermore, according to these teacher education students, PBL made explicit a range of learning and teaching processes that will inform their future teaching practice.

PAPER PRESENTATION

What we measure with ratings of instructional quality - An application of generalizability theory

Anna-Katharina Praetorius, University Koblenz-Landau, Germany; Gerlinde Lenske, University Koblenz-Landau, Germany; Karina Karst, Deutsches Institut für Internationale Pädagogische Forschung (DIPF), Germany; Andreas Helmke, Universität Landau, Germany

Instructional quality is often measured through observer ratings (e.g., researchers). In other research fields many studies have been conducted to determine the amount and the causes for errors associated with such ratings. In contrast, in instructional research these topics have rarely been investigated as of yet. To bridge that research gap we analyzed ratings of a total of 110 participants' via generalizability theory. Each participant rated three lesson sequences on a basis of nine items at any one time. The results show that about 22 percent of the variance can be attributed to observed differences between instructional quality itself, about 12 percent to rater bias components and about 19 percent to an interaction between lesson sequence and items. These results are thought-provoking in respect of whether it is admissible to treat instructional quality ratings like measurements of instructional quality. As a conclusion, variance component analysis in the scope of generalizability theory seems to be a useful tool for further investigations concerning ratings about instructional quality.

If several people rate the instructional quality of the same lessons with rating scales, they often differ significantly in their ratings (e.g., Pietsch & Tosana, 2008; Hoyt, 2000). This variability is problematic: It implies that the judgments contain information (e.g., different item comprehension) in excess of the subject-matter which should be measured (equals: instructional quality). If the amount of such further information is large, conclusions from ratings for research on instructional quality as well as the development of instructional quality in school practice are difficult to make. For reducing these biases it is important to determine the amount and also the causes for biases associated with this variability. Surprisingly little investigations focused on this topic until now. The few existing investigations focus first and foremost on ratings of pupils and students (see e.g., Aleamoni, 1987). Thus we know only little about biases in measures of instructional quality made by observers. The aim of the current study is to gain a first insight into this topic. Therefore we will focus on two research questions:

- 1) How large is the amount of specific variance components like, for example, the instructional quality itself as well as rater effects?

2) Are there differences between diverse rater populations of observers (students, student teachers, schools inspectors) concerning these variance components?

Method

To investigate these research questions we used generalizability theory, which allows separating multiple sources of error via variance component analysis (Brennan, 2001; Shavelson & Webb, 1991). For analysis, the software urGENOVA (Brennan, 2001) was used.

The 110 participants (r) rated three ten-minute lesson sequences (s) of grade four in primary school (2 German lessons, 1 Math lesson). The participants can be divided into three different groups (g): students (14 raters), student teachers (69 raters), and schools inspectors (24 raters). The ratings were based on items (i) taken from a questionnaire of Helmke et al. (2010). The questionnaire deals with interdisciplinary instructional quality. For the present study 9 items of a total of 30 items were selected (example: "The whole time was used for the lesson content"; strongly disagree (1), disagree (2), agree (3), strongly agree (4)).

The design deduced from these data is an unbalanced, partially nested (r:g) x s x i design, thus all raters rating all sequences on all items with the add-on that the raters were nested in groups. Object of measurement (dependent variable) are the responses on the items.

Results

The analysis shows that the main effect for the lesson sequence is the second highest source of variance with about 22% of the whole variance. Hence, about one fifth of the variance in ratings is due to what is intended to measure. The third highest variance source is the sequence-by-items interaction (19%). Taking all effects together concerning the rater effects (rater main effect, rater-by-item and rater-by-sequence interaction; all these effects are nested in groups), about 12% of the variance is due to rater bias. In addition, the variance component analysis shows that the three rater groups (students, student teachers, and schools inspectors) differ in their ratings: The percentage of the whole variance dedicated to the group main effect, the rater-within-group effect, the group-by-items, group-by-sequence as well as group-by-sequence-by-items effect is about 7 percent. The biggest variance component (about 31% of the whole variance) is due to the highest order interaction (r:g) x s x i, which is confounded with an unspecific error component.

Discussion

Research on instructional quality often takes observer ratings as an indicator for instructional quality. However, as we know from other research fields (e.g., Cronbach, 1990; Myford & Wolfe, 2003), such ratings are error-prone. The amount of these errors has hardly been investigated as of yet and the errors themselves have not taken into account for conclusions from results in the field of instructional quality research. The results of the present study show that this would be necessary: Only about one-fifth of the variance in ratings about instructional quality really can be attributed to this quality.

A large variance source is due to rater bias. However, compared to results from other studies in instructional quality research (e.g., Pietsch & Tosana, 2008) as well as in other research fields (e.g., Hoyt, 2000) the amount found here is approximately as large as in these former studies. Whereas the raters in the studies mentioned above were trained raters, the raters in the present study were not trained to rate instructional quality. As one would expect trained raters to make fewer mistakes in their ratings, the same amount of rater bias for untrained as well as trained raters is kind of unexpected.

The present investigation also showed differences between rater groups. Causes for these differential functioning can in particular be clarified by using qualitative research approaches in future.

Summing up one can say that research in the field of instructional quality should treat observer ratings in future more differentiated. Ideally, one should use generalizability theory to clarify the amount of residual variances in a certain study and – if possible – to minimize these variances.

PAPER PRESENTATION

Comparing peer and expert assessment of science web-portfolios

Olia Tsivitanidou, University Of Cyprus, Cyprus; Zacharias Zacharia, University of Cyprus, Cyprus; Tasos Hovardas, University of Cyprus, Cyprus

The purpose of this study was to investigate how peer assessment compares to expert assessment, in a context of a reciprocal online peer-assessment of web-portfolios in a science course in secondary education. In doing so, 28 students anonymously assessed the web-portfolios that their peers prepared after studying web-based material that concerned a unit on CO₂ friendly houses. All of the student web-portfolios were also assessed by two experts. Four data sources were used for the purposes of the data analysis, namely, the peer and expert assessments produced, a questionnaire and the screen-video captured data taken throughout the intervention. Findings showed that both the validity (correlation between expert assessments and peer assessments for the same web-portfolio) and the reliability of peer assessment (correlation between different peer assessments for the same web-portfolio) were low, which implies that there is a strong need for training or supporting students while they enact peer assessment. Moreover, it was found that although a significant majority of assessees stated that they favor expert feedback over peer feedback, changes adopted by assessees were significantly related only to parameters of their peers' feedback, namely, the number of negative judgments (incorrect or incomplete handling of aspects related to a student's work) and feedback size (word count).

Introduction

Peer assessment is conceptualized as an educational arrangement where students judge peers' performance by providing grades, and/or offering written or oral feedback. It is most often integrated in the wider context of formative assessment. Research revealed through numerous studies the positive impact of peer assessment on students' cognitive, meta-cognitive and social-affective domain and emphasized the need for its presence in a learning environment (Kollar & Fischer, 2010). However, researchers have argued that the enactment of such an assessment is a rather complex undertaking, because it requires understanding of the goals of the task(s), the criteria for success and the ability to make judgments about the relationship of the product or performance to these (Topping, 2009).

Aims

Given this complexity, we investigated whether secondary-school students can implement peer assessment when receiving the assessment criteria to be used. Up-to-date, research has not provided a thorough picture in terms of what students are capable of doing on their own when it comes to assessing their peers' work (even when the assessment criteria are available), especially at the secondary-school level (Authors, 2010). In light of the fact that peer assessment can be operationalized in many forms (e.g., paper-based or computer-based) and types (e.g., one-way, reciprocal, mutual), any research in the peer assessment domain should be well defined, both in terms of its form and type, in order to avoid confounded conclusions (Topping, 2009). In the case of this study we focused on reciprocal (peers assess each other, e.g., in pairs; hence, a student undertakes both the roles of the assessor and of the assessee), supported (students were given the assessment criteria), anonymous, and on-line (asynchronous) peer assessment context. Given this context, we asked secondary-school students to create (in pairs) web-portfolios and then to assess (individually) the web-portfolio of another pair/group (see Figure 1). The same web-portfolios were also given to two experts to assess them, while using the same criteria as the ones given to the students. All assessors had the opportunity to accompany a criterion with both a grade and written comments. After both the students and the experts completed their assessments, we compared (a) the peer assessments with the expert assessments and (b) the peer assessments of the peer assessors who assessed the same web-portfolio between them. These comparisons aimed at answering the following research questions: 1. How do the peer and expert assessment compare in terms of their validity and reliability? 2. How do the peer and expert assessments compare in terms of their structural components, namely, positive judgments, negative judgments, and changes proposed by assessors? 3. Do assessees respond in a different way when receiving peer and expert assessments? 3.1. More specifically, does the time they spent on reviewing their peer and expert assessors' assessments differ? 3.2. Do they adopt any changes from the peer and expert assessments? If yes, how do these changes compare? 4. Do students perceive the same way the usefulness of peer and expert assessments?

Methods

The participants were 28 seventh-graders, who studied web-based material that were developed for the purposes of the SCY project (Authors et al,2010) and concerned the construction of CO2-friendly houses. The data collection process involved four data sources, namely, peer and expert feedback, each participant's response to the feedback received (through the use of a questionnaire) and the screen-video data that were captured throughout the intervention. The data analysis involved both qualitative and quantitative procedures. Specifically, we followed open coding from grounded research methodology (Strauss & Corbin,1998) to analyse the peer and expert feedback and the participants' responses to the feedback received. In the case of the screen and video captured data we followed a contextual inquiry based analysis (Druin et al.,1999). All of the data that resulted from the qualitative analysis were also coded and treaded quantitatively through the use of: Spearman's rrank correlation index, k-means clustering, Kendall's tau b correlations, Kruskal-Wallis testMann-Whitney test. ,

Results

Findings showed that both the validity (correlation between expert assessments and peer assessments for the same web-portfolio) and the reliability of peer assessment (correlation between different peer assessments for the same web-portfolio) were low. We also found that both peer and expert assessors provided both grades and written comments for every assessment criterion in their feedback. However, it was found that the structural components included in these written comments differed between the students and the experts. Specifically, it was found that the peer assessments included more positive judgments and proposed fewer changes than the expert assessments. Concerning the responses of assessee groups to peer and expert feedback, the results showed that assessee groups devoted more time to review expert feedback and revisited expert comments more frequently than they did with their peers' feedback. This finding complied with the fact that the majority of assessees, as stated in their questionnaires, perceived expert feedback as more useful that the peer feedback. Moreover, it was found that the assessees were resistant in proceeding with changing their web-portfolio. In the cases where they proceeded with changes, it was found that they were significantly related only to parameters of their peers' feedback, namely, the number of negative judgments (incorrect or incomplete handling of aspects related to a student's work) and feedback size (word count).

Conclusions

The findings of this study showed that the peer-assessment procedure was problematic across several aspects (e.g. validity, reliability), even though the participants were provided the assessment criteria. This indicates how complex peer assessment is in nature and points to the need for training and scaffolding students' before and while enacting peer assessment. A finding that seems to be quite peculiar and needs to be further investigated is the fact that expert feedback was not found to have influence on the changes actually adopted by peer assessees, even though the students considered it as more valid than the peer one.

PAPER PRESENTATION

Differential effects of low-stakes mandatory testing on data based school improvement

Uwe Maier, University Erlangen-Nuernberg, Germany; Carolin Ramsteck, University Erlangen-Nuremberg, Germany; Annette Fruehwacht, University of Wurzburg, Germany

This study investigates differential effects of low-stakes mandatory testing systems in two German federal states on acceptance and usage of performance feedback data in schools. We first analyzed the mandatory testing systems and their implementation in Baden-Wurttemberg and Thuringia on the basis of a theoretical framework for school performance feedback systems (SPFS). Although both states implemented low-stakes mandatory testing, the "Kompetenztests" in Thuringia provide more elaborated and reliable feedback information and a more coherent support strategy for schools compared to the "Vergleichsarbeiten" in Baden-Wurttemberg. A quantitative survey study revealed that teachers in Thuringia are more likely to discuss feedback data in faculty meetings and to use mandatory tests for self evaluation. This qualitative follow-up study aims at elaborating the quantitative differences of data usage and at determining what aspects of the SPFS-model account for the differential effect on feedback usage. We therefore conducted a qualitative interview study with secondary school teachers in Thuringia (N=27) and Baden-

Wurttemberg (N=38) on how they interpret and use school performance feedback data on the classroom level and on the level of faculty meetings. Results show that a majority of teachers in both German states rejects the idea of test data based instructional improvement. We only found some teachers in Thuringia who described pedagogical relevant faculty discussions around performance feedback data or who integrated demanding test assignments into future teaching.

In the last decades, educational policy makers implemented test-based school accountability systems to enhance both, internal school improvement and external quality assurance of public schooling. Anglo-Saxon countries have a long tradition of high-stakes testing whereas policy makers in many European countries, e.g. the German federal states, did not attach any severe sanctions to test results and argue that teachers and principals should be the owner of feedback data. However, it is not clear if low stakes testing is an effective approach to school improvement. Another problem within Germany is that some federal states developed and implemented different strategies to report feedback data to schools and teachers. The overall aim of this paper is to investigate differential effects of low-stakes mandatory testing systems in two German states on acceptance and usage of performance feedback data in schools.

Research on the effects of test-based school accountability is very complex and diverse. An abundance of research literature in the U.S. or England investigated negative side effects of high-stakes testing on teaching or student motivation (e.g. Amrein & Berliner 2003). Another strand of research focused on how teachers, department heads and principals understand and make use of mandatory performance feedback data for the purpose of school improvement (e.g. Louis, Feby & Schroeder 2005). Visscher and Coe (2003) and Verhaeghe et al. (2010) reviewed this literature and provided a theoretical framework for synthesizing relevant factors of school performance feedback systems (SPFS) influencing data usage in schools such as design process, SPFS-features, implementation process and school organization features.

This theoretical model allows to analyze similarities and differences in implementation and feedback strategy between low-stakes mandatory testing systems in Thuringia and Baden-Wurttemberg. Both states administer external tests in secondary education to assess academic student achievement at the end of two year learning periods in math, German language and English language. Thuringia administers mandatory tests ("Kompetenztests"), monitors the implementation, offers a set of further instruments for school self evaluation and provides up to three feedback reports for schools and teachers with detailed and value-added measures. In contrast, Baden-Wurttemberg does not monitor the process of implementing the "Vergleichsarbeiten" and does not provide any external or tailored feedback reports to schools.

According to the SPFS-model we assumed that the acceptance and usage of performance feedback data is supposed to be more intensified in Thuringia than in Baden-Wurttemberg. We were already able to test this assumption in a pre-study (Maier 2009). Analysis of quantitative survey data showed that teachers in Thuringia rather accept mandatory testing and describe performance feedback information as more useful for educational diagnosis, student tutoring, and repetition. Although these differences in teacher evaluation of mandatory testing were significant, it is not clear if they are relevant for school improvement and the quantitative study also does not reveal what features of the testing system account for the differences. Our research questions:

- (1) Can we describe pedagogical relevant differences in interpretation, usage and discussion of performance feedback data between teachers/schools in Thuringia and Baden-Wurttemberg?
- (2) What factors of the SPFS-model account for the differences in teacher evaluation of mandatory testing in Baden-Wurttemberg and Thuringia?

We conducted an interview study with secondary teachers in Thuringia (N=27) and Baden-Wurttemberg (N=38) to answer our research questions. The interviews were held on the basis of a semi-structured questionnaire involving teachers' individual acceptance and usage of performance feedback data and the process of interpreting and discussing feedback data in faculty meetings. We used qualitative content analysis (Mayring 2010) to summarize, categorize, and relate different types of acceptance and usage to the respective factors of the theoretical framework. The results show that some teachers use performance feedback data on the classroom level to evaluate their teaching and to complete their diagnostic information on student achievement. But teachers in both states also said that the upcoming test influences their instruction in the weeks before (test preparation, teaching of test-taking skills). However, only few teachers in Thuringia describe that they integrated demanding and complex test assignments into regular teaching and that this made them think about the cognitive level of their instruction. Faculty discussions on interpretation and usage of performance feedback are rare in both German federal states and only some teachers in Thuringia reported pedagogical relevant discussions.

We also found versatile reasons for dismissing the concept of feedback data as an instrument for self evaluation. These reasons can be linked to the theoretical framework of Visscher and Coe (2003) and Verhaeghe et al. (2010). Design process: Teachers in both states understand mandatory testing as bureaucratic part of the school administration and were not able to take ownership of the data. SPFS-features: Although Thuringia developed value-added feedback data, teachers still complain about the amount of feedback reports and bad feedback timing. School organization features: Some teachers complain about problems, like poor school financing, which inhibit any further efforts of data-based school improvement.

On the one hand, this study gives some suggestions on how to understand the differences in acceptance and usage of performance feedback data revealed by the quantitative study. On the other hand, this qualitative study shows that even an elaborated feedback system such as the "Kompetenztests" in Thuringia had no broad and relevant impact on school improvement. It is suggested that theoretically relevant similarities of both mandatory testing systems are responsible for a low level of acceptance and usage of feedback data in schools.

PAPER PRESENTATION

Teacher-Student perceptions of assessment practices as predictors of student motivation to learn

Ron Pat-El, Leiden University, Netherlands; Harm Tillema, Universiteit Leiden, Netherlands; Mien Segers, Maastricht University, Netherlands; Paul Vedder, Leiden University, Netherlands

Self-Determination theory proposes that the needs for autonomy, competence and relatedness need to be fostered for a student to become intrinsically motivated. Student's perceived teacher support is often touted as important for learning motivation. Recent studies, however, have indicated that efficacious teachers and students with lower language proficiency misalign in their perceptions of instructional support through provision of "assessment for learning" activities: monitoring and scaffolding (Pat-El, Tillema, Segers, & Vedder, 2010). These perception-disagreements may lead to a loss in intrinsic motivation in students. Multilevel Structural Equation Modeling (MSEM) was used to test this hypothesis. The study was conducted, using a cross-sectional questionnaire design, in a sample of 650 students and 38 teachers in seven pre-vocational high schools in the Netherlands. MSEM confirmed the hypothesis ($\chi^2(28) = 27.840$; CFI = .993; Gamma = .996; SRMR = .036; RMSEA = .035). Alignment in teacher-student perceptions of scaffolding and monitoring activities positively predicted intrinsic motivation. The relationship between Scaffolding and intrinsic motivation was mediated by relatedness and perceived competence. Monitoring had a direct positive effect on intrinsic motivation and was partially mediated by relatedness. The results of this study indicate that the relative perceptions of both teachers and students have a significant impact on student motivation. The results have implications for educational design in that designers should take into account that teachers' efforts could still be lost in translation.

Aims

Learning enhancement through students' self-motivation, is regarded as the pinnacle of learning achievements in literature on student motivation and assessment for learning. Student's perceived teacher support is often touted as important for learning motivation and interest regulation. Recent studies, however, have indicated that efficacious teachers and students with lower language proficiency misalign in their perceptions of instructional support (Pat-El, Tillema, Segers, & Vedder, 2010). But it is still unclear why perception-misalignments between students and their teacher may lead to a loss in intrinsic motivation in students.

It has been found that learning activities that are being perceived as autonomy-supportive are associated with higher levels of students' intrinsic motivation for those learning activities (Black & Deci, 2000). And students who perceive

teachers as having failed to provide support show less interest and enjoyment in school. (Dray et al, 1999). Self-determination theory of motivation proposes a framework for the relation between alignment and motivation (Ryan & Deci, 2000). Perceptions of support by both students and teachers have been found to correspond with these three basic needs: Learning environments that are perceived as autonomy supportive tend to foster students' perceived competence (Black & Deci, 2000), relatedness to the teacher (Jang, 2008) and perceived autonomy (Levesque, Zuehlke, Stanek, & Ryan, 2004). Therefore we contend that students' motivation depends on the perceived instructional support for learning in the interactions between students and their teachers (Covington, 2000).

The notion of Assessment for Learning (AfL) describes the instructional support given to students by stressing the role of formative use of assessments through feedback and classroom dialogue to promote student learning (James & Pedder, 2006). It is therefore of interest to look into the degree of alignment between teacher and students' perception on the provision of assessment meant to foster learning in the classroom (Birenbaum, 2009). Teachers efficacious in constructing supportive learning environments and students low in language proficiency tend to show larger disagreements in perceptions of the provision of activities that monitor student progress and scaffold learning to realize growth (Pat-El, Tillema, Segers, & Vedder, under review). We are interested in possible misalignment in the perceptions of assessment practices between teachers and students as they may lead to a loss in motivation, caused by misunderstanding and misinterpretation of the assessment information (Norman, 1986, Bartholomew, Parcel, Kok, & Gottlieb, 2001).

The aim of this study is to test whether teacher efficacy and student language proficiency, as predictors of student-teacher alignment in perception of the supportive nature of assessment practice, will affect intrinsic motivation. A positive AfL alignment would positively predict fulfillment of the needs for autonomy, competence and relatedness and interest regulation.

Method

Sample. A sample of 650 students (323 girls, 326 boys; 1 missing) and 38 teachers (20 females, 18 males) across seven vocational high schools in the Netherlands took part in this cross-sectional questionnaire study. Teachers represented a broad domain of subjects, ranging from arts to sciences. The average class size was 17.6 students (SD = 4.88; min = 11; max = 27). Students were on average 13.9 years old (SD = 1.13). Teachers were on average 44.5 years old (SD = 11.21).

Instruments. Students and teachers received self-report questionnaires measuring teacher's and students AfL perceptions of Monitoring and Scaffolding (AfL-Q; Pat-El, Tillema, Segers, & Vedder, 2008) for a specific class, in conjunction with teachers' efficacy for teaching (OSTES; Tschannen-Moran & Hoy, 2001), students' language proficiency (Berry, Phinney, Sam, & Vedder, 2006) and the three basic needs for motivation, namely need for autonomy, competence and relatedness; and their interest/enjoyment (IMI; Deci, Schwarz, Sheinman, & Ryan, 1981). **Analyses.** Multilevel structural equation modelling (MSEM) with MUML estimation in EQS version 6.1 was used to test whether the teacher-student differences in perceived monitoring and scaffolding were negatively related to basic need fulfilment and interest. In the hypothesized (2-(1-1)-(1-1-1)-1) upper-level mediation teacher efficacy was measured at level-2 while all other variables were available at level 1. The following criteria for good fitting models were used: RMSEA and SRMR below 0.05 and CFI and Gamma scores above 0.95 (Browne & Cudeck, 1992; Fan & Sivo, 2007).

Results

Intraclass correlations (ICC) (Table 1) indicate that multilevel procedures are desirable. Especially the high ICCs of the differences in perceptions of monitoring and scaffolding show that there is a strong homogeneous level of perception (dis)agreement within classrooms.

The upper-level mediation model was tested in a multilevel structural equation model. Models were tested on the student-level based on the within-covariance matrix and the class-level based on the between-covariance matrix. The combination of the between and within models in a MSEM fitted the data very well ($\chi^2(28) = 27.840$; CFI = .993; Gamma = .996; SRMR = .036; RMSEA = .035). Aligned teacher-student perceptions of scaffolding and monitoring positively predicted intrinsic motivation. The relationship between Scaffolding and intrinsic motivation was fully mediated by relatedness and perceived competence. Monitoring had a direct positive effect on intrinsic motivation, was partially mediated by relatedness. As hypothesized Teacher efficacy negatively predicted, and Language proficiency positively predicted, monitoring and scaffolding alignment.

Conclusions

The initial model analyzed; that misaligned monitoring and scaffolding perceptions could be predicted by both teacher efficacy (negatively) and student language proficiency and would lead to reduced effectiveness in intrinsic regulation was confirmed in this study. Research on instructional effectiveness usually focuses on the perceptions of students, or teachers. The results of this study indicate that the relative perceptions of both teachers and students have a significant impact on student motivation. The important role of relatedness in the explanation of the relationship between alignment and motivation elicits the question whether aligned perceptions might foster students' feelings of interpersonal safety. The results have implications for educational design in that designers should take into account that teachers' efforts could still be lost in translation.

PAPER PRESENTATION

Effectiveness of Voluntary Postsecondary Remediation Programs in Mathematics

Dirk Tempelaar, Maastricht University, Netherlands; Bart Rienties, Maastricht University, Netherlands; Bas Giesbers, Maastricht University, Netherlands

This contribution evaluates a postsecondary remediation program in mathematics, aiming to ease the transition from high school to college and to improve the success rates in the first year of bachelor studies. The remediation program consists of the administration of a diagnostic test and the organisation of voluntary bridging education in the format of an 80 hours online summer course. Participants of the summer course are prospective students of the international university programs business and economics of Maastricht University, and are mainly students educated in different secondary schooling systems than the Dutch one. Large dissimilarities in European high school programs, and schooling discontinuities rather common in several European countries, cause strong heterogeneity in mathematics mastery of these freshmen.

Focus of this contribution is the investigation of the effectiveness of the bridging course. Since participation in the course is on voluntary basis, the design relevant for this effect analysis is that of the quasi-experiment. This design brings along several risks in the estimation of effects, such as the presence of self-selection. In order to address these risks, the treatment effect found by comparing participants and non-participants in terms of academic success, is corrected by applying the propensity score method, taking into consideration a large set of student background data collected on both participants and non-participants: type of secondary education, high school mathematics level, learning styles, achievement goal orientations, metacognition, academic motivations, and subject-specific achievement motivations. This study is based on six cohorts of students, containing 5000 freshmen, of whom 68% are international students, with 650 participants in the bridging courses.

This article focuses on bridging education directed at easing the transition from high school to college and improving the success rates in the first year of bachelor studies. In Europe, bridging education has a specific focus beyond that of addressing learning deficits: that of internationalisation of European higher education. Secondary school systems, even in neighbouring countries, are very different, producing strong heterogeneity in knowledge and skills of prospective students. The longest tradition of bridging education is to be found in the Anglo-Saxon educational settings and specifically in the US. Therefore, most empirical studies into the effect refer to the US context: Bahr (2008), Bettinger and Long (2008), Jamelske (2009). The specific US context determines the way of doing effect research: entrance to US higher education is selection-based, and part of most selection procedures is that prospective students participate in a placement test and, scoring less than a certain cut-off point, are required to take developmental education. In such a context impact studies compare the academic success of students scoring just below the cut-off score (obliged to participate bridging education) with that of students who score just above the cut-off score (excluded from bridging education), using so-called regression-discontinuity models. In the European context, generally no selection takes place upon entering university, so the option is missing to obligate some, and to exclude other, students from bridging education (Brants & Struyven, 2009; Rienties et al., submitted). Still, both contexts share important characteristics: absence of experimental design, since participation is not by random assignment but on the basis of the outcome of a placement test or self-selection. Direct comparison of academic success of participants and non-participants is therefore no proper way to find treatment effects, the two groups being non-equivalent, requiring a correction of the differences observed between experimental and control groups on the basis of differences in background statistics of students in both groups. In the US based empirical studies, it is the score on the placement test that distinguishes students in both groups and allows the use of regression discontinuity methods. The typical European case lacks such a discontinuity, and directs the investigator to methods for the quasi-experimental setup with non-equivalent groups: propensity-score based correction methods (Fraas, 2007; Guo & Fraser, 2010; Shadish, Cook, & Campbell, 2002; Yanovitzky, Zanutto, & Hornik, 2005). Against a US background of cumulating evidence that developmental education is expensive, but doubtful in its effects, the central question of

this European study is if an optional summer course is an effective instrument to help international students bridge math deficiencies caused by differences in national secondary school systems?

Methods

The adaptive e-tutorial ALEKS

Summer courses are delivered with the adaptive, electronic tutorial: ALEKS College Algebra module. The ALEKS system is an intelligent tutoring system based on principles of knowledge space theory, a branch of artificial intelligence (Doignon & Falmagne, 1999; Falmagne, Cosyn, Doignon, & Thiééry, 2006). The system combines adaptive, diagnostic testing with an electronic learning and practice tutorial. Participants

This study is based on six cohorts of first year students in the programs business and economics, containing about 5000 first year students, with 68% international students.

Statistical analyses

Participation in the summer being voluntary, a quasi-experimental setup is relevant. Our design contains a post-test, but no pre-test, so is best characterized as quasi-experimental with non-equivalent groups and post-test only (Shadish et al., 2002). This embodies the risk of self-selection. In line with advices on finding causal effects in observational studies (AERA 'think tank white paper': Schneider, Carnoy, Kilpatrick, Schmidt, & Shavelson, 2007), a broad range of students' background factors potentially related to self-selection effects is included. These are used to correct the treatment effect for non-equivalent group composition (Fraas, 2007; Guo & Fraser, 2010; Shadish et al., 2002; Yanovitzky et al., 2005), using propensity scores: the conditional probabilities that an individual belongs to the experimental group, or to the control group, given a set of covariates. The correction can take place in different ways of data balancing: using propensity scores as matching variables, as stratification variables, or as covariate (Guo & Fraser, 2010). In this study both of these last approaches will be used: given the unequal size of treatment and control groups, stratification is regarded as more appropriate than matching.

The covariates: students' background characteristics

Covariates originated from long term research into study achievements in the first year. Background factors refer to students' approaches to learning according the learning patterns model of Vermunt (Entwistle & Peterson, 2004). Vermunt distinguishes four domains/components of learning: cognitive processing strategies, metacognitive regulation strategies, learning conceptions, and learning orientations. Next, students' goal orientations are measured with an instrument designed by Grant and Dweck (2003) that classifies goal orientations into six types: intrapersonal outcome goals, intrapersonal ability goals, normative outcome goals, normative ability goals, and two different types of learning goals. Metacognitive abilities are measured by the ALLI instrument (Tempelaar, 2006), based on Flavell's three component model of metacognition: knowledge, skills, and attitudes. The Academic Motivation Scale (AMS; Vallerand et al., 1992), based upon Ryan and Deci's (2000) model of intrinsic and extrinsic motivation, is applied to achieve motivational profiles of students containing different types of intrinsic, extrinsic, and a-motivation. Lastly, subject achievement motivations based on Eccles' expectancy-value theory (Eccles & Wigfield, 2002) are measured with an instrument derived from the SATS developed by Schau and co-authors (Tempelaar et al., 2007).

Results

Effect analysis suggests that bridging education with a broad coverage of topics and flexible content steered by adaptive testing can be very effective: the non-corrected effect of successful participation in our summer course exceeds the effect of math prior schooling at advanced level, with basic schooling as reference. Correction on the basis of the propensity score method indicates that indeed part of the non-corrected treatment effect should be attributed to selection-effects, but that after correction for non-equivalent group composition, substantial treatment effects remain, in the order of size of about half the effect size of being educated at advanced math level in high school.

PAPER PRESENTATION

Reliability of Examinee Proficiency Classifications based on the European Framework of Reference

Simon Tiffin-Richards, Freie Universität Berlin / Institute for Educational Quality Improvement (IQB) Berlin, Germany;
Hans Anand Pant, Institute for Educational Progress (IQB) Berlin, Germany

Criterion-referenced assessments allow the classification of examinee ability on discrete levels of proficiency, such as basic, proficient and advanced, where each level is defined by criteria of increasing qualitative and quantitative demand. Proportions of examinees falling into different proficiency levels can yield valuable information for

stakeholders and form a basis of educational accountability systems. However, when reporting measures of a continuous trait on a discrete ordinal scale it is important to address the issue of individual measurement error.

The present study considers an item response theory (IRT) based approach (Rudner, 2001) and the implications of increasing numbers of proficiency levels on examinee proficiency classification reliability.

The method was implemented with the response data of a representative sample of German secondary school examinees (N=31,426), assessed on their reading comprehension in English as a foreign language (EFL). The items employed in the assessment were based on the guidelines of the German National Educational Standards (KMK, 2003) and the European Framework of Reference for Languages (CEFR, Council of Europe, 2001).

PAPER PRESENTATION

Comparing Primary and High-School Teachers' Attitudes towards Testing and Accountability

Beno Csapo, University of Szeged, Hungary; Edit Toth, University of Szeged, Hungary

As a part of a major project aiming at developing an online diagnostic assessment system for the first six grades of primary school, a survey was carried out to map out teachers' attitudes towards testing and accountability. Research questions of the present paper focus on the differences between primary and secondary teachers, assuming that their different involvement in several assessment processes result in different attitudes. An online system was used to survey 1150 primary and 1147 secondary school teachers. The schools were representatively chosen from the schools of Hungary. The online questionnaire consisted of ten blocks of questions, each block representing a particular assessment or accountability procedure. For analyses of results we used descriptive statistics, parametric tests and relation analyses. Results indicate that teachers consider regular assessments as an important incentive to improve achievements. This tendency is more characteristic of primary school teachers especially who began to prepare their students well before the tests. Primary school teachers feel significantly pressurized by national mandatory assessments and a little less pressurized by international standardized measurements. Secondary school teachers feel under pressure rather due to maturity exams. Primary school teachers consider preparing students for the assessments more important. They tend to change their instructional practice more likely than their secondary school counterparts. The survey showed overall positive attitudes, it also indicated several points where better training and improved presentation of assessment results may increase teachers' engagement.

Background

In the economically developed countries the evaluation of students' achievement with standardized tests in international and national context has an essential role in monitoring public education, in policymakers' decision-making and in comparing educational systems or institutions (OECD, 2007). Depending on the purpose of the survey certain stakes are connected to the large-scale achievement tests. Increasing number of countries use mandatory assessments, which form the bases of accountability. Due to the stakes, achievement assessments may have a lot of positive and negative effects on teaching and learning process (e.g. Koretz, 2005; Stecher, 2002; Hanushek, 2005). Teachers' understanding of assessment, acceptance of the goals and their cooperation is an essential precondition of an efficient monitoring and feedback system. Therefore, research of teachers' reactions on testing programs is highlighted in the educational sciences both in national (e.g. Hamilton et al., 2007) and in international contexts (e.g. OECD, 2009).

Aims

Hungary participates in large-scale international testing programs (PIRLS, TIMSS, PISA) and a national assessment system has been introduced that measures every student's achievement in reading and mathematical literacy in grades 4, 6, 8, 10; furthermore, there is a maturity exam for every student finishing high school at the end of grade 12. Until recently, teachers' attitudes towards these assessments have been a largely uncovered area. The aim of our study was, on the one hand, the examination of the differences of primary and secondary school teachers' attitudes towards international and national testing programs and the maturity exam, and, on the other hand, to identify the differences in the attitudes of teachers, who prepare their students for national assessments and who do not.

Methods

Participants

1150 teachers from 245 representatively selected primary schools participated in the survey. A comparable sample of high school teacher was chosen (1147 teachers from 100 schools) and surveyed in the same way. Teachers were selected into the sample based on the subjects they teach.

Instruments

The questionnaire consisted of ten blocks of questions, each block representing a particular assessment or accountability procedure. The questions in the study focus on teachers' view on regular assessments and their reports, test preparation strategies and perceived pressure. To allow international comparison, some parts of the instrument were composed of questions known from literature, while other parts contained country specific questions. The questionnaire is reliable (Cronbach's alpha 0,811–0,897). Teachers' opinions were mainly assessed on a four and five level Likert scale (1=disagree; 4/5=agree).

Procedures

Data were collected anonymously from March to June, 2010, electronically by the TAO-CAPI system, participation was voluntary. For analyses of results we used descriptive statistics, parametric tests and relation analyses.

Analysis and results

Teachers in secondary schools rather think that achievement tests should be conducted on a regular basis than primary school teachers. Assessments rather cause trouble and problem for primary school teachers; however, they also feel more motivated by them. Teachers, who are preparing their students for state assessments, experience achievement assessments more useful. Regarding large-scale assessments primary school teachers perceive the strongest pressure when it comes to national mandatory assessment, 50% of them feel somewhat pressured, 19% of them a lot, and the ratio in the other group is 45% and 10%.

Teachers who practiced with students for the measurement feel more pressurized. 64% of the primary and 52% of the secondary school teachers start practicing several months before the test. Teachers tend to prepare their students for the tests by trying to improve students' test taking skills, motivation, and practice test formats, tasks that are similar in the mandatory assessment. Their instruction mostly changed in that they search more effective teaching methods, focus more on educational standards, and on the competences assessed. These are less characteristic of secondary school teachers than of primary school teachers and it is more characteristic of those who spend at least one month with preparing students for the forthcoming mandatory assessment.

Among the achievement assessments the maturity exam pressurizes secondary school teachers mostly. Half of the secondary school teachers think that there is a need to further clarify the frameworks of the two levels of the maturity exam, 60% claims that a life science subject should be integrated into the assessment programs as well. 40% of primary school teachers and 20% of secondary school teachers are not familiar with the feedback international assessment programs provide. Teachers partly agree that the reports of the Hungarian mandatory assessments are clear and comprehensible, however, they are less convinced that the feedback data mirrors Hungarian students' knowledge. In all mentioned cases differences between groups and variables are significant ($p < 0,05$).

Educational and scientific importance

The present work is a part of a major project aiming at introducing an online diagnostic assessment system for the first six grades of primary school. The diagnostic assessment system is designed to improve educational outcomes by providing students and teachers with frequent, detailed student level feedback. These low-stake assessments try to minimize stress and perceived pressure. Implementing such a system in the everyday practice requires teachers' positive attitudes in general, understanding the outcomes of the assessment and willingness to be engaged in interpreting and utilizing feedback information in their everyday teaching practice. The survey showed overall positive attitudes, it also indicated several points where better training and improved presentation of assessment results may increase teachers' engagement.

PAPER PRESENTATION

Does it count? The effect of item order on test performance

Rianne Janssen, K.U. Leuven, Belgium; Dries Debeer, K.U. Leuven, Belgium

The question whether order of the items in the test has an effect on the test score already has been investigated in different fields, such as personality and clinical psychology, survey research, and educational measurement. Several models have been proposed to investigate the effect of item order on the test scores. These models differ along the following dimensions: (a) whether the effect is investigated in a design of test administration where different item orders are presented or not; (b) whether the effect is investigated at the level of the test score versus at the level of individual items and (c) whether individual differences in the effect of item position are taken into account or not. A new model is proposed that analyzes the item-order effect at the level of items but that takes individual differences into account as well. It is applied to a computer-based test on listening comprehension of French as a foreign language.

Introduction

The question whether the position of an item has an effect on the obtained test score already has a long past in educational measurement. For example, Guertin (1954) showed that the order of item presentation yielded a significant difference in performance on the arithmetic subtest of the Wechsler-Bellevue. As another example, Hambleton and Traub (1974) investigated the effects of item order on test performance and stress. They found for a mathematics test that the mean number of correct answers was significantly lower for questions arranged in the difficult-to-easy order than for the reverse order. The difficult-to-easy order also increased heart rate more than the easy-to-difficult order. In current practice, test constructors have different opinions about the order in which items should be presented to the testees, for example, should item difficulty be taken into account or not?

Apart from educational measurement, item-order effects have been studied in different research fields, such as personality and social psychology, clinical psychology, and survey research. Studies on the item-order effect in different contexts obtained opposite results. For example, in educational measurement, both an increased performance (or so-called practice effect) and a decreased performance (or a so-called fatigue effect) towards the end of the test have been reported (Bejar, 1985; Kingston & Dorans, 1982). A more intriguing example of opposite results is related to effect of item order on the relationship of the item with the latent trait. Findings in personality assessment suggest that the number of items preceding the item may increase the correlation with the latent trait (e.g., Hamilton & Shuminsky, 1990; Knowles, 1988). In educational measurement on the other hand, a decrease in the correlation of the end-of-test items with the latent trait can be expected in some situations given that test takers may change to a pure guessing strategy (e.g., Yamamoto & Everson, 1997). Hence, as Knowles (1988) concluded, studies on the item-order effect show that measuring may change the measure.

Aims

The purpose of the present paper is to give an overview of the existing research designs and models that have been proposed to study item-order effects. Moreover, a new, general framework for studying item-order effects is proposed. The framework will be illustrated with several examples relevant to the field of educational assessment.

Overview of Existing Frameworks and Models.

Two main types of research designs can be discerned to study item-order effects: designs with a single test administration on a single group of respondents and between-group designs with a different order of presentation of the test items across groups of respondents. The former type of designs focuses on the effect of item order on the person side: individual differences in response behavior during the test administration (e.g., at the beginning or at the end of the test) are the focuses of interest. Hence, these designs focus on the measurement of change. The latter type of designs focuses on the effect of item order on the item side: differences in item parameters between the different orders of item administration are the focuses of interest. Hence, these designs focus on the change of the measure.

In both type of designs, two groups of models can be discerned: models based on classical test theory (CTT) or structural equation modeling (SEM), on the one hand, and models based on item response theory (IRT) on the other hand. Examples of the former type of models can be found in Knowles (1989), Hartig, Hßlzel, and Moosbrugger (2007) and Schweizer (2010). Examples of IRT-based models of item-order effects are Steinberg (1994), Hahne (2008), Kubinger (2008), and Verguts and De Boeck (2000).

It will be argued that models for studying item-order effects should take into account the individual item level. Hence, an IRT-based approach is generally to be preferred above a CTT or SEM approach, as will be illustrated with a small simulation study on a particular application. However, it will also be argued that both differences on the person side (measurement of change) and on the item side (change of the measure) should be taken into account when modeling item-order effects.

A new framework for studying item-order effects

A general IRT-model for studying item-order effects is presented, which encompasses possible effects at both the person and item side. The framework is based on the Generalized Linear Mixed Modeling (GLMM) approach to IRT proposed by De Boeck and Wilson (2004). The modeling framework is applicable in both types of research designs. Its main advantage is that specific hypotheses concerning item-order effects can be tested by significance testing of specific parameters. The model is illustrated with an application on a computer-based test on listening comprehension of French as a foreign language.

Educational Significance

The proposed general framework for studying item-order effects aims to present more conceptual and methodological clarity in the study of item-order effects. The main advantage of the general modeling framework is that specific hypotheses concerning item-order effects can be tested by significance testing on parameters. Within educational measurement the framework may allow to control for confounding effects of item order, but it may also be applied in cases where the change in the latent ability due to item order is the focus of interest (e.g., to investigate learning during the test, or stress-resistance).

PAPER PRESENTATION

Eco systems thinking and conceptual development

Diana Garavito-Bermudez, Stockholm University, Sweden; Cecilia Lundholm, Stockholm University, Sweden

Knowledge of social-ecological systems is required to promote adaptability in decision-making on natural resources (Folke, 2006). Therefore, research into possible conceptual challenges encountered by different professional groups is important for enhancing our understanding of decision-making. This study focuses on ecological knowledge and its implications for natural resource management. An interview study was carried out focussing on professional fishermen's conceptualizations of ecosystems, and how these conceptualizations are involved in processes of natural resource management. Two geographical areas in Sweden are in focus: Lake Vättern and the Archipelago of Blekinge (Baltic Sea). The results show the role of systems thinking in the organization of knowledge regarding structure and functional dynamics in the ecosystem. Invisibility of interrelations between biological components in aquatic ecosystems is a barrier for understanding biological, chemical and physical processes occurring comparing to other ecosystems such as mountains, forests, arid/semi-arid and agricultural. However, the fishermen are able to create hypothetical causal relations and elaborate on these using inductive and deductive reasoning. This study contributes to the comprehension of the conceptual challenges involved in the understanding of biological complex systems and its professional implications. Previous research has mainly investigated students' systems understanding in educational settings; however, this project addresses learning in informal and professional contexts. By this we hope to contribute to general and theoretical understanding of knowledge regarding systems complexity. Furthermore, the project has practical implications regarding the role of knowledge and learning in decision-making (on natural resources) in professional settings.

Aim

With the aim to describe the content of ecological knowledge and its conceptual development, the research questions for this study are:- What kind of reasoning is involved in these conceptualizations? What is the role played by systems thinking?- How do these conceptualizations affects resource extraction and processes of resource management? These questions are closely related to the populations' dynamics of Great charr (*Salvelinus umbla*) and American crayfish (*Pacifastacus leniusculus*) in Lake Vättern, in terms of their ecological state and their economical and traditional value in the region.

Methodology

Geographical area

The geographical area studied in this paper is Lake Vättern, which is situated in the middle of four counties, and twenty-one municipalities in the south of Sweden. Lake Vättern is the sixth biggest lake in Europe, 1912 km².

Nowadays, about 250.000 people take water from Vättern for their daily consumption and some of them benefit of fishing (Länsstyrelsen i Jönköpings län, 2009). The fishing of Great charr (*Salvelinus umbla*) has been strongly reduced and economically compensated by the fishing of crayfishing. Today the foreign specie, American crayfish (*Pacifastacus leniusculus*), derives a significant income for some stakeholders, especially professional fishermen. Moreover, this unique aquatic system was one of six "pilot" projects selected for a 'co-management initiative' by the Swedish Board of Fisheries in 2004. This "Co-management Initiative Project" worked successfully for the development of regional co-management of fishing. In 2009 this process, characterized by including multiple stakeholders into decision-making, finished with an official document – a management plan - that will be the road map for future management. Fishing in Lake Vättern is classified into four categories: leisure fishing (sport fishing and households fishing), tourist fishing, fish farming and professional fishing (Länsstyrelsen i Jönköpings län, 2009). This last category requires the possession of a professional fishing licence given by the Local County Administrative Board. These categories are defined by different types of catch methods, species focus and fish water. Fishing is common both for sustenance and recreation, hence, professional fishing is main target group for this study. The kind of fishing in the study area is small-scale fishing. 11 of 22 professional fishermen have been interviewed so far. All of them are men and the majority of them are localized in the northern part of the study area. They are between 27 and over 66 years old (in 2009).

Data collection

The data collection method was basically structured interviews and a few direct observations during fishing. The interview format was structured around central themes such as knowledge of ecosystem, knowledge generation and its effects on resource management, and communication of ecological knowledge among scientists, managers and local stakeholders. This paper presents results on the first of these aspects.

Findings

An overview of the whole material shows that fishermen's fishing concern 13 species of the 30 existents at Lake Vättern (in Sweden there are around 50 species). American crayfish (*Pacifastacus leniusculus*) is today the most frequent specie in professional fishing occupying the first place, followed by European perch (*Perca fluviatilis*) in second place, and Common whitefish (*Coregonus* sp.) and Great charr (*Salvelinus alpinus*) in third place. We identify two main levels of understanding ecosystems complexity, which are structure and functional dynamics (Hmelo et al., 2000; Hmelo-Silver & Green Pfeffer, 2004; Hmel-Silver et al., 2008). When looking at the structural level, we find different ways of understanding the relationships between ecosystems biological (food webs) and non-biological (disturbance factors influence the whole system) components among fishermen. Similarly, looking at the functional dynamics level, there is understanding of some processes considering complexity such as hierarchy, feedback effects, non-linear causality and emergence proprieties of ecosystems components.

Systems

Invisibility in aquatic systems is a barrier for the understanding of ecosystems structure and functional dynamics. But this does not prevent fishermen from creating explanations based on experience, beliefs and guesswork. In this way, fishermen are able to produce hypothetical connections between biological and non-biological component using deductive and inductive reasoning. However, the understanding of ecosystems functional dynamics seems to be more difficult than the identification of ecosystems structure and requires a deeper comprehension of invisible processes and decentralized thinking (Hmelo-Silver & Green Pfeffer, 2004). Likewise, the results show strong connections between resource dependence and knowledge elaboration. It seems that fishermen who focus their fishing on several fish species generate a greater understanding of ecosystems functions and dynamics, compared to those who only focus on American crayfish fishing. Time and place are also two relevant elements in the understanding of ecosystems functional dynamics in relation to populations' dynamics and biological changes of fishing species (reproduction, nutrition and temporal-spatial distribution).

Discussion

The paper discusses the role of systems understanding in relation to the profession of being a fisherman, and we highlight some questions; Is systems understanding of functional dynamics part of core knowledge? Is it part of their professional reflection (cf. Schön (1983, 1987) and reflection-in-action)? Secondly, it seems that scientific knowledge represented by experts, and knowledge represented by fishermen is complementary, and have different origins when relating to theory, and experiences of time and place.

Theoretical and educational significance

This study contributes to the comprehension of the conceptual challenges involved in the understanding of biological complex systems and its professional implications. Previous research has mainly studied addressed systems understanding in educational settings; however, in this project we are looking at learning in informal and professional contexts. By this we hope to contribute to our general and theoretical understanding of knowledge regarding systems

complexity. Furthermore, the project has practical implications regarding the role of knowledge and learning in professional contexts where decision-making (on natural resources) is of particular interest.

PAPER PRESENTATION

The Effect of Answering Questions that Differ in Specificity on Mental Effort and Text Retention

Liesbeth Kester, Open University of the Netherlands, Netherlands; Huib Tabbers, Erasmus University Rotterdam, Netherlands; Chantal Gorissen, Open University of the Netherlands, Netherlands; Paul A. Kirschner, Open Universiteit, Netherlands

Tested information is retained longer than studied information. This, so called, testing effect is thoroughly studied in memory research. Recently, a renewed interest in the testing effect in an educational context can be observed. This study is placed within this line of research and investigates two aspects of the testing effect, namely, effortful retrieval and retrieval induced facilitation. Participants were randomly assigned to one of three experimental conditions that differed in the learning strategy used. Participants either restudied a text that they had received, answered specific questions after studying the text, or answered less specific questions after studying the text. It is assumed that more effort is needed to answer the less specific questions than to answer the specific questions. Therefore, we hypothesize that the less specific questions will produce a stronger testing effect than the specific questions. In addition, we investigate if the benefits of taking an initial test spill over to answering questions that were not initially tested. The results of this study confirm that answering less specific questions requires more effort, however, this does not pay off in a better retention of facts after a week. Nevertheless, a testing was found for the specific questions. No spill over effects were found.

Tested information is retained longer than studied information. This, so called, testing effect is thoroughly studied in memory research (Roediger & Karpicke, 2006). Recently, a renewed interest in the testing effect in an educational context can be observed. This study is placed within this line of research and investigates two aspects of the testing effect, namely, effortful retrieval and retrieval induced facilitation. The effortful retrieval hypothesis holds that the testing effect occurs because it costs less effort to restudy a wordlist or word-pair list than to retrieve it from memory and that the extra effort that is invested to retrieve a fact results in a stronger and more elaborated memory trace of that fact which makes it easier to retrieve the fact at a later moment (Bjork, 1994). Retrieval induced facilitation means that the benefits of testing on retention spill over to related facts that were not initially tested (Chan, McDermott & Roediger, 2006).

To investigate the effortful retrieval hypothesis, this study examines the effects of specific (e.g., 'What did the dogs in Pavlov's experiments do when they heard a bell ringing?') and less specific questions (e.g., 'Describe how Pavlov proved that dogs can distinguish between different stimuli') on expository text retention. It is assumed that more effort is needed to answer the less specific questions than to answer the specific questions. Therefore, we hypothesize that the less specific questions will produce a stronger testing effect than the specific questions. In addition, we investigate if the benefits of taking an initial test spill over to answering questions that were not initially tested.

Method

Participants

Ninety-three Dutch high school juniors and seniors (57 males, 36 females; mean age = 16.32, SD = .90) from general secondary education participated in this experiment during regular school hours.

Materials

Instructional text. An expository text on the 'Pavlov reaction' (861 words) was used as learning content. The text was divided in ten paragraphs printed on separate pages.

Initial specific test. Ten specific, short-answer questions were formulated to determine recall of specific facts from the text. These questions required a one-or-two-words response and their answers were literally available in the text. Each correct answer received 1 point.

Initial less specific test. Ten less specific, short-answer questions to measure how well the participants could recall combinations of facts from the text were formulated. The questions allowed for a few-sentences response and their answers could be found literally in the text. Each correct fact received 1 point.

Final test. The final test consisted of the initial specific test with four new, specific questions and the initial less specific test with four new, less specific questions. The final test was scored in the same manner as the initial tests.

Effort measure. Paas' (1992) subjective 9 point rating scale was used to measure retrieval effort. It ranged from very, very, very low effort (1) to very, very, very high effort (9). Participants were asked 'How much effort did it cost you to understand the paragraph?' or 'How much effort did it cost you to answer the question?'.

Design and Procedure

Participants were randomly assigned to one of three experimental conditions that differed in the learning strategy used. Participants either restudied a text that they had received ($n = 29$), answered specific questions ($n = 35$) after studying the text, or answered less specific questions ($n = 29$) after studying the text.

The participants had 1 minute to study each paragraph and fill in the effort scale, then 5 minutes to perform a distracter task. Next depending on the experimental condition they were in, they restudied the text, answered the specific or less specific questions. They had 1 minute to restudy each paragraph or answer each question and fill in the effort scale, then 5 minutes to perform a distracter task. After a week, they took the final test. They were given 1 minute to answer each less specific test-question and 30 seconds to answer each specific test-question.

Results and Discussion

ANOVA revealed a significant effect of learning strategy on mean effort invested during the 'learning strategy phase', $F(2, 90) = 35.41$; $MSE = 52.52$; p

A MANOVA revealed a significant effect of learning strategy on the initially tested specific questions, $F(2,90) = 7.57$; $MSE = 18.98$; $p .05$. A Bonferroni post-hoc test revealed that participants who had answered the specific questions before performed better on these questions after a week than participants who had restudied the text or who answered the less specific questions (both ps

Discussion

Although a testing effect was found for the specific questions, no testing effect was found using the less specific questions and no spill over effects were found in this study. Reasons for these unexpected results will be discussed during our presentation at EARLI.

PAPER PRESENTATION

Conceptual Change in Physical Science: Ontological, Epistemic and Meta-representational Changes.

NATASSA / ANASTASIA KYRIAKOPOULOU, UNIVERSITY OF ATHENS, Greece; Stella Vosniadou, National and Kapodistrian University of Athens, Greece

In this article we will argue that conceptual change requires the reorganization of children's intuitive theories, but it also involves changes in children's understanding of the mental world (Theory of Mind) and in the way they come to know the world and justify, interpret and construct knowledge and knowing (Personal Epistemology). In order to empirically investigate these relations, we combined instruments from the Theory of Mind, Personal Epistemology and Conceptual Change research tradition. Forty-six fifth graders were administered measures of their ability to attribute false beliefs, of their epistemic stance and of their ability to reason about different conceptual models of the physical world. The results showed statistically significant correlation between the ability to understand different beliefs and children's epistemic beliefs. The results also showed statistically significant correlations between children's beliefs about their mental states and nature of knowledge in general and their ability to reason about different conceptual models of the physical world. A set of hierarchical regression analyses showed that children's theory of mind and epistemic beliefs appear to be strong predictors for children's ability to reason on different interpretations of the physical world. The cluster analysis with k-means method also showed that the epistemological distinction in the physical world is accompanied by better performance on Theory of mind and epistemic tasks as opposed to non-resolution of the ontological problem, where children can not attribute false beliefs and believe in absolute truth.

Most researchers in the area of cognitive development agree that at the end of the pre-school age and before the time that the systematic science instruction starts, most children have constructed initial naïve theories that makes it possible for them to interpret phenomena of the physical world. These "theories" are very different from the scientific theories in terms of their broadness, their explanatory significance, their internal coherence and their social acceptance.

The difficulty for the children is how to reconcile in an internally consistent framework their everyday intuitive experiences of the phenomena with the scientifically accepted explanations of these phenomena. This requires a reorganization of the initial cognitive structures and a replacement of the established beliefs with a new explanatory framework. Learning science can be conceptualized as a process of conceptual change in the context of theory change.

In this article we will argue that conceptual change requires the reorganization of children's intuitive theories, but it also requires the reorganization of children's perceptions of knowledge, learning and knowing, as well as changes in their ability to think and manipulate different representations of the world.

In particular, we will argue that this process also involves changes in children's understanding of the mental world (Theory of Mind) and in the way they come to know the world and justify, interpret and construct knowledge and knowing (Personal Epistemology). The underlying feature of all these changes is the awareness of our and others beliefs, the ability to recognize them as different perspectives and to understand how these perspectives can affect the interpretations of our experiences.

We will report an exploratory study that investigates the possible theoretical relationship between the constructs of Theory of Mind and Personal Epistemology and Conceptual change in Physical Science.

According to our proposed theoretical framework, the development of the representational nature of beliefs and the awareness of our beliefs (Theory of Mind) precedes the development of a more general Personal Epistemology. Understandings of the different interpretations of the same situation in the world, of the different knowledge claims that can arise through exposure to different aspects of knowledge, of the importance of the sources of knowledge, are the first metaconceptual steps towards a view of the knowledge as an individual construct. These metaconceptual abilities are assumed to positively contribute to the development of the coordination between the subjective and objective dimensions of knowledge and to the subsequent recognition of the uncertain and constructive nature of knowledge (Personal Epistemology).

Finally, we have assumed that the initial recognition that knowledge is constructible and uncertain goes along with and facilitates considerably the comprehension of phenomena of the physical world where the child should recognize that representations of situations in the world are theoretical entities, hypotheses that can be tested, found wrong and replaced by others (Conceptual Change).

In order to empirically investigate these relations, we combined instruments from the Theory of Mind, Personal Epistemology and Conceptual Change research tradition. Forty-six fifth graders were administered measures of their ability to attribute false beliefs, of their epistemic stance and of their ability to reason about different conceptual models of the physical world.

The results showed statistically significant correlation between the ability to understand different beliefs and children's epistemic beliefs. A set of regression analyses seemed to support the proposed theoretical model. Theory of mind seemed to be a strong predictor for children's epistemic views.

The results also showed statistically significant correlations between children's beliefs about their mental states and nature of knowledge in general and their ability to reason about different conceptual models of the physical world. The awareness of our and others beliefs, as well as the appreciation that knowledge is constructible and not determined from an exterior reality, appeared to significantly relate with the understanding of physical phenomena where the child should recognize that there are contradictory conceptions of reality and not a simple and reliable causal relation between the real situation of the world and our scientific explanations for it. A set of hierarchical regression analyses showed that children's theory of mind and epistemic beliefs appear to be strong predictors for children's ability to reason on different interpretations of the physical world.

The cluster analysis with k-means method also showed that the epistemological distinction in the physical world is accompanied by better performance on Theory of mind and epistemic tasks as opposed to non-resolution of the ontological problem, where children can not attribute false beliefs and believe in absolute truth. Discriminant function analysis showed that theory of mind of 3rd order and beliefs about the nature of science are good predictors for group membership. Factor analysis extracted two factors, one that refers to our meta-representational ability and one that refers to the coordination of the subjective and objective dimensions of knowledge.

Understanding that representations of our world are those that determine our actions and not the world itself, is the most important achievement which governs all three domains. In the domain of Theory of mind develops the representational aspect of belief, in the domain of Personal Epistemology develops the understanding of the uncertain and non-absolute knowledge which is not based on simple observations of the external world but is constructed by humans, and in the domain of Conceptual Change in the Physical world develops the understanding that there can be different representations of the same external reality and we can shift from one representation to another.

If we want to have students who think in a critical way, we should take into consideration the possible relation of these three theoretical constructs and how it develops as a foundation of instruction.

PAPER PRESENTATION

Exploring the development of leadership epistemology in adolescents

Cynthia Knechtges, University of Toledo, United States; Florian Feucht, The University of Toledo, United States

Little is known about beliefs of teenagers about leadership in education for a global networked society. The study explores the beliefs of students ($n = 80$) about leadership and the nature of knowledge and knowing (i.e., epistemic beliefs). A cross-sectional design (i.e., 6th to 12th grade) was applied to identify potential developmental progressions and interrelations between leadership beliefs and epistemic beliefs using interview and picture drawing techniques. The preliminary data analysis reveals that younger students define leadership in their family settings and close friendship circles while older students broaden the context of leadership to their local community and national politics. Most of the students believed that leadership knowledge is domain-specific and can be acquired over time, while less students believe in universal, often innate leadership knowledge. Results provide important information on how to development and improve leadership programs for high school students.

Exploring the development of leadership epistemology in adolescentsMost research on leadership focuses on adult leadership, and more specifically, the focus is on defining the leadership competencies, categorizing leadership, and predicting who will be a future leader. Identifying individuals with the propensity to become good leaders has financial implications for organizations pertaining to selection, training, and development of people (Bono & Judge, 2004). McKinsey and Company states that "there is a growing shortage of people willing to take on leadership roles in their careers," and as the large population of baby boomer retire, the shortage is expected to intensify (cited in Michael, Kartford-Jones & Axelrod, 2001). However, research yields little success in identifying criteria for predicting future leaders in global networked societies (Bono & Judge, 2004). Currently, little is known regarding youth's beliefs about leadership. Most of the existing research about leadership is conducted with adults. Therefore, many researchers

make one of two assumptions: (1) the youth and adult definitions are the same or (2) youth do not have a fully/ properly developed belief system about leadership. One study suggests that youth have a fully developed belief system about leadership, which is different than the belief system commonly held by adults (Roach, 1999). Therefore, more research is needed to explore what youth know about leadership, how youth develop knowledge about leadership, and how they use this knowledge to understand the world around them (i.e., epistemic beliefs) (Haerle & Bendixen, 2008; Kuhn & Weinstock, 2002).

Purpose of the Study

This study aims to explore the overlap between the leadership beliefs and epistemic beliefs in youth. Specifically, the interest is in the characteristics of these beliefs, their developmental progression, and their potential interplay. The overlap is characterized, for example, by beliefs about the definition, behavior, and attitudes of leadership as well as beliefs about the nature of leadership knowledge and processes of knowing (i.e., epistemic beliefs) (Haerle & Bendixen, 2008; Kuhn & Weinstock, 2002; Roach, 1999).

Method

A cross-sectional research design was used to tap the beliefs system of youth about leadership, their potential developmental progression, and to explore their epistemological underpinnings. Semi-Structured interviews were conducted.

Participants

The overall sample ($n = 80$) of the study encompassed students from the grades 6th, 8th, 10th, and 12th and was randomly drawn from a Midwest suburban school district. The sample was stratified to account for an even balance of male and female students per grade level (male students $n = 10$; female students $n = 10$).

Materials

The interview protocol revolved around the following example questions: 1. Could you explain to me what a leader is? 2. Please draw a picture of a good leader in action. Use speaking bubbles to describe what the leader would typically say or think. 3. How does a leader know what to say and what to do? 4. Does this knowledge change? To complete the drawing task, participants were provided with a black marker and a square piece of white paper.

Procedure

We conducted semi-structured interviews with all participants. This technique combines a structured interview protocol with the flexibility to ask ad hoc questions (i.e., subsequent questions that emerge during the interview). Ad hoc questions were posed to interviewees to verify and/or elaborate on aspects of their answers. The total interview time was approximately 25-30 minutes for each participant. The picture drawing task took place in the first third of the interview. Participants had up to 5 minutes time to silently complete their picture using a black.

Analyses

We will use the method of qualitative content analysis (Mayring, 2002), which evolved from the classical, more quantitative method of content analysis (Kohlbacher, 2005; Titscher, Meyer, Wodak, & Vetter, 2000). The more quantitative content analysis has been criticized for its inability to account for context, underlying themes, and distinctions among individual cases/participants (Ritsert, 1972). Qualitative content analysis aims to overcome these shortcomings by applying a systematic, theory-guided approach to text analysis using inductive coding schemes. Mayring's approach is guided by a sequential model that encompasses three distinct analytical procedures (Kohlbacher, 2005; Mayring, 2002): summarizing, explicating, and structuring. In our data analysis, we will apply all three of the above procedures. The software ATLAS.ti will be used to facilitate that process of data analysis.

Preliminary Results

A brief screening of the data indicates that the majority of participants believes that a leader is a responsible person who is in charge of a group of people. A developmental progress might be identifiable across the different age section of the sample. That is, 6th and 8th graders seem to refer to leadership within their micro system, such as their family (e.g., siblings or parents) or friends. Older students tend to refer to project leader at school (e.g., art project), athletic clubs (e.g., captain of the soccer team), and/or at the state and national level (e.g., President Obama). Most participants stated that leadership is an acquired skill and not an innate ability per se. Most participants seem to believe that knowledge about leadership is changing. Around 60 percent of the participants seem to believe that leadership knowledge is domain specific, while the answers of the remaining students suggest more a domain-general belief. A more systematic data analysis is required to complete and inform the future result section of the paper. The data set will be completely analyzed at the time of the presentation.

Educational Implication

This exploration provides evidence on what youth know about leadership, how youth grow their knowledge about leadership, and how they apply this knowledge to understand their world. By knowing more about the development of leadership beliefs and epistemic beliefs in youth and their potential interplay, educators can identify the youth's knowledge gaps or misconceptions of leadership, thereby more effectively targeting performance and learning objectives for the youth leadership development program (Conger, 1999; Roach, 1999).

PAPER PRESENTATION

Applying a western learning model across cultures: an Activity Theory analysis

Janneke Frambach, Maastricht University, Netherlands

Educational methods are often distributed from western to non-western countries, which some characterize as (neo)colonialism. Applying western learning models in contrasting cultural settings can indeed be problematic, regarding differences in students' learning behaviors and beliefs across cultures. This research aims to analyze the process of applying a western educational model in contrasting cultural contexts in terms of a two-directional influence: a) the colonization of local students' learning backgrounds, b) the domestication of the western model.

This influence is based on Habermas' notions of colonization of the lifeworld and domestication of the system. Socio-cultural Activity Theory serves as a framework to analyze this complex issue. Problem-based Learning (PBL) serves as a case example of a western educational model. A comparative case study was conducted in three PBL universities located in different cultural regions: Egypt, Hong Kong and The Netherlands. Data were collected through interviews with first and third year students, teachers and staff; class observations of PBL sessions; documents about PBL application; and context information. Template Analysis was used as method of analysis.

Several themes were identified concerning the mutual influence and development of students' learning backgrounds and the PBL model. A combination of cultural and contextual factors and domesticating measures determine the extent of colonization of students' learning backgrounds. These results serve institutes worldwide in better knowing and preparing what they choose for when adopting foreign educational models. Furthermore, the results indicate a global convergence of applying western educational models, and simultaneously a divergence into culture-specific models.

Problem statement

Educational methods are increasingly being distributed around the world, which often means a one-way export of western methods to non-western countries. Some therefore characterize educational globalization as westernization or (neo)colonialism, since inherently western cultural traits steeped in these methods are rarely questioned, along with their applicability in different cultural settings (Tikly, 2004; Bleakley et al., 2008; Nguyen et al., 2009). This applicability can indeed be problematic, for it may not consider differences in students' learning behaviors and beliefs across cultures (Tweed and Lehman, 2002; Li, 2005; Chinn, 2007; Nguyen et al., 2009).

Practice however shows numerous cases of successful adoption of western educational models by non-western institutes. This raises the question of how these adoption processes take place: do students adapt to the foreign model? Or does the model adapt to the students? Furthermore, how can these processes inform the ongoing educational globalization debate? This research aims to analyze a two-directional adaptation influence when applying a western educational model in a contrasting cultural context. The following research questions are addressed: How

and to what extent does the western model mediate (or: colonize) the cultural-specific learning beliefs and behaviors of students in contrasting cultural settings? How and to what extent do these students' learning backgrounds mediate (or: domesticate) the western model?

Theoretical and conceptual framework

The above concepts of colonization and domestication are derived from Habermas' notions of colonization of the lifeworld and domestication of the system (Habermas, 1984; 1987). The original learning behaviors and beliefs of students show similarities with Habermas' concept of lifeworld, which becomes colonized by the system. The western learning model shows similarities with this concept of system, which consequently can be domesticated by the lifeworld. Investigating the cross-cultural application of western learning models in these sociological and philosophical Habermasian terms, can inform and shed a new light on the educational post colonialism debate.

Socio-cultural Activity Theory (AT), originating from Vygotsky (1978) and expanded by Engeström (1999), serves as a theoretical framework to analyze this complex issue. The organizing principle in AT is the activity system, which takes the relevant actors, their goals, the mediating artifacts, and contextual matters that are part of a particular activity into account, as well as their mutual interactions. A western learning model can be regarded as a mediating artifact likely to contradict with other system components when it is implemented in an educational activity system in a contrasting cultural setting. In the dynamics that result from these contradictions lie the answers to the research questions.

The concept of western learning model is based on the Socratic learning model defined by Tweed and Lehman (2002). This model is characterized by students' verbal expression, individualism, independence, rationality, self-directedness and critical and questioning tendencies, and is argued to be more common in western students and institutes, while not being restricted to them, nor being employed by all of them. Problem-based Learning (PBL), as described by Barrows (1996), serves as a case example of a Socratic/western educational model.

Methods

A comparative cross-cultural case study was conducted in three higher education institutes (Medical Schools) which extensively apply the PBL model and are located in different cultural regions: Suez Canal University in Egypt, The University of Hong Kong, and Maastricht University in The Netherlands. The institutes were purposively selected based on suggestions made by experts in international medical education according to several criteria. A qualitative approach, based on principles of ethnography, was used to grasp the complex nature of the activity systems and their interrelated components.

Data were collected through various instruments and sources. First, individual semi-structured interviews were conducted with first and third year students, PBL teachers and educational leaders (30 per case, 90 in total). Sampling of a target participant group was purposive, while participants from that group were self-selected. Second, class observations of first and third year PBL sessions were conducted. Third, documents about the application of PBL were gathered. Fourth, context information was gathered by document analyses and participant observation.

Measures enhancing trustworthiness included: method triangulation, inclusion of western and non-western cases, data saturation, member checking, iterative data collection and analysis, and analysis by multiple researchers. The study was approved by the ethical review boards of the institutes, and informed consent was obtained from the participants. The transcribed interviews, field notes, and documents were analyzed according to the Template Analysis method (King, 2010).

Results and conclusions

A number of themes was identified concerning the nature, interrelations, and development of the students and the PBL model. The analysis revealed certain 'universal' student behaviors, which consequently can be enhanced or weakened by cultural and contextual factors. Students in the three cases are able to adapt their way of learning to the PBL model and experience change, e.g. learning more self-directed. In this sense, they can be said to be (partly) colonized by the PBL model. The opposite occurs as well: the PBL model is adapted or domesticated by the students and the institutes to better suit their needs, e.g. adding more lectures to the model. However, besides these similarities, the activity systems look different across the cases due to interactions with different cultural and contextual factors. The Dutch AT system shows less contradictions when PBL is introduced than the Egyptian and Hong Kong systems. Consequently, Dutch students appear to be less colonized than Egyptian students, who significantly change their learning beliefs. On the contrary, Hong Kong students do not experience such a development, but they do significantly domesticate the PBL model into a hybrid approach.

Concluding, a combination of cultural and contextual factors, and domesticating measures determine the extent of colonization of students' learning beliefs and behaviors when a western learning model is applied. These results might help institutes worldwide in better knowing and preparing what they choose for when adopting a foreign educational model, and in predicting how feasible their expectations are. Regarding the issue of educational globalization, the results indicate a global convergence of applying western educational models, but at the same time a divergence into culture-specific models.

PAPER PRESENTATION

Understanding academic performance of international students in a globalised networked society

Bart Rienties, University of Surrey, United Kingdom; Simon Beausaert, Maastricht University, Netherlands; Susan Niemantsverdriet, Hogeschool Leiden, Netherlands; Piet Kommers, Universiteit Twente, Netherlands; Ria Jacobi, Universiteit Leiden, Netherlands

More than 3 million students study outside their home country, primarily at a Western university. A common belief among educators is that international students are insufficiently adjusted to higher education in their host country, both academically and socially. Furthermore, several groups of international students experience considerable amounts of stress while adapting to the culture of the host-institute. Several researchers argue that studies on adaptation of international students should widen its focus to the underlying mechanisms that leads towards this "misalignment". In a cross-institutional comparison among 958 students at five business schools in the Netherlands, differences in academic performance between local and international students were identified by focussing on their levels of academic and social integration. Students' academic integration was measured with the Students' Adaptation to College Questionnaire (SACQ), while students' social integration was measured with a newly developed and validated questionnaire.

The results indicate that the degree of academic success of international students is multi-faceted. International students with a (mixed) western ethnic background perform well on both academic and social integration, and also attained higher study-performance in comparison to domestic students. In contrast, international students with a non-Western background are less integrated compared to other international students. Nevertheless, they have a similar study-performance. Finally, academic adjustment is the main predictor of study-performance for Dutch, Western and Mixed-Western students. Social adjustment was negatively related to study-performance. The lack of fit for predicting long-term study success of non-Western students indicates that their academic and social integration processes are more complex and non-linear.

1. Aim of study

An increasing number of students prefer to study at a university abroad (Russell, Rosenthal, & Thomson, 2010). In 2007, 3 million students studied abroad, which is almost three times higher compared to the figures of 1990 (OECD, 2009). A common assumption in higher education is that academic integration, that is the extent to which students adapt to the academic way-of-life (Tinto, 1975), of international students is not well-aligned with the requirements of higher educational institutes (Asmar, 2005; Morrison et al., 2005). Recent research has found a mixed picture on whether international students underperform in academic integration and academic performance. Therefore, Morrison et al. (2005) claim that research should widen its focus from comparing international - versus domestic students' performances to finding out the underlying mechanisms of academic and social integration. We define social integration as the extent to which students adapt to the social way-of-life at university. The prime goal of this paper is to characterise the typical differences in academic- and social integration between domestic and international students. Secondly, we assess whether differences in academic and social integration between domestic and international students have an impact on study-success after their first year of study.

2. Methodology

Students' academic integration was measured amongst 957 first-year bachelor students at five business schools in the Netherlands by the Student Adaptation to College Questionnaire (Baker & Siryk, 1999), which consists of 62 items and is divided into four scales, namely: academic adjustment; social adjustment; personal-emotional adjustment; and attachment. Students' social integration was measured by our own developed questionnaire (Author A, 2010), which consists of 15 items, divided into four constructs, namely: perception of the faculty; study support; student's satisfaction with social life; and financial support. The scales were validated by exploratory and confirmatory factor analysis. The Cronbach's alpha for eight scales ranged .67-.87

Ethnicity was measured by four open questions, namely mother's mother tongue, father's mother tongue, own mother tongue and official citizenship(s). 79 nationalities and 129 ethnic identities were present in the database. In order to prevent a fragmented approach of comparing a limited number of students within each ethnic category, students were categorized according to the "degree of Westernness", which is inspired by the cultural classification system of Hofstede (2001). We assumed that the more Western influences a student underwent, the easier it is for the student to adjust to the Dutch educational culture. Thus, in each of the four categories a distinction was made between Western (EU, USA, Canada, Australia, New Zealand) versus non-Western cultures. Consequently, four groups (Dutch, Western, mixed-Western, non-Western) were distinguished.

3. Findings

Correlation analysis illustrate that GPA is significantly positively correlated with academic adjustment, personal-emotional adjustment, attachment and the perception of the faculty, while ECTS only correlates with academic adjustment and attachment. The students' GPA and ECTS do not correlate significantly with the newly added social integration scales.

Subsequent ANOVA analyses among the different (sub)groups of international students show that Western students score significantly higher on all scales of academic integration with the exception of personal/emotional adjustment. Western students attain a higher GPA and a higher number of ECTS than Mixed-Western, Dutch and non-Western students. Mixed-Western student score significantly higher on all dimensions of academic integration and indicate to have more support by family and friends and social life. GPA and ECTS scores of mixed-Western students are similar to Dutch students but significantly lower than those of Western students. Finally, non-Western students score significantly lower on all elements of academic integration with the exception of academic adjustment, which indicates that adaptation to the ('Western') way of life at university is more difficult. Despite lower scores on academic and social integration, non-Western students perform similar to the domestic and the mixed-Western students.

The hierarchical regression analysis of the academic integration components on ECTS and GPA, controlling for the background variables gender and ethnicity, showed that academic adjustment ($b = .25$; p

4. Theoretical and educational significance of research

A main significant finding is that study-success is affected positively by academic integration irrespective of ethnic background. Quite surprisingly, mixed-Western students have significantly higher academic and social integration scores in comparison to domestic students. A possible explanation why mixed-Western students perform equally or better than domestic students may be due to job-prospects and subsequent reputation following business education, which may have a positive impact on motivation and support given by their social network. Furthermore, despite lower scores of non-Western students on academic and social integration in comparison to other students, non-Western students perform equally well after one year of study as domestic students, which is primarily due to the successful academic adjustment of non-Western students. Finally, in contrast to Tinto (1975) we find a compensatory relationship between academic and social adjustment and study-performance.

Most institutes for higher education provide several introduction activities and social support structures for new students in order to facilitate their academic and social integration. Based upon our findings, rather than focussing purely on social integration we encourage higher educational institutes to specifically address measures that can enhance academic adjustment of (international) students. This can for example be done by providing more information about the educational culture of the institute before international students move to the host university. Even better would be to allow international students to experience the educational learning approach of the host institute before starting with their bachelor program.

PAPER PRESENTATION

Net-based Communication in Higher Education: The Influence of Culture

Miriam Hansen, Goethe-University Frankfurt, Germany; Lisette Scholz, Goethe-University Frankfurt, Germany; Regina Jucks, WWU Munster, Germany

We report results of an online-study with 186 university lecturers teaching Psychology courses at German universities. The task was to respond to an email request of a student. The nationality of the requesting student (German vs. Chinese) and the communication style of the request (Western vs. Asian) were varied. Results showed that the nationality did have an effect on the lexical alignment, with more alignment in German nationality conditions, whereas the communication style influenced cultural adjustment, with more adjustment in Asian style conditions.

Regarding the appraisal of the student, incongruent conditions with Asian communication style and German nationality were particularly unfavorable, as the lecturers provided the highest number of negative descriptions in this condition.

1. Introduction

The internationalization of German universities increased enormously during the last years. For instance, lectures and courses are held in English, new international components are integrated in courses of studies or even new international courses of studies are established. As a consequence, more and more foreign students attend German universities and technical colleges. Contact with students from different countries and cultures means daily routine for lecturers at German universities. However, intercultural differences are likely to have an impact on the communication between lecturers and students.

2. Theoretical Background: Individualism-Collectivism and Communication

Particularly broad differences may be expected between cultures scoring on opposite sides of the individualism-collectivism dimension (Hofstede, 1980), which is often used in cross-cultural psychology. On this dimension, Germany is to rank as a more individualistic culture. A collectivistic culture is, for example, China.

Role perception of lecturers and communication style in teaching settings are two examples for intercultural differences between Germany and China that affect everyday life at universities: In China, the “professor” is perceived quite as a father and supports the students even with regard to general issues of studies and life (Lin-Huber, 2001). However, at German universities, the lecturers’ role is mainly limited to knowledge communication or support of knowledge acquisition. As in most individualistic cultures, a rather direct communication style is common practice in Germany; whereas a rather indirect communication style is predominant in collectivistic China (Gudykunst, 2002).

3. Aim of the Study

An important proportion of the communication between lecturer and student is net-based written communication. Thereby, cultural clues are mainly reduced to the name of the student as well as the communication style.

The aim of the study was to analyze, if there was an influence of the student’s nationality (indicated by the student’s name) or the communication style on the lecturer’s email response and/ or on the lecturer’s appraisal of the requesting student.

4. Participants and Task

186 lecturers from 22 German universities that gave courses in Psychology participated in the study. They were asked via email to participate. The task was to respond to an email request of a female student that has been created with the online survey-software Unipark. In this request, a pretended course participant of the lecturer was asking for a record of achievement even though she had been far more absent than permitted.

5. Design and Procedure

The nationality of the requesting student (German vs. Chinese) and the communication style of the request (Western vs. Asian) was varied in a 2x2-factorial design. A third factor consisted in the variation of single words (two synonymous versions) to allow the analysis of lexical alignment (Pickering & Garrod, 2004). The nationality of the student was indicated by the student’s name (Katrin Schneider vs. Li Hua); the communication style was operationalized as follows: The Western request was written in a direct style. The substantial items were written in a few sentences, concisely but politely strung together without any additional statements or explanations. The Asian request was written in an indirect style: To preserve the harmony and to meet the hierarchical differences, the personal situation of the student was illustrated in long introductory explanations and the course of the lecturer was praised. Only then the student asked for getting the record of achievement, continuously in a very polite and excessive manner. The Asian version was developed in cooperation with a Chinese colleague, who is well grounded in German language. Thus, incongruent conditions comprised a request written in Asian indirect communication style and signed by “Katrin Schneider” or respectively a request written in Western direct communication style and signed by “Li Hua”. In the other two conditions, nationality and communication style were congruent.

Each participant (lecturer in psychology) got access to one version. After reading the request, the participant had to compose an answer into a text box. Subsequently, the participant was requested to complete a short questionnaire consisting of socio-demographical questions as well as questions concerning the appraisal of the student.

A coding system was developed to analyze the answers as well as the appraisal of the student. We used three groups of dependent variables: (1) Lexical alignment (use of manipulated terms), (2) cultural adjustment (directness and politeness), and (3) appraisal of the student (number of negative descriptions).

6. Results and Discussion

A calculation of MANOVA revealed the following effects: The nationality of the student had an effect on lexical alignment: In conditions with German nationality of the student, the lecturers did use more of the terms written in the request (instead of synonymous terms) than in conditions with Chinese nationality. This shows a strategic component of lexical alignment, as the lecturers did align their answers depending on the information on the student's nationality.

The communication style had an effect on cultural adjustment regarding directness and politeness: In conditions with Asian communication style lecturers wrote longer answers and did also use more words for introduction as in Western communication style conditions. Further, they formulated more utterances showing understanding. This indicates an automatic process of cultural adjustment, as the lecturers adapted their cultural style directly to the student's regardless whether she had a German or a Chinese name.

There was a significant interaction of nationality and communication style on the appraisal of the student: The lecturers did not use a single negative description in the congruent condition of German nationality and Western communication style, whereas the incongruent condition of German nationality and Asian communication style caused the highest number of negative descriptions. The lecturers felt annoyed because of the 'strange' behavior of the student, as they had no evidence for a culturally grounded communication style. This is of practical relevance, as some students may have German or European names but still stem from other cultures.

Based on these results, intercultural trainings could be developed aiming to sensitize lecturers for culture, cultural effects on communication, or on role perception and to improve intercultural communication in university teachings.

PAPER PRESENTATION

Visual Skills Development in Adolescence: from Child Art to Networked Visual Culture

Andrea Karpati, UNESCO Centre for Multimedia in Education, Hungary; Laszlo Papp, Graduate School of Educational Sciences, University of Szeged, Hungary

This paper introduces new methods of evaluation of the development of visual skills and abilities in adolescence. Investigation goes beyond drawing and surveys areas of creation identified in an initial survey as important areas of visual language use: photography, film making, digital imaging and multimedia design (of cartoons, avatars, web pages etc.), street and land art, dressing and make-up. Adolescents practice these art forms in creative groups, so we conducted case studies on the media and genres of creative practice; content and style of creations; technical and creative skills and abilities involved; patterns of school, peer and self teaching and learning. We also described networked creation: the social aspects of adolescent art making.

In 2009, 297 Visual Creation Communities were identified in Hungary, with more than 1400 members actively engaged in 7 visual media. In 2010-11, a case studies are being conducted in each genre. The paper presents a video film production group that is network based, uses a peer learning model, and engages in a series of filming genres to express ideas about self and society. An evaluation of visual learning in the community shows significant growth in content management (understandable and effective expression of ideas), compositional skills, abilities related to media technology and collaboration. Works by 15-18-year-olds disprove the traditional model of artistic development where the age of adolescence is considered as a period of decline of visual creativity.

Adolescence is considered by many researchers (for example Efland, 1976, Gardner and Winner, 1984, Davis, 1991, Pariser, Kindler, Van den Berg, Dias, B. & Chen Liu, 2007) is considered the end of creative and expressive "child art", the period of decline of visual skills and the onset of technological deficiencies, copying and general disinterest in art making. Other researchers (for example, Lowenfeld and Britain, 1975, Korzenik, 1996, Wilson, 1981, 2006, Haanstra, Damen & Van Hoorn, 2010) document the unique and creative use of visual language by adolescents and its role in the

process of identity construction. As some studies employed evaluation of a collection of works by trained jurors while others employed standardised tests, results and conclusions are difficult to compare. In the meantime, art programs in secondary schools are reduced because educational policy makers who believe there is no significant visual skills development in adolescence. Therefore, art education should only be offered as an elective with broadly formulated and rarely assessed developmental goals.

In the first phase of our research, we wanted to prove that visual skills and abilities significantly develop during adolescence and quantitative measures may be employed in their assessment. We studied 700 Hungarian 12-18-year-old secondary school students through a battery of standardised tests and revealed significant improvement in performance. The Clark Drawing Development Test and our own Spatial Abilities Test showed substantial growth in mental manipulations in space, reconstruction and spatial memory, especially in late adolescence, ages 17-18. The Visual Narrative Task by Wilson (1986) revealed improvement in compositional structures, figure variation and combination as well as detailed and proportionally correct representation of humans between 15 and 17 years of age. The Test for Creative Thinking – Drawing Tasks (Urban and Jellen, 1986) showed significant increase in performance, especially in ages 14-16.

In the second phase of our study, therefore, we decided to go beyond drawing and survey other areas of creation among adolescents. An initial survey involving all the secondary schools (20 in total) in one Hungarian county revealed photography, filmmaking, digital imaging and multimedia design (of cartoons, avatars, web pages etc.), street and land art, dressing and make-up as major areas of visual creation. Students indicated creative communities as places of engagement in these activities, so we conducted an internet search to identify communities of practice and describe, through case studies done by participant observation, the following aspects of these Visual Creation Communities:

- media and genres of creative practice
- content and style of creations
- technical and creative skills and abilities involved
- patterns of school, peer and self teaching and learning
- networked creation: the social aspects of adolescent art making

In order to prove that the creative use of visual language is actively used in adolescence, we restricted our sample to non-professional groups where the majority of members were 15-18 years of age that practised their art form as a hobby, in their free time and achieved high levels of expression. Groups were considered non-professional when their creation was unrelated to vocational studies, involved regular engagement and ongoing learning behaviour. Artistic excellence was evaluated by a list of criteria developed by media education experts. In 2009, 297 Visual Creation Communities were identified, with more than 1400 members actively engaged in 7 visual media. In 2010-11, 7 case studies are being conducted to describe activities of a group in each media to describe the characteristics and developmental patterns of the visual language of adolescents and show the significance of these interdisciplinary creative endeavours for Art and Design, Media and Information and Communication Technologies (ICT) education.

In this paper, we report findings about one of the most popular forms of visual expression in adolescence: video film production. Our internet search and interviews with teachers of the elective discipline "The Moving Image and Media Science", we identified a large national network of adolescent film makers (about 80 active groups). The case study was done in one of the largest groups (43 students), active, with changing members, for more than 2 decades. All group members were involved in the study with their mentor as participant observant. Data collection was done between February and June 2010. The study began with an assessment of written and media works (electronic portfolios) of group members to identify visual skills involved in media production, skill levels characteristic for different age groups and compare production with works collected at media competitions and final examinations that served as benchmarks. Three rounds of focus group interviews followed, and the study ended with a questionnaire filled out by all members individually to clarify some aspects of learning and creation in the group.

Results indicate that production in adolescent media works are social constructions, co-creations of pairs and triads. The community is network based, tasks are distributed, handed in and criticised using Social Web tools. Communication is frequent and involves peer learning as well as motivation, management and criticism. Members are 15-20 years of age, girls and boys are almost equally represented. They work in the media group between 10-18 hours a week and stay with the group for 5-6 years. They prefer documentary genres and interviews to express ideas about self and society. Some of their productions are shown on community television and receive professional feedback, others are discussed in Social Web arenas. Text analysis of portfolio entries of junior and senior members integrate these knowledge elements, show growing media literacy and sensitivity to creative processes. When

describing reasons for joining the community, media literacy development and emotional attachment are mentioned with an almost equal frequency though professional gains are more relevant.

An evaluation of visual learning in the community (based on 3-6 works of members produced in the course of 2 years and evaluated by two experts) shows significant growth in content management (understandable and effective expression of ideas); compositional skills; abilities related to media technology; and collaboration.

Works by the media community disprove the traditional model of artistic development where the age of adolescence is considered an age of decline of visual creativity and indicate a need for integration of ICT, Media and Visual Arts studies for the development of a 21. century visual literacy.

PAPER PRESENTATION

Challenges, Limits and Perspectives Regarding Teaching Practices in Mathematics, Sciences and Techno

Ghislain Samson, Université du Québec à Trois-Rivières, Canada

In a study subsidized by Fonds québécois de la recherche sur la société et la culture (FQRSC), questionnaires were sent out to over 200 math, science and technology teachers in the province of Québec to document their opinion on interdisciplinary practices in high schools. Interviews (N=10) were also conducted to better understand their perceptions regarding the challenges, limits and perspectives of both teaching practices and future research. Based on a literature review and preliminary results pertaining to integrative approaches, creating connections between math, science and technology (MST) and other subjects (Samson, 2004; Hasni, 2006) in high school is an issue. Interdisciplinarity is generally accepted, however the concept is highly ambiguous and its implementation creates many challenges for school faculty. Suggestions are made regarding initial training (in university) and continuous learning (in the workplace). Integration and interdisciplinarity in scientific and technological education are considered.

Towards integrated approaches such as interdisciplinarity- Many studies underline the determinant effect of teaching practices on learning and academic achievement (Bru, Altet & Blanchard-Laville, 2004; Mottier-Lopez, 2003). Therefore, the ability to articulate science and technology teaching practices to the students' daily reality is a major issue. It is difficult to maintain their interest and achievement in these courses (Davis, 2003; Gibson & Chase, 2002). As mentioned by Conseil de la science et de la technologie (CST, 2004), when teaching scientific courses, it is important to use approaches that are based on « discovery and production pedagogy, experimental and contextualized learning situations » (p.68). Some authors consider science and technology pedagogy to be contextualized and integrated. Interdisciplinarity improves integration in S&T courses. These approaches support the Ministry of Education's (MEQ, 2004; MELS, 2007) current expectations to favor contextualized teaching methods as well as open and integrated situations.

Teacher training and professional development- In Québec as in other OCDE countries (Council for Excellence in Government, 2003; OCDE, 2006), using knowledge from research is a crucial factor to insure the improvement of teaching practices and to promote better professional development. New S&T programs promote interdisciplinarity. Québec universities offer teachers a monodisciplinary approach. Authors underline limits pertaining to initial training with regards to teaching strategies and methods (Lenoir & Vanhule, 2006; Tardif, Lessard & Gauthier, 1998). They also criticize the traditional framework of the tools used for continuous learning that often favor an application based model. As underlined by the Conseil supérieur de l'éducation (CSE, 2005, 2006), recent literature on teacher professionalism emphasizes both theoretical (from research) and practical knowledge.

Objective-

The objective of this study is to examine the implementation of MST integration and interdisciplinarity in high school. Specifically, it aims to : 1) describe teaching methods and approaches used by S&T teachers in high school; 2) support teachers in the development, implementation and validation of interdisciplinary methods related to S&T learning for high school students; 3) describe teaching practices implemented in S&T courses and determine the professional development needs of teachers.

Method-

The methodology framework is based on two key concepts : a) collaborative research (Desgagné, 2001), based on the active participation of all the concerned actors (researchers, students, school faculty). Scientific knowledge and

school faculty mobilization are expected outcomes; b) teaching methods (Altet, 2002; Bru, 2002; Robert & Rogalski, 2005). Teaching practices implemented before, during and after class (preactive, interactive and postactive phases), while taking into account the content, the goals, the learning methods, the context and the didactical resources used.

Two types of data are retrieved : a1) individual interviews (N=10) and questionnaires completed by teachers (N=55) voice their opinion on integrative approaches and teaching practices. a2) descriptive information on effective teaching practices (N=10). This procedure requires three phases : an interview on teacher planning (preactive phase); teaching practices observed in class (video taping was necessary) (interactive phase); an interview on the teacher's impression of the class activity (postactive phase). The data analysis is inspired by methods previously used in other studies regarding representations and teaching practices (Larose & Ponton, 2000). The data retrieved by the questionnaires and the preactive and postactive phases are analysed using quantitative and qualitative techniques (Larose & Lenoir, 1995), content analysis (Bardin, 2001), lexicometric analysis as well as statistical analyses using textual data (Larose, Jonnaert & Lenoir, 1996). The direct observation sequences are analysed using grids developed according to the conceptual framework used in previous studies.

Results-

The results from the questionnaires (N=55) show that teachers believe that connections between subjects (in general) are very important, whereas it seems to be important when it comes to scientific disciplines. The level of difficulty perceived by teachers regarding the connections between scientific disciplines varies from difficult to very difficult. However, these connections are considered mostly important or very important for most teachers. Finally, many teachers consider it easier to establish links between physics and math than between biology and math.

Our results also show that : 1) teachers are open to interdisciplinarity; 2) S&T teachers say that they use interdisciplinarity less than other teachers; 3) S&T and math teachers use other disciplines in their interdisciplinary practices, whereas their disciplines are rarely used by other teachers; 4) teachers mention many constraints when implementing interdisciplinarity (Hasni & Samson, in press).

Discussion and conclusion-

Conceptually, integration challenges the traditional model of scientific training which addresses disciplines individually when taught in high school. The new Québec curriculum seems to promote decompartmentalization. Furthermore, the ambiguous definition of integration does not facilitate the task.

According to teachers, operationalizing interdisciplinarity is not clearly described in the Québec program and the repartition of the disciplinary content is a major obstacle. For example, some mathematical content that could easily be taught in relation to S&T content in the secondary first cycle is only taught in the second cycle.

Regarding the organizational aspect, time management, teacher workloads and the organization of student groups must be reviewed to guarantee the most favorable conditions for the implementation of interdisciplinary approaches as specified by government officials (Gouvernement du Québec, 2004; 2007).

Teachers as designers of modeling-centered curriculum materials

Marios Papaevripidou, University of Cyprus, Cyprus; Costas Constantinou, University of Cyprus, Cyprus; Zacharias Zacharia, University of Cyprus, Cyprus

The purpose of this study was to examine the influence of a professional development course on the development of teachers' curricular knowledge about Modeling-Centered Scientific Inquiry (MCSI) and curriculum design skills. The participants were twenty science teachers enrolled in 13 three-hour sessions of a professional development course about MCSI. The course was organized in two phases. During Phase 1 ("Teachers as Learners"), a curriculum titled "Modeling 1-D elastic collisions" was implemented through which teachers were engaged in multiple cycles of model development and deployment of collision phenomena. During Phase 2 ("Teachers as Thinkers of Curriculum Design") teachers shifted from learners to thinkers of the underlying design principles of curricula that were grounded on the MCSI perspective, and were also asked to re-design an existing unit from their science curriculum to foster the development of understanding of the unit's concepts through a MCSI approach. Teachers' responses to a written pre/post questionnaire about their understanding of modeling as both a learning process and a teaching approach, and their own created curriculum designs served as data sources for evaluating their informed understandings about the underlying design principles of MCSI instruction. Findings revealed that the participants expanded their curricular knowledge about MCSI and, at the same time, efficiently transformed this knowledge for the purposes of the design of their own MCSI curriculum.

Background

In spite of persistent calls of reform documents in science education for Modeling-Centered Scientific Inquiry (MCSI) as an instructional approach, evidence in the literature (Duschl et al., 2007) attests that modeling is not routinely practiced at schools. It has also been reported that teachers (i) possess limited and/or alternative views of the role of models and modeling in science (Crawford & Cullin, 2004), (ii) appear to have difficulty with or are resistant to creating classroom environments in which students are supported in creating their own constructions of knowledge through model building (Windschitl & Thomson, 2006), and (iii) have not been adequately equipped with knowledge and skills to enact science instruction through modeling (Schwarz & Gwekwerere, 2006). These findings can be attributed to the absence of teaching practices within teachers' professional development that emphasize the development of scientific knowledge as a continuous process of building and refining models (Justi & van Driel, 2005). Consequently, there is an emergent need to explore possible ways of how to design instructional settings that would better support teachers' professional development about the design and enactment of science instruction through MCSI.

Purpose

The purpose of this study was to examine the influence of a professional development course on the development of teachers' Curricular Knowledge (CK) about MCSI and curriculum design skills. Specifically, the two research questions that this study aims to address are:

- (i) In what ways a professional development course influences teachers' development of CK about MCSI?
- (ii) What are the characteristics of teachers' MCSI curriculum designs?

Methods

The participants were twenty science teachers enrolled in 13 three-hour sessions of a professional development science education course about MCSI. The teacher training approach followed placed the teacher directly in the role of inquirer in simulated research experiences throughout the course (Crawford, 2005).

The course was organized in two phases. During Phase 1 ("Teachers as Learners"), a curriculum titled "Modeling 1-D collisions" was implemented through which the teachers (working in dyads) were engaged in multiple cycles of model development and deployment of elastic collision phenomena. Specifically, teachers observed collision phenomena, created models with the use of Stagecast Creator to represent the observed phenomena, revised their models, compared their models with their peers' models, and validated their models by applying it in new collision phenomena.

During Phase 2 ("Teachers as Thinkers of Curriculum Design") teachers shifted from learners to thinkers of the underlying design principles of curricula that were grounded on the MCSI perspective, and were asked to re-design an existing unit from their science curriculum to foster the development of understanding of the unit's concepts through a MCSI approach. To better scaffold teachers' work, we organized various reflective activities (e.g., teachers revisited the curriculum that were engaged with during Phase 1 and identified the learning objectives of each set of activities). As part of the requirements for their curriculum designs, teachers were asked to: (i) formulate learning objectives, (ii) organize the activity sequence of their curriculum in a map, (iii) provide descriptions of the design and

the implementation of each activity,(iv)design activity sheets based on their activities' descriptions, and (v)design assessment tasks to evaluate their learning objectives.

Data sources and analysis

Two sources of data were used for the purposes of this study. The first one was a questionnaire (administered before and after Phase 1) through which we collected data about teachers' understandings of MCSI as both a learning process and a teaching approach, and their knowledge about the types of teaching activities and the assessment tasks that are involved within a unit that is fostered through a MCSI approach. The second source of data was the MCSI curriculum that teachers created after Phase 2 of the study.

The data were analyzed qualitatively using open coding from grounded research methodology (Strauss&Corbin,1998). The written responses of teachers in the questionnaire were reviewed, one by one, to characterize each participant's CK for MCSI. Additionally, the focus during the analysis of teachers' curriculum designs was on the content and the structure of the activities that teachers incorporated within their curriculum designs, while at the same time an attempt was made to identify possible links between these activities and their CK for MCSI.

Findings

At the beginning of the course, all teachers' responses to the questionnaire revealed a limited understanding of how MCSI approach should look like in a science class. Moreover, their knowledge about the types of teaching activities and the assessment tasks that are involved within a unit that is fostered through a MCSI approach was found to be inadequate or incomplete. After their engagement with the MCSI curriculum materials of Phase 1, the majority of teachers seemed to have developed comprehensive understandings of the design principles of MCSI approach. They also stated that their experiences with the course helped them refine their view of MCSI, revealing that it was a more complex and dynamic process than they had originally presumed.

With respect to the characteristics of teachers' MCSI curriculum designs, it was found that all curriculum designs encompassed 19 different types of activities that were grouped in three clusters of activities (see Table 1,Appendix). However, the nature of the models that teachers created and anticipated to be developed from their students was different in some cases. For instance, the majority of teachers' models represented aspects of the phenomenon under study, provided a mechanism for how the phenomenon functions, and enabled the formulation and test of prediction. In a few other cases, the teachers' models represented only observable patterns from a phenomenon, lacked of a mechanism that explains how the phenomenon evolves over time, and had a limited predicting power.

Conclusions

The teachers who participated in our long-term course as both active learners and thinkers expanded their CK about MCSI and, at the same time, they efficiently transformed this knowledge for the design of their own MCSI curriculum. The findings of the present study designate that by positioning teachers in the active role of designers of curriculum materials enabled them to efficiently transform the knowledge and experiences obtained throughout the course for designing productive MCSI curriculum materials. We believe that by allowing teachers to design their own curriculum materials, we offered them opportunities to think of issues like "How does MCSI look like in practice?" or "What do I expect from my students to develop during their engagement with MCSI activities?" Hence, we argue that without teachers' personal involvement in developing these materials, the understanding and implementation of the aspects of MCSI, to the extent that appeared to occur because of their personal involvement, wouldn't be possible.

PAPER PRESENTATION

Teaching Magnetism to Primary School Children by Combining Expository Instruction and Guided Inquiry

Christof Wecker, University of Munich, Germany; Alexander Rachel, University of Munich, Germany; Eva Heran-Dorr, University of Bamberg, Germany; Christine Waltner, University of Munich, Germany; Hartmut Wiesner, University of Munich, Germany; Frank Fischer, Universitat Munchen, Germany

The idea behind inquiry learning is that learners discover relations among observable phenomena themselves. A problem during inquiry learning might be that theories that assume unobservable entities such as (theoretical) molecular magnets cannot easily be discovered because the learners' hypothesis space will hardly contain assumptions about them. Therefore this study investigated whether primary school children can acquire knowledge about functional relations among observable variables and understanding of scientific theory during inquiry activities if supported appropriately. In particular, we investigated the short- and longer-term effects of prior and summary expository instruction as well as guidance of high vs. low content-specificity. A 2x2x2-factorial design with the factors

content-specificity of guidance (low/high), prior expository instruction (without/with) and summary expository instruction (without/with) was implemented in a curriculum unit about magnetism with a sample of 684 4th-grade students from 31 classes. Knowledge about functional relations and understanding of the scientific theory were measured in immediate and delayed posttests. In the presence of prior expository instruction, summary expository instruction or both, learners acquired deeper understanding of the scientific theory than without both of them. In the delayed posttest, however, this effect disappeared. Instead, there was a significant main effect in favour of the conditions with prior expository instruction. Prior expository instruction also had a positive effect on knowledge about functional relations in the delayed posttest. In sum, this study demonstrates that primary school children can learn about challenging topics involving scientific theories that cannot readily be discovered, provided that they are supported appropriately.

The idea behind inquiry learning is that learners discover relations among observable phenomena themselves (de Jong, 2006). A more far-reaching goal of science education, however, is acquiring an understanding of explanatory scientific theories that go beyond observable relationships. For example, in phenomena related to magnetism, (theoretical) molecular magnets cannot be observed directly. A problem during inquiry learning might be that theories that assume such unobservable entities cannot easily be discovered because the learners' hypothesis space (Klahr & Dunbar, 1988) will hardly contain assumptions about them. In a prior study we found that secondary school students can acquire better understanding of explanatory scientific theories if they receive prior expository instruction about such a theory before investigating the phenomena themselves, whereas summary expository instruction about the same theory after an inquiry phase had no lasting effect (Rachel et al., 2010). The current study focused on the question whether primary school children can likewise learn during inquiry activities if supported appropriately. In particular, we investigated the short- and longer-term effects of prior and summary expository instruction and guidance of high vs. low content-specificity.

Method

Participants.

The participants in this study were 684 German primary school students from 31 4th grade classes (49 % female, 51 % male; age: $M = 9.26$, $SD = 0.52$). Design. Three to four intact classes were randomly assigned to each condition of a 2x2x2-factorial design with content-specificity of guidance (low/high), prior expository instruction (without/with) and summary expository instruction (without/with) as independent variables.

Procedure and learning environment.

The students first completed a 20 minute pretest. Then they worked on an inquiry unit about magnetism for 120 minutes in which they conducted hands-on experiments in dyads at up to eleven learning stations. Finally they completed a 25 minute posttest. Two months later they completed a 25 minute delayed posttest in their classrooms. Independent variables. Dyads in the low content-specificity guidance condition received general prompts to engage in the three inquiry activities of predicting, describing and explaining. Dyads in the high content-specificity guidance condition received content- and task-specific prompts for these inquiry. In the conditions with prior expository instruction, initially a 30-minute introduction to the theoretical background of magnetism was provided by a teacher. No such introduction was given in the conditions without prior expository instruction. In the conditions with summary expository instruction a 30-minute teacher-led wrap-up phase about the same topics as in prior expository instruction took place at the end of the learning phase, while there was no such phase in the conditions without summary expository instruction.

Dependent variables.

Knowledge about functional relations among observable variables was measured by 15 multiple-choice and true-false items (immediate posttest Cronbach's $\alpha = .63$; delayed posttest Cronbach's $\alpha = .64$). Understanding of the scientific theory was measured by means of 15 multiple-choice and true-false items (immediate posttest Cronbach's $\alpha = .79$; delayed posttest Cronbach's $\alpha = .81$). A shorter version of the test for knowledge about functional relations was used for the pretest (9 items, Cronbach's $\alpha = .52$).

Statistical analysis.

Data were analyzed by means of single ANCOVAs with the respective posttest measure as the dependent variable, content-specificity of guidance, prior expository instruction and summary expository instruction as fixed factors, class as a random factor nested within the cells of the design and the pretest as a covariate. The significance level was set to 5 %.

Results

With respect to knowledge about functional relations, in the immediate posttest no significant main or interaction effects of the independent variables were found. In the delayed posttest a small main effect in favour of the conditions with prior expository instruction was detected, $F(1; 23.36) = 4.48$; $p = .01$. With respect to understanding of the scientific theory, in the immediate posttest significant main effects in favour of the conditions with low content-specificity of guidance, $F(1; 23.12) = 9.50$; $p = .05$, and the conditions with summary expository instruction, $F(1; 23.12) = 6.62$; $p = .03$, as well as an interaction effect between prior expository instruction and summary expository instruction, $F(1; 23.13) = 6.32$; $p = .03$, were found: In the presence of prior expository instruction, summary expository instruction or both, learners acquired deeper understanding of the scientific theory than without both of them. In the delayed posttest, however, this interaction effect and the main effect of summary expository instruction disappeared. Instead, there was a significant main effect in favour of the conditions with prior expository instruction, $F(1; 23.28) = 9.24$; $p = .03$.

Discussion

The results indicate a superiority of low content-specificity of guidance during inquiry activities with respect to the understanding of scientific theory. With general prompts for inquiry, the function of the current activity in the investigation of theoretical assumptions might be more transparent to the learners than with highly content-specific questions. Furthermore, prior expository instruction proved beneficial for knowledge about functional relations among observable phenomena and understanding of the scientific theory. While immediately after the learning phase a summary might be at least a functional equivalent to prior expository instruction – as evidenced by the interaction of prior and summary expository instruction –, in the long run prior expository instruction proves superior. This effect might be explained by the opportunity provided by prior expository instruction to apply the theory to be learned during inquiry activities, thereby yielding deeper theoretical understanding. In sum, this study demonstrates that primary school children can learn about challenging topics involving scientific theories that cannot readily be discovered, provided that they are supported appropriately.

PAPER PRESENTATION

Use of concept maps to follow up the effect of discussing atmosphere dynamics with satellite images

Camila Cicuto, Universidade de Sao Paulo, Brazil; Paulo Correia, Universidade de Sao Paulo, Brazil

Concept maps (Cmaps) are useful for representing students' knowledge to foster meaningful learning. However, assessment of Cmaps in real classrooms is a time-consuming task which hinders its application by teachers. We proposed an assessment procedure based on the use of a compulsory concept and its neighbors to check the students' understanding about a specific aspect of a topic. Our case study involved a discussion about climate change during the Natural Science course offered for 1st-year higher education students. Preliminary results confirmed the possibility to get relevant information from Cmaps after assessing only part of the whole propositional network.

Aims

Concept maps (Cmaps) were proposed by Novak and colleagues during the 1970s. They can be defined as a set of concepts embedded into a propositional framework. Concept mapping plays a key role as a tool to represent knowledge held by a learner, and also the structure of knowledge in any subject matter domain (Novak, 2010). The aim of this work is to propose a new way to evaluate students' Cmaps, based on the use a compulsory concept to check the quantity and the quality of propositions established from it. Our hypothesis suggests this analysis reduces the time required for assessing the Cmaps without compromise the information obtained about the students' understanding about the compulsory concept.

Methodology

Data collection

Individual Cmaps ($n=69$) were produced by 1st-year higher education students during the Natural Science course offered at Universidade de Sao Paulo (Correia et al., 2010). Climate change was the topic under discussion (classes 6-10) and a video with satellite images (NOAA, USA) was used to show the atmospheric dynamics (class-8). Dispersion

(of pollutants) was assumed as the key-concept to allow an in-depth understanding about climate change local and global consequences (Fenger, 2009; Ungar, 2000). Therefore, dispersion was the compulsory concept and must be used by the students during the Cmap elaboration (class-10).

Data analysis

All Cmaps were analyzed considering only the propositions (n=175) that involved “dispersion” as the initial or final concept. They form the data subset to be considered in this paper. The evaluation of Cmaps followed these steps:

1. Count the number of “neighbor concepts” associated with dispersion through propositions.
2. Check what are the “neighbor concepts” more used by the students, by using the word cloud provided by Wordle (wordle.net).
3. Categorize the propositions considering their semantic meaning (content analysis). Two different researchers took part into the process of category creation to minimize subjectivity.
4. Compare the number of “neighbor concepts” (1) and the categories assigned for the propositions for each Cmap (3).

Results and discussion

All Cmaps presented a total of 985 propositions. The concept “dispersion” was present in 175 propositions (18% of the total), and it was used as the final concept in 60% (n=102) of them. Two or three “neighbor concepts” were associated with “dispersion” in 73% of the Cmaps (Figure 2).

The frequency of the concepts used in the propositions containing “dispersion” was qualitatively estimated by using the word cloud obtained in Wordle website (Figure 3). More frequent concepts (e.g. climate change, global, greenhouse gases, and pollution) are in bigger fonts, while the less frequent ones (e.g. atmosphere, energy, fossil, and technology) are in small fonts. It should be highlighted that the frequent concepts were not always used by the students to express ideas accepted by the current scientific understanding about climate change. The naive use of this concept may be related to the previous knowledge that the students have about the current environmental problems, which are noticed by the mass media. On other words, the evaluation of the propositional meaning (right/wrong) was not considered until now.

The content analysis classified the propositions into eight different categories. Table 2 shows that the category environment predominated in the Cmaps with 1-5 neighbor concepts. Students who used 2-3 neighbors presented a broad understanding of dispersion and how to relate this concept into the propositional framework. On the other hand, the Cmaps with 6 and nine concepts showed a large number of meaningless and wrong propositions, suggesting these students used “dispersion” without any concern.

Two illustrative Cmaps (Figure 4) were selected to highlight the bad (Fig.4a) and the good (Fig.4b) use of dispersion.

Theoretical and educational significance of the research

The comparison of these Cmaps suggests the proposed Cmap analysis using only the neighbor concepts and propositions may be useful for speeding up the assessment of a large number of Cmaps. This strategy overcomes one of the main obstacles to the constant use of Cmaps in real classrooms.

PAPER PRESENTATION

Comparing three theories of visual expertise: A meta-analysis of eye movements

Andreas Gegenfurtner, University of Turku, Germany

The purpose of this study was to compare three theories of visual expertise by a meta-analysis of eye movements. The theories were the theory of long-term working memory (Ericsson & Kintsch, 1995), the information-reduction hypothesis (Haider & Frensch, 1996), and the holistic model of image perception (Kundel et al., 2007). Analysis

included forty-four eye-tracking studies which compared experts, intermediates, and novices during comprehension of domain-specific visualizations; domains represented sports, medicine, transportation, and science. Meta-analytic procedures were used to correct for sampling error and to integrate research findings across studies. Results indicated support of the hypotheses. Contrary to expectations, however, experts partly had longer fixation durations than novices, indicating less efficient information processing. New directions for future research are suggested, and instructional implications of the findings are discussed with regard to attention guidance in professional training environments.

1. Aims and Hypotheses

The simple purpose of this study was to compare three theories of visual expertise by a meta-analysis of eye movements. Visual expertise refers to reproducibly high performance in comprehending domain-specific graphics (e.g., X-ray slides, flight traffic maps). The basic assumption of the study was that eye movements can reflect processes underlying expert performance. To explain expertise differences, research on graphics comprehension frequently cites three theories: the theory of long-term working memory (Ericsson & Kintsch, 1995), the information-reduction hypothesis (Haider & Frensch, 1996), and the holistic model of image perception (Kundel et al., 2007). The current meta-analysis was designed to test the assumptions of those three theories.

First, the theory of long-term working memory assumes that expertise extends the capacities for information processing owing to the acquisition of retrieval cues. Experts with retrieval cues access long-term memory directly and rapidly; novices without retrieval cues access long-term memory less efficiently. It follows that rapid processing of information during graphics comprehension should be reflected in shorter dwell times.

Hypothesis 1: Compared to intermediates and novices, experts have shorter fixation durations.

Second, the information-reduction hypothesis holds that expertise optimizes the amount of processed information by a neglect of task-irrelevant information and an active focusing on task-relevant information, which is accomplished through strategic considerations to selectively allocate attentional resources. If this hypothesis is true, experts and non-experts should employ a different amount of visual fixations.

Hypothesis 2: Compared to intermediates and novices, experts have a larger number of fixations on task-relevant areas and a smaller number of fixations on task-irrelevant areas.

Third, the holistic model of image perception holds that expertise changes the temporal organization of perceptual processes: advanced learners are able to start from an initial global analysis and to extract information from parafoveal regions. It follows that expertise encompasses an extended visual span. This should be visible at saccade length and initial fixation time.

Hypothesis 3: Compared to intermediates and novices, experts have longer saccades and a shorter time to first fixate task-relevant areas.

2. Method

2.1. Meta-analysis

Meta-analysis seemed appropriate to test the three hypotheses. Because eye-tracking studies usually have a small sample size, sampling error is likely to bias individual research findings. Meta-analytic procedures can correct for sampling error and integrate research findings across studies (Hunter & Schmidt, 2004).

2.2. Literature search and coding

Studies published up to September 2010 were searched using the PsycINFO and PubMed databases. 44 studies were located. Domains included sports, medicine, transportation, and science. Key words were (1) for expertise: expert, novice, skilled, elite, expertise and (2) for eye movements: eye tracking, fixations, saccades, eye movements. Eye movements were coded as duration of fixations on task-relevant, task-irrelevant, and total areas; as number of fixations on task-relevant, task-irrelevant, and total areas; as time to first fixate task-relevant areas; and as saccade length. Additionally, performance measures were collected and coded as performance accuracy and decision time.

2.3. Analysis

Point-biserial correlation coefficients r_{pb} were used to analyze between-group differences (expert-novice, expert-intermediate, intermediate-novice). Effect sizes other than r_{pb} (Cohen's d , Hedges' g , F , t , c^2 , or Z statistics) were converted using formulae provided by Rosenthal and DiMatteo (2001). Correlations were then individually corrected for sampling error (rc ; Hunter & Schmidt, 2004).

3. Results

3.1. Study characteristics

The 44 articles averaged a total of 530 experts, 166 intermediates, and 596 novices ($N_{\text{total}} = 1,292$). Experts had a mean age of 26.07 years ($SD=6.39$) and 10.76 years of domain experience ($SD=5.61$). Intermediates had a mean age of 24.26 years ($SD=8.09$) and 6.49 years of domain experience ($SD=7.89$). Novices had a mean age of 22.46 years ($SD=4.43$) and 2.09 years of domain experience ($SD=2.95$).

3.2. Eye movement measures

3.2.1. Hypothesis 1: Fixation duration. Results indicated that experts had shorter fixation durations than novices on task-irrelevant ($r_c=-.37$) and total areas ($r_c=-.06$). Contrary to expectations, experts had longer fixation durations on task-relevant areas ($r_c=.25$).

3.2.2. Hypothesis 2: Number of fixations. Experts compared to novices had more fixations on task-relevant ($r_c=.33$) and less fixations on task-irrelevant areas ($r_c=-.26$). Experts and novices differed marginally on total areas ($r_c=-.02$); there, experts had less fixations than intermediates ($r_c=-.26$), who had less fixations than novices ($r_c=-.25$).

3.2.3. Hypothesis 3: Saccade length and time to first hit task-relevant areas. Results indicated that experts had shorter times to first fixate task-relevant areas than novices ($r_c=-.31$). Experts also had longer saccades than intermediates ($r_c=.38$) and novices ($r_c=.31$); intermediates had shorter saccade lengths than novices ($r_c=-.12$).

3.3. Performance measures

Experts were more accurate and more rapid than both intermediates ($r_c=.45$ and $r_c=-.41$, respectively) and novices ($r_c=.45$ and $r_c=-.31$, respectively); intermediates were more accurate ($r_c=.44$) and more rapid ($r_c=-.43$) than novices.

4. Discussion

The purpose of this study had been to compare three theories of visual expertise by a meta-analysis of eye movements. Results confirmed the assumptions of information-reduction hypothesis (Haider & Frensch, 1996) and the holistic model of image perception (Kundel et al., 2007). However, results only partly confirmed the theory of long-term working memory (Ericsson & Kintsch, 1995): contrary to expectations, gaze durations on task-relevant areas had been longer for experts than for non-experts.

4.1. Implications for future research

There are at least two explanations why experts needed more time than novices to comprehend task-relevant information. First, this finding may be moderated by different criteria used in the primary studies to categorize participants' relative expertise, which may imply within-group heterogeneity regarding retrieval cue acquisition. Second, this finding may be moderated by the visual modality, for primary studies used stimuli at different levels of realism and information transience. Future moderator analyses may examine these two directions.

4.2. Implications for instruction

Eye movements have been indicated to uncover some of the processes underlying expert performance. Despite doubts on the validity of process measures for informing professional training (e.g., Feldon, 2007), superimposing expert gaze on graphic stimuli can guide attentional resources of novice learners (Grant & Spivey, 2003). The effectiveness of using eye movements as attentional procedure cues needs further exploration with complex graphic stimuli as they are representative for vision-intensive workplaces.

PAPER PRESENTATION

Education for creativity: Understanding and developing adolescent creativity

Carly Lassig, Queensland University of Technology, Australia

In the knowledge age, creativity and innovation are becoming increasingly valued as driving forces for our global society. For successful participation in society, now and in the future, students will require transferable lifelong learning skills, such as creative thinking, to manage increasing change, ambiguity and complexity. This paper will report findings from a grounded theory study designed to describe and theorise about adolescents' experience of creativity. Twenty creative students were selected to participate in the study, and data were collected through focus groups, individual interviews, and an online discussion forum. Participants were selected from two academically selective schools: 10 students from an arts school; and 10 students from a science, mathematics and technology

school. Results revealed that the adolescent creative process involves six components: creativity motivation; creativity stimuli; the sub-processes of creativity; managing challenges in the creative process; producing divergent outcomes; and creativity affecting self/others. The success of the adolescent creative process is affected by: (a) internal influences from the individual students; and (b) supportive and inhibiting external influences, many of which relate to teaching and learning environments. Today's creative adolescents are tomorrow's leaders. Understanding adolescent creativity and the conditions that foster the development of creative achievement is a matter of significance for all educational stakeholders who aim to nurture our future leaders.

Introduction

A consequence of the contemporary knowledge age is that knowledge becomes obsolete at an accelerated rate (Michael, 2001), necessitating a refocusing of schooling on the skills of knowledge production or creativity (McWilliam, 2008). In a world where the fabric of society will surely be tested, individuals and communities will depend on the intellectual skills and creativity of our young people. Solving the mounting personal, social, health, environmental, and political problems facing our global society will require creative thinkers as leaders. This paper proposes that educational stakeholders need a shared understanding of students' creative processes and products, and the conditions that influence their creative abilities, to improve educational effectiveness in teaching for creativity. This study aims to contribute to those understandings, by exploring the experiences of creative students, to propose a grounded theory of adolescent creativity.

Aims of the Research

The aim of the research was to explore adolescents' experiences of creativity to create a substantive theory of adolescent creativity. To develop a multidimensional perspective of creativity, Rhodes's (1961) four P's framework – person, process, product, and press (environment) – was adopted. Therefore, the study explored: (a) the adolescent as a creative person, and the personal factors that influence adolescents' creativity; (b) the creative process of creative adolescents; (c) adolescent creativity manifested as a creative product; and (d) social and environmental press factors that influence adolescents' creativity.

Research Design and Methods

Given the limited research on adolescent creativity, a grounded theory methodology guided data collection and analysis. Grounded theory is a qualitative approach intended to develop theory that is grounded in the data (Glaser & Strauss, 1967). The study adopted Strauss and Corbin's procedures for coding and analysing data (Corbin & Strauss, 2008; Strauss & Corbin, 1998), and Charmaz's (2006) constructivist approach to analysis and theory development as a co-construction of the researcher's and participants' views and interpretations. The fundamental elements of both approaches are: (a) gathering rich, detailed data; (b) theoretical sampling; (c) the constant comparative method of analysis conducted simultaneously with data collection; and (d) integrating categories and moving to a high level of abstraction to construct theory (Charmaz, 2006; Corbin & Strauss, 2008). The study was conducted at two academically selective high schools in Australia, one with a focus on science, mathematics and/or technology and the other in the arts (including music, visual arts, theatre arts, and film and multimedia). Ten creative students, aged 15 to 17 years, from each school were selected to participate. Theoretical sampling for participant selection was based on Creative Personality Scale (Gough, 1979) scores, Creative Self-Efficacy measure (Tierney & Farmer, 2002) scores, and teacher, peer and self nominations of creativity. Data sources included focus groups, individual interviews, and an online discussion forum.

Findings

Analysis revealed that the adolescent creative process entails the following six, interactive components: creativity motivation; creativity stimuli; the sub-processes of creativity; managing challenges in the creative process; producing divergent outcomes; and creativity affecting self/others. The study also recognised that the creative process occurs within, and is influenced by, a range of micro and macro environments. Exploration of these contextual conditions revealed contributing internal influences, as well as supportive and inhibiting external influences. The overarching core category of adolescent creativity was "difference". First, creativity requires a different perspective, and a different way of using existing knowledge and skills. Second, creativity results in the development of products that are different from what is known, either by the individual, by others, or both. Finally, supporting and developing creativity requires different educational pedagogies. The proposed paper will provide an overview of findings regarding the adolescent creative process, but will then focus predominately on the conditions influencing creativity to discuss how creativity can be encouraged and developed in schools.

Significance and Implications

Creativity requires something different: students who think differently and produce original outcomes, supported by different pedagogies in schools. This research was conducted with students who were creative in diverse domains,

from the arts, to humanities, to science, mathematics and technology. Although there were some domain-specific differences, overall the research revealed numerous similarities in adolescents' creative processes and the conditions that influence their creativity across domains. Existing empirical research of adolescent creativity is limited. This study is novel in its multidimensional approach to studying the creative experience from the perspective of creative adolescents. It builds on existing understandings about personal, social and environmental factors that can support or inhibit creativity, with a particular focus on the role of schools. The research has theoretical implications for educational researchers in cognition, learning and instruction, and policy and pedagogical implications for educational stakeholders in all curriculum areas. This substantive theory of adolescent creativity can contribute to establishing empirically-based learning and instructional practices to enhance educational effectiveness in developing students' creativity.

PAPER PRESENTATION

Fortune Favors the Bold (and the Italicized), but Why? Revisiting the Disfluency Effect

Katharina Scheiter, Knowledge Media Research Center, Germany; Anne Schueler, Knowledge Media Research Center, Germany

Recent research has shown that texts that are printed in less legible format (e.g., in terms of font type and style) result in better verbal retention than a regular layout. The reason for the occurrence of this disfluency effect is yet unclear: Possibly, learners with less legible texts spend more effort into processing low-quality instructional materials, thereby overcompensating for potential harmful effects. In the current study, we aimed at replicating the disfluency effect while at the same assessing eye tracking data to get a better insight into its underlying mechanisms. It was assumed that learners with less legible text would invest more effort into reading as indicated by slower overall reading times, a higher number of fixations on the text, and longer average fixation durations as an indicator of processing difficulty. Moreover, we were interested in whether verbal as well as visual working memory capacity would play a moderating role in the disfluency effect. Seventy-four university students were randomly assigned to a condition with either high or a low legible text. Subsequently to reading the text, learners were asked to answer eight retention questions. The study replicated the disfluency effect in that learners showed better retention after having read low legible texts; however, students' reading behavior remained unaffected by the manipulation. Moreover, only learners with low visual working memory capacity benefited from low legible text. To conclude, these findings run against the predominant recommendation to always aim at optimizing instructional design to facilitate learning.

Diemand-Yaumann, Oppenheimer, and Vaughan (in press) have shown that contrary to what one would expect texts that are printed in less legible format (e.g., in terms of font type and style) result in better verbal retention than a regular layout. Even more astonishingly, this disfluency effect is not limited to the retention of simple facts in laboratory tasks. In a second study, Diemand-Yaumann et al. asked high-school teachers to submit their supplementary teaching materials. For half of the classes, the materials were sent back unaltered, whereas for the other half, the materials' quality was reduced before sending them back to the teachers (e.g., by making blurry photocopies or printed materials or by altering the appearance of digital materials). Teachers were then asked to use

these materials for their teaching. Achievement on regular assessment tests served as dependent variable. Again the results showed that across a variety of different domains and levels learners with less legible materials performed better in the assessment tests.

While the effect appears to be robust, there is little evidence pointing towards a possible explanation. Possibly, learners with less legible texts spend more effort into processing low-quality instructional materials, thereby overcompensating for potential harmful effects. In the current study, we aimed at replicating the findings by Diemand-Yaumann et al. using their materials from the laboratory study, while at the same time assessing eye tracking data to get a better insight into possible mechanisms underlying the disfluency effect. It was assumed that learners with less legible text would invest more effort into reading as indicated by slower overall reading times, a higher number of fixations on the text (e.g., caused by regressions within the text), and longer average fixation durations as an indicator of processing difficulty.

Moreover, we were interested in whether working memory capacity would play a moderating role in the disfluency effect. On the one hand, one might assume that learners with low verbal working memory capacity might show less improvement with less legible text, because they have fewer resources available to counteract its potentially harmful effects. On the other hand, research by Logie, Della Sala, Wynn, and Baddeley (2000) suggests that manipulations of superficial text features like the ones used in the before mentioned studies impact processing in visual working memory. Hence, it might well be that learners with low visual working memory capacity will be most affected by disfluency manipulations, whereas learners with high visual working memory capacity will learn well regardless of the text layout.

Method

Seventy-four university students were randomly assigned to one of two experimental conditions. In the high legibility condition, two texts each describing 13 characteristics of inhabitants of a fictitious star were printed in regular Arial black font type with 16 pt font size. In the low legibility condition, the same texts were printed in italics, Comic Sans MS 75% greyscale font type with 12 pt font size. The presentation order of the two texts was counterbalanced. Students could read the texts for as long as they liked. Eye movements were recording during reading. Because the manipulation was embedded as a distractor task in a different study, the learning phase of this study was presented after the disfluency materials (the combination of experimental conditions of the disfluency experiment and the second study was counterbalanced). Afterwards, learners were asked to answer eight retention questions asking for specific facts from the two texts. Prior to the experiment, students' verbal working memory capacity was assessed with the digit span test (Wechsler, 2000), whereas visual working memory capacity was measured with the Visual Pattern Test (Della Sala, Gray, Baddeley & Wilson, 1997).

Results

Two separate ANOVAs with experimental condition as a between-subjects factor and each of the two capacity measures serving as continuous factors were used to analyze verbal retention performance. The ANOVA with verbal working memory capacity revealed a marginal significant disfluency effect only ($p = .07$), but no effect of working memory capacity and no interaction. Instead, the ANOVA with visual working memory capacity revealed a significant disfluency effect ($p = .03$), a main effect of working memory capacity with better retention achieved by those with a higher capacity ($p = .01$), and an interaction ($p = .03$). Follow-up simple slope analyses revealed a disfluency effect only for those learners with low visual working memory capacity ($p = .003$), but not for learners with high capacity. Finally, and contrary to our expectations there were no reliable effects of experimental condition on any of the eye tracking parameters. Moreover, a mediation analysis did not confirm that changes in reading behavior cause the disfluency effect either.

Discussion

The study replicated the findings by Diemand et al. (in press); however, there is yet no idea as to its possible cause since students' reading behavior remained unaffected by the manipulation. Moreover, the findings showed that only learners with less favorable entry characteristics, namely low visual working memory capacity, benefited from this counterintuitive instructional manipulation. Future research needs to investigate whether the effect is limited to retention or whether less legible texts will also improve deeper comprehension. In any case, these findings run against the predominant recommendation to always aim at optimizing instructional design to facilitate learning that is, for instance, being pushed forward in Cognitive Load Theory research (e.g., Sweller, van Merriënboer, & Paas, 1998).

PAPER PRESENTATION

The development of cognitive skills and abilities as an effect of competence-based trainings

Tibor Vidakovich, University of Szeged, Hungary; Edit Katalin Molnar, University of Szeged, Hungary

This study was carried out in the framework of an experimental project, aimed at the development of competences of students. Two areas were in the focus of the project: (1) text processing competence, and (2) mathematical competence. Some further cognitive skills and abilities were not developed directly, but their development was also hypothesized. Two tests served the assessment of the basic skills and abilities underlying the competence models: (A) deductive and inductive reasoning, and (B) systematizing and combinative abilities. Two other tests assessed the skills and abilities targeted in the competence-based programs: (C) written composition, and (D) word problem solving. The program was piloted in 90 volunteering schools. In the analysis, the samples of 5-6th graders, approximately 1,950 subjects were involved. On the tests of skills and abilities (A and B), the performances showed significant improvements. On both tests, students participating simultaneously in text processing and mathematical programs outperformed the others, but the development of students participating only in one program was not significantly different. On the tests of target variables (C and D), the improvement of the achievements was significant as well. On the written composition test, the results of students improved similarly, but on the word problem solving test, the improvement of students participating in both programs were significantly greater. Our results verified the significant effect of simultaneous application of the two competence-based programs on the development of basic skills and abilities. The results did not verify the hypothesized effects in reducing group inhomogeneity.

OBJECTIVES

This research was carried out in the framework of an experimental project, aimed at the development of text processing and mathematical competences of students (specifically targeting reading literacy and written composition; and mathematical understanding and word problem solving, respectively). It was also hypothesised that cognitive skills and abilities will be indirectly effected by the intervention; of these deductive and inductive reasoning, and systematizing and combinative abilities were monitored. When reporting the findings of the project, the following issues are discussed: (1) the development of cognitive skills and abilities underlying the applied competence models, (2) the differences in the development of groups participating in text processing and/or mathematical competence programs.

THEORETICAL FRAMEWORK

To implement competence-based education in schools, an experimental project has been running since 2005, with programs developed for several key competence areas. Two of these are in the focus of the present study: (1) text processing competence, and (2) mathematical competence; both are prioritised in international assessment programs as well. In the competence-based program, the frameworks of development and assessment were based on combined models. As regards text processing, the training program focused on reading literacy and written composition (e.g. Kirsch, 2003; Hayes, 1996). In the field of mathematical competence, the model was informed by factor analytic research (e.g. Carroll, 1996), and the program focused on the development of mathematical understanding and word problem solving in everyday contexts. There were other basic components (deductive and inductive reasoning, and systematizing and combinative abilities), that were not directly targeted by developmental efforts, but which, because of their importance in cognitive development (c.f. Royer, 2003), were assessed as well. Over and above text processing and mathematical achievements, a significant improvement in performances and a decrease in standard deviations of these basic components were also expected.

ASSESSMENT TOOLS

When designing the assessment tools, the main objective was that they should be appropriate for identifying students' developmental stage, and for comparisons between the development of basic skills and abilities as well as text processing and mathematical competences. Two tests covered the basic skills and abilities of the applied

competence models, namely, (A) deductive and inductive reasoning, and (B) systematizing and combinative abilities. Two other tests were selected to provide indicators for the assessment of the skills and abilities targeted in the training programs, i.e. (C) written composition, and (D) word problem solving. All tests were of good reliability (with Cronbach alphas of about 0.9). The basic principles and the standard process of test development (Vidákovich, 2002) warranted the content and structural validity of the tests. Our hypothesis was that both text processing and mathematical competence training would result in the development of basic skills and abilities too, and this effect could be strengthened by the simultaneous application of the two programs.

DATA SOURCES

The experimental competence-based program was piloted in 90 volunteering schools. Schools had the opportunity to participate in one or more of key competence programs. The analysis presented is based on data from the sample of 5-6th graders. The number of students participating in both the pre- and the post-test was about 1,950. This sample was further divided into four sub-samples, groups of students participating (1) both in the text processing and the mathematical programs, (2) only in the text processing program, (3) only in the mathematical program, and (4) only in other competence-based programs of the project. At the beginning and the end of the one-year experimental period, all students were administered tests of deductive and inductive reasoning, and systematizing and combinative abilities (i.e. tests A and B). Students in the text processing and/or mathematical programs were administered the appropriate written composition test (C) and/or word problem solving test (D) as well.

RESULTS

Performances were examined to assess the effects of the given programs on basic skills and abilities, and on text processing and mathematical competences as well. Both on the tests of reasoning (A) and abilities (B), there was a possibility to compare the achievements of the four groups, while the results of the tests of text composition (C) and word problem solving (D) could be compared between groups (1) and (2), and groups (1) and (3), respectively. In the case of basic skills and abilities (tests A and B), the performances of the four groups were similar on the pre-test. On the post-test, all groups showed significant improvements (p). The improvements in the achievements were significant (p

EDUCATIONAL SIGNIFICANCE

The results verified the significant effect of the simultaneous application of the two competence-based programs on the development of basic skills and abilities. The findings showed that the development of written composition was independent from the mathematical competence program, while the development of word problem solving seemed to be effected by the text processing competence program. The results did not verify the hypothesized effects in reducing group inhomogeneity, neither in the case of cognitive skills and abilities, nor in the case of target variables.

PAPER PRESENTATION

Evaluating the educational effectiveness of an intervention programme for social-emotional learning.

Mary Sheard, University of York, United Kingdom

The paper presents a critical reflection on the first two years of a longitudinal randomised evaluation of Together 4 All, a social and emotional intervention programme introduced in the Craigavon area of Northern Ireland in 2008. The evaluation uses quantitative and qualitative methods to investigate possible changes in children's personal development, attitudes and behaviour associated with the implementation of the programme. These include interviews with a range of stakeholders in the school community, teacher ratings of pupil behaviour and individual assessments of children's social-emotional development. Observation measures were developed to capture a range of teaching and pupil behaviours associated with the aims of the Together 4 All programme. The paper argues that an evaluation of the educational effectiveness of a teaching programme should carefully consider the processes of implementation and pedagogic change as well as outcomes related to pupil achievement and attainment. The paper reports on the development and reliability of observation measures of teaching behaviours and pupil behaviours and findings obtained from the observation measures, and from statistical analysis of teacher ratings completed prior to and during the implementation period. From a socio-cultural perspective, the paper draws conclusions about the evaluation process and the contribution made by the various measures to our understanding of educational effectiveness in the context of a social and emotional intervention programme.

The paper presents a critical reflection on a longitudinal randomised evaluation of Together 4 All (T4A), a social and emotional intervention programme introduced into six Primary Schools in an area of religious, cultural, social and economic diversity in Northern Ireland in 2008. T4A focuses on promoting children's self esteem, emotional

intelligence, pro-social behaviour and mutual respect and understanding. The main evaluation question is 'What are the impacts of the programme on children's pro-social and classroom behaviour, mutual respect and understanding, and emotional and social development?'

Theoretical framework

The T4A programme is an agent of cultural change and social action. It focuses on children's interactions with other people, objects and events in the environment and on activities that require cognitive and communicative participation.

From this socio-cultural perspective, teachers, parents and other significant adults are more experienced social partners from whom children learn the social practices and cultural conventions of social interactions characteristic of conflict as well as co-operation. The social emotional language of T4A and its associated discourses and visual representations, for example compliment slips, Child for the Day, and control signals, may be viewed as mediating cultural change. Central to the evaluation is how the programme impacts on the pedagogic behaviours of teachers as pupils' social partners and agents of cultural change.

Methods

The evaluation draws on a range of quantitative and qualitative methods to investigate possible changes in children's personal development, attitudes and behaviour associated with the programme's implementation. Instruments used include interviews, teacher ratings of pupil behaviour, classroom observations of teaching and pupil behaviours, playtime observations of pupil behaviour, and individual assessments of pupils' social and emotional competence.

Interviews

Structured interviews conducted with key stakeholders in the school community at three points over the course of the evaluation period focus on changes in children's confidence, self-esteem, behaviour, and recognition and self-regulation of emotions.

Teacher ratings of pupil behaviour

Teachers rated children's behaviour on 26 items using the following 6 point scale: 'Never or almost never', 'Rarely', 'Sometimes', 'Often', 'Very often', and 'Almost always'.

1711 teacher ratings were completed at pretest and again after six and eighteen months of implementation.

Classroom Observations and playtime observations

Lesson observation measures were developed to capture thirteen teaching behaviours associated with the programme's aims, such as emotion modelling, positive behaviour modelling, and supporting peer interaction, and nine pupil behaviours including items on positive coping strategies, co-operation in learning, and showing mutual respect and understanding. The focus of pupil behaviour in the playtime observations includes turn-taking, including others and showing mutual respect and understanding.

Observations were rated on a 4 point scale for prevalence and frequency.

Individual assessments of pupils' social - emotional development

Several measures of social-emotional development at pretest and posttest are obtained for each participating child.

Findings

Teacher ratings of pupil behaviour

Teacher ratings of pupil behaviour analysed using an analysis of covariance (ANCOVA). To statistically control for baseline differences in teacher ratings, "adjusted" posttest means were computed for the intervention and control groups. A clustering design was not used with teacher rating data in the preliminary analysis; liberal analyses with high power was considered to be more appropriate since the intervention was fairly recent and implementation was at an early stage. However, subsequent ratings data was analysed by clustering within teachers, as a replication analysis using basic and HLM analyses.

In a comparison of pretest with interim teacher ratings after six months of programme implementation for children aged 5 and 6, the non-statistically significant directional pattern of comparison between means across the 26 rated items favoured the intervention group on 13 items and the control on 10 items (identical means were obtained on 2 items).

For children aged 9 and 10, statistically significant differences (p < 0.05) were found for 3 items and the directional pattern of the comparisons between means favoured the control group on an additional 9 items.

After eighteen months of programme implementation, for the younger cohort (P2/P3), the intervention group was significantly superior on 16 (64%) of the behaviours (median effect size = +0.26), whereas the control group was significantly superior on only 2 behaviours (8%).

For the older cohort, the intervention group was significantly superior on 7 behaviours (median ES = +0.22) (28%), and directionally superior on 11 behaviours (44%). The control group had no significant advantages (0%) and only 5 (20%) small directional advantages.

Classroom Observations and playtime observations

Analysis of baseline classroom observations of teaching behaviour undertaken after 6 months of implementation suggests superior teaching behaviour in the intervention classes on 10 out of 11 items, including positive behaviour management, provision of interpersonal support and emotion modelling.

Analysis of baseline classroom observations of pupil behaviour after 6 months of implementation suggests superior pupil behaviours in the intervention classes in:

- Showing mutual respect and understanding
- Positive coping strategies
- Self expression of feelings
- Identifying feelings of others

Directional advantage for the control group was found in co-operative learning.

Analysis did not reveal strong patterns in pupils' playtime behaviour. Directional advantage included less physically aggressive behaviour in the intervention group and more turn-taking in the control group.

Using the same observational measures after eighteen months of programme implementation, findings were equivocal for intervention and control groups.

Individual assessments of pupils' social - emotional development

While analysis is ongoing, preliminary findings will be reported.

Educational importance

The paper takes a critical stance in arguing that evaluating the educational effectiveness of teaching programmes should carefully consider the processes of implementation and pedagogic change, as well as outcomes related to pupil achievement and attainment.

Implications for educational research and educational effectiveness are critically appraised in reference to the various instruments and measures used. In evaluating the contribution of teacher ratings and individual child assessments, important considerations are raised about the coding and interpretation of children's responses in problem-solving scenarios.

PAPER PRESENTATION

Towards an Understanding of Motivation Regulation in Collaborative Learning Groups

Thomas Martens, German Institute for International Educational Research, Germany; Ana Remesal-Ortiz, Universidad de Barcelona, Spain

In this study university students were provided with specific information on the motivational process in a collaborative learning group in order to evoke motivational self- and coregulation and thus improve intrinsic motivation. Therefore the "Quality of Working in Groups Instrument (QWIGI)" from Boekaerts and Minnaert (2003) was used. Each member of a learning group has to answer eight questions on a regular base measuring Interest and the three psychological

needs proposed by Deci & Ryan: Autonomy, Competency and Social Relatedness. The used online version of the QWIGI provided a tailored visual feedback of their scores compared to the group scores. Two courses in Educational Psychology (n=30, n= 55) participated. The students had to solve five complex problem-based authentic activities in groups of 4-6 members. Twice in the course, special discussions are carried out in order to promote groups' reflection about their motivational processes. At the end of the course a final questionnaire was collected from the students measuring different antecedents of motivation, motivation and different aspects of the QWIGI usage. These data were combined with longitudinal data assessed by the QWIGI and qualitative self-reported data describing the learning process. The results show that the usage of the graphical feedback is one key factor for enhancing intrinsic motivation.

In higher education, a lack of motivation for learning is frequent. This is particularly outstanding in teaching and learning contexts in which new information and communication technologies are applied. Students are not willing to actively invest time and effort in their studies and if they do so, an often heard complaint is that they rely on passive strategies, without showing any real interest in the subject matter. The use of collaborative learning is one way of influencing the quality of student learning concerns. Of course, collaborative learning may suffer strongly from suboptimal group processes such as the free rider effect, in which team members feel that some group members do less than others (Strijbos, Kirschner, & Martens, 2004).

To prevent such effects, students in this study were provided with specific information on the motivational group process in order to evoke motivational coregulation and thus improve intrinsic motivation. This would lead to - so the authors hypothesized - increasing engagement in learning and assessment activities.

For this purpose the "Quality of Working in Groups Instrument (QWIGI)" from Boekaerts and Minnaert (2003) was used. Each member of a learning group has to answer eight questions on a regular base measuring Interest and the three psychological needs proposed by Ryan & Deci (2000): Perceived Autonomy, Perceived Competency and Perceived Social Relatedness. The used online version provided an additional feedback modus, so that students got a tailored visual feedback of their scores compared to the group scores.

Ideally, the QWIGI and the associated graphical feedback work in 3 steps:

- 1.) Answering the QWIGI: first reflections about personal motivational start.
- 2.) Looking at the graphical feedback: reflections about personal motivational situation in comparison to the motivational group situation take place. A perceived discrepancy between personal and group mean scores can be the starting point of regulation processes. The questions of the QWIGI provide a "language" to communicate about motivational problems.
- 3.) Participate in group discussion: The group gets room and space for regulating their basic needs. Reasons for motivational discrepancies of group members are identified. The need for changing these discrepancies will be discussed. Ways of changing the group learning situation accordingly are reflected.

It has been demonstrated in a control group experiment that graphical feedback associated with the QWIGI questionnaire, improves intrinsic motivation in a collaborative setting for learning statistics (Martens & Martens, 2009).

So, the here presented work is built upon these five premises: (1) The Basic Needs sensu Decy & Ryan are necessary for Intrinsic Motivation. (2) Intrinsic Motivation is necessary for Academic Learning. (3) Intrinsic Motivation can compensate negative side effects of CSCL. (4) Measuring and graphical feedback of the Basic Needs with the QWIGI increase Intrinsic Motivation. (5) The increase of Intrinsic Motivation is a result of regulation processes.

The research presented in this paper aims to reveal the underlying mechanisms for motivational co- and self-regulation. The improvement of intrinsic motivation might be an effect of motivational self-regulation or motivational co-regulation in the group or most probably a mixture of both regulation processes. Furthermore is not clear which of the basic needs is in the focus of regulation processes using the QWIGI. A first step to reveal the processes of motivational regulation and co-regulation will be the analysis of the actual QWIGI usage: is the usage of the QWIGI feedback, especially the usage of the graphical feedback, the key factor for regulation processes regarding intrinsic motivation?

A Spanish online version of the questionnaire was implemented in a teacher education course of Educational Psychology. Two courses of students (n=30, n= 55) working in teams of 4-6 members participated. The questionnaire was embedded in the general course program for one complete academic year. The students had to perform five different complex collaborative and problem-based activities. Twice in the course, special discussions are carried out

in order to promote groups' reflection about their motivational processes. At the end of the course a final questionnaire was collected from the students measuring different antecedents of motivation, motivation and different aspects of the QWIGI usage. These data were combined with longitudinal data assessed by the QWIGI and qualitative self-reported data describing the learning process.

A regression model predicting motivation demonstrates that the measures for the QWIGI usage, namely "Graphical Information", "Graphical Benefit" and "Evaluation of Experience" provide a significant change of R-square. So the results point to the interpretation that the usage of the graphical feedback within the learning group is one key factor for enhancing intrinsic motivation. This finding also explains results from a previous study where the usage of the QWIGI didn't include an explicit time slot for discussing the graphical feedback and therefore resulted in no significant change in intrinsic motivation.

Next steps of analysis will focus on participants' conceptions and attitudes towards collaborative learning and collaborative skills/working style; individual learning strategies and learning approach, and how these factors might be moderating the data presented here.

PAPER PRESENTATION

Achievement Emotions In Different School Tasks And Subject-Matters

Daniela Raccanello, University of Verona, Italy; BIANCA DE BERNARDI, UNIVERSITY OF VERONA, Italy

This study focused on achievement emotions characterizing different contexts, in terms of both scholastic tasks and subject-matters, in students from elementary and middle school. Considering the pervasiveness of different emotions in school, many scholars have studied the mutual relationships between affect and motivational or cognitive dimensions related to learning, and recently particular interest has been focused on discrete emotions rather than states pertaining to different valences. Referring to the control-value theory on achievement emotions, our study involved 330 Italian students, attending the fourth grade and the seventh grade. They completed two questionnaires, one focused on Italian and the other on Mathematics. They were asked to evaluate ten discrete emotions about two non-evaluative tasks (attending a lesson, doing homework) and two evaluative tasks (standing a written test, standing an oral test) on 5-point Likert-type scales. Results showed that, as age increased, positive emotions decreased and negative emotions increased, with some exceptions. Moreover, non-evaluative tasks were characterized by higher levels of enjoyment, pride, relief, relaxation and boredom, while evaluative tasks were characterized by higher levels of hope, anxiety, anger and fault. Finally, boredom and hopelessness were stronger for Italian rather than Mathematics. These data point out that discrete emotions are sensitive to different contexts, mostly in terms of kind of learning tasks than in terms of school subject-matters, and that they follow different developmental trends.

Introduction.

In the light of the relevance of context within educational psychology (Anderman, 2004), this study focused on achievement emotions characterizing different contexts, in terms of both scholastic tasks and subject-matters, in students from elementary and middle school. While emotions can be defined as "multi-component, coordinated processes of psychological subsystems including affective, cognitive, motivational, expressive, and peripheral physiological processes" (Pekrun, 2006, p. 316), achievement emotions are those emotions related to achievement activities or achievement outcomes (Pekrun, 2006). Given the pervasiveness of different emotions in scholastic contexts, many scholars studied the mutual relationships between affect and motivational or cognitive dimensions related to learning (Linnenbrink, 2006; Pintrich, 2003; Schultz, 2006), and recently particular interest has been focused on discrete emotions rather than states pertaining to different valences (Kleine, Goetz, Pekrun, & Hall, 2005; Pekrun, Goetz, Titz, & Perry, 2002). According to the control-value theory, for example, academic achievement would be linked to positive-activating emotions in terms of beneficial effects and to negative-deactivating emotions in terms of

detrimental effects, while the role played by negative-activating and positive-deactivating emotions seems ambivalent (Pekrun et al., 2002; Pekrun, 2006).

As regards our specific aims, we focused on the transition from elementary to middle school, expecting decreases in positive emotions and increases in negative emotions, mirroring a trend typical of some motivational dimensions related to learning, such as self-efficacy, task-value, or achievement goals (Bouffard, Boileau, & Vezeau, 2001; Chouinard & Roy, 2008; Pintrich, 2000; Raccanello & De Bernardi, 2010; Wigfield & Eccles, 2000). Then, following suggestions about the possibility to generalize results related to university students in university settings (Pekrun, Goetz, Daniels, Stupnisky, & Perry, 2010), we explored differences in discrete emotions between different scholastic tasks, expecting higher positive emotions for non-evaluative tasks and higher negative emotions for evaluative tasks. Finally, we explored differences related to Italian and Mathematics, given that emotions such as enjoyment, anxiety and boredom seem to follow domain-specific lines, at least for students from grades 7 to 10 (Goetz, Frenzel, Pekrun, & Hall, 2006).

Method.

The participants were 330 Italian students, attending the fourth ($N = 159$; $M = 9$ years, 10 months) and the seventh grade ($N = 171$; $M = 12$ years, 10 months). For each age group, there was about the same number of females and males. They completed two questionnaires, one focused on Italian and the other on Mathematics. The students were asked to imagine to be involved into four different scholastic tasks, two non-evaluative tasks (attending a lesson, doing homework) and two evaluative tasks (standing a written test, standing an oral test). For each task, they were asked to evaluate, on a 5-point Likert-type scale, ten discrete emotions (Kleine et al., 2005). Among them, there were three positive-activating (enjoyment, pride, hope), two positive-deactivating (relief, relaxation), three negative-activating (anxiety, anger, guilt) and two negative-deactivating emotions (boredom, hopelessness). In addition, academic achievement related to the two subject-matters was asked.

Results and discussion.

For the analyses the mean values for items related to the same emotion and the same task, separately for the two subject-matters, were calculated. Repeated-measure ANOVAs were carried out on each emotion, with Level (4th, 7th graders) as between-subjects factor, and Task (non-evaluative, evaluative) and Subject (Italian, Mathematics) as within-subjects factors (p Level resulted significant for most of the emotions (enjoyment: $F(1,327) = 82.725$, $p < .001$; pride: $F(1,328) = 43.855$, $p < .001$; relief: $F(1,328) = 37.079$, $p < .001$; relaxation: $F(1,328) = 38.218$, $p < .001$; anger: $F(1,328) = 16.512$, $p < .001$; boredom: $F(1,328) = 11.438$, $p = .001$), and it interacted significantly with Task for hope ($F(1,327) = 27.136$, $p < .001$) and anxiety ($F(1,327) = 36.239$, $p < .001$). Specifically, as age increased, endorsement of most of the positive emotions decreased while endorsement of most of the negative emotions increased, with some exceptions. Among positive emotions, hope related to evaluative tasks increased. Among negative emotions, anxiety related to non-evaluative task decreased, and there were not differences for fault and hopelessness. Second, a significant effect of Task emerged for all the emotions with the exception of hopelessness (enjoyment: $F(1,327) = 84.766$, $p < .001$; pride: $F(1,328) = 12.708$, $p < .001$; hope: $F(1,327) = 62.049$, $p < .001$; relief: $F(1,328) = 85.328$, $p < .001$; relaxation: $F(1,328) = 152.713$, $p < .001$; anxiety: $F(1,327) = 192.818$, $p < .001$; anger: $F(1,328) = 39.637$, $p < .001$; fault: $F(1,328) = 22.324$, $p < .001$; boredom: $F(1,328) = 65.754$, $p < .001$). On the one hand, non-evaluative tasks were characterized by higher levels of enjoyment, pride, relief, relaxation and boredom compared to evaluative tasks. On the other hand, evaluative tasks were characterized by higher levels of hope, anxiety, anger and fault compared to non-evaluative tasks. Third, Subject was significant only for boredom ($F(1,328) = 12.159$, $p = .001$) and hopelessness ($F(1,327) = 10.192$, $p = .002$), that were stronger for Italian rather than Mathematics.

These results suggest, on the one hand, that discrete emotions are sensitive to different contexts, mostly in terms of kind of learning tasks than in terms of school subject-matters. On the other hand, they point out different developmental trends for the emotions, with decreasing positive emotions and increasing negative emotions in the transition from elementary to middle school. Considering both the theoretical and the applied relevance to focus on achievement emotions (Goetz et al., 2002; Pekrun, Hall, & Haag, 2006; Schultz, 2006), future studies should examine more deeply these issues, using for example qualitative methods such as interviews to explore students' reasons underlying the documented changes.

PAPER PRESENTATION

Effects of a reattribution training - combining quantitative and qualitative methods of evaluation

Several studies show when observing teachers in classroom the frequency of giving feedback is low, especially when looking at powerful feedback. Focusing feedback processes in every day school situations the aim of our project is to examine how attributional feedback impact on young children. A pre-post-follow up treatment-control group design is implemented to analyse the effects of a reattribution in 10 to 13 year old children. For this reason, we tested a sample of 527 children at three time points with standard psychological tests and questionnaires (using quantitative methods). Moreover, qualitative data like observations, interviews, and log books is used to have a deeper understanding of the implementation and helpful or obstructive factors of the training. First results of the quantitative study suggest that there were effects of the reattribution training in the individual data comparing both groups e.g. in the attributional style of the tested children. Results of the qualitative studies show that the teachers had several problems in implementing the training e.g. in "hard" subjects and direct instruction. Additionally, results of the qualitative data give hints for a deeper analysis and interpretation of the quantitative data. The study shows that training teachers to give adaptive and attributional feedback seems to be a good chance to improve dealing with individualized feedback in every-day classroom.

Introduction

Many empirical studies investigate the role of feedback during instruction. They are covering topics like task related feedback, process related feedback, timing of feedback, self-related feedback and so on (Hattie & Timperley, 2007). Nevertheless, when observing teachers in their every day classroom several studies show that the frequency of giving feedback is low, especially when looking at powerful feedback (Bond, 2000). Focusing these feedback processes the aim of our project is to examine how attributional feedback impact on young children. For this reason, a pre-post-follow up treatment-control group design is implemented to analyse the effects of a reattribution training (Ziegler & Schober, 2001, 2002) in 10 to 13 year old children. Moreover, qualitative data (observations, interviews, log books) is used to have a deeper understanding of the implementation and helpful or obstructive factors of the training (Dresel & Ziegler, 2006).

Theoretical Framework

According to the attribution theory students are more or less motivated due to their beliefs about causalities of success or failure. Concerning this, the aim of reattribution trainings is to change causal explanations from lack of ability to lack of effort and to improve the student's beliefs in the cause of their failures and successes to promote future motivation. Ziegler and Schober (2001, 2002) designed attributional retrainings to be applied in the classroom. Teachers are trained to comment written and verbal learning performances of their students. So far, only few studies have examined the effects of attributional feedback in young children and little is known about effects of attributional feedback used in reattribution trainings on self-related cognitions such as goal orientation, evaluation of mistakes, and so on.

Aims

The aim of our study is to investigate how the feedback given by the trained teachers impact on self related cognitions such as attributional style, self-concept etc. in comparison to the feedback given by untrained teachers. The design and analyses of the data will combine two perspectives: a) the role of attributional feedback in teaching and learning with respect to individual differences (using quantitative methods) and b) enhancing and hindering factors by implementing attributional training in every day classroom (using qualitative methods).

Method

Collection of individual data was conducted at three time points, namely as pre-, post-, and follow-up-test (one year after the intervention) to examine effects of the training. Five teachers applied the training for 15 weeks. Children were tested with standard psychological tests and questionnaires assessing self-concept, intelligence, memory capacity, goal orientation, attention, learning strategies, evaluation of mistakes, and epistemological beliefs. Furthermore, we collected data in several qualitative studies to get an impression of how the teachers implemented the training in their regular classroom, which kind of problems the teachers had, and which classroom factors or instruction variables were helpful or obstructive for the implementation of the training. For this reason, we observed the trained teachers during their school lessons for several hours. Moreover the teachers had to keep a weekly feedback diary over the whole training phase, and we conducted a half-structured interview with each of the five teachers at the end of the training.

Sample

We tested a sample of 527 children between the ages of 10 to 13 years (at the first data point) in their natural school setting. We investigated children of the German 5th (n = 256) and 6th (n= 271) grades. Half of the children (n = 260)

were assigned to the intervention group and got the reattribution training, half of them (n = 267) served as control group and got no training.

Results

First results of the quantitative study suggest that there were effects of the reattribution training in the individual data comparing both groups. For example, children in the control group rated significantly higher at the second data point on the attributional style in case of failure to a lack of ability than before the training ($F(1, 478)=8.25$, p

Results of the qualitative studies show that the teachers had several problems in implementing the training. The teachers told that it was easier for them to give feedback in group situations and in "softer" subjects (e.g. history, music) than in direct instructions and "harder" subjects as maths. Analyses of the feedback diaries suggest that there were phases in which the teachers had problems to concentrate on the training.

Data analyses of the follow-up-data are still running at this point. Further results concerning the effects of the training in relation to individual differences in regard with the results of the qualitative data will be presented on the conference.

Summary and Implications

First results of the study show that training teachers to give adaptive and attributional feedback seems to be a good chance to improve dealing with individualized feedback in every-day classroom. Bringing together the data of the quantitative and the qualitative studies we have a deeper understanding of what happened when the training was implemented. Moreover, the qualitative data allow us to improve the training for the teachers for future investigations and teacher education.

PAPER PRESENTATION

Mathematics Motivation, achievement, gender and social support in the classroom

Vera Monteiro, Instituto Superior Psicologia Aplicada, Portugal; Lourdes Mata, Instituto Superior de Psicologia Aplicada Instituto Universitario , Portugal; Francisco Peixoto, I.S.P.A. - Instituto Universitario, Portugal

The aims of this study were to characterize mathematics motivation among Portuguese students and analyse their relation with gender, classroom social support and achievement.

The participants were 925 Portuguese students from 5th grade to 9th grade. They completed two questionnaires, one that measured their maths motivation considering five domains: Value, Enjoyment, Choice, Competence and Pressure and another considering the social support of teacher and their colleagues in the maths classroom. The achievement level was calculated considering their grades in maths classroom.

Results allowed us to analyse the multidimensional profile of students' maths motivation. Findings show significant differences between boys and girls in maths motivation, with girls feeling more pressure about maths, perceiving themselves as less competent but considering maths as a more valuable subject than boys. Social Support in classroom was also an important variable related with motivation as well as the achievement status of the student (low, medium, high).

Self-determination theory (Deci & Ryan, 1991) is a social theory of motivation that when is applied to education, is focused on promoting in students an interest in learning, a valuing of education, and a confidence in their own capacities and attributes (Deci, Vallerand, Pelletier & Ryan, 1991). According to the authors, high levels in these dimensions mean being intrinsically motivated. The results of their researches suggest that the social environment

affects people's intrinsic motivation. One important aspect of self-determination theory is that social contexts that support relatedness (e.g., the interpersonal involvement of teachers) will increase motivation in general but also will increase intrinsic motivation, especially if this is an autonomy support that provides choices (Grolnick & Ryan, 1989). In terms of classroom climate, the social support given by teachers and peers has been shown to be positively related to intrinsic motivation (Sousa, Monteiro, Mata & Peixoto, 2010).

Some empirical studies have revealed an association between academic achievement and classroom motivation. Goldberg and Cornell (1998) found a positive relationship between intrinsic motivation and academic achievement in second and third graders. Gottfried (1985, 1990), in his researches with elementary- and middle-school-aged children, verified the relevance of academic intrinsic motivation on children's school achievement. He showed that young children with higher academic intrinsic motivation had significantly higher achievement and were more successful in school. The results of the study conducted by Broussard and Garrison (2004) supported that intrinsic classroom motivation was positively related to academic achievement in maths, particularly for third-grade children.

For many years the literature presents gender differences in favor of boys in maths achievement for many years. According to Georgiou, Stavriniades, and Kalavana (2007) this has created the stereotype that girls are not good at maths. However, no significant differences were found between boys and girls in actual maths achievement. These authors found significant differences in the way boys and girls explain their success and failure. It seems that boys tend to attribute their success to ability, while girls attribute to effort. Girls attribute their failure in maths to lack of ability whereas boys to the lack of effort. These kinds of attributions are going to affect girls' and boys' motivation and attitudes towards maths.

Aims

The aims of this study were to characterize mathematics motivation among Portuguese students and analyze their relation with gender, classroom social support and achievement

Method Participants

The participants were 925 students from fifth- to ninth-grade mathematics classrooms in several schools in Lisbon and around Lisbon. There were 458 (49,5%) boys and 467 (50,5%) girls. The age range was from 10 to 16 years old.

Measures

We used two instruments: The Mathematics Motivation Questionnaire and The Social Support Questionnaire. Students' perceptions of teachers' and peers' support were assessed by The Social Support Questionnaire, comprising 10 items (Cronbach's Alpha=.838). Students were asked to rate a series of statements, to assess the degree to which they felt their teachers' and peers' support at the mathematics classroom. For all (Cronbach's Alpha=.838) the items a 6-point Likert-type scale (ranging from 1=strongly disagree to 6=strongly agree) was used. To assess mathematics motivation we used the Mathematics Motivation Questionnaire, a 22 item questionnaire adapted from the IMI (Intrinsic Motivation Inventory, from Ryan, Koestner & Deci, 1991). This is a multidimensional instrument that assesses students' enjoyment (Cronbach's Alpha=.911), perceived competence (Cronbach's Alpha=.786), value (Cronbach's Alpha=.897), felt pressure (Cronbach's Alpha=.748), and perceived choice (Cronbach's Alpha=.848) while performing mathematics, thus yielding five subscale scores. All items were rated on a 1-6 Likert scale.

Results

Gender, achievement and social support effects on mathematic motivation

A multivariate analysis of variance, considering gender, achievement and support, revealed statistically significant differences for gender (Pillai's Trace=0,044, $F(5,866)=7,945$ p

Considering gender, the analyses revealed effects of gender on three subscales: the Value subscale ($F(1,881)=4.007$ p=0.046), the Perceived Competence subscale ($F(1,881)=10,220$ p=0.001) and the Pressure subscale ($F(1,881)=5,380$ p=0.021). Girls felt more pressure about maths, perceived themselves as less competent but considered maths as a more valuable subject than boys.

Regarding achievement, the analysis considering three levels of students' achievement (Low, Medium, High) revealed reliable effects on all the five subscales: the Value subscale ($F(2,881)=47.999$ pppp

Finally the analyses considering Social Support also revealed significant effects in four motivational dimensions with those students who felt lower Social Support being less motivated in all these dimensions (Value ($F(1,881)=117.230$ p In terms of the relations between mathematics motivation and gender, grades and social support (teacher and peers) results in this study indicated that significant gender, social support and grades differences were found. No significant differences were found for gender in the actual achievement in mathematics, but girls perceived themselves as less competent than boys. They also felt more pressure about maths and considered maths as a more valuable subject

than boys. The findings also suggested that students with high maths achievement have a significantly higher mean score in all dimensions of motivation and felt less pressure on maths activities, when compared with students with medium and low achievement. Additionally, students who felt a more positive social support in their maths classroom present higher mean scores in motivation than students that perceived to have less social support in their classes.

Implications of these results for learning and learning motivation will be discussed.

PAPER PRESENTATION

Effects of reading motivation on reading competence: Do they depend on students' achievement levels?

Maik Philipp, University of Applied Sciences Northwestern Switzerland, Switzerland

Past research has demonstrated positive effects of intrinsic reading motivation on reading competence (cf. Baker & Wigfield, 1999). It is supposed that high reading motivation enhances reading frequency leading thereby to improved text comprehension (cf. Guthrie & Anderson, 1999). However, we expect such improvements to be larger for students of high-achieving (HA) school tracks as opposed to low-achieving (LA) school tracks. HA-students are better self-regulated learners and may read more difficult text types in their spare time (e.g., novels versus comics). Thus, their reading competence should be more improved as a consequence of high reading motivation than LA-students' reading competence. To test this assumption, we examined the effects of intrinsic reading motivation on reading competence between grades 5 and 6 in samples of HA- students ($n=198$) and LA-students ($n=207$). Correlations confirmed that intrinsic reading motivation (grade 5) was significantly associated with reading competence (grade 6) in the sample of HA-students, but not in the sample of LA-students. By means of structural equation modeling, it was further confirmed that HA-students' intrinsic reading motivation in grade 5 significantly predicted the development of reading competence between grades 5 and 6 (controlling for gender and migration background). In the sample of LA-students, however, intrinsic reading motivation proved to be unrelated to changes in reading competence between grades 5 and 6. In sum, the present findings suggest that intrinsic reading motivation contributes to increased reading skills only in high-achieving students but not in low-achieving students.

A number of studies (e.g., Baker & Wigfield, 1999; Mucherah & Yoder, 2009) provided empirical evidence that intrinsic reading motivation fosters independent out-of-school reading and, consequently, reading achievement (cf. Guthrie & Anderson, 1999). However, these effects have been rarely investigated longitudinally. Furthermore, there is a lack of studies exploring the effects of intrinsic reading motivation separately for students of high-achieving versus low-achieving school tracks. Students of high-achieving school tracks probably read more difficult texts as a consequence of high intrinsic reading motivation, e.g. because they have more elaborated interests, and more sophisticated books available. In contrast, students of low-achieving tracks with high reading motivation are likely to prefer comics or magazines which are less conducive to their reading competence. Thus, the major objective of this study was to test the assumption that intrinsic reading motivation is a better predictor of reading competence for high-achieving than for low-achieving students.

Four hundred and five students were tested in grade 5 and, seventeen months later, in grade 6 (students who participated only once, in grade 5 or grade 6, were excluded from the present analyses). One hundred ninety-eight students attended a high-achieving school track (Gymnasium); two hundred and seven students were of school tracks with a low (Hauptschule) or medium achievement level (Realschule; both levels are summarized here as "low"). At both time points, intrinsic reading motivation and reading achievement were assessed. Intrinsic reading motivation was measured by a seven-item questionnaire (e.g., "I read for pleasure during spare time"; $\alpha = .84/.89$ in grade 5/6). To assess reading achievement in the 5th grade, we used teacher judgments on reading competence as well as German grades ($\alpha = .58$). In grade 6, standardized tests on reading comprehension ($\alpha = .87$) and reading speed ($\alpha = .84$) were administered (LGTV 6-12; Schneider, Schlagmüller & Ennemoser, 2007). In addition, gender and migration background were assessed. Missing values were estimated by NORM 2.03 (Schafer, 1999).

In line with our assumptions, correlations revealed that in the sample of high-achieving students, intrinsic reading motivation in grade 5 was significantly associated with reading competence in grade 6, whereas no such relation was found in the sample of low-achieving students. To test the assumption that intrinsic reading motivation in grade 5 predicts the development of reading achievement between grades 5 and 6, structural equation modeling was applied. The hypothesized cross-lagged panel model (Figure 1) included four latent variables: reading motivation in grade 5 and in grade 6 (items as indicators), reading achievement in grade 5 (teachers' judgments and German grades as indicators) and reading achievement in grade 6 (reading comprehension and reading speed as indicators). We assumed that intrinsic reading motivation in grade 5 contributes independently of prior reading achievement (grade 5)

to the prediction of reading achievement in grade 6. The model also hypothesizes the reversed effect of 5th grade reading achievement on 6th grade intrinsic reading motivation as has been suggested by Morgan and Fuchs (2007). Effects of gender and migration background on all variables were taken into account. The model was tested separately for students of high-achieving and low-achieving school tracks by means of Mplus (cf. Muthen & Muthen 1998-2006). The fit of the model proved to be acceptable for both high-achieving students ($\chi^2_{[55df]} = 94.3$, p

PAPER PRESENTATION

The Identification Of Core Motivational Strategies During Physical Education

Nathalie Aelterman, Ghent University, Belgium; Maarten Vansteenkiste, Ghent University, Belgium; Bart Soenens, Ghent University, Belgium; Lynn Van den Berghe, Ghent University, Belgium; Jotie De Meyer, Ghent University, Belgium; Leen Haerens, Ghent University, Belgium

Self-determination theory proposes that the provision of autonomy support and the creation of a well-structured and warm environment contribute to the satisfaction of the basic psychological needs of autonomy, competence and relatedness. Previous studies measuring a need-supportive learning climate in physical education solely relied on questionnaires to assess the subjective perceptions of need support. This study went beyond the assessment of subjective perceptions and aimed at developing a reliable and valid coding scheme for observing PE teachers' teaching behaviors. Video-images of 102 PE teachers during PE class (60.8% male, M age = 37.51 \pm 10.78) were coded using a 25-item observation protocol. The items had acceptable inter-rater (91% ICC > .50) and intra-rater (92% ICC > .70) reliabilities. Exploratory factor-analysis (Promax) resulted in three factors explaining 50.67% of the variance in the teaching behavior items: 1) Vitality (e.g. being enthusiastic), 2) Autonomy-support (e.g. offering choice), and 3) Structure (e.g. providing positive feedback). Inter rater reliabilities for the total scores of each component were satisfactory for Vitality (ICC = .54), Autonomy support (ICC = .53) and Structure (ICC = .52). In line with previous research providing evidence for three distinguishable components of autonomy support, structure and involvement, the 25 specific motivational strategies observed in the present study were also allocated to similar constructs. This observation tool allows us to formulate evidence-based recommendations towards specific motivational teaching behaviors.

Introduction

Self-determination theory proposes that students are more likely to be intrinsically motivated if their basic needs for autonomy (e.g., experiencing a sense of volition and psychological freedom), competence (e.g., feeling effective), and relatedness (e.g., experiencing a sense of closeness and friendship with the teacher) are fulfilled. Hence, to understand how to structure physical education (PE) classes to foster optimal motivation, it is important to understand which social-contextual factors, including teaching behaviors, contribute to the satisfaction of the three basic needs. According to SDT, a need-nurturing environment is characterized by the provision of autonomy support and by the creation of a well-structured and warm environment.

To date, many studies focused on the relationship between subjective perceptions of need support (measured by questionnaires) and need satisfaction to identify features of need-supportive class environments. These studies have a number of shortcomings, however, both in terms of methodology and in terms of practical implications. At the methodological level, due to the self-reported nature of perceived need support measures, many studies in this area cannot rule out the possibility of shared method variance. Further, to develop interventions aimed at increasing

teachers' need support, we need a detailed account of what need-supportive teachers actually do. For these reasons, this study went beyond the assessment of subjective perceptions and aimed at developing a reliable and valid coding scheme for observing PE teachers' teaching behaviors.

Methods

An initial broad list of 25 need-supportive teaching behaviors was developed based on a review of the literature supplemented with expert observations of video tapes of PE classes. Inter-rater and intra-rater reliability was tested based on videotapes of 30 PE classes using single measure intra class correlation coefficients (ICC). Additionally, 102 video-images of PE lessons taught by different PE teachers (60.8% male, M age = 37.51 \pm 10.78) were coded by means of the protocol. At the end of each lesson, 1163 secondary school pupils (52.2% boys, M age = 14.71 \pm 1.90) filled out a questionnaire measuring their perceptions of teachers' need support.

The 25 need-supportive teaching behaviors were subjected to an exploratory factor-analysis relying on a principal component analysis (PCA) with oblique rotation (Promax). Multilevel regression analyses with pupils nested within classes were used to investigate whether specific observed need-supportive behaviors were related to perceptions of need support by the students. This abstract includes preliminary regression results based on a subsample of 60 PE teachers and 657 pupils. Results of the full sample will be presented at the conference.

Results

Intra rater reliability was acceptable (ICC > .70) for 92% of the observed items, inter rater reliability was acceptable (ICC > .50) for 91% of the observed items.

Because we expected the theoretical constructs of autonomy support, structure and involvement to emerge, we fixed the number of factors to extract on three. Three factors with an eigen value above 2 (i.e., 5.20, 3.72, and 2.74) could be retained, together explaining 50.67% of the variance in the teaching behavior items. After Promax rotation the three factors could be interpreted as 1) a Vitality component, including items such as being enthusiastic and empathic, providing clear instructions and being energetic, 2) an Autonomy-support component including behaviors such as offering choice, asking questions and providing the opportunity to work independently, and 3) a Structure component including items such as providing positive feedback and offering help. Vitality was found to be positively correlated to Autonomy support, $r(1163) = .22$, $p < .001$, and Autonomy support and Structure, $r(1163) = .00$, ns were not significant.

Internal consistencies were acceptable for the three components, with Cronbach's alpha coefficients of $\alpha = .80$, $\alpha = .71$ and $\alpha = .66$ for Vitality, Autonomy support and Structure, respectively. Inter rater reliabilities for the total scores of each component were satisfactory for Vitality (ICC = .54), Autonomy support (ICC = .53) and Structure (ICC = .52).

To assess external validity of the three factors retained, relationships with pupil's perceptions of teachers' teaching behaviors were explored. Preliminary multilevel regression analyses in a subsample of 657 pupils from 60 secondary school classes showed that perceptions of autonomy support were significantly positively related to the following observed behaviors: a) teachers asking questions about students interests, values or problems ($b = 0.60$, $SE = 0.27$), b) teachers offering choice to the students ($b = 0.89$, $SE = 0.41$) and c) teachers paying attention to what students are saying ($b = 0.58$, $SE = 0.17$). Perceptions of structure were significantly positively predicted by modeling behaviors ($b = 0.51$, $SE = 0.20$).

Discussion

Previous research using factor-analysis on self-reports of a need-supportive environment already provided evidence for three distinguishable components of autonomy support, structure and involvement. The present study is unique because based on observations the same components of a motivational climate could be identified. In addition, this study allowed to identify specific 'core' need-supportive strategies that are likely to be perceived as motivating by many students. Teachers' asking questions, offering choice and listening to the students are perceived as more autonomy supportive by their students. The results furthermore revealed that modeling is perceived as an effective strategy to implement structure during PE. The results of the present study will, in a second step, form the basis for the development of an intervention aimed at creating need supportive class environments by training PE teachers on how to teach in a need supportive way.

PAPER PRESENTATION

How does the perceived degree of their teacher's fairness affect the marks of high school students?

Karsten Stegmann, University of Landau, Germany; Hannah Freienstein, University of Munich, Germany

The degree of perceived fairness within organizational structures is regarded an important factor for the performance outcome of employees because it positively affects motivation and behaviour in organizations. Our contribution addresses the question whether this relation can also be found in school. Four aspects of fairness can be differentiated: distributive, procedural, informational and interpersonal fairness. These aspects may positively affect effort via intrinsic motivation. Furthermore, effort usually correlates with performance. To test our model, we conducted a survey with 95 high-school students (13th grade – final school year). We measured the perceived fairness regarding a self-selected course, as well as intrinsic motivation, effort and grade in the respective course. In order to control the effects of prior knowledge and intelligence on marks, we also included the marks in the respective subject that had been achieved two years before and the overall grade of the final high school exam. To test our model, we conducted a path analysis using AMOS. We observed a good model fit. The results show that interpersonal and informational fairness are significant positive predictors for intrinsic motivation. Intrinsic motivation is a significant positive predictor for effort and finally effort is positively correlated with marks. The results provide evidence that fairness is not only an important factor in organizations, but also in schools. Further experimental research has to provide evidence to what extent teachers can affect intrinsic motivation and effort by increasing the degrees of interpersonal and informational fairness.

How does high school teachers' fairness affect motivation, effort and grades of learners? So far, the degree of perceived fairness within organizational structures has been regarded an important factor for the performance of employees. Perceived fairness positively affects employee/s motivation and behaviour (Cohen-Carah & Spector, 2001; Colquitt, et al. 2001). Four aspects of fairness can be differentiated (Colquitt 2001). (a) Distributive fairness is based on the equity theory by Adams (1965): an outcome is perceived as fair if one's task input vs. one's task output corresponds with the input and output ratio of others. (b) Procedural fairness includes aspects like consistency and accuracy of procedures, as well as the extent to which a person can express his view during the process of decision making (voice effect; Lind and Tyler 1988). Interactional fairness (Bies & Moag 1986) can be divided into two factors (Greenberg 1993): (c) Informational fairness describes to what extent prompt and elaborated information about decision procedures is provided. (d) Interpersonal fairness describes the dignity and respect in communication during the decision making process. The four aspects of fairness may positively affect effort mediated by motivation. Effort usually correlates with performance.

Whereas traditional organizational research focussed on the effects of procedural fairness on performance and reported modest relationships between both (see meta-analysis by Cohen-Carah & Spector 2001; Colquitt, et al. 2001) more recent work might argue that the concepts of interpersonal and informational fairness might influence performance (Masterson, et al. 2000; Robbins, et al. 2000). Our research question addresses the extent of relationships between fairness, intrinsic motivation, effort and grades within a high school setting.

Method

To test our model, we conducted a survey with 95 high-school students (13th grade, final school year), aged between 18 and 22 ($M = 19.06$, $SD = 0.63$), 67, 4 % of which were female. We measured the perceived fairness regarding a self-selected course, as well as intrinsic motivation, effort and grade in the respective courses using self-reporting measures. The reliability of all scales was sufficiently high. To control the effects of prior knowledge and intelligence on marks, we also included the marks of the respective subject achieved two years before and the overall grade of the final high school exam. To test our model, we conducted a path analysis using AMOS. The global fit indexes of the model indicate that the hypothesized factor structure fits the data well ($\chi^2 = 23,302$, $df = 16$; n.s.; CFI, GFI, IFI, TLI $>.94$, RMSEA $<.08$).

Results

Our results show that interpersonal and informational fairness are significant positive predictors for intrinsic motivation. No significant beta weights could be found regarding distributive and procedural fairness. Intrinsic motivation is a significant positive predictor for effort and effort positively correlates with marks (controlled for prior knowledge and intelligence). In our study, we also checked whether fairness could explain variance of the marks that is not mediated by motivation/effort. We found a significant beta weight of procedural fairness that was not mediated by effort.

Conclusions

Our results provide evidence that fairness is not only an important factor in organizations, but also in schools. The outcome matches findings in organizational settings which highlight the importance of informational and interpersonal fairness for performance. Further experimental research has to provide evidence whether teachers can affect intrinsic motivation and effort by increasing interpersonal and informational fairness. However, our results raise questions regarding the relation between objective and perceived fairness. The outcome that procedural fairness, including the aspect that a person has a say during the procedure, is related with marks even if the mediator motivation is controlled, allows a serious question: Are some teachers discussing and adjusting their marks until students are satisfied? However, this question requires observations, not self-report studies.

PAPER PRESENTATION

Social language environment, social practices and events in Swedish preschools

Martina Norling, School of Education and Communication, Sweden; Lena Almqvist, Malardalen University, Sweden

The aim of this study is to develop knowledge about language and literacy stimulated activities in preschool. Children have own experiences which depends on culture and values. Children come to preschool with those values and try to understand the environment by their own experiences. Making meaning and also share this values with peers and teachers. According to Barton (2007) it is important to create such situations, we learn all the time, we change values and "this change is the key to learning".

This study has mix methods design. Questionnaires, observations and focus groups interviews were used, in order to create a larger picture about the social language environment in Swedish preschools.

The results among other things showed that most teachers received high ratings in items such as Responsiveness and Child perspective which are aspects of the quality dimension Emotional support, but low ratings in Concept development which is an aspect of the quality dimension Instructional Support.

Further and extended findings will be exposed during the presentation.

Background

Children's language and literacy practices are situated in broader social relations in preschool. That makes it necessary for preschool teachers to arrange social settings of language and literacy events and support children's interaction with adults and peers (Barton, 2007).

Social events make opportunities for practical language modeling and develop the child's own thinking and cognition. This requires a child perspective and education to create good conditions for children's language development. It also depends on preschool teacher's values what decisions that are made in the language environment, also how

preschool teachers structure and plan activities, values and how preschool children fit into the language environment (Barton, 2007).

Aims

This study is a part of the research project Preschool as a context for language development in children and the overall aim is to investigate the social language environment in Swedish preschools. The aim of this study is to develop knowledge about language and literacy stimulated activities in preschool. Focus is on the emotional tone of the preschool environment and the interaction between teachers and children. The study wants to explore the kind of relations that occur, as eye contacts, and physical contacts like hugging. Also preschool teacher's attitudes to listen and ask questions and respond for deeper understanding how children think and learn, in preschool activities (Pianta, 2006).

We investigate and analyze the social setting of language, communication and literacy events, to understand the social language environments. Following research questions are investigated: How do teachers structure and organize children's language environment at preschool to improve their language development? What quality has the language environment in preschool?

Methodology

This study has mix methods design. Questionnaires, observations and focus groups interviews were used, in order to create a larger picture about the social language environment in Swedish preschools.

The questionnaires were designed with twenty statements about the social language environment. The participants scored each question from one to seven. The questionnaires were coded and were personally collected by the researchers during next visit at the preschool units. The questionnaires were processed in data programme, SPSS.

The observations were carried out at various activities in the preschool environment. The observation instrument is inspired and also piloted (Sandberg, 2007) by the observation instrument, Classroom Assessment Scoring System (CLASS). CLASS instrument is measuring the social language environment and four main divisions are measured, Emotional support, Preschool Organisation, Instructional Support and Child Outcomes (Pianta, 2006).

The researchers observed each preschool teacher for twenty minutes, and the observations of the social language environment were scored based on the four main groups that mentioned above. The scoring scale was from one to seven.

The focus group interviews (Krueger, 1994; Morgan 1998) lasted one and a half hour and the preschool teachers that worked in the same team were interviewed together. The most common number of participants was three in each focus interview, but sometimes there was one more or less, because of illness or working shifts. The focus group interviews started with feedback from the researcher regarding to the observation procedures and the diverse scorings. Then the focus group interviews continued with open ended questions, regarding the teacher's conceptions and vision about the social language environment in preschools.

Findings

In general, the preschool teachers scored the social language environment in the preschools fairly high. When dichotomizing the social language environment into the categories low quality social language environments (1-4, 46.8%) and high quality social language environment (5-7, 53.2%), the distribution was quite even. The distribution between separate statements were not, as even as in the general social language quality score. Descriptive analyses showed that there was an overweight of preschool teachers who scored low in statements such as "we challenge the children's ideas by posing thought provoking questions that do not demand a correct answer but space for several possible answers" and "we encourage the children to make up their own stories", but high in item such as "we deliberately use everyday situations in order to create opportunities to stimulate language learning" and "play is considered a deliberate and significant aspect of the preschool activities".

The instrument CLASS was used to observe teachers' interaction/ how teacher interact with the children in the preschool environments. The observation scores were tricotomized into the categories, low quality 1-2, mid quality 3-4 and high quality 6-7. The results among other things showed that most teachers received high ratings in items such as Responsiveness and Child perspective which are aspects of the quality dimension Emotional support, but low ratings in Concept development which is an aspect of the quality dimension Instructional Support. Further and extended findings will be exposed during the presentation.

Theoretical and educational significance of the research

This paper seeks to identify key issues which need to be addressed in order for successful, social language environments in preschools to develop, and to reflect on the implications for practice. Conclusions are drawn with reference to the implications for the development of real and meaningful experiences for preschool teachers and children in early childhood education. Concerning education, preschool teachers can use the results appearing in this study to discuss the social language environment from their own experience to make visible and discuss the values and attitudes that exist about the social language environment in preschools. Probably the findings will open for new theoretical discussions on social language environments.

PAPER PRESENTATION

Orchestrating collaboration based on complementary expertise

Raija Hamalainen, University of Jyväskylä, Finland

Future research needs to focus on flexible ways to orchestrate learning in future technology-enhanced learning environments. It must also refer to the challenge of supporting collaboration in naturalistic, complex learning settings. The aim of this paper is to discuss the theoretical grounding for need to orchestrate computer-supported collaborative learning (CSCL). Secondly, this knowledge is used to further orchestrate collaboration in naturalistic learning setting based on previous research findings. Thirdly, we will illustrate how groups' knowledge construction is mediated mainly by shared problem solving, providing information, contextual questions and management of interaction in orchestrated learning setting. To conclude, this theoretical paper will illustrate orchestrating CSCL based on research findings of productive collaboration. Added to this empirical examples will illuminate why orchestrating learning is beneficial for collaboration. More specifically, how and why teachers pre- and real time orchestration mediate groups' knowledge construction activities.

The aim of this paper is to discuss the theoretical grounding for need to orchestrate computer-supported collaborative learning (CSCL). Secondly, this knowledge is used to further orchestrate collaboration in naturalistic learning setting based on previous research findings. Thirdly, we will illustrate how teacher's pre and real time orchestration mediate groups' knowledge construction.

Theoretical grounding

The potential of technology-enhanced learning (TEL) in supporting collaboration is widely agreed. However, even collaboration is often set as a target in CSCL contexts; in reality "ideal" high level and productive collaboration is relatively rare (Hämäläinen 2010), and is challenging to "create" (Kollar, 2010) in technology-enhanced school settings yet. The CSCL research has typically focused on how environments itself can support collaboration. For example on collaboration scripts as a particular kind of instructional approach to support CSCL, typically without real time teachers activity (Kobbe et al., 2007). Recent critical studies have suggested that focusing only on specific scripts reduces—or even negates—the role of teachers in supporting collaboration (Dillenbourg & Jermann, 2010). Thus, there should also be an emphasis on how to support collaborative learning with technology and human guidance, as any technology alone cannot replace the teacher in supporting creative collaboration processes (Littleton 2009), for example how teacher can pre-design and offer real time support for productive knowledge construction activities. Recently, within CSCL research society, flexible orchestration has widely been suggested as a solution for arranging collaboration in naturalistic learning situations. As such, the concept of orchestrated learning is not new (Brown, 1992); along with the development of new technologies, orchestrating has again become a topical issue because new learning spaces challenge the teacher to support collaborative learning in new ways. Thus, with the development of collaboration scripts, it is necessary to pay attention to the effective and flexible use of the potential offered by future learning environments with regard to orchestrated learning.

At the current state "orchestrating learning" has been used to refer different types of activities; teacher orchestrating collaboration in the classroom (Brown, 1992), relation of organization and learning styles (Watts, 2003), improving individual students learning (Braaksma et al., 2004), enhancing productive peer learning (Palincsar & Herrenkohl, 2002), or organization of collaborative learning scenarios (Pinkwart et al., 2003). Thus, a common feature of orchestrating CSCL is that it draws systematically on research-based productive collaborative learning situations in the design and implementation of teaching. The main idea is to combine the design and the improvisation. The curriculum sets the starting points for activities, environment supports collaboration, teacher designs and orchestrates the structure for learning processes (based on research findings of productive collaboration; e.g. solving cognitive conflicts) and then the learners are given a certain freedom for shared knowledge construction. More over during the collaborative learning situation the teacher simultaneously designs, monitors and supports learning processes during the groups' work based on contextual needs.

This empirical example will illuminate how and why teachers pre- and real time orchestration mediate groups' knowledge construction activities. The study orchestrates learning in naturalistic learning setting and lies in between socio-cultural approaches and instructional design (Dillenbourg & Tchounikine, 2007). The subjects of the study are one teacher and 26 students of online course "Learning and Interaction" that took place at the Open University of Jyväskylä University (OUJY), Finland.

Firstly, the analysis addressed whether students were active during the course (total = 293 utterances). Since students' activity levels in a virtual environment does not necessarily illustrate collaboration processes itself, focus is on students knowledge construction activities mediated by teacher's pre and real time orchestration (based on quantitative and qualitative content analysis, Berelson, 1952). First (1), the learners received different sets of theoretical background information (all the students were novices in this phase). Two groups of students (n=13) read an article which focus was more on the socio-cultural perspective of collaboration (Puntambekar, 2006), whereas the two other groups (n=13) read an article concerning collaboration more on the socio-cognitive perspective (Weinberger, & Fischer, 2006). This procedure based collaborative knowledge construction on scientific knowledge. In the second phase (2), each student participated in the discussion (total 133 utterances) with other students reading the same background materials and become experts in their own perspective (socio-cultural or socio-cognitive) (Perkins, 1993). Teacher pre orchestrated this procedure with instructive questions (based on external recourses) for students to facilitate their reading and understanding of the materials. In the third phase (3), students worked in pairs with the complementary expertise (Hermann, Rummel, & Spada, 2001) of the socio-cultural and socio-cognitive perspectives. Each of the students participated in discussion (total 160 utterances) (both as an expert and a novice (e.g. expert of socio-cultural perspective was novice in socio-cognitive approach).

The aim of this phase was to make the opposite sides visible and to lead to shared knowledge construction. To achieve these goals, the teacher pre orchestrated this procedure with open-ended, ill-structured themes or questions for the group discussions. In this presentation we will illuminate that groups' knowledge construction was mediated mainly by shared problem solving (39 % of the utterances) and providing information (32 % of the utterances), contextual questions (5 % of the utterances) and management of interaction (9 % of the utterances). Added to this, presentation will illustrate empirical examples (with 35 subcategories) how and why teachers pre- and real time orchestration mediated knowledge construction.

PAPER PRESENTATION

Developing Scholarly Identity – Becoming a PhD in Teacher Education

Auli Toom, University of Helsinki, Finland; Kirsi Pyhälto, Helsinki University, Finland

Although PhD students within the context of teacher education are highly motivated and talented, many of them never finish. There is variation among students: doctoral project in teacher education is often launched either because educational practitioners find doctoral studies as route for professional development, or because a professional research career is the aim. This study explores critical incidents of PhD candidates within teacher education. The participants reported critical incidents related to resources; supervision and scholarly community; and internal factors regulating PhD process. In the incidents, the notions of development of scholarly identity were related to participation, appreciation, task, and role within the scholarly community. Motivation, emotional factors and identity development play an important part when becoming a professional researcher. Multiple professional and scholarly communities produce multiple identities for doctoral students in teacher education. The pedagogical means for supporting students to overcome critical barriers during PhD process within teacher education should be developed.

INTRODUCTION

Research on doctoral education has identified factors influencing to doctoral experience. Supervisory relationship (e.g., Aspland, Edwards, O'Leary & Ryan, 1999; Mackinnon, 2004; Hasrati, 2005; Murphy, Bain & Conrad, 2007; Sambrook, Stewart & Roberts, 2008), scholarly community (Beauchamp, Jazvac-Martek, Mc Alpine, 2009; Authors, 2009) and students' and supervisors' beliefs about research (e.g., Brew, 2001; Kiley & Mullins, 2005; Meyer, Shanahan & Laugksch, 2005; Åkerlind, 2008; Lee, 2008) contribute to doctoral experience and to scholarly identity. A better understanding of the nature of PhD process is needed in order to develop PhD education further.

This study explores the PhD process within teacher education. The research questions are:

- 1) What kind of critical incidents do PhD students find either promoting or hindering their studies?
- 2) What kinds of topics concerning the development of scholarly identity dominate the PhD students' critical incident descriptions?

THEORETICAL FRAMEWORK

Scholarly community plays an important role in students' experiences of doctoral journey and perceptions as scholars (Bair & Haworth, 1999; Gardner, 2008; Authors, 2009b). Doctoral students are exposed to various subcultures; they participate in peer groups, adopt roles and get experiences of memberships (cf. Becher, 1989; Becher & Trowler, 2001; Authors, 2009). Interactions within and between the scholarly communities provide often tensed opportunities for agency, avoidance, and opposition and resistance (Authors, 2010b).

Developing professional identities refers to various meanings of one's work, oneself and meanings attributed by others (Beijaard, Meijer & Verloop, 2004). Becoming an academic expert is about knowledge, but also developing scholarly identities (McAlpine, Jazvac-Martek & Hopwood, 2008; Authors, 2009a; Authors, 2010). The development of scholarly identity is reflected in PhD students' engagement, perceptions of peers and things they learn (Archer, 2000, 2003; Billet & Somerville, 2004) and is related with participation in communities of practice (Wenger, 1999). Attaining and developing one's membership continuously and cyclically plays an important part in professional learning starting from PhD process throughout academic career. It provides opportunities for developing professional autonomy and contributing to community (Eteläpelto & Vähäsantanen, 2008).

THE STUDY

This study is a part of a larger research project on PhD education in Finland. It aims to understand the factors students perceive promoting or hindering their studies. PhD students (n=66) in different phases of studies responded in the survey at Department of Teacher Education, University of Helsinki.

Data and methods

The qualitative data is gathered with open-ended question addressing PhD students' experiences: "Describe your PhD process! What are the key events or turning points that have had significant effect on your PhD process?" Doctoral students pass challenges which affect on their striving towards doctorate. We use critical incidents as a tool for reflection (cf. Woods, 1993; Tripp, 1993; Tripp, 1994; Francis, 1997; Angelides, 2001). When the incidents are chosen by students, the basic elements of personal ways of feeling, thinking and acting during PhD process could be considered.

The data were content analyzed using an abductive strategy. First, the data was coded into two categories: hindering and promoting incidents. Then categories were classified into three contentual categories and validated by the research group (cf. Miles & Huberman, 1994; Yin, 1994). Critical incident descriptions were analyzed in a more detailed way focusing on development of scholarly identity (cf. Becher, 1989; Becher & Trowler, 2001).

PRELIMINARY RESULTS

The promoting and hindering critical incidents during the PhD studies

About 76% of critical incidents were promoting, whereas 24% were challenging. Their amounts and focuses are in Figure 1.

The majority of incidents (51%) related to internal factors regulating the PhD process like identity development, domain specific questions and learning of generic skills. Students described incidents promoting their personal interest, self-efficacy, empowerment and engagement as positive resources. Interesting results and acceptance of first article were important. Good self-regulation and academic writing skills and deadlines were identified as significant assets. In turn, events undermining students' sense of agency, competence and identity development were burdening. About 35% of incidents related to supervision and scholarly community. Students emphasized getting constructive feedback, encouragement and emotional support from supervisors. Dialogue with peers and members of scholarly community were considered positively. Lack of supervision, its destructive frictions and lack of scholarly community were highly problematic.

A minority of incidents (14%) related to working facilities and resources. Getting funding for doctoral studies – or not getting it – was emphasized. Some reported external working facilities and structures important.

Figure 1. The promoting (blue) and hindering (red) critical incidents during the PhD studies.

The development of scholarly identity in the PhD students' critical incident descriptions

Doctoral students reflected their identity in terms of (I) participation in scholarly community. They problematised traditions of community, familiarized themselves with ways of communicating and took a stand towards professional norms. Students experienced their community positively, though different interpretations existed. Some interpreted the relation between themselves and community problematic and felt isolation and marginality.

Students deliberated their identity from the viewpoint of (II) appreciation and respect from community by describing the valuations and treatment from peers. They experienced strong appreciation and felt themselves important "flag bearers" of their discipline. Conversely, some had experienced weak appreciation by being the lowest in the hierarchy, undervalued and "exile".

Scholarly identity was reflected as a (III) task within community. Students emphasized the quality, core and meaningfulness of research work and their important duty in creating new scientific knowledge. They also mentioned – quite conversely – their task as a mere completion of duties, like bringing money and credits and completing the goals set on administrative level.

Students described their (IV) role in scholarly community. They memorized their development and pondered possible professional ways. Some perceived themselves as appreciated novices or apprentices – or growing research professionals, full members of scientific community rather than mere novices.

EDUCATIONAL IMPORTANCE OF THE STUDY

Motivation, emotional factors and identity development play an important part when becoming a professional researcher. Multiple professional and scholarly communities produce identities for doctoral students in teacher education. Pedagogical practices promoting learning of research and generic skills, sense of agency, competence and sense of belonging should be in focus of doctoral education within teacher education.

PAPER PRESENTATION

Teacher learning – The Norwegian model in an international context

Cecilie Flo Jahreie, University of Oslo, Norway

Over the last 30 years, teacher learning has become one of the most important concerns of the educational establishment. It has been more or less assumed that teachers who know more, teach better. Discourses regarding teacher education are regarded traditionally as national issues. In the last decade however, educational reforms have become embedded in an escalating globalization process. The aim of the paper is to review the historical evolution of the education of teachers Norway, in an international perspective. A special emphasis will be on the relationships between universities and schools. This implies that the development of the Norwegian model will be reviewed, followed by a review of the models in England, Finland, and the Professional development schools (PDS) in the US.

This paper discusses these models by using three conceptualizations of knowledge (Cochran-Smith & Lytle, 1999). The analyses revealed striking differences, based on radically different conceptions of teacher learning, but also significant international trends, in the design of different teacher education programs. The paper concludes with a theoretical discussion of the three forms of knowledge and proposes an alternative conceptualization of teachers' learning grounded in cultural historical activity theory (CHAT).

Over the last 30 years, teacher learning has become one of the most important concerns of the educational establishment. It has been more or less assumed that teachers who know more, teach better. Discourses regarding teacher education are regarded traditionally as national issues. In the last decade however, educational reforms have become embedded in an escalating globalization process. Even though, teacher education in Europe has a high degree of complexity and variation in relation to structure, curriculum, length of education, and achievement standards (Garm & Karlsen, 2004). The aim of the paper is to review the historical evolution of the education of teachers in Norway, in an international perspective. A special emphasis will be on the relationships between universities and schools. This implies that the development of the Norwegian model will be reviewed, followed by a review of the models in England, Finland, and the Professional development schools (PDS) in the US. The review is based on the Norwegian white papers, national and international documents and evaluations of teacher education, and research literature. The four models are analyzed and discussed by using three conceptualizations of knowledge (Cochran-Smith & Lytle, 1999). The paper concludes by proposing an alternative conceptualization of teachers' learning grounded in Cultural historical activity theory (CHAT). From this backdrop, the following research questions are raised:

What characterizes the historical evolution of teacher education in Norway and internationally?

What is the dominant conception of teacher learning in the four models reviewed?

How can CHAT be a fruitful approach for understanding teacher learning?

Knowledge and learning in the educational system, as in professional life, are increasingly stretched beyond the nation state and into an extended globalized market. This expansion is related to the construction, adaptation and enactment of transnational discourses of knowledge. The 'logics of practice' inherent to knowledge production and validation in other areas of society, diffuses into the educational sector (Nerland, 2010). This contributes to what is often called an overall epistemification in society (Knorr Cetina, 2006). Epistemification is used to describe the developments in which the general significance of expert knowledge is increasing, as is the prevalence of science-generated knowledge in the organization of everyday life. It is not possible to understand the evolution of teacher education without this societal trend.

Cochran-Smith and Lytle (1999) divide between three prominent conceptions of knowledge. The first conception is referred to as knowledge-for-practice and teaching is understood as a process of implementing, translating, or otherwise putting into practice what is learned of the knowledge base. The second conception is knowledge-in-practice. The emphasis is now placed on knowledge in action: the knowledge is expressed or embedded in practice and in teachers' reflections of practice. The third conceptualization is knowledge-of-practice where formal and practical knowledge is seen as different forms of knowledge which is constructed with others in a community.

In the analysis it was found radically different conceptions of teacher learning. The analyses revealed striking differences, but also significant international trends, in the design of different teacher education programs. One can conclude that the concept of teacher education is both complex and ambiguous when looking at the relationships between universities and schools. Discussing the findings with Cochran-Smith and Lytle's conceptualization of knowledge, it is argued that the English model can be conceptualized as knowledge-in-practice. While the English model emphasizes practice to qualify as a professional teacher, the Finnish approach claims that the positive potential of practice can only be utilized if it is research-based. It is therefore argued that the Finnish model is emphasizing knowledge-for-practice. In the discussion of the Norwegian model the paper will highlight an ongoing tension between two conflicting conceptualizations of knowledge: knowledge-for-practice and knowledge-in-practice. PDS are supposed to provide new spaces for student teachers to learn along with experienced teachers as they construct knowledge of their practice and are ideally based on a knowledge-of-practice approach. However, research literature suggests that PDSs are driven by each of the conceptions of teacher learning, and takes many forms and has many different meanings (Cochran-Smith & Lytle, 1999).

The paper ends with a theoretical discussion of the three forms of knowledge. In knowledge-in-practice and knowledge-for-practice, theory and practice are seen as a dichotomy that has to be bridged or integrated. According to Cochran-Smith and Lytle, the conceptualization of knowledge-of-practice has transcended the dichotomy between theory and practice, while seeing them as two types of knowledge. The paper proposes CHAT as an alternative perspective in which theory and practice are conceptualized as different types of cultural practices or activity systems.

While research on teacher learning is either studied as a teacher's individual development or as organizational change (Jahreie, 2010), it is proposed to understand learning to teach as a societal activity that incorporates historical tools, rules, and the division of labor from the cultural practices or activity systems of both universities and schools.

There is little research focusing on the historical evolution of the education of teachers. The educational contribution of this paper is an awareness of how various structures of teacher education lead to very different ideas in terms of how to improve teacher education and professional development. Theoretically, the paper contributes to a view of teacher learning that goes beyond the leading approaches in teacher education.

PAPER PRESENTATION

Whole-class talk – a criterion of teaching effectiveness in Biology Education

Julia Rixius, Biology Education, Germany

The question how to improve teaching effectiveness in science education – recently asked by international assessment studies like PISA or TIMSS – is important for any educational system which wants to raise the pupils' learning achievement (Johnson, Kahle & Fargo, 2006). In this context, the presented project focuses on the interaction between whole-class talk in science classrooms and pupils' learning achievement. In order to explore whole-class talk, a sample of 47 videotaped 9th grade grammar school biology lessons on the topic 'blood and blood circulation' has been analyzed through a differentiated coding tool: 7 categories define different kinds of speech acts of whole-class talk. The pupils' learning achievement variables were collected by a pre-post-achievement-test, and concept maps (Tiemann, Rumann, Jatzwauk, & Sandmann, 2006; Wadouh, Sandmann & Neuhaus, 2009). The Pearson correlation coefficient was calculated to measure correlations between the data obtained from the video analysis and the pupils' outcome.

One of the findings is a positive correlation between the amount of 'pupil-questions' and the accuracy of the knowledge structure ($r = .41$, $p \leq .02$; $N = 45$), indicating the importance of pupils' development of own questions for their learning processes. A deeper understanding of biological content might therefore be triggered by providing teaching time for pupils to verbalize questions (Scardamalia & Bereiter, 1992).

1. Theory

The question how to improve teaching effectiveness in science education – recently asked by international assessment studies like PISA or TIMSS – is important for any educational system which wants to raise the pupils' learning achievement (Johnson, Kahle & Fargo, 2006). The impact of teaching on the pupils' learning achievement is still not consistently proven (Seidel & Shavelson, 2007). To obtain distinct results, Seidel and Shavelson (2007) suggest choosing variables of high importance for the pupils' learning process. Whole-class talk should be important, because an interaction between knowledge construction and language is expected by cognitive psychologists (e.g. Anderson, 2005).

So far, whole-class talk in science education, mostly analyzed within case studies except for the TIMSS 1999 Video Study (Roth et al., 2006), is interpreted qualitatively by applying general analytic instruments which rarely consider individual speech acts (SA) (Scott et al. 2006). Thereby, the influence of whole-class talk on the pupils' learning achievement can only be assumed. To prove its influence empirically and enable in-depth analysis of whole-class talk, the following elementary research question will be answered:

Does the frequency of different SA within the whole-class talk correlate with the pupils' learning achievement?

2. Methodology

The whole-class talk was analyzed through the coding of a sample of 48 videotaped 9th grade secondary school biology lessons on the topic 'blood and blood circulation'. Each lesson had been taught by a different teacher.

To deepen the understanding of whole-class talk, this study applies a differentiated coding scheme with 7 categories using video data. A teacher's SA is coded either as a 'teacher-task', a 'teacher-feedback', or 'teacher-information'. A task is defined as a request to think or to act. A feedback is a descriptive or evaluative uptake of a pupil's assertion, whereas a content-related input or descriptions of the learning process defines 'teacher-information'. A pupils' SA is categorized as a 'pupil-assertion' in case of the verbalization of their opinion, or as a 'pupil-question', if information is asked for. All SA were coded using the software Videograph.

To test the objectivity of the coding manual, we calculated the interrater reliability of 10 % of the video sample regarding the number of identified SA, which is 85 %, and the coded category of SA, which is 88 %. The Pearson correlation coefficient was calculated with SPSS 17.0 to compute correlations between the data obtained from the video analysis and the pupils' outcome.

The pupils' learning achievement variables were collected by a pre-post-achievement-test and concept maps (Tiemann, Rumann, Jatzwauk, & Sandmann, 2006; Wadoudh, Sandmann & Neuhaus, 2009).

3. Results

Description of the observed SA

In 37 % of the SA teachers use 'teacher-tasks', whereas they only use 12 % of the SA to provide 'teacher-information'. Teachers use 14 % of their SA to give 'teacher-feedback'. Pupils ask fewer questions (4 %) compared to the number of 'pupil-assertions' they develop (27 %).

Examples for correlations between the SA and the pupils' learning achievement

The amount of 'teacher-tasks' correlates negatively with the pupils' factual knowledge gain ($r = -.36$, $p \leq .02$, $N = 45$), whereas the amount of 'pupil-questions' correlates positively with the accuracy of the pupils' knowledge structure ($r = .41$, $p \leq .02$, $N = 45$).

4. Discussion

Description of the observed SA

The result of former studies (e.g. TIMSS), that pupils' opportunity to take part in whole-class talk is restricted by the amount of teacher talk (Roth et al., 2006), can be confirmed for German biology lessons. Regarding the different kinds of SA, the high amount of 'teacher-task' compared to the small amount of 'pupil-questions' points out that whole-class talk is mostly initiated by the teacher – a finding which confirms the existence of the often described pattern of whole-class talk (Lemke, 1990).

Correlations between the SA and the pupils' outcome

The high density of 'teacher-tasks' might hinder the learning achievement, which can be explained by the cognitive overload: The higher the amount of tasks, the shorter the time slots in which the pupils can think about a possible answer (Dillon, 1882). In contrast, the pupils' verbalizations of their thinking process by asking questions seem to help to correctly construct knowledge.

5. Forecast

In the upcoming month, we will expand the coding tool by defining quality-variables of the various SA. After further video analysis, interaction-effects between the quality-variables and pupils' learning achievement variables will be calculated, and will be presented at the EARLI.

Considering these future results, a training concept for prospective secondary school teachers will be developed to enhance the quality of their talk.

PAPER PRESENTATION

The Use of Wikis in University Courses: How do Students Cooperate in Writing Articles?

Tatjana Hilbert, University of Mainz, Germany

The Wiki-technology enables Internet users to not only read contents but also to edit existing articles and to write about new topics. In a recent study, students from six university courses (N = 167) were advised to use a Wiki in a virtual learning platform for follow-up course-work. All students had to write at least one article about a topic discussed during the university course. Participants in two courses were only given technical support (n = 51). Two courses additionally were given a checklist on minimum standards for the articles (n = 59). In the remaining two courses, new articles additionally were read and discussed in the course (n = 57). The Wiki articles in each course were analysed according to their length, quality, and structuredness. Additionally, the interrelation of the articles in the Wiki and log data on how many students edited the articles and on how students edited their fellow students' articles gave information on how students cooperated in writing their articles. On the whole, the analysis showed that the quality of articles was better in courses where students discussed their fellow students' articles. However, students interlinked their articles more in the courses who were given the checklist on minimum standards. For using the Wiki-technology for follow-up course work, results indicate that more support helps students to write high-quality articles.

Background

Writing and summarising texts for learning in university courses is a long and often complex task. Thus, students often try to collaborate in producing understandable texts on different topics they have to learn for their exams. On the one hand, pooling their resources can lead to results that are richer and more complex than those produced by one individual. On the other hand, collaborative writing also makes the writing process more complex (Newman & Newman, 1992). Therefore, some projects are overseen by an editor or editorial team. If the collaborative writing task is part of a university course teachers will often adopt this role. To support the collaborative writing process, online tools can be used (Engstrom & Jewett, 2005). Ideally, these tools should enable all learners to add, edit and remove text. Thus, the writing process becomes a recursive task in which each change may prompt others to make more changes. The advantage of using online tools for collaborative writing also is the possibility to monitor what users are contributing and when they contribute. Individual responsibility for the progress of the writing process enhances students' motivation to participate in the collaborative writing task.

One such tool for collaborative writing are Wikis. The Wiki-technology enables Internet users to not only read contents but also to edit existing articles and to write about new topics. The perhaps most famous example of a Wiki surely is Wikipedia. The Wiki-technology, however, can also be used in closed online environments such as virtual learning platforms in university courses.

Research questions

The general aim of this study was to examine the use of the Wiki-technology for follow-up course work in university courses. Especially, the influence of several support methods on the quality of the writing process and product and students' collaboration was in the focal point of this study. We asked the following research questions: (1) Does more

support lead to qualitatively better articles in a collaborative writing task? (2) How do students contribute to their fellow students' articles in a Wiki? (3) How do students interlink their articles with their fellow students' articles? (4) Are there differences in students' collaboration caused by the different support?

Sample and Design

The sample consisted of 161 students (124 female, 37 male) from six university courses for teacher students in their fourth semester. In three courses, diagnostic issues like grading, quality criteria, and construction of exams were discussed, the other three courses dealt with school-related theories in social and personality psychology. Students from all six courses were given a collaborative writing task. We advised them to write a Wiki about the course-topics with the aim to create a library of understandable texts they could use for learning for their psychology exam which is due after their fifth semester. For each course, a Wiki was provided on the virtual learning platform (Moodle), only course members were able to read, write, and edit articles.

The courses were randomly assigned to one of three support conditions in a way that both types of course content appeared in each condition. Two courses were given only technical information on how to use the Wiki ("no support; n = 51). Two courses additionally were given a checklist on minimum standards (e.g., articles should be interlinked, headlines should be used for a good structure of the text, or information sources should be cited) for their articles ("minimum standards"; n = 59). In the remaining two courses, new articles additionally were read and discussed in the course ("discussion"; n = 57). Therefore, the course teacher printed the newest articles and handed them out at the beginning of the course. Groups of two students shortly discussed and annotated the articles, strength and weaknesses of the articles were then discussed with the whole course. The authors of discussed articles were given the annotations.

Data and Analysis

Quality of students' articles in the Wikis are analysed according to length (i.e. number of words), structuredness (i.e. number of headlines, tables etc.), and overall quality (rated from 1 = very bad to 6= very good). To assess, how students collaborated in producing the Wiki, the interrelation of the articles is assessed by the number of internal links. Log data were analysed according to the number of articles students wrote as first author, the number of articles students edited, how often students edited fellow students' articles, and according to the kind of revision students made.

Results

Up to now, the analyses of the quality have been completed for about 70% of the articles. First results show, that students in the minimum standard courses and in the discussion courses used more headlines etc. to structure their articles than students in courses without support. Students in the minimum standards courses also used more links to their fellow students' articles which indicates that they engaged in reading other articles in the Wiki. The overall quality of students' articles was highest in those courses which discussed new articles. Their articles contained many examples and very good explanations of the theories. The analyses of the articles' quality and on the log data should be finished soon. The presentation will focus specifically on data that indicate how students collaborated in this Wiki writing task. A first tentative conclusion of the results is that students need more than merely technical support. Especially the discussion of articles in the course led to high-quality articles.

PAPER PRESENTATION

Instructional Patterns remain the same across a Segregated Educational System: The Case of Chile

David Preiss, Pontificia Universidad Catolica de Chile, Chile; Valeska Grau, Pontificia Universidad Catolica de Chile, Chile; Monica Nunez, Pontificia Universidad Catolica de Chile, Chile; Isabel Alegria, Pontificia Universidad Catolica de Chile, Chile; Ana Espinoza, Pontificia Universidad Catolica de Chile, Chile; Llery Ponce, Pontificia Universidad Catolica de Chile, Chile

By assessing the patterned nature of mathematics teaching in Chile, the study tests the hypothesis that Chile has a country-specific pattern for mathematics teaching and assess whether this instructional pattern remains the same across different segments of the educational system. Specifically, the focus of this work is on the instructional

principles that, in Chile, provide cultural and personal meaning to the task of teaching mathematics and how these principles translate into real teaching practices. Thus, we infer folk pedagogies from the teaching practices they inform, using video surveys and looking at those aspects of teaching practice that most influence the learning process: teacher talk and lesson structure (Preiss, 2010). Schools from the main urban centers in Chile were randomly sampled and invited to participate. 18 public schools, 20 schools receiving mixed funding, and 22 private schools accepted to be part of the study. The results reveal that teachers basically display the same classroom structure and type of interaction regardless of the type of school where they teach. It is worth noting that the only differences found were at the variables that measured student talk. Hence, the striking differences in academic performance among the different types of schools do not seem to be explained by differences in teaching activities or interactions. Therefore, the educational gap seem to be related to students' cultural capital instead of classroom dynamics

By assessing the patterned nature of mathematics teaching in Chile, the study tests the hypothesis that Chile has a country-specific pattern for mathematics teaching and assess whether this instructional pattern remains the same across different segments of the educational system. Chile is one of the countries with the highest levels of inequality worldwide and the educational system reproduces this social segregation (Baker & LeTendre, 2005). Public schools and partially subsidized schools recruit the majority of students' population (around 44% for public education, 48% for partially subsidized, 7% for totally private schools) with public schools recruiting those from more disadvantaged backgrounds. Social segregation manifests in an entrenched educational gap between public and private schools –with subsidized schools in between- that has been replicated from the time the national standardized testing was established in Chile. By comparing the instructional pattern prevailing in these different kinds of schools, we intend to assess whether the educational gap is related to differences in the instructional pattern implemented at these different schools or whether they rest on variables other than classroom interaction. In so doing, we attempt to tap into teachers' folk pedagogies (Olson, 2003). Specifically, the focus of this work is on the instructional principles that, in Chile, provide cultural and personal meaning to the task of teaching mathematics and how these principles translate into real teaching practices. Thus, we infer folk pedagogies from the teaching practices they inform, using video surveys and looking at those aspects of teaching practice that most influence the learning process: teacher talk and lesson structure (Preiss, 2010).

Methods

Participants. Schools from the main urban centers in Chile were randomly sampled and invited to participate. 18 public schools, 20 schools receiving mixed public and private funding, and 22 private schools accepted to be part of the study.

Teacher Talk Study

Coding Scheme. The final coding scheme for teacher talk included three broad categories: teacher lecturing, teacher questions and teacher follow-ups, which were coded separately. Teacher lecturing included three codes: Task-related lecturing, content-related lecturing, and metacognitive lecturing. Teacher questions included the following codes: Control, Inform, Implement, Opinion, Demand, Elaborate and Review. Teachers' follow-ups were coded as Monosyllable/Neutral. Repeat. Evaluate. Reformulate. Student codes mirrored those used for teachers and included a specific code for student initiated IRF sequences (elicitations).

Coding Procedure for teacher talk

Two independent raters coded a transcript of the first 10 minutes of each lesson. All of the consistency ($r > .75$) and consensus values ($p > .7$) were acceptable

Results

Table 1 shows the descriptive information for all the talk variables. Student codes are identified. All other codes are teacher codes. The dominant code for lecturing was task-related lecturing; the questions teachers make more frequently during their lesson openings are inform, control, and implement; finally, repeat follow-ups are the most frequent. As regards, student talk, the most frequent interventions are definitions, followed by implement, elicitations, and report. All of the other codes had less than 3 interventions.

A multivariate analysis was performed on the teacher and student talk variables. The grouping variable was school type. There were not significant differences between school types in all the teacher variables. However, there were significant differences in the following student variables: elicitations, $F(2,59) = 6.5$, $pF(3,123) = 4.6$, $pF(3,123) = 3.97$, $pF(3,123) = 3.5$, p

Lesson Structure Study

The final coding scheme for lesson structure followed closely the coding scheme used by the TIMSS 1995 and 1999 video surveys and included three broad categories: mathematical-work, mathematical-organization and interaction. Mathematical work codes include time allocated to introducing new content, practicing new content, and reviewing content. If students were performing mathematical work, the coding scheme distinguished between solving independent or concurrent problems, discussing problems solved previously and discussing non-mathematical content. Mathematical organization codes included time allocated to discuss goals or summarize the contents of the lesson. Interaction included codes for teacher-lead exchanges, student-lead exchanges, individual private-work, and group private-work. The full lessons were coded using The Observer. Consensus was estimated by the index of percent agreement using adjacent categories and kappa. All of the consensus values were acceptable ($p=.76$; $\kappa=.71$)

Results

Values indicate seconds of time allocation. Average duration of the lessons was 4161 seconds ($SD=951$). Teachers allocated most of the time of their lessons to the practice of content ($M=2409$, $SD=998$), followed by time allocated to introducing new content ($M=744$, $SD=790$). Whereas teachers allocated most of the time to practice, the kind of practice they performed involved practice with concurrent problems mostly ($M=928$, $SD=1179$). As regards the kind of interaction that shaped most of the lessons, teachers favored the development of teacher-lead segments ($M=2597$, $SD=1021$) instead of the independent exploration of contents either in groups or individually. Surprisingly, there were not many significant differences per type of school in the variables related to the structure of the class. "Summarizing the content" was significantly higher in public schools ($F=4.037$; p In terms of interactions in the classroom, no significant differences were found in any of the variables (teacher-led interaction, student-led interaction, private-group interaction, private-individual interaction and no-interaction).

Educational significance

These results reveal that teachers basically have the same classroom structure and type of interaction regardless of the type of school where they teach. It is worth noting that the only differences found were at the variables that measured student talk. Hence, the striking differences in academic performance among the different types of schools do not seem to be explained by differences in teaching activities or interactions. Therefore, the educational gap seem to be related to students' cultural capital instead of classroom dynamics.

The study has some limitations: the sample was not representative and there may be some self-selection bias. Still, the findings obtained are very similar to others seen in other Chilean classrooms using analogue methodologies.

PAPER PRESENTATION

The role of Language-in-use in Knowledge Building activities

Albert Walsweer, Rijksuniversiteit Groningen, Netherlands

In this paper the first results are being presented of an ethnographic research project that was carried out from 2007 until 2010 on ten small primary schools in a bilingual region in the northern parts of the Netherlands. The aim was to describe the consequences of an intervention that provides a shift from direct instruction to a pedagogy of participation and knowledge building in classrooms and how this relates to changing interactional patterns. Drawn from observational and video data, but also from interviews and questionnaires we found that all teachers involved, were able to provide more space for students to 'work with ideas' and making them aware of their language-in-use. We also found that a few teachers were able to change their interactional behavior from 'instructional' to 'dialogic teaching': they participated more often as a guide in knowledge building activities by summarizing, nominating and asking 'information seeking questions'. In these situations also different interactional roles of the children are being observed. They changed into initiating participants, who commented and criticized statements of the teacher and of the other students and proposed alternatives.

In this paper the first results will be presented of a research project in Dutch primary schools, regarding the improvement of the language use of the pupils in classroom interaction by an important change of the instruction model. The project was carried out on small primary schools in a rural area of Fryslân, which is a bilingual region in the northern part of the Netherlands. The aim of this research was to describe the consequences of an intervention that provides more space for knowledge building for students and the relationship with changes in (classroom) interaction and teacher beliefs. At the start in 2007, the schools worked in the tradition of direct instruction. Although this instruction model is proven to be highly effective in general, in situations where teachers work with several classes in one classroom, with different textbooks for every level, teachers confine themselves to give instructions, but are not able to use the possibilities to interact and discuss problems with children.

This research project draws on two theoretical perspectives on learning & knowledge building: Learning as a social or cultural & situated process (Lave & Wenger, 1991) and learning as a knowledge building process (Bereiter, 2002). The theoretical framework is complemented by theories about the central role of the use of language in learning activities (Wells, 2007) and being translated into a set of basic principles for a pedagogy of learning and instruction, which we used as a framework for teacher instruction and evaluation. These principles involve a switch from education seen as knowledge transmission, to education seen as a process of participation and knowledge building, characterized by dialogic teaching (Alexander, 2004) and scaffolding (Wood, Bruner & Ross, 1976). According to this we informed teachers how to make efforts of integrating language and learning into the process of cultural learning (Gee, 2008). We oriented them on the possibilities of language tasks and on the importance of 'exploratory talk' in peer interaction (Barnes, 1976) for knowledge construction.

Methodology:

Intervention and research data

The teacher training program that was attached to the intervention can be described as a guided reinvention of the role of language use in knowledge building. The training consisted of the continually negotiation of meaning through interaction, leading to topics for their own 'action research'. The intervention aimed to reinstate the teacher as a professional by giving him or her the opportunity to translate principles of the theoretical framework into two projects a year. Each project lasted for three weeks and consists of different stages. In the first couple of days, teachers discussed the topic of the project with the pupils and tried to challenge them to write down their first ideas. This is what we called the 'chat session'. Children were writing and discussing all the possibilities and were making a plan what to do, that means: how to get the needed information, how to analyze it and how to present it. In the next couple of weeks small groups of children carried out their ideas, by selecting, and reading texts, by interviewing informants, by discussing important points in their own group and with the teacher, by writing and by presenting the answers to their questions into written and oral products, which were presented to the other children, but also to their parents etc.

The role of the teacher was to help the children to integrate talking, reading and writing into the knowledge building activities and to make the children aware of their language-in-use. The methodology we used in this research is ethnographic (Freebody, 2003). This means that developments are described in their relevant cultural and social contexts and that they are used to improve the practices of users. Most important for this paper are the observational and video data of whole classroom and peer interaction, collected with five teachers and their pupils of grade 6, 7 and 8 during three years. Their process of change is also being documented by using data from written down notes from their 'action research', and from interviews and three types of questionnaires. This data asked for triangulation in the description of patterns in the process of change of teachers and their pupils. Findings It was found that the changing of most teachers followed a general pattern. In the first stage of the intervention, the teachers focused on the pedagogy of 'giving space to pupils' and switching from 'activity driven' to 'working with ideas'. In the second stage we found that teachers were engaged in all the 'language-based tasks' in the projects and being able to share this with the pupils and to improve the quality of language-in-use.

Changing teachers behavior in classroom interaction was the most difficult part of the intervention. Some teachers hardly changed their interactional patterns, but with others we saw the interesting changes we had expected. A qualitative analysis of the development of the interactional patterns in the project lessons of one teacher will be presented. It will be pointed out how the teacher manages to change her role in classroom discussions from an instructor who mainly puts 'known information questions' (Mehan, 1978) to a 'guide' who participates in knowledge building activities, by summarizing, nominating and asking clarification questions. In line with this finding, different roles of the children could also be observed: they changed from replying in short answers and waiting for an evaluation of the teacher into initiating participants, who commented and criticized statements of the teacher and of the other students and proposed alternatives.

PAPER PRESENTATION

Guided Cognition homework increases mathematics learning for low and average ability students

William B. Whitten II, Fordham University, United States; Mitchell Rabinowitz, Fordham University, United States; Sandra E. Whitten, Fordham University, United States

Our focus is on learning in unsupervised environments (represented by most homework). Guided Cognition structures study tasks to guide the learner to engage in specific, observable cognitive events. These events are hypothesized to elicit underlying theoretical cognitive processes that have been shown to improve learning.

Initial Guided Cognition experiments found that English literature students performed better on unexpected quizzes after Guided Cognition (GC) homework than after Traditional (T) homework (Whitten, Whitten, & Rabinowitz, 2006). More recent experiments demonstrated that Guided Cognition homework is also effective for learning mathematics. The current experiment was designed to evaluate the effectiveness of GC homework across mathematics ability levels. Low and average ability seventh-grade middle-school mathematics students participated.

“In-class homework” was given for two successive topics—multiplying fractions and mixed numbers, and dividing fractions and mixed numbers. Condition T problems were traditional story problems that required students to interpret and set up the problems, then to execute the calculations. Condition GC problems were identical, but also included one of four Cognitive Events that we have studied extensively in our previous research on learning English literature: relate to prior experience, visualize and illustrate, consider divergent answers, and role play. Within each ability level, half received T and half received GC homework.

An unexpected Review Activity (quiz) was given to measure students’ performance on problem interpretation and set up, and on calculation accuracy. Results clearly showed that low-ability and average-ability mathematics students performed better on story problems and numerical problems after GC homework than after T homework.

Our focus is on learning in unsupervised environments (represented by most homework). Guided Cognition structures study tasks to guide the learner to engage in specific, observable cognitive events. These events are hypothesized to elicit underlying theoretical cognitive processes that have been shown to improve learning.

Initial Guided Cognition experiments found performance on an unexpected three-day delayed quiz to be 21 and 18 percentage points better after Guided Cognition (GC) homework than after Traditional (T) homework, for average and advanced English literature students, respectively (Whitten, Whitten, & Rabinowitz, 2006). Subsequent experiments determined this advantage was not due to differences in time spent on the two forms of homework, to teaching that preceded the homework (Whitten, Rabinowitz, and Whitten, 2006a, 2006b), or to novelty (Whitten, Rabinowitz, and Whitten, 2007), and that Guided Cognition homework is effective for students from a wide range of ages (Whitten, Whitten, and Rabinowitz, 2009).

Our new experiments demonstrate that Guided Cognition homework is also effective for learning mathematics. The experiment we will report was designed to evaluate the effectiveness of GC homework across student ability levels.

Method

Participants.

Six classes of low-to-average ability seventh-grade middle-school mathematics students participated. Students were partitioned into two groups based on course performance, to create low and average ability groups.

Materials.

“In-class homework” materials were constructed for two successive topics—multiplying fractions and mixed numbers, and dividing fractions and mixed numbers. Condition T problems were traditional story problems that required students to interpret and set up the problems, then to execute the calculations. Condition GC problems were

identical, but also included one of four Guided Cognition Cognitive Events that we have studied extensively in our previous research on learning English literature: relate to prior experience, visualize and illustrate, consider divergent answers, and role play.

Review Activity materials were constructed to determine whether the GC experience helped students with problem interpretation and set up, or with executing calculations. The Review Activity consisted of 8 numerical problems that required only calculations and 8 story problems that required interpretation and set up, and calculations.

Design and Procedure.

Within each ability level, half received T and half received GC study activities. The mathematics topics were taught as usual, but evening homework was replaced by in-class homework to assure a high participation rate.

Following the teaching and in-class homework of the two topics, students were given a previously unannounced Review Activity consisting of 8 numerical problems and 8 story problems.

Results

Analysis of Review Activity (quiz) performance, without regard to problem type, confirmed a main effect of Condition, $GC > T$, $F(1, 92) = 7.925$, $p = .006$; a main effect of Ability Level, Average $>$ Low, $F(1, 92) = 12.577$, $p = .001$; and no interaction, $F(1, 92) = .108$, $p = .743$. Thus, GC facilitated learning similarly for low and average ability students.

This analysis gives more weight to story problems since each story problem was worth 5 points, and each numerical problem was worth 2 points. This analysis is, however, analogous to how an actual quiz might be graded, with more points based on more complex problems, and represents nearly a letter grade improvement due to GC, assuming that letter grades are 10 percentage points apart.

Condition means are given in Table 1 of the Appendix.

To equalize the weighting of story and numerical problems, point totals for each problem type were converted to percent correct values for each student. Analysis of in-class homework condition (T vs. GC) by Review Activity problem type (Numerical vs. Story) by Ability Level (Low vs. Average) revealed a main effect of condition, $GC > T$, $F(1,92) = 8.801$, $p = .004$; a main effect of problem type, Numerical $>$ Story, $F(1,92) = 239.281$, $p = .001$; a main effect of ability level, Average $>$ Low, $F(1,92) = 11.115$, $p = .001$, and no significant interactions. These results indicate that GC facilitated learning similarly for low and average ability students for both types of problems.

Condition means are given in Table 2 of the Appendix.

Summary

These results clearly show that mathematics students performing at low and average levels can benefit from Guided Cognition homework tasks. It is especially important to confirm that the lowest third of ability can benefit because these students are most at risk for failure.

To date, our reported research has demonstrated that the learning advantage of Guided Cognition study is not due to specific content, time-on-task, teaching effects, or novelty, and is obtained across a range of ages, abilities, and subject matters. Guided Cognition homework appears to be a very cost-effective instructional design strategy that can be implemented without extensive task analysis, new technology, new textbooks, or extensive training.

PAPER PRESENTATION

The role of perceptions on using learning tools

Norma A. Juarez Collazo, Katholiek Universiteit Leuven, Belgium; Jan Elen, Katholiek Universiteit Leuven, Belgium; Geraldine Clarebout, Katholiek Universiteit Leuven, Belgium

Evidence on tool use gives rise to concerns about the role of learners' perceptions when confronted with the opportunity to use tools. These concerns relate more specifically to the question whether learners are able to perceive differences in tool functionalities. This paper addresses this question by employing a psychomotor task which consists of building a LEGO[®] figure and two tools: a high functional one (step-by-step guideline) and a low functional one (a high-paced video). According to Perkins' conditions (1985), and the Technology Acceptance Model (TAM) (Davis, Bagozzi, & Warshaw, 1989), tools functionality gets first assessed. Rather than measuring students' perceptions through questionnaires (Davis, 1989), this study deduced students' perceived functionality from their tool choice behavior. It is assumed that learners select the tools they perceive to be most functional. Additionally, research indicates self-efficacy and metacognition as variables influencing tool use, the mediating role of these variables was also addressed.

Results reveal that the tools are functional, the experimental conditions with video (V), with guideline (G) and with guideline and video (GV) outperformed the control (C) condition without tools. However, contrary to the expectations, the (V) condition outperformed all other experimental conditions. The observations of tool choice behavior in the (GV) condition suggest that learners perceived the tools functionality because they all picked a tool. However, they were not sufficiently equipped to identify the video as the most functional tool. Concerning the learner variables, no significant effects were found. Theoretical implications and specifications for further research are discussed.

Introduction

Perkins (1985) suggested that there are three conditions to grasp learning opportunities: The learning opportunity has to be there. Learners should recognize the functionality of the learning opportunity and they should be motivated to grasp it. Tools that are added in a learning environment can be considered as such a learning opportunity (Clarebout & Elen, 2009). Translated this means that a tool has to be functional, that the learners have to perceive this functionality and that they have to be motivated to use them. However, it appears that even when tools are proven to be functional, learners do not recognize their functionality. They seem to think they know how to use tools when they actually do not, and/or they are not motivated to use them effectively (Kvavik, 2005). Additionally, research revealed that not only motivational factors play a role in tool use, but also cognitive and metacognitive learner-related variables (Aleven, Stahl, Schworm, Fischer, & Wallace, 2003). As illustrated in the Technology Acceptance Model (TAM), learners' perceived functionality of the tools will influence whether or not they will use the tool. While in previous studies, perceived functionality was measured through questionnaires, evidence suggests that perceptions are subjective and do not necessarily reflect reality (Davis, 1989). Thus, we approach these perceptions through students' actual tool choices. The assumption is that learners will choose to use the tool they regard to be most functional. Given Perkin's conditions (1985), we wonder whether learners are capable of distinguishing between a highly functional tool and a low functional one. Second, the question is whether this perceived functionality is affected by students' self-efficacy and metacognition.

Method

Participants

Participants were fifty-eight university students. Seventy-four percent was female, on average 23 years old ($SD=3.51$). Design and procedure A quasi-experimental design was used with four conditions: with guideline (G, $n=17$), with video (V, $n=17$), with guideline and video (GV, $n=17$) and without tools (C, $n=7$). In a first session, an adapted questionnaire on self-efficacy ($\alpha=.89$) (Lodewyk & Winne, 2005; Pintrich, Smith, Garcia, & McKeachie, 1991) and the Metacognitive Awareness Inventory ($\alpha=.71$) (Schraw & Dennison, 1994) were administered. In a second session, participants were randomly assigned to a condition. They were asked to construct a figure with LEGO[®] bricks (learning phase) while they could access the tool(s). Then, they completed a word puzzle as a distracter. Finally, they received the bricks back to build the figure again but without tools (performance). One tool was a purposely-lowered-in-functionality video, showing hands building the figure without verbal instructions, pausing or guiding; The other tool was highly functional step-by-step guideline. Perceived functionality was measured through observation of tool choice behavior. First, the tool(s) learners picked was recorded. Second, if they chose multiple tools, the order in which they used them was noted.

Data analysis

To assess the tools functionality, an ANOVA with condition as independent variable and performance as dependent variable was performed. For perceived functionality, an observation in the (GV) condition was conducted. With this data, two Kruskal-Wallis (due to the amount of participants) were conducted. One with tool choice as independent variable and performance as dependent variable; another with tool choice order as independent variable. For learner variables, we checked if there was a difference between conditions and variables with ANOVA's. Then we ran different Kruskal-Wallis in the (GV) condition to see if variables interacted in the perceived functionality.

Results

The ANOVA indicates that the tools were functional, $F(3,54)=5.53$ $p=.024$. The experimental conditions outperformed the control conditions, but contrary to the expectations, the Tukey post hoc test revealed the video was the most functional tool. The perceived functionality observation showed that all participants picked a tool. Fifty-three percent picked both guideline and video and 47% the guideline. None picked the video only. From the 53% that opted for both tools; 67% started using the guideline and finalized with the video, 11% chose the video then ended with the guideline, 11% used the video, then guideline, and video. The rest used the guideline, then video and finally guideline. Learners with only the guideline did slightly better. However, it was not significantly affected by the tool(s) they picked $H(1)=.60$ $p=.44$, nor by the tool choice order $H(3)=3.96$ $p=.27$. No influence was found of self-efficacy and metacognition.

Discussion

The results indicate that both tools were functional, but that the video was the most functional. Learners did identify the tools functionality but could not perceive the video as the most functional one. It seems that having two tools in the (GV) condition "disoriented" the learner (Iiyoshi & Hannafin, 1998). Zydney (2008, 2010) already suggested that combined tools were not found as effective as individual tools. Furthermore, the video tool design was on purpose lowered in functionality. Learners might have perceived this and interpreted the tool as not the most functional. Thus, they might have eluded it to avoid complications –cognitively speaking- (Aleven et al., 2003) and selected what they perceived as the most functional tool (guideline). Additionally, in line with previous research (Iiyoshi & Hannafin, 1998), tool familiarity might also have affected the tool selection. Lastly, tool flexibility may have been another element that also influenced learners' perceptions in the (GV) condition. Evidence indicates that even when learners get the chance to explore and have control over their learning, it may also overwhelm them (Shapiro, 2008).

Conclusion

This study contributes in different ways to research on tool use. It establishes a baseline for studies on tool use using psychomotor tasks and on measuring perceptions on tool functionality. It sets a need for more research that explores perceived functionality and the learner variables that might be mediated by this perception. It also suggests more research on tool features such as tool design and tool type influencing learners' perceptions. Finally, while the TAM certainly provides a base model for tool use, these findings point to the necessity for establishing a model that specifically refers to tool use.

PAPER PRESENTATION

Dealing with heterogeneity: Differentiated instruction in small rural schools in the alpine region

Robbert Smit, Pädagogische Hochschule St. Gallen, Switzerland

Rural areas in the alpine regions suffer from dwindling student numbers. Differentiated instruction could help to improve teaching culture to ensure adaptivity to heterogeneous mixed-age student groups. A survey with 162 teachers and 1180 students was conducted to examine the use of differentiating practises in the Eastern alpine regions of Switzerland.

Since the cross-sectional study is embedded within a school improvement project, we are interested about the linkages between school leadership, team and teacher. A SEM model for teacher data was constructed. It shows an effect from school leader on team culture but not on learning climate. Team culture seems to be the most effective variable, influencing climate and practice of differentiated instruction. Interestingly, there is no direct path from climate to practice of differentiated instruction. Further multilevel analyses show differences between schools for school leader, team culture and learning climate but not for differentiated instruction.

A multilevel path model, constructed with data from the student questionnaire, explores the relationship between the students' perception of teaching relating to differentiated instruction, the learning context and their motivation to learn. On class level we include their teacher's perception of the quality of his or her differentiated instruction. Teachers who differentiate their instruction foster students' motivation but not achievement. However, team collaboration, which positively influences differentiated instruction, favours student outcomes.

Introduction and research questions

Alpine and subalpine regions face a demographic decline, which threatens the survival of the rather small schools (Meusburger, 2005). Dwindling population numbers in rural regions are a key problem to schools in Europe (Hargreaves, Kvalsund & Galton, 2009), in the United States (Barley & Beesley, 2007) as well as in developing countries (Little, 2006).

The aim of our project "alpine schools" (www.schulealpin.org) is to provide research-based information for the local authority and policy makers as a help to ensure favourable conditions for teaching and learning in small classes with heterogeneous mixed-age groups. One well-known but not yet very well researched teaching concept for dealing with heterogeneity is differentiated instruction (Tomlinson et al., 2003). Our study focuses on the teachers' actual instruction habits of differentiation in the Eastern alpine regions of Switzerland. Besides we are interested in factors, which might support the use and quality of differentiated instruction.

This leads to the following research questions:

1. To what extent is differentiated instruction used in small rural alpine schools?
2. What is the influence of school factors on the use of differentiated instruction by teachers?
3. How do students perceive differentiated instruction?

Methodology

The sample includes 8 primary schools (grade 1 to 6) and 14 secondary schools (grade 7 to 9). All schools are situated in the rural alpine region of the Eastern part of Switzerland. 162 teachers (29 primary and 133 secondary school teachers) and 1180 pupils (154 primary and 929 secondary school students) responded to the questionnaires described below. For a part of the sample we could assign the data of a standardized achievement test in mathematics and German language to the survey data.

As instrument we used a questionnaire for teachers with 104 items and a few open questions. On teacher level a SEM-model was constructed with four latent variables: school leadership, pedagogical team culture (TC), differentiated instruction (DI) and learning climate. The latent variables were used for further analysis as second order factors. A parallel questionnaire for pupils with totally 72 items with similar and additional variables, e.g. learning context to describe the learning condition of the students, was constructed.

Results

The teachers stated that on average 38% (SD = 26%) of their weekly lessons were differentiated. Since our study is embedded within a school improvement project we are interested about the linkages between school leadership, team and teacher. The final SEM-model (fig. 1) shows an effect from school leader on team culture but not on learning climate. Team culture seems to be the most effective variable, influencing climate and practice of DI. In addition there is no direct path from climate to practice of DI. This implies that a good climate in school and classroom is not a precondition for implementation of DI, something teachers always use as an excuse for not practicing DI (Tomlinson, 2001). The final model has the following fit indices: chi-square = 79.37, df = 74, p = .31, CFI = .99, TLI = .99, RMSEA = .02. Further multilevel analyses show differences between schools for school leader, team culture and learning climate but not for differentiated learning.

A multilevel path model (fig. 2), constructed with data from the student questionnaire, explores the relationship between the students' perception of teaching relating to differentiated instruction, the learning context and their motivation to learn. On class level we include their teacher's perception of the quality of his or her differentiated instruction.

School type and teacher gender play no significant role and were eventually excluded from the final model. On student level only one – the times books are a topic at home – of three context variables is included in the final model. The fit indices are good: chi-square = 23.74, df = 7, p = .00, CFI = .96, TLI = .91, SRMRwithin = .05, SRMRbetween = .13, RMSEA = .05.

The quality of differentiated instruction as perceived by the teachers has a positive effect on the motivation of their classes ($\text{Beta} = .33$). Motivation in class is influenced by the learning context (e.g. school and classroom climate) ($\text{Beta} = .41$) and the context variable "books topic at home" ($\text{Beta} = .36$, $p = .08$). Teachers' and class' views on differentiated instruction correlate moderately ($r = .23$). Interestingly there is no significant path between perceived instruction and class' motivation in the final model.

On the individual level there is a strong relationship between perceived instruction and learning context ($r = .51$). Whereas there is a medium effect of learning context on student motivation ($\text{Beta} = .31$) relationship between student motivation and perceived instruction is low ($r = .18$). Finally there is some minor influence from the context variable "books topic at home" on student motivation ($\text{Beta} = .11$).

For about half of the sample, data from a standardised Mathematics and German language test was available to test for effects from differentiated instruction on students' achievement. DI shows no significant effect, neither on mathematics nor on German test results. Since DI is influenced by team culture (TC) a second model proofs whether TC influences achievement. Whereas TC shows a significant effect for Mathematics ($\text{Beta} = 1.65$), the effect for German is not significant due to the high standard error ($\text{Beta} = 2.05$).

To conclude, in our study we couldn't find any differences between schools regarding a culture of differentiated instruction, but there is some variation between teachers. The teachers' practice of differentiated instruction is over all not very elaborated. In our model there is no direct path between school leadership and DI, but there is an indirect one via team culture. Hence, the influence of a school leader for school improvement is limited without the involvement of the school team. As it was suggested by research, differentiated instruction seems to have positive influences for student motivation. Our model shows effects at class level and to a lesser extent at student level. However, this study could not confirm the positive results from DI on students' achievement.

PAPER PRESENTATION

Does the Testing Effect Apply to Learning from Worked Examples?

Tamara Van Gog, Erasmus University Rotterdam, Netherlands

A recent study showed, in line with the worked example effect, that for novice learners instruction consisting of examples only or of example-problem pairs was more effective than instruction consisting of problem-example pairs or problem solving only. There were no differences in mental effort invested or learning outcomes attained between the examples only and example-problem pairs conditions. However, only an immediate test was used in this study. Example-problem pairs allow students to retrieve what they have learned from the example during problem solving, and research on the testing effect has shown that retrieval is more effective for long-term retention than restudying, which the examples only condition does. So, if the testing effect would apply to learning from worked examples, one would predict that while there may be no differences between examples only and example-problem pairs at an immediate test, the example-problem pairs would lead to higher delayed test performance. This hypothesis was investigated with 27 university students learning about electrical circuits troubleshooting from examples only ($n = 13$) or example problem pairs ($n = 14$). In contrast to the prediction based on the testing effect, results showed that participants in the examples only condition performed better on the delayed test. Moreover, they had to invest less effort during learning.

Research on the worked example effect (Atkinson, Derry, Renkl, & Wortham, 2000) has shown that for novice learners, a heavier reliance on studying worked examples than on problem solving is more effective and efficient for learning. A recent study by Van Gog, Kester, and Paas (in press) showed that both example study only and example-problem pairs, in which example study is alternated with problem solving, were more effective for novices' learning than problem-example pairs or problem solving only. There were no significant differences in learning outcomes between the examples only and the example-problem pairs conditions, nor in invested mental effort. However, Van Gog et al. used an immediate test only. Based on research on the testing effect, one might expect the example-problem pairs condition to outperform the examples only condition after a delay.

The testing effect (Roediger & Karpicke, 2006a) has been demonstrated with word lists or texts, and recently also with multimedia learning materials (Johnson & Mayer, 2009), but –to the best of my knowledge– never with worked examples. It demonstrates that after an initial study opportunity, testing is more effective for long-term retention than restudying. At an immediate retention test after 5 minutes, there may be no difference or restudy may even be

more effective, but after a delay of one week, the testing condition outperforms the restudy condition (e.g., Roediger & Karpicke, 2006b).

Given that example-problem pairs allow learners to retrieve and apply what they have just learned from an example, whereas examples only allow for restudying, the testing effect might be expected to apply to worked examples. Therefore, the present study investigated effects of examples only and example-problem pairs on learning after 5 minutes and 1 week.

Method

Participants and Design

Participants were 27 university students (5 male; age $M = 20.67$, $SD = 4.18$), mostly enrolled in Psychology (3 were enrolled in other programs). They were randomly assigned to conditions (Examples only: $n = 13$; Example-problem pairs: $n = 14$). None of them took science classes in the later years of secondary education.

Materials and Procedure

The materials used concerned parallel electrical circuits troubleshooting tasks and were identical to those used by Van Gog et al. (in press); only an equivalent alternate version of the posttest was added. Participants first completed a conceptual knowledge pretest consisting of seven open-ended questions on troubleshooting and parallel circuits principles. In the learning phase, they either studied four worked examples, or studied an example followed by a problem to solve twice. The tasks were the same in both conditions, the only difference was that in the example-problem pairs condition tasks 2 and 4 did not have a worked-out solution. A filler task of approximately 5 minutes followed the learning phase, after which participants completed the immediate posttest. One week later they completed the delayed posttest. There were two equivalent versions (A and B) of the posttest (max. score on each test: 8 points), which each consisted of two troubleshooting problems. These were retention tasks; no new conceptual or procedural knowledge was required to solve them, only different values of voltage, current, and resistance were used. Half of the participants received version A for the immediate and version B for the delayed test, while the other half received version B for the immediate and version A for the delayed test. After each task in the learning and test phases, participants rated the amount of mental effort they invested on the 9-point rating scale developed by Paas (1992).

Results

There were no significant differences in pretest performance between the conditions.

Mental effort invested in the learning phase was significantly lower in the examples only condition ($M = 4.5$, $SD = 1.51$) than in the example-problem pairs condition ($M = 6.91$, $SD = 1.27$), $F(1,25) = 20.27$, $p = .000$. There were no significant differences in mental effort invested in the immediate or delayed posttest.

Performance on the immediate posttest did not differ significantly between conditions. Performance in both conditions significantly decreased from the immediate to the delayed posttest, $F(1,25) = 9.28$, $p = .005$. On the delayed posttest, however, the examples only condition ($M = 5.35$, $SD = 1.66$) outperformed the example-problem pairs condition ($M = 4.39$, $SD = 1.78$), $F(1,25) = 4.83$, $p = .037$.

Discussion

Based on the findings concerning the testing effect, one would have expected the example-problem pairs condition, in which students first studied an example and then had a chance to test their knowledge by attempting to solve an equivalent problem, to outperform the examples only condition on the delayed posttest. However, our results showed an opposite pattern, with the examples only condition performing better on the delayed posttest. Future research should attempt to address whether this could be due to differences in the nature or complexity of learning to solve problems compared to learning word lists or texts.

PAPER PRESENTATION

Learning And Instructing With Objects: Tutor-student interaction in university dental training

Lewis Hyland, King's College London, United Kingdom

In this paper we explore the interaction which occurs in dental training around mannequin simulators and more specifically, the significance of the passing of objects from tutors to students during training conversations. Through the analysis of video data of naturally occurring interaction, these more mundane aspects of interaction are found to be critical to the organisation of tutor-student interaction in dental training. I begin by investigating the ways in which smaller objects used for teaching, such as individual teeth, the jaw, and x-rays, are exchanged between tutors and students. This is then expanded to explore the significance of exchange for the training encounter, in terms of how students display and tutors assess understanding. Finally, we review the relevance of the analysis for (i) our understanding of the interactional organisation of tutor-student conversations in dental training and (ii) the practical implications for the design of new simulator technologies (<http://www.haptel.ac.uk>). The paper is organised around the analysis of audio-visual recordings of naturally-occurring episodes of dental training. The methodological orientation of the paper is drawn from ethnomethodology and conversation analysis.

As part of the ESRC/EPSRC hapTEL project (<http://www.haptel.ac.uk>) which is designing, developing, and evaluating haptic dental simulators, this paper displays findings from an investigation of interaction with and around existing mannequin dental simulators which are currently being used for teaching. It takes precedence from the burgeoning area of research known as workplace studies which has revealed that; "there is more to the design and deployment of complex systems than simply identifying new functionalities for computer systems." (Luff et al. 2000: xii). It is also valuable to gain an understanding of learning and instruction using existing novel technologies, by analysing practices with and around those technologies (Jewitt 2006). This is because the success of technology is only possible if it is designed for the specific requirements of the users. To discover and analyse these existing practices, the methodological orientation is drawn from approaches in ethnomethodology and conversation analysis as applied to video data (Heath et al. 2010), which allows me to unpack the organisation of social interaction in dental training conversations. The paper is organised around the analysis of audio-visual recordings of naturally-occurring episodes of dental training. Full ethical approval for the study was secured from the University ethics committee, and all participants provided written consent for the collection, analysis and presentation of data.

Central to the focus of the paper is the exploration of the passing of objects which is a common occurrence found in the data. When around the simulator objects are often passed from tutor to student, and vice versa, at certain points in the training conversations. This is an interesting feature of instruction and learning because of the way the possession of the object needs to be negotiated. In this paper we explore this issue, notably focusing on how the passing of objects is achieved, and the relevance of these moments of exchange for the co-participants. Through the analysis of naturally occurring data, we are able to highlight the interactional organisation of exchanges involving smaller objects used for teaching, such as individual teeth, jaw, and x-rays. This is then expanded upon to reveal notions about the concept of exchange as a component in learning. By exploring the significance of the possession of an object in the changing of a topic or closing moments of a training conversation, the "terminal exchange" (Sacks 1973), the pedagogic relevance of such acts for both tutor and student is identified. Finally, we review the ways in which members create a context of dental training, and the responsibility hand held objects have in the process of learning dentistry more broadly.

The paper contributes then in three ways. (i) Analytically; In terms of identifying the ways conversation and body movement is interrelated into the environment, or 'furnished frame' (Goffman 1971: 284), in which one is situated. This involves contributing to our understanding of how the passing of objects is achieved sequentially in relation to sense making acts. (ii) Empirically; Despite there being a longstanding interest in the study of medical training, dentistry is massively underrepresented (Fugill 2005). Therefore, this study sheds light on dental education specifically, and begins to fill the gap in the literature on dentistry in the social sciences. Further to this, this work

relates to our understanding of learning and instruction with objects more broadly, which may have relevance for the vast array of other learning environments in which objects play a part. (iii) And finally, this study has a practical application by contributing to our understanding of what types of interactions will need to be supported and/or provided for by new forms of training simulator.

PAPER PRESENTATION

Non-present Talk in Early Social Interaction at Home; Relevance for Literacy Development at Age 7

Akke De Blauw, Amsterdam Center for Language and Communication, Universiteit van Amsterdam, Netherlands; Anne Baker, Amsterdam Center of Language and Communication, Netherlands; Judith Rispens, Amsterdam Center for Language and Communication, Netherlands

Use of non-present talk in early adult-child interaction - discussing what is perceptually not here and now - promotes later literacy development (Ninio & Snow 1996; Tabors & Dickinson 2001). Information on the development of non-present talk is missing. This paper presents longitudinal data of an observational study of three children in interaction with their parents and focuses on the dimensions of non-present talk in spontaneous adult-child interaction in relation to later language proficiency. Three monolingual children were followed. Spontaneous interaction sessions from age 1; 9 to 3; 9 were analyzed on the development of non-present talk-interactions and the roles of adults and children in these interactions. At age 7 narrative ability was assessed. Results indicate that non-present talk interactions takes place in 10 -20% of the time. Deeper analysis reveals a variety of subcategories that are increasingly refined over time. Non-present talk interactions heavily depend on the adults. At age 7 all three perform well on the narrative ability tasks. Although there are differences in language proficiency. The findings highlight the importance of promoting high quality interactions on non-present topics in educational settings. Implications are discussed in relation to the school curriculum and teacher professionalisation on interaction strategies.

This paper focuses on the importance of high quality interaction in children's early years at home and in daycare centers for language and literacy education in primary school. Learning decontextualized features of ongoing face-to-face interaction are assumed to be necessary features in order to be able to report real or fictional events (Ninio & Snow 1996; Tomassello 2003). The use of non-present talk in early adult-child interaction - discussing what is perceptually not here and now - promotes later language and literacy development, especially narrative ability (Tabors & Dickinson 2001, Uccelli et al. 2005). Although we know that non-present talk starts in early adult-child interaction (Uccelli 2009, Hendrichs 2010) we still lack a clear and uniform definition of non-present talk and detailed information on what might be crucial developments from age 2 to 4 in relation to later school competencies.

This paper presents data of a ten year videotaped observational study of three children in interaction with their parents and focuses on the following research questions:

- (1) How does non-present talk emerge in parent-child interactions at home, and how does it develop up to age 4?
- (2) What are the prospective relations to the children's narrative ability at age 7?
- (3) What might be educational implications for school settings?

Method

Data from longitudinal case studies. Three monolingual, Dutch-speaking children in two middle class families, a boy and two twin-sisters were followed, three-monthly, from age 0 onward. Spontaneous parent child interactions in a variety of everyday activities were video recorded and the parents were interviewed. For this paper 14 sessions of 60

– 180 minutes between children's ages 1; 9 and 3; 9 were analyzed on the use and development of non-present talk-interactions and the roles of adults and children in these interactions.

All videos were analyzed and non-present talk segments were selected. These segments were fully transcribed, together with a description of the context. Analyses took place on quantitative and qualitative aspects of non-present talk in comparison to present talk, on the precise nature of non-present talk, and on the scaffolding role of the adults. At age 7 narrative ability was assessed with two narrative tasks: Mercer-Mayer's Frog story and Renfrew's Bus story.

Results

From age 1;9 on parents and children are engaged in non-present talk interactions, for 10-16% of the time. At children's age 3;9 for 12 -25% of the time. At 2;9 however non-present talk is much higher than at 3;9. More detailed analysis reveals that this result is due to one of the non-present talk subcategories: fantasy talk. Non-present talk reveals to contain subcategories such as discussing past events, discussing future events, fantasy talk, discussing knowledge. These subcategories gradually emerge and are increasingly getting refined over time. Up to 3;9 initiating moves as well as sustaining moves heavily depend on the adults. For fantasy talk however children initiate more frequently.

When the children are seven years old, all three children perform comparably well on the narrative ability tasks. Although there are differences in language proficiency, on syntax and vocabulary.

What had been found are relationships between individual developmental pathways and parental scaffolding strategies. Quantity of early child language production has an impact on the quality of parental feedback.

Educational implications

The children of this longitudinal study were engaged in non-present talk interactions from an early age on. On a regular basis they experienced and developed skills in discussions on past events, future events, fictional events, knowledge, memory. And so they got acquainted with the necessary features in order to report real or fictional events (Ninio & Snow 1996). Research on non-present talk in other settings, such as teachers at daycare centers (De Haan et al. 2009), in different cultures (Tabor & Dickinson 2001; Melzi & Ely 2008) and at home in comparison to primary education (Henrichs 2010) indicate great variety in the use of decontextualized interactions in the communication between adults and children.

The reported differences highlight the importance of promoting these high quality interactions on topics that are not-present early in educational settings. The findings are discussed in relation to primary school curriculum and the implications for teacher professionalisation on interaction strategies.

PAPER PRESENTATION

School's pedagogical practices as mediators for student participation and on task behaviour

Kirsi Pyhalto, Helsinki University, Finland; Suvi Krista Westling, University of Helsinki, Finland; Janne Pietarinen, University of Eastern Finland, Finland

Research on learning and instruction has shown that pedagogical practices guide and re-shape student learning and behavior in different ways. There is also evidence that by using collaborative and activating instruction, higher achievement, better improvement in conceptual and application skills, better mastery of goal orientation and more positive social relations have been promoted than by preferring learning by rote, competition or individual study.

This study aims to gain better understanding about the kinds of pedagogical practices pupils participate as part of their everyday school life. The classroom practices are analyzed in terms of what kind of forms, opportunities, restrictions and challenges for pupils' participation they provide. Data were collected with the semi structured observation. Semi structured observations included structured observations on classroom interactions, initiatives and boundary crossings made during the lesson and classroom climate and open-ended descriptions of classroom activities.

Classroom practices included teacher- and subject-matter oriented activities as well as more learner-centered, activating and collaborative activities that stimulated pupils to take responsibility for their own studying. Moreover preliminary results suggested that pupils made both more initiatives and on task boundary crossings in co-regulated and pupil regulated lessons. Results also suggested that pupils are not only influenced by the pedagogical practices

adopted by teachers. They also actively direct and re-direct their behaviour as well as the practices they participate in by making initiatives and by occasionally bringing their reality outside the classes into the lessons.

Learning and studying are situated in the pedagogical practices of school. Accordingly, pupils' success in studying is affected both by the quality of pedagogical practices as well as by their opportunities and abilities to participate in school activities (Zhao & Kuh, 2004). Research on learning and instruction has shown that pedagogical practices guide and re-shape student learning and behavior in different ways. Pedagogical practices adopted by teachers have been reported to have affected for example pupil cheating and help-seeking behavior in classes (Anderman & Midgley, 2004; Murdock, Hale & Weber, 2001). There is also evidence that by using collaborative and activating instruction, higher achievement, better improvement in conceptual and application skills (Gillies & Ashman, 2003), better mastery of goal orientation (Midgley, 2002) and more positive social relations (Blatchford, Baines, Rubie-Davies, Bassett, & Chowne, 2006; Tolmie, Topping, Christie, Donaldson, Howe, Jessiman, Livingston & Thurston, 2010) have been promoted than by preferring learning by rote, competition or individual study. Moreover, there is some evidence that promoting complex cognitive communication, for instance by using project-, inquiry- and problem based learning, stimulates the students' academic performance as well as the quality of peer interaction (Gillies & Ashman, 2003; Prince, 2004; Topping, Peters, Stephen & Whale, 2004). Yet, not that much is known about the variety of pedagogical practices pupils participate during their school day, especially in subject teacher system. This study focuses on exploring pedagogical practices pupils participate in a Finnish lower secondary school.

Aims

This study aims to gain better understanding about the kinds of pedagogical practices pupils participate as part of their everyday school life. The classroom practices are analyzed in terms of what kind of forms, opportunities, restrictions and challenges for pupils' participation they provide and how pupils engage in the practices. The study is part of a larger national research project: "Learning and Development in Comprehensive School" (2004-2009).

Methods

Data were collected with the semi structured observation. Observations were carried out during the spring 2010, in two 7th grade classes, in Finland. Observations were carried out in two periods each lasting for a week (altogether 4 weeks). Trained research assistants observed all the lessons during the period (altogether 120 lessons and over 20 subject teachers). Semi structured observations included structured observations on classroom interactions, initiatives and boundary crossings made during the lesson and classroom climate and open-ended descriptions of classroom activities. At first all the lesson reports were content analyzed to identify the variety of pedagogical practices carried out in the lessons. The analysis resulted three basic-categories: pupil regulated; teacher regulated and co-regulated activities. After this, the quality and quantity of initiatives within each basic-categories were coded. Also boundary crossings made by pupils and subject teachers were analyzed to find out if pupils' and teachers' experiences outside the classroom were utilized during the lessons.

Results

Results suggested that pupils face different kinds of pedagogical practices in subject teacher system. Classroom practices included teacher- and subject-matter oriented activities as well as more learner-centered, activating and collaborative activities that stimulated pupils to take responsibility for their own studying. However, teacher centered activities were the most dominant classroom practice.

Further investigation showed that there was also variation in the ways in which pupils engaged in the classroom practices. Pupils, for instance, made different kinds of initiatives concerning learning task, peers and teacher-pupil interaction. Both teachers and pupils also made boundary crossings by bringing their previous knowledge and experiences from informal settings into the classroom interaction. Moreover preliminary results suggested that pupils made both more initiatives and on task boundary crossings in co-regulated and pupil regulated lessons.

Discussion

Results suggested that pupils participate in a variety of pedagogical interactions and activities in their everyday school life and, indeed, during a single school day. Accordingly, they are exposed to various pedagogical subcultures and expectations, they engage in different kinds of peer groups and they adopt various roles in the school's dynamic and complex multilayered community of practice (Wenger, 1998). Moreover results suggested that pupils are not only influenced by the pedagogical practices adopted by teachers. They also actively direct and re-direct their behaviour as well as the practices they participate in by making initiatives and by occasionally bringing their reality outside the classes into the lessons. However, based on our findings it seems that pupils' opportunities for active agency and collaboration are still often quite limited in the pedagogical practices of classrooms.

PAPER PRESENTATION

Assessing lesson structures via videotaped lessons of Dutch and Indonesian secondary school teachers

Ridwan Maulana, GION - University of Groningen, Netherlands; Marie-Christine Opdenakker, University of Groningen, Netherlands; Kim Stroet, University of Groningen, Netherlands; Roel Bosker, University of Groningen, Netherlands

This study investigated the structures of Dutch and Indonesian secondary school lessons and explored between classes differences in terms of the structures of lessons across the school year. A procedure to assess lesson structures was developed which revealed six lesson segments characterizing the general structures of lessons in both countries. Twelve Dutch and 12 Indonesian mathematics and EFL teachers volunteered to participate in the study. Each class was videotaped 12 times across four different occasions and three videotaped lessons of each class were selected for analyses.

The preliminary results (of Dutch videotaped lessons) showed that all six segments were found. Of all six elements, reviewing and student work time appeared to be the most prevalent segments over time. Differences between homogeneous (high ability track) and heterogeneous (mixed ability track) classes regarding reviewing and student work time were found. Teachers in homogeneous and heterogeneous classes allocated much more time reviewing extensively across time. With respect to student work time, the results illustrated that both teachers in homogeneous and heterogeneous classes spent relatively more time having contact with individual/small group of students than having contact with the whole class. In general, teachers in heterogeneous classes dedicated more time making contact with individual/small group of students than their colleagues in homogeneous classes. On the contrary, teachers in heterogeneous classes spent less time making contact with the whole class than their colleagues in homogeneous classes.

Rationale

Research suggests that student engagement decreases during the first year of secondary education and that a decline in the quality of learning environments (structure, autonomy support and teacher involvement) plays an important role (Opdenakker & Maulana, 2010). Particularly, this research reveals that the structure support is higher in homogeneous classes (high ability track) compared to heterogeneous classes (mixed ability track) over time. Moreover, this study unravels that academic engagement decreases over time, with a higher rate in homogeneous classes compared to heterogeneous classes, but this decrease becomes less pronounced over time in homogeneous classes compared to heterogeneous classes.

Other studies indicate that the quality of teacher-student interpersonal relationships determines the decline of student motivation across the school year (Maulana, Opdenakker, den Brok & Bosker, 2010; in press). Furthermore, research indicates that the quality of instructional behaviour plays a significant role in the decrease of student motivation across the school year (Opdenakker & Maulana, 2010). It is unclear about the reasons for which the quality of teacher-student relationships deteriorates over time. Hence, a more detailed investigation of classroom practices is needed. Previous research indicates that assessing lessons according to type of situations can be of significant contribution (den Brok, et al. 2004) and that analysing lesson structures offers a promising account for understanding the complex interplay between teaching and learning outcomes (Savola, 2008). On this basis, this study was designed to investigate lesson structures that are common in Dutch and Indonesian secondary education and to explore the role of class type (homogeneous; high ability track vs. heterogeneous; mixed ability track) in explaining differences between classes across the school year.

Research questions

- (1). How do Dutch and Indonesian secondary school teachers configure the lesson across the school year? Specifically, how do they distribute time across lesson segments over time?
- (2). Are there differences between homogeneous and heterogeneous classes with respect to structuring the lessons across the school year?
- (3). Are there differences between Dutch and Indonesian teachers regarding the lesson structure over time?

Method

Sample

Twenty four Dutch and Indonesian secondary school teachers volunteered to participate in this longitudinal study. Each class of the teachers was video-taped 12 times across the school year.

Measure

A Coding scheme to analyze types of lesson segments was developed. The scheme focuses on the pedagogical function of lesson structures. An inductive process approach was applied including review and re-review lessons. The coding scheme consisted of four categories and within categories lesson segments were determined. Those categories were: Opening (Introduction and Review), Main content (New content and Student work time), Closing and Other.

Procedure

The final coding scheme was used to analyze 72 video-taped lessons from 24 teachers. Two raters with knowledge of lesson structure analysis coded about 15% of the videotaped lessons to establish inter-rater reliability. Cohen's Kappa of .89 was reached, indicating a satisfactory level of agreement between the coders.

Data analysis

Descriptive and multilevel analyses will be applied to answer the research questions.

Preliminary findings (Dutch data)

In general, the Dutch secondary school teachers seem to spend most time on student work time during the lesson over time. Reviewing material appears to be the second most prevalent segment characterizing Dutch secondary classrooms, followed by introducing new content. Merely less than 5% of class time is allocated for giving introduction and closing the lesson (Figure 1).

Figure 2 displays the comparison between homogeneous and heterogeneous classes regarding distribution of time for all six lesson segments. The results show that teachers in homogeneous classes tend to allocate more time on student work time segment, while their colleagues in heterogeneous classes spend more time on review segment. In both type of classes, teachers seem to spend time about the same on introducing new content. In addition, heterogeneous class teachers allocate more time on introduction and on closing segments.

An independent-samples t-test was conducted to compare relative proportion of time spend for the six segments between the two class types. The results show that differences in review ($t = -2.42, p = .03$) and student work time ($t = 3.11, p = .01$) between homogenous and heterogeneous classes are statistically significant.

A more detailed inspection of the Review segment in both class types (Figure 3) reveals that teachers in both class types allocate much more time reviewing extensively across time. Interestingly, teachers in heterogeneous classes never do short review, while their colleagues in homogeneous classes allocate little time to do short review over time. Figure 4 displays that all teachers spend relatively more time having contact with individual/small group of students than having contact with the whole class. In general, teachers in heterogeneous classes spend more time making contact with individual/small group of students than their colleagues in homogeneous classes. On the contrary, teachers in heterogeneous classes spend less time making contact with the whole class than their colleagues in homogeneous classes. Results from Indonesia will be included in the full paper.

Significance of research

The present study provides empirical evidence regarding common teaching practices in the Netherlands and Indonesia in terms of lesson structures that may reveal the importance of some lesson segments for student outcomes and may indicate some effectiveness-enhancing factors within lesson structures. This study may offer cues to improve the effectiveness of teachers and the quality of learning and instruction in terms of the organization of lesson structures. In addition, a new and promoted approach to analyze teaching practices was used: teaching practices were studied within a longitudinal design using a video-based approach paying attention to changes over time and to differences between classes.

PAPER PRESENTATION

Improvable objects, dialogue and the Interactive Whiteboard

Alison Twiner, The Open University, United Kingdom; Caroline Coffin, Open University, United Kingdom; Karen Littleton, Open University, United Kingdom; Denise Whitelock, Open University, United Kingdom

This presentation will focus on how a now-common educational tool – the interactive whiteboard (IWB) – can be orchestrated with talk to resource and evidence progressive construction of knowledge. We will outline a major pedagogic challenge teachers face, of how to support continuity and cumulation of learning experiences, and how use of psychological and technical tools (such as talk and the IWB) can be oriented to address this challenge. We will highlight some technical and pedagogic affordances of the IWB, including: supporting teacher planning of lessons and flexibility within them; potential for building a pre-prepared but 'improvable' frame of reference that can be viewed, reviewed and revised; and that changes can be saved or discarded as appropriate. Our research adopts a sociocultural approach to teaching and learning, based on a substantial data set collected from UK primary schools. We draw particularly on sociocultural principles of talk as the central meaning-making resource, and knowledge as mediated and discursive, co-constructed in interaction. In our Sociocultural Discourse Analysis we utilise the concept of the 'improvable object' (Wells, 1999).

The IWB is one mediational device on which users can project and play with 'objects' to resource activities. How talk is used to bring IWB resources or activity into focus, and to suggest, query or narrate physical interaction with projected resources, will be central in our interpretations. This presentation is of significance in addressing the multimodal orchestration of available resources, with a temporal view of how 'improvable objects' are used in the knowledge construction and stabilisation process.

This presentation will focus on how a now-common educational tool – the interactive whiteboard (IWB) – can be orchestrated with talk to resource and evidence progressive construction of knowledge. We will outline a major pedagogic challenge that teachers face, that of how to support continuity and cumulation in respect of learning experiences, and how use of psychological and technical tools (such as talk and the IWB) can be oriented to address and ease this challenge. We will highlight some of the technical and pedagogic affordances of the IWB, including: supporting teacher planning of lessons and flexibility within them; potential for building a pre-prepared but 'improvable' frame of reference that can be viewed, reviewed and revised; and that changes can be saved or discarded as appropriate. Our research is underpinned by a sociocultural approach to teaching and learning and is based on a substantial data set collected from UK primary schools. We draw particularly on the sociocultural principles of talk as the central meaning-making resource, and of knowledge as mediated and discursive, co-constructed in interaction.

Our presentation makes a significant practical contribution, addressing the orchestration of complex technologies that are now more common in teaching-learning environments but being used in new ways to offer a multimodal learning experience. It is important to explore how these digital resources are entering the knowledge construction processes in contemporary teaching and learning over a continuous series of lessons. This links to the theoretical significance of our presentation, as we explore how temporal challenges were addressed, using a sociocultural framework to view the role of 'improvable objects' (Wells, 1999) in this construction and 'stabilising' of knowledge (Ludvigsen, et al., 2011) within class interactions. Adopting a case study approach, we present data collected over four weeks in the 2009/10 academic year. Lessons were in a London primary school with a Year 2 class (aged 7-8 years), and covered the Great Fire of London history topic. The class had two lessons each week on the topic, one in the hall and one in the classroom. Both learning environments had a wall-mounted IWB. All eight lessons were video-recorded by one of the presenters. Consent was requested from pupils and their parents before pupils were recorded. Teachers were also interviewed before and after the series of lessons. A focus group was carried out with a small group of pupils after the eight lessons. In our Sociocultural Discourse Analysis we utilise the theoretical concept of the 'improvable object' (Wells, 1999).

The IWB is one mediational device on which teachers and learners can project and play with 'objects' to resource their activities. How talk is used to bring IWB resources or activity into play, and to suggest, query or narrate physical interaction with or modification to projected resources, will be central in our interpretations. In analysing this data, we

addressed the general research question: How do teachers and pupils use discursive and technological tools, to foster continuity and cumulation between learning experiences? From this we oriented to our more detailed research question: How do teachers employ talk and IWBs in developing improvable objects between themselves and their pupils, as progressive and historical records to resource developing understanding? In addressing these questions and presenting our findings, we will share video footage of the lessons. We will illustrate the teacher's use of one particular IWB resource across the eight topic lessons. As part of the Great Fire of London topic, the teacher addressed the learning objective 'locate the event on a timeline' largely through the discursive activity around and physical interactions with a focal pre-prepared IWB slide. We will demonstrate how displaying the slide –a timeline with numbered century markers – offered a means to contextualise the historical event. It also became a quick orientation cue to pupils in each lesson, encouraging them to think about the Great Fire and when it happened. This consistent but initially sparse resource was annotated in most lessons. Viewing the timeline slide as an 'improvable object', both temporary and permanent 'improvements' to the slide were made across the eight lessons. This demonstrates the IWB's capacity to support such flexible use.

Analysis revealed that talk around use of the resource remained crucial across the eight lessons, in keeping the depicted content relevant. This was true whether or not annotations were made, removed, or left as they were. We will demonstrate how pupils' questions and responses to the teacher's introduction of the topic offered a perhaps unexpected but equally important opportunity for the teacher to offer targeted and meaningful support to his pupils. The technical capacity of the IWB and teacher's knowledge of the topic and of his pupils (and of the technical capacity of the IWB) enabled him to improvise and be flexible in his verbal and written replies. Thus verbally and visually the class were building a context in which they could learn more about the topic. We will show how through the series of lessons the pupils refined their verbal expressions and historically-contextualised understanding of when the Great Fire of London happened. This was evident as they offered key information themselves, and fewer annotations were made to the slide. Thus the scaffold of the timeline slide which was initially used by the teacher to bring salience to key points both visually and verbally, provided a catalyst for pupils' own curiosity and concerns to check understanding. Subsequently direct use of the visual resource was faded because it was no longer needed as a key reference point. Through pupils participating in the verbal activity around the mediational IWB slide, they had constructed and appropriated a locally progressive discourse for some of the key but related facts about the historical event. Therefore through continuity of resource and activity, with sufficient change to allow cumulation of contextual information added to the progressing discourse and display, the teacher made effective use of the tools at his disposal in covering the stipulated learning objective.

PAPER PRESENTATION

Learning pathology in a virtual microscopy environment: a naturalistic experiment

Markus Nivala, University of Turku, Finland; Roger Saljo, Goteborg University, Sweden; Hans Rystedt, University of Gothenburg, Sweden; Erno Lehtinen, University of Turku, Finland

The objective of this paper is to explore how students' reasoning is shaped by collaborative use of virtual microscopy and different levels of visual and textual scaffolding.

Fifteen pairs of second-year medical students attending an introductory course in pathology examined six authentic tissue samples using a virtual microscopy application with different level of scaffolding in each case: from fully annotated slides with visual-textual cues to visual cues only or no cues whatsoever. Students' actions were videotaped and their written answers (findings and diagnosis) were assessed by an experienced pathologist.

The number of diagnostically relevant findings in student's answers increased along with the level of scaffolding. Yet, mere visual cues did not reduce the number of false findings, whereas cues with both textual and visual information reduced them remarkably. Furthermore, without cues, the false findings arise mostly while examining irrelevant features of the slide. The video recordings revealed a certain hierarchy of mistakes. Firstly, due to faulty or insufficient examination of the specimen, students often miss important findings altogether. Secondly, although visually detected, critical features of the specimen are overlooked and dismissed because of students' inability to discern abnormal from normal. Thirdly, findings are deemed relevant but are not recognized or are misinterpreted.

This study reveals both the difficulties medical students face while examining pathological specimens and how visual-textual cues can be used to help students to pay attention to the relevant features of the slide and thus reach a level of performance otherwise unattainable.

Introduction

In general, it seems that the capability of finding the relevant diagnostic information is where medical experts excel and novices fail (e.g. Elstein, 1978; Myles-Worsley et al., 1988). Furthermore, experts seem to reason from the "patient data to the diagnostic hypotheses" (Patel & Kaufman, 2001: p.9516) whereas novices mainly use hypothesis-driven reasoning. Yet, when faced with non-routine tasks, even experts resort to hypothesis-driven strategies. (Patel, et al., 2005) Novices, to whom almost all diagnostic tasks are more or less non-routine, mainly make use of hypothesis-driven reasoning because of "their lack of substantive knowledge or their inability to distinguish relevant from irrelevant knowledge" (Patel et al., 2005: p.8).

Recently it has been recognized that doctors "are not solitary thinkers, but live in a social world thick with artifacts and populated by other agents who jointly determine the decision processes and outcomes" (Patel et al., 2002). The context of this study, an introductory course in pathology, illustrates how the same applies to the medical students. Students engage in authentic diagnostic tasks and work in pairs to reach a shared understanding of the phenomenon. The cases students engage with are authentic (i.e. real patient cases) and complex, as even the simplest of cases requires biomedical knowledge of, and attention to, multiple levels: cellular, tissue and structural level. The learning process is truly "thick with artifacts" that also shape the future skills and practices of the practitioners (Kushniruk et al., 1996). Our aim is to explore how these practices are shaped by collaborative use of virtual microscopy and how visual and textual scaffolds support novices' reasoning.

Method

Fifteen pairs of medical students attending an introductory course in pathology took part in two video-taped problem solving sessions, one in the beginning and one at the end of the course. The pairs were given six authentic tissue samples using a virtual microscopy application called the WebMicroscope. Depending on the group they were assigned to the pairs had different level of scaffolding: five pairs had fully annotated slides with visual-textual cues, five only visual cues and five no cues whatsoever. The task was to write down the findings and diagnosis in collaboration with each other. Students' written answers were assessed by an experienced pathologist. The findings were classified into diagnostically relevant, irrelevant, or false. False findings were further classified according to whether students focused in the relevant area or level of the sample while coming up with the finding. In addition, students' diagnoses were rated from 0 to 2 points. In video analysis of the diagnostic episodes we focus on different difficulties students face and how annotations affect their reasoning.

Results

Table 1. shows the sum of relevant, irrelevant and false findings in each condition. Surprisingly, visual cues alone did not reduce, but increased, the number of false findings, whereas cues with textual and visual information reduced them remarkably.

Table 1. Number of findings and diagnostic accuracy in each condition

In Table 2., false findings are classified into wrong focus, correct focus and unclassified (findings not credited to any specific area). Without cues, the false findings arise mostly while examining irrelevant features of the slide. Although visual cues increase the amount of false findings (Table 1.), they arose while examining an appropriate part of the slide.

Table 2. Students' focus during the generation of false findings

The case of gastritis, caused by helicobacteria, illustrates the processes behind the aforementioned phenomena. With cues (visual or visual-textual), four out of five pairs were able to find helicobacteria, whereas only one pair in the "No cues" group was able to do the same. Although most of the pairs (7 out of 9) that found helicobacteria during the first session used hypothesis-driven reasoning (they were looking for the bacteria before visually encountering it), in two cases it was evident that this component of their diagnosis was triggered by the annotation.

As revealed in the video recordings, the most common reason for missing helicobacteria was failing to pay attention to the relevant areas or zooming levels in the specimen. Out of the seven pairs that missed the bacteria, four did not inspect the areas of the slide where helicobacteria are visible with appropriate magnification. Further, there was one pair in each group that clearly inspected and commented a relevant area but failed to recognize the bacteria.

Conclusions

Students often miss important findings due to insufficient examination of the specimen. Secondly, although visually detected, critical features of the specimen are dismissed because of inability to discern abnormal from normal. Thirdly, findings can be deemed relevant but are misinterpreted.

To reach a correct diagnosis, one must physically see the relevant diagnostic feature. Furthermore, one must be able to recognize it as an abnormality and thus attach a certain level of relevance to it. Finally, one must be able to conclude various facts into a coherent diagnosis. The new affordances WebMicroscope offers, i.e. visual-textual cues, support students' reasoning enabling them to avoid the most obvious pitfalls and thus reach a level of performance otherwise unattainable.

PAPER PRESENTATION

Collaborative Argumentation In Structured And Unstructured Chat Environments In Secondary School

Timo Salminen, University of Jyväskylä, Finland; Miika Marttunen, University of Jyväskylä, Finland; Leena Laurinen, Agora, Psykocenter, University of Jyväskylä, Finland

Although many studies have shown positive learning effects when using computer-supported learning environments to practise argumentation skills, more research on students' argumentation in web-based environments, for example, on using chat facilities is needed. This study focuses on whether structured synchronous chat interaction promotes upper secondary school students' collaborative argumentation and knowledge co-construction. In the study 16 Finnish secondary school students engaged in dyadic chat discussions through structured and unstructured chat. The discussion themes were vivisection and gender equality. The argumentativeness of the students' speech turns, the quality on their counterarguments, and their counterargumentation strategies were investigated. The results suggest that secondary school students are able to engage in (counter)argumentative chat discussions. However, to foster the use of different counterargumentation strategies, attention should be paid to students' preparation for the discussions.

The ability to argue has been regarded as an important part of academic literacy in secondary school. However, it has been shown that both adolescents (e.g. Chan, 2001; Marttunen et al., 2005; Mikkonen, 2010) and university students (Marttunen, 1997) have difficulties in mastering argumentation skills. Although many studies have shown positive learning effects when using computer-supported learning environments to practise argumentation (see e.g. Andriessen et al., 2003), more research on students' argumentation in web-based environments, for example, on using chat facilities, is needed.

This study focuses on whether structured synchronous chat interaction promotes upper secondary school students' collaborative argumentation and knowledge co-construction. The study compares the quality of students' argumentation during structured and unstructured chat. The research questions are the following: 1) How argumentative are the students' dyadic chat debates? 2) Are the mode of chat (structured vs. unstructured) or the discussion topic (vivisection vs. gender equality) associated with the argumentativeness of the debates? and 3) What kind of counterargumentation strategies do the students use?

The data consist of students' 16 dyadic chat discussions. Eight discussions concerned vivisection and eight gender equality. Eight discussions were carried out through structured chat, and eight through unstructured chat. Before engaging in debates the students read three articles containing arguments both for and against the topic. The

students were asked to think about the different viewpoints towards the topics presented in the texts and how the viewpoints were supported. The teacher formed the student pairs as to maximise the number of mixed gender pairs. She also paired those students whom she knew could work well together. The students were asked to discuss the following topic-related claims: "Vivisection should be allowed." / "There is gender equality in Finland."

The data analyses focused on the argumentativeness of the students' speech turns (n=609), the quality on their counterarguments, and their counterargumentation strategies. The discussions were analysed by categorising the speech turns into eleven categories. In the categorisation the following analysis schemes were utilized: a model to analyse the process of argumentation by Björk and Räisänen (1996), the so-called Rainbow method for analysing functionally computer-mediated pedagogical debates by Baker et al. (2002), the regular patterns of argumentative strategies (i.e. the templates of the structured chat tool used in this study; Hirsch et al., 2004), and the respond-position taking classification of speech turns (Marttunen & Laurinen, 2002). Further, the students' ways to formulate their counterarguments in order to express a justified disagreement were categorised into three counterargumentation strategies (Leitão, 2000): 1) supporting the other side of the question, 2) bringing the truth of a claim into question, and 3) questioning a reason-position link.

The results showed that 44.7% of the students' speech turns were argumentative (justified disagreement 20.2%, argument 16.8%, request an argument 4.8%, main claim 1.6%, request a clarification 1.3%) and 55.3% were non-argumentative (comment 29.2%, opinion 10.5%, unjustified agreement 5.1%, off-task 5.1%, request an opinion 3.9%, unjustified disagreement 1.5%). The students engaged in counterargumentation quite often since 20.2 % of their speech turns were categorised as justified disagreement. The most often used counterargumentation strategy was questioning a reason-position link (41.7%) and the least used strategy was bringing the truth of a statement into question (18.9%). During the unstructured discussions justified disagreement was most often used to question the arguments supporting the claim of the interlocutor (47.4%), whereas during the structured discussions justified disagreement was mainly used as a strategy to support indirectly the person's own standpoint on the issue (43.1%).

The results suggest that secondary school students are able to engage in (counter)argumentative chat discussions. During structured interaction supporting indirectly one's own claim as a counterargumentation strategy is not a dialogical and constructive way to think critically because it does not bring the merit of the interlocutor's arguments into question (cf. Leitão, 2000). However, deep-level processing of the opponent's arguments, in addition to both formulating one's own arguments and managing the discussion may cause cognitive overload for a novice arguer (Kuhn & Udell, 2003) since several cognitively demanding activities must be processed simultaneously. To decrease students' cognitive load in order to enhance their learning through argumentation, more attention should be paid to students' preparation for the discussions, i.e. that students have sufficient knowledge on both the discussion topic and argument schemes (i.e. the logical structure of informal arguments).

PAPER PRESENTATION

The Impact of Situated Learning on Knowledge Construction in an Ubiquitous Learning Environment

Birgit Reisenhofer, University of Salzburg, Austria; Gerhard Schrangl, University of Salzburg, Austria; Michael Schneider, University of Salzburg, Austria; Joerg Zumbach, University of Salzburg, Austria

In this research, the influence of a situated, ubiquitous and mobile learning scenario is compared to a paper-based and multimedia learning scenario. Three different versions of learning material in the area of science education content from Biology mixed with History were compared: A mere paper-based version, a multimedia learning program using audiovisual inputs and an outdoor educational trail using GPS devices. All three conditions contained the same information. Results reveal that the outdoor condition and the multimedia learning software lead to highest performances regarding knowledge acquisition. Subjective cognitive load was highest within the text-based version. Participants in the outdoor condition showed highest scores in intrinsic motivation regarding interest and the feeling of being challenged by the learning environment. Taken together, results indicate that explorative teaching scenarios and multimedia based learning environments might lead – if properly designed – to higher motivation and higher learning success.

Introduction

Active exploratory and inquiry-based learning plays a major role in current school reforming. The main focus of this kind of learning is, here, on active and problem-solving learning. The possibility of situated and active learning enables the opportunity of merging the instructional learning environment with the natural environment. The self-driven activity of learners is essential for designing lessons for situated and active problem-solving learning. A major goal is thereby to evoke and maintain cognitive information processing as well as motivation and interest in problem solving in order to avoid under- or overburdening of learners. There are many ways to implement exploratory and inquiry-based learning. One of the currently most popular ways of approaching the natural environment with instructional designed learning environments is Geocaching, Geocaching is a wide-spread private activity among students, which is also apt to navigate on virtual educational trails using GPS technology combined with instructional material. Practical experience provides learning opportunities for active problem solving within situated learning environments. This kind of learning enables learners a way of multi-modal and multi-codal learning that might not or only scarcely be realized within classroom instruction. Especially self-paced multimedia learning material provides learning opportunities that might not only provide situated learning in combination with ubiquitous learning technologies but also seems to be cognitively adequate (cf. Mayer, 2005; Low & Sweller, 2005). For this research, an action-oriented teaching scenario was designed, where students had the possibility to explore prepared learning paths by using GPS devices. As a result a situated learning environment has been created which allows knowledge transfer to everyday situations and, subsequently, intensely dealing with presented topics. Based on assumptions of situated cognition and motivational issues of self-determination theory, it can be assumed that such a kind of learning environment might be beneficial to the individual learning progress as well as supportive for intrinsic motivation in modern day teaching.

Method

Learning material

Three different versions of teaching material containing the same information were developed. The first version was a mere paper-based version; the second version was a multimedia program, using text, video, and animation. In the third version students had the possibility to go outdoors and see the visual material the learning material was about directly and additionally had the opportunity to listen to the auditory instructions after they reached their destinations by means of GPS devices.

Participants

Fifty-six participants took part in this study. They all were High School students with an average age of 14.27 years. Assignment to one of the three conditions was random (paper-based with n=19, multimedia with n=17, outdoor with n=20).

Instruments and Procedure

A multiple-choice test and a test with open questions were designed in order to assess knowledge acquisition. Cognitive load was measured by using the Mental Effort Rating Scale by Paas and van Merriënboer (1994). Motivational aspects were measured by using the FAM (Rheinberg et al., 2001). First, participants had to complete the

pre-test (knowledge acquisition, cognitive load, attribution) and were then randomly assigned to one of the three conditions, which lasted about 40 minutes each. Afterwards, the post-test was conducted. Participation in this study was voluntary and took about 60 minutes.

Results

For analyzing the differences between the three different conditions, a MANCOVA with the different treatments as independent variable, performance in knowledge pre-test as covariate and performance in knowledge post test as well as motivational scales in post-test as dependant variables was calculated. Both, the multimedia as well as the outdoor condition led to increased performance in the knowledge post test; participants using the text-only version achieved significantly lower results in knowledge acquisition (p). Regarding motivational aspects, participants showed significantly low interest in using the multimedia software than learning with the other two conditions. Participants assumed the outdoor condition to be most challenging (p). Discussion Results show that the multimedia learning software as well as the outdoor condition lead to best performance in the knowledge post-test. Cognitive load as experienced by the learners was highest within the paper-based version compared with the other two conditions.

These results seem to confirm in an applied educational setting what experimental research has foretold: students dealing with visual inputs only, apparently have to invest more effort in processing the information while a multimodal information contribution might contribute to reduced cognitive load and, thus, higher learning outcomes. Nevertheless, these findings have also to be interpreted carefully. First, the outdoor learning environment was not more effective regarding cognitive issues than a learning software program. This might at a first glance be an argument against outdoor experience. Nevertheless, it lead to comparable results although distracting stimuli and a dual-task (the GPS-navigation) have to be taken into account. And therefore it is astonishing that even experienced cognitive load was not significantly different from multimedia condition. But the rather and major advantage of the outdoor-condition remains in motivational issues: the outdoor condition was significantly rated as the most challenging but also most interesting condition. On the contrary, the multimedia condition was significantly rated the least interesting and least challenging condition.

An explanation for this shift from computer-assisted teaching methods to explorative teaching methods could be the contemporary extended use of new media in classroom situations. In general, results show that explorative teaching scenarios can contribute to higher motivation without risking deficits in cognitive parameters.

PAPER PRESENTATION

Effects of Electronic Outlining on Students' Argumentative Writing Performance

Milou de Smet, Open University of the Netherlands, Netherlands; Hein Broekkamp, UVA, Netherlands; Saskia Brand-Gruwel, Open University, Netherlands; Paul A. Kirschner, Open Universiteit, Netherlands

Writing is an important competence in a knowledge-driven society. Education therefore devotes much attention to its development. Students' writing skills may be further increased when they make use of widely available word processors and profit from the tools incorporated in them that support writing. Seemingly important but underused are, for instance, tools for electronic outlining. These tools help students to develop a structured list of ideas, which they can use as a writing plan.

The central aim of this study is to determine the effect of electronic outlining on the quality of students' writing products and on students' experienced cognitive load during the writing task. In addition it examined how students appropriate and appreciate the outline-tool and whether they need an explicit instruction in order to engage in planning. The writing products and self-report data from 34 ninth-grade students of a Dutch secondary school were analyzed. Students wrote two similar argumentative texts with or without an electronic outline-tool. Results indicate

that without instruction, students devote almost no time to planning their texts. This is regrettable since results show that electronic outlining improves the quality of students' argumentative texts. Furthermore, the cognitive load that students reported was lower for tasks that required the use of outline tools. Answers to a retrospective questionnaire showed that the short instruction on the outline-tool was sufficient for students to understand the working of the outline-tool and that most students experienced the outline-tool as beneficial to their writing.

Writing is an important competence in a knowledge-driven society. Education therefore devotes much attention to its development. Nevertheless, students often have trouble writing a well-structured text. Students' writing skills may be further enhanced if they learn to effectively use the widely available word processors profit from the tools incorporated in them that support writing such as the outline-tool. Outlines allow students to think about the organization and structure of a desired product or the steps according to which this product should be established. Outlining has proven to be the most successful planning strategy to benefit students' writing performance (Walvoord, et al., 1995). Using computer tools that support outlining can enhance beneficial effects (Kozma, 1991).

The aim of this study is to investigate the effects of using an electronic outline-tool on the quality of students' argumentative texts. Based on prior studies (Kozma, 1991; Walvoord et al., 1995), it is expected that for most students, a brief outline instruction will lead to an improvement of text quality. In addition, based on Kellogg's research on writing and cognitive load (2008), it is hypothesized that electronic outlining will decrease experienced cognitive load. Moreover, this study seeks to determine whether students appropriate and appreciate working with the outline-tool.

Method

Participants in this experiment were 34 Dutch ninth-grade students from an academic high school. The group consisted of 16 male and 18 female participants between the ages of 15 and 17 ($M=15.66$; $SD=0.60$). This study compared two experimental conditions in a combined within-subjects and between-subjects design. Students carried out two argumentative writing tasks about a much-discussed, current issue. For each task, 75 minutes were given to write a text of 600 to 800 words. According to the design below, students were or were not required to make an outline before elaborating their full text. Task1 Task2 O-O+ condition ($n=18$) No outline Outline O+O+ condition ($n=16$) Outline Outline (O+=With Outline-Tool; O?=Without Outline-Tool) All students first completed a general questionnaire on their computer skills, writing style, use of news media and prior knowledge of the argumentative text structure. Prior to the first writing task with outlining, students received a 10-minute instruction in which the tool and its working were explained; no instruction was given on outlining as a text-structuring technique. The tool used in the experiment was the outline function embedded in the 'view' menu in Microsoft Office Word 2007. After each writing task, students completed a retrospective questionnaire on tool use and on perceived cognitive load. To assess text quality, an assessment protocol for the assessment of argumentative text-quality developed by Erkens, Kanselaar, Prangma and Jaspers (2002) was adapted and applied. The evaluation procedure distinguished the degree to which students were able to (1) correctly and completely establish a text structure (i.e. distinguish and elaborate an introduction, text body and conclusion) and (2) clearly present this structure (i.e. distinguish paragraphs, use connectives and anaphors). Hypotheses concerning outlining effects were tested by univariate ANCOVAs for between subject comparisons. In the case of the within subjects comparisons, Paired Samples T tests (one-tailed; p

Results and conclusions

Results indicate that text quality was affected by electronic outlining in different ways. Students using the outline-tool during the first task, tended to elaborate their text's structure slightly more deeply than students who did not outline ($F(1, 30)=3.29$, $MSE=13.00$, $p=.081$, $\eta^2=.11$). Concerning the effects of repeated outlining, the second text of students from the O+O+ condition showed a significantly more deeply elaborated structure than that of students from the O?O+ condition ($F(1, 25)=7.97$, $MSE=12.09$, $p=.010$, $\eta^2=.27$). Moreover, students from the O+O+ condition showed a significant improvement in structure elaboration ($t=?1.95$, $p=.037$, $df=12$) and a marginal improvement in structure presentation ($t=-1.62$, $p=0.07$, $df=12$) over both tasks. Although positive effects of student's first experience with electronic outlining do not all reach statistical significance, there are trends that may not be neglected. Results suggest that electronic outlining has beneficial effects for structuring and presenting text structure. The fact that the positive effects are most prominent for the O+O+ condition on the second writing task, suggests that students profit more from electronic outlining when they use the tool more frequently. On the second writing task, students in the O+O+ condition reported a decrease in cognitive load as opposed to the first writing task ($t=1.75$, $p=.052$, $df=13$). What is more, students in the O?O+ condition reported a significant decrease in cognitive load over the two writing tasks ($t=2.80$, $p=.008$, $df=13$). The intervention (i.e. the outline-tool) during the second writing task reinforced the decrease in perceived cognitive load. According to self-report data, only 10% of the respondents reported having used the outline-tool prior to the experiment. Though this was the case, students indicated that they immediately understood the functioning of the tool. The O+O+ and the O?O+ condition scored 4.47 and 4.93 respectively on a 5-

point Likert scale on tool appropriation. Only a short outline instruction and the requirement to use the tool, appears to initiate a process of appropriating the tool for writing. After performing both writing tasks, 54 % from the O+O+ condition and 69% from the O?O+ reported that they intended to use the outline-tool for subsequent writing tasks.

The outline-tool's straightforward nature and its user-friendly design enabled students to quickly appropriate and appreciate it. It is important to realize that students, in general, do not spontaneously use the outline-tool, or any other planning strategy. Students may profit most from electronic outlining when it is combined with effective and explicit instruction by teachers. Therefore, future research should focus on developing valid guidelines for teachers to instruct students on using outline-tools and integrating them optimally in their education.

PAPER PRESENTATION

Listening to an Educational Podcast While Walking or Jogging. Can Students Really Multitask?

Joke Coens, Katholieke Universiteit Leuven, Belgium; Ellen Degryse, Katholieke Universiteit Leuven, Belgium; Marie Paul Senecaut, Katholieke Universiteit Leuven, Belgium; Geraldine Clarebout, Katholieke Universiteit Leuven, Belgium

The advent of podcasting offers opportunities for students to learn while performing another activity (e.g. listening to an educational podcast while jogging). Two experiments were set up to examine the effect of performing a secondary task while learning with an iPod. In the experimental group, the participants had to combine a learning task (listening to an educational podcast) with a secondary task (walking or jogging). The control group only had to perform the learning task. Afterwards, all the participants had to complete a learning test. In study one, there were no significant differences between the learning performances of students of the different conditions. In study two, the students who were sitting down outperformed the students who were jogging while studying.

Introduction

In recent years, podcasting has seen a significant growth in education (McGarr, 2009). A possible explanation may be that podcasting offers opportunities for education because it has the advantage of allowing learners to choose when and where they study (Evans, 2008). This increased flexibility relates to a specific feature of mobile learning in general and podcasting in particular: students can learn while performing another activity (e.g., listening to an educational podcast while waiting for the bus, while driving a car or while doing the dishes; studying while being on the move). Students can become real educational 'multitaskers'.

The main aim of the reported studies is to address the effect of multitasking while learning. Can students really multitask? Or is it a myth (Kirschner, 2010)? Research, often conducted within laboratory settings, reveals that, although people often believe that they can successfully combine two tasks, it is not so evident for people to do two things at the same time and to divide their attention between multiple tasks (e.g. Pashler, 1994). In the field of educational multitasking, the research results are not univocal. Some studies reveal clear significant effects of multitasking (learning with a mobile device while doing something else) on the learning performances of students (e.g., Doolittle & Mariano, 2008), other studies do not (e.g., Coens, Reynvoet, & Clarebout, 2009).

Two experiments were set up to examine the effect of performing a secondary task (walking or jogging; difference in intensity) while listening to an educational podcast. It was examined what the consequences are of multitasking for learning with a mobile device.

Method

Participants

In study 1, the participants were 36 first year Physical Education bachelor students from a Belgian university college (academic year 2009-2010). Twenty-five male and 11 female students, on average 18.81 years old ($SD = 1.09$), participated voluntarily. In study 2, 75 secondary education students participated (school year 2009-2010). Twenty-eight were male, 47 were female. They were on average 15.05 years old ($SD = 0.73$). Participation in the study was obligatory.

Procedure

In both studies, participants were randomly divided into three groups. Students of the control group listened to an educational podcast while they were sitting down. Students of the first experimental group were asked to walk while listening and students of the second experimental group had to jog at a moderate pace while listening.

In study 1, the podcast was part of the physiology course. The provision of the podcast replaced the traditional face-to-face lecture. The podcast took four minutes; students had to play the lesson twice. In study 2, the topic of the podcast was dyspraxia and the content was not part of a specific course. The podcast took 11 minutes and 40 seconds; students had to listen to the lesson once.

All students had to complete a prior knowledge test before they listened to the podcast. Afterwards, they completed a learning test.

Analyses

ANOVA's were performed with the learning performances of the students as dependent variable. Two independent variables were included. Condition (sitting – walking – jogging) was included to examine the effect of performing a walking or jogging task. Also possession of an MP3 player was included because it is assumable that students who possess an MP3 player are more used to listen to it while doing something else than students who do not possess their own player. It is assumable that it is easier for those students to learn while walking or jogging.

Results

Study 1

The descriptives show that students who were sitting down while listening to the podcast learned the most. Students who were jogging while learning learned the least. However, the differences between the learning performances of students of the different conditions (sitting – walking – jogging) are not significant; $F_{condition(2,30)} = .58$; $p_{condition} = .57$; $\eta^2_{condition} = .04$.

The descriptives also show that students who possess an MP3 player learned more than students who do not possess an MP3 player. However, also here the difference is not significant; $F_{MP3(1,30)} = .095$; $p_{MP3} = .76$; $\eta^2_{MP3} = .003$.

Study 2

The descriptives show that students who were sitting down while listening to the podcast learned the most. A significant effect was found of condition (sitting – walking – jogging) on the learning scores; $F_{condition(2,69)} = 3.09$; $p_{condition} \leq .05$; $\eta^2_{condition} = .08$. The post-hoc test reveals that students who studied while sitting down outperformed the students who studied while jogging; Bonferroni; $p = .05$. Students in the walking condition took a middle position. They did not differ significantly from one of the other conditions.

The descriptives show that students who possess an MP3 player got a better score on the learning test than the students who do not possess an MP3 player. However, the difference is not significant; $F_{MP3(1,69)} = 0.98$; $p_{MP3} = .33$; $\eta^2_{MP3} = .01$.

Conclusion and discussion

Two studies were presented where part of the participants were asked to walk or to jog while listening to an educational podcast. Both studies reveal different results. In study 1, no significant differences were found between the learning performances of students in the stationary condition, the learning performances of students in the walking condition and the learning performances of students in the jogging condition. In study 2, the learning outcomes of the participants in the different conditions differed significantly. Students who studied while sitting down outperformed the students who studied while jogging.

The results of both presented studies are not univocal. In a certain way, they are a reflection of the different research results found in the field of educational multitasking so far.

The different results of study 1 and study 2 could be caused by the different podcasts that were used. In study 1, the podcast took four minutes and students had to listen twice. In study 2, the podcast took almost 12 minutes and students had to listen only once. The different results of both studies could be an indication that the use of podcasts while being mobile is more suitable for situations in which small chunks of content have to be learned.

PAPER PRESENTATION

Teachers' reluctance to use ICT in their pedagogical practices

Karel Kreijns, Open Universiteit Nederland, Netherlands; Marjan Vermeulen, Open Universiteit Nederland, Netherlands; Hans van Buuren, Open Universiteit Nederland, Netherlands; Frederik Van Acker, Open Universiteit Nederland, Netherlands

Abstract

Teachers' reluctance to use ICT in their pedagogical practices is addressed in the context of teachers' usage of digital learning materials (DLMs). Analysis using structural equation modeling revealed that the dispositional variables attitude, subjective norm, and self-efficacy towards DLMs are significant predictors of teachers' intention to use DLMs. The contribution of subjective norm, however, is rather limited. The dispositional variables mediated the effects of the distal variables 1) previous use of DLMs, 2) perceived knowledge and skills to use DLMs, and 3) colleagues' usage of DLMs on intention. Persuasive communication and skills based training seem, therefore, appropriate interventions to promote a positive attitude towards DLM and improve self-efficacy in using DLMs.

Introduction

Information and communication Technology (ICT) are considered to be a set of tools enabling, supporting, and reinforcing educational reform that fits the educational demands of the knowledge society (Ward, 2005). However, research on teachers' use of ICT revealed that teachers are reluctant to integrate ICT in their pedagogical practices. Therefore, the question arises why this is so. In this paper we address the question in the context of teachers' usage of digital learning materials (DLMs).

Theoretical framework

We use the Integrative Model of Behavior Prediction (IMBP, see Fishbein, 2000) to gain insight in the factors that explain teachers' reluctance to use ICT. In IMBP the three dispositional variables attitude, subjective norm, and self-efficacy towards DLMs use are the immediate antecedents of teachers' intention to use DLMs. Intention, in turn, is a predictor of real usage of DLMs by teachers. The relationship between intention and real usage of DLMs is moderated by environmental variables that may impede real usage (e.g., the non-availability of appropriate DLMs) and by teachers' actual knowledge and skills to use DLMs in a pedagogical manner. Figure 1 displays IMBP for the domain for the advancement of the integration of ICT in teachers' pedagogical practices. This figure also shows that the variables are grouped into proximal, distal and ultimate variables. Proximal variables include all the dispositional variables. The distal variables encompass all the variables at the level of teachers' characteristics and school organization, and the ultimate variables the variables at the level of local, regional, and governmental organization.

Research Questions

Two research questions are addressed in this paper: R(1): How is 1) attitude, 2) subjective norm, and 3) self-efficacy related to teachers' intention to use DLMs. R(2): What is the influence of 1) previous use of DLMs, 2) perceived knowledge and skills to use DLMs, and 3) colleagues' usage of DLMs on the three dispositional variables. Method A questionnaire encompassing all relevant measures was administered electronically in December 2009 to teachers of primary and secondary schools. Analysis and Results The data is, after the removal of outliers, analyzed using structural equation modeling (SEM) with SPSS AMOS version 18. Figure 2 depicts the initial model.

When inspecting the model, the initial model from Figure 2 showed poor fit. According to Byrne (2010) and others (Hu & Bentler, 1999) a Goodness of Fit Index (GFI), an Adjusted Goodness of Fit Index (AGFI) and a Comparative Fit Index (CFI) of between .9 and 1.0 indicate good fit. The Root Mean Square of Error of Approximation (RMSEA) should be between the .0 and .10. The initial model does not comply with the suggested requirements ($\chi^2(df = 8, N = 1207) = 749.2$, $p 2(df = 7, N = 1207) = 85.5$, p Figure 3 depicts the alternative model.

Path analysis using SEM revealed that a considerable part of the variance in intention is explained by the three dispositional variables attitude, subjective norm and self-efficacy ($R^2 = .73$, $p b = .56$, $p b = .35$, $p b = .09$, $p b = .22$, $p b = .22$, $p b = .21$, $p b = .06$, $p = ns$; $b = .02$, $p = ns$; $b = .07$, $p b = .18$, p Conclusion Interventions that are aimed to increase the use of DLMs in teachers' pedagogical practices should pay attention to improve self-efficacy of teachers,

for example, by providing them with skills based training programs. Besides, initiatives that promote a positive attitude towards DLMs use may also contribute to the use of these. For example, by means of campaigns that are based on the persuasion communication model (McGuire, 1985) and that elaborate the added value of DLMs in education. Furthermore, personnel policy should, if teachers apply for a job, favor those teachers that already have some experience with DLMs.

PAPER PRESENTATION

Learning with interactive videos: the interplay of features, training and task characteristics.

Martin Merkt, Knowledge Media Research Center, Germany; Stephan Schwan, Knowledge Media Research Center, Germany

Whereas recent research with videos revealed the necessity of self-regulated information processing on a local level, the usefulness of features facilitating the location of information has not gone undisputed (Merkt, Weigand, Heier, & Schwan, in press). This study was designed to identify prerequisites for successful implementation of videos allowing different levels of interactivity in a classroom plus homework scenario. Before working with a common video allowing self-regulated information processing on a local level or an enhanced video additionally facilitating the location of information inside the video, 64 9th graders from eight German history classrooms finished either an experimental training demonstrating the efficient use of features facilitating the location of information or a control training focusing on the integration of new information with prior knowledge. While watching the video as a homework assignment, students wrote two essays (E1: summary; E2: inference) about the video's content and finished a search task. Whereas the enhanced video outperformed the common video on the search task independent of training, the experimental training was necessary for students to benefit from additional interactivity when summarizing the video's content. However, when inferences were required, the experimental training benefitted the common video, whereas there was no training effect for the enhanced video. These results indicate that even if students are aware of the distribution of facts across media, features allowing the location of information are most beneficial for tasks that require the extraction of information rather than inferencing about the contents.

Theoretical background

Videos are an integral component of the educational environment students face today (Feierabend & Klingler, 2003). However, earlier media comparisons found videos to be inferior to print when people learned complex content (e.g. Walma van der Molen & van der Voort, 2000). In contrast to print, videos used in these studies did not afford self-regulated information processing that positively affects learning outcomes (use of lookbacks: Hyßnä, Lorch, & Kaakinen, 2002; use of an index: Yussen, Stright, & Payne, 1993). Recent studies with videos affording self-regulated information processing revealed beneficial effects of interactivity (Schwan & Riempp, 2004), so that videos were comparable to print (Merkt, Weigand, Heier, & Schwan, in press). Whereas the use of features facilitating information processing on a local level (stopping, browsing) was unproblematic, the implementation of features facilitating the location of information in a medium (table of contents, index) led to the consideration of information from less chapters when students wrote essays about the media's contents. These results may be due to students' misconceptions about the distribution of information across media leading to a neglect of information from chapters that are not explicitly linked to the wording of an essay task. The current study aimed to back this explanation with evidence by implementing a training fixing potential misconceptions. Additionally, we tested for positive effects of features allowing the location of information on searching for isolated facts.

Method

The study was implemented in a classroom (two lessons à 45 minutes) plus homework context in eight German history classrooms (9th grade). Sixty-four students (38 female; mean age = 14.84) were randomly assigned to one of four

conditions and finished the entire experiment. In lesson 1, individual prerequisites (prior knowledge, interest and self-appraisal in history, reading strategies, homework motivation) that might influence the study's outcome were assessed. Then, the students were given a homework assignment which consisted of training and a video. Both training and the video were manipulated experimentally. The experimental training gave an overview of different characteristics of media (e.g. distribution of information) and about how features like table of contents and index could be used when locating information. Additionally, the activation of prior knowledge was addressed, because the control training described information acquisition as a process of integrating new information with prior knowledge. With regard to the video, the level of interactivity afforded by the videos was varied. Whereas a common video offered basic features like start / stop and browsing via forward and rewind, an enhanced video offered features like chapter selection via slider or table of contents as well as an index in addition to start / stop and browsing via slider.

After the training, students wrote two essays about the implementation of the Potsdam Treaty (essay 1) and about whether the separation of Germany was predictable from the events between 1945-1949 (essay 2) while watching the video about "Post-War Germany" after World War II. Whereas essay 1 required the extraction of information from various chapters of the video, essay 2 required inferences going beyond the information explicitly mentioned. After the essays, the students had five minutes to finish a search task in which they had to locate eleven details in the video. Due to changes to the search task after assessing the first classroom, results for the search task are only available for seven classrooms. The students' navigation through the video was recorded via logfiles. In lesson 2, a multiple-choice test about the content of the video as well as a questionnaire about the students' experiences with the videos was administered.

Results

The knowledge test revealed no difference between the experimental conditions, all $p > .17$. Essays were coded by two independent raters for the number of information mentioned. For essay 1, there was an interaction between the factors video and training, $F(1,60) = 3.98$, $p = .051$, with the enhanced video benefitting from the experimental training, whereas there was no training effect for the common video. For essay 2, there was an interaction between the factors video and training, $F(1,60) = 3.88$, $p = .054$, with the common video benefitting from the experimental training, whereas there was no training effect for the enhanced video. For the search task, the students working with the enhanced video found more facts - independent of training, $F(1,46) = 19.46$, p

Discussion

Ninth grade students can successfully use the enhanced video to search for information. However, when summarizing information from various chapters, awareness about the distribution of facts across media is necessary so that students can benefit from the enhanced video. In contrast, when inferences about the video's content are required, this awareness does not lead to an improvement in the enhanced video condition, but in the common video condition. These results indicate that features facilitating the location of information are most beneficial for tasks that merely require the extraction of information from videos rather than for tasks that require inferencing about the videos' contents.

PAPER PRESENTATION

The Preparation of Teachers for Global Learning Environments - The Integration of Virtual and Actual

Ken Stevens, Victoria University of Wellington, New Zealand; Barbara Craig, Victoria University, New Zealand

Teachers are increasingly likely to teach in the spaces between schools as well as within the institutions to which they are appointed. Moreover, teachers are interacting with learners beyond the confines of the traditional school day. Teachers in some parts of the world are providing instruction beyond traditional classrooms in networks of schools that are located beyond major centres of population. In other places they are collaborating in networks of schools in inner city urban communities. Small, geographically isolated and large inner city urban schools alike are finding new opportunities in a global networked society. Using new digital technologies (Web 2.0) in the delivery of teaching and learning creates possibilities for teachers today to network and collaborate beyond their institutional walls (Granic, C'ukusic & Walker, 2009; O'Brien, Varga-Atkins & Qualter, 2008). Research on rural and urban learning networks is based on the convergence of two conceptual frameworks: (i) open and closed schools and (ii) horizontal and vertical integration. The convergence of these two frameworks guides the transfer of knowledge and skills from teacher education designed for teaching in traditional, physical, classrooms to include virtual teaching and learning based on a matrix of conceptual, pedagogical, technological and organizational change (Stevens, 2007). A process of teacher education is outlined in which teachers are prepared for the integration of actual (or physical) classes with virtual learning environments as schools are networked. The implications for teaching and learning in a global networked society have institutional, policy, financial and pedagogical implications.

This research is based on the convergence of two conceptual frameworks: (i) open and closed schools and (ii) horizontal and vertical integration. The convergence of these two frameworks will guide the transfer of knowledge and skills from traditional teacher education, focused on single classrooms, to open learning environments that include both inter-institutional teaching and learning and local and global community engagement. The two frameworks will be interpreted within a matrix of conceptual, pedagogical, technological and organizational change (Stevens, 2007). Schools as we have known them are autonomous institutions with their own teachers, their own students and their own cultures. Schools in each community to a considerable extent duplicate what schools are doing in other communities with students being taught by teachers assigned to teach face to face to whole classes, small groups and, in some cases, individually. There is nothing remarkable about this model of the school and it is an accepted part of the global educational landscape. Perhaps the most remarkable feature of this model of the school is that it remains largely unchallenged. This will be considered to be a "closed" model of the school. The "open" model is based on schools academically and administratively integrating with one another and with other institutions for at least part of a school day. Information and communication technologies facilitate the linking of classes in schools to share teaching, learning and resources. New digital technologies encourage learners to take control of their own learning, connecting them to experts locally and globally and allowing participation in virtual spaces. The open model challenges the closed model of the school by questioning the need for appointing all teachers to schools, rather than, in appropriate cases, some teachers being appointed to networks of schools (Ertl & Plante 2004). It questions the appropriateness of learners engaging solely with their peers within their own, physical classrooms and, it questions the very notion of a school itself. The open model of the school is grounded in the application of information and communication technologies to teaching and learning and the construction and deconstruction of virtual classes. In the open model of the school teaching and learning takes place electronically between as well as in classrooms. In the open model teaching and learning involves collaboration and connections between students, between students and teachers, students and experts, and, more often than not, beyond the confines of their own classrooms, their own school and their own country. In the closed model, teaching takes place only in classrooms.

The electronic linking of schools across dispersed sites to create academically and administratively integrated educational structures that support traditional, on-site teaching and learning, can be conceptualized as "horizontal integration" (Stevens & Stewart, 2005). By extending this model at the local or community level through connecting digitally with selected homes, services, libraries and businesses, "vertical integration" can be achieved. By vertically integrating homes into sites (local schools) that are horizontally integrated into federated teaching and learning structures (school district intranets), intellectual and skill capacity building can be leveraged. This model challenges the traditional concept of the school that is open only certain hours of the day and certain weeks of the year.

There are implications of the shift from closed to open classes and in the horizontal and vertical integration of schools for global learning (Barab, et. al., 2001). Schools can be extended in terms of time, space, organization and capacity. This will be demonstrated on the basis of New Zealand research in inner city urban environments (Craig & Coman, 2009) and from Canadian research in rural communities (Hawkes & Halverson, 2002; Stevens & Stewart, 2005). The New Zealand research considers the pedagogical advantages of aggregating 6 urban high schools into a learning network and connecting them to wider opportunities through a bridge onto the Kiwi Advanced Research and Education Network (KAREN).

There are implications for the professional education of teachers for schools that have the capacity to engage with global learning environments (Green & Hannon, 2007; Lai, 2005; Scardamalia & Bereiter, 2006). New Zealand and Canadian research identifies specific technology gaps, teacher preferences for training approaches as well as new ways of relating to learners, to learners' parents, to networks and to communities that have implications for teacher professional development. Five implications will be analyzed in concluding this paper and will, hopefully, generate discussion that will inform current and future research.

PAPER PRESENTATION

Dynamic model toward school changing experimentations

Nadia Rousseau, Universite du Quebec a Trois-Rivieres, Canada; Helene Fournier, U. du Quebec a Trois-Rivieres, Canada; Luc Prud'homme, Universite du Quebec a Trois-Rivieres, Canada; Caroline Vezina, Universite du Quebec a Trois-Rivieres, Canada

School plays a crucial role in student development and affects student perseverance. Quebec's high dropout rates induce the necessity for change. For instance, in 2007-2008, 25.7% of Quebec teenagers were not enrolled in school, had not completed high school and therefore were considered as dropouts (MELS, 2009). In this study, we consider the changing process in the Quebec school context that promotes student success and well-being. We examine specifically the essential requirements contributing to changes in schools pertaining to pedagogical and organisational practices.

An action research protocol focusing on training is chosen throughout the three years of the study (2007-2009). Various procedures are carried out and monitored: documenting the challenging issues faced by the four participating schools, planning the expected experimentations, and implementing them.

Introduction

School plays a crucial role in student development and affects student perseverance. Quebec's high dropout rates induce the necessity for change. For instance, in 2007-2008, 25.7% of Quebec teenagers were not enrolled in school, had not completed high school and therefore were considered as dropouts (MELS, 2009). In this study, we consider the changing process in the Quebec school context that promotes student success and well-being. We examine specifically the essential requirements contributing to changes in schools pertaining to pedagogical and organisational practices.

Objectives

- 1) Mobilise school teams (teachers and principals) to change their practices
- 2) Document and analyse the changing process
- 3) Create a theory of the research-supported change process

Theoretical Framework

An extensive literature review on the educational changing process is completed using six electronic documentary bases. 226 texts are selected regarding environment, teachers, schools, students, teaching, and education. This intensive literature review displays the complexity of change in Education (Schermerhorn, Hunt & Osborn, 2002) and the difficulty to support actors of the changing process in this context. (Garant, 2003).

Methodology

An action research protocol focusing on training is chosen throughout the three years of the study (2007-2009). Various procedures are carried out and monitored: documenting the challenging issues and critical incidents faced by the four participating schools, defining and planning the expected experimentations, and implementing them. 69 teachers, educators and school principals are involved in the study. A major data collection is carried out to document the procedures previously mentioned. Field observations, recordings of workshop group activities and reflections of the participants, and a questionnaire are the main instruments used. Also, the researchers were collecting data through their research journal.

A qualitative network analysis approach is used with Atlas-ti (Weitzman, 2000). An inductive coding is performed on 2,794 pages to obtain 106,352 meaning units and create 558 codes.

Findings and discussion

A dynamic model of school change is created based on the data collected. The changing process includes three steps: 1) identification of challenges associated with the school orientation and mission; 2) implementation of change; and 3) assessment and identification of new challenges. The model is composed of the following themes: challenges generated by the school orientation and mission; current context, school culture as well as proximal and distal actors.

Identification of the school orientation and mission reveals to be a crucial component of the school change process. Considered as the starting point for the actions to be carried out through the experience of change, the orientation appears as the keystone that maintains coherence between these actions, therefore acting as a lighthouse for participants, pointing toward these principles that they have agreed on. Furthermore, this orientation becomes the basis to help define concrete objectives to follow before planning experimentations. Along our process, we agreed that the school mission identify the process of articulating concrete objectives for action conveying a concrete vision of the orientation. This initial part of the process tends to help participants to observe the actions conducted in the school in order to evaluate their coherence and consistency, to look more attentively at what we preach (orientation and mission) and what we practice (culture of the school). In other words, it helps consider to what extent the school is ready for change.

A continuum of readiness is considered to situate the participants: 1) No, there is no need to change; 2) There is a need to change, but...; 3) Yes, there is a necessity to change.

Promoting conditions for change are numerous. Among these conditions are: personal and professional characteristics of the participants closely involved in the changing process, relationships with students, actual hope to change, and tolerance toward novelty. Obstacles, which can vary from one school or individual to the other, are the followings: narrow-mindedness, disengagement, lack of cohesion, personal and professional insecurity, lack of leadership, negative attitudes, resistance to change, lack of time, concerns for the extent of the task, and project feasibility. Promoting conditions and obstacles can affect minimally, moderately or fundamentally the participants.

Conclusion and Educational Significance of the Study

The proposed dynamic model is grounded on a wide-reaching empirical study. It can be applied in numerous school contexts. The many produced reports and created working instruments can guide numerous official bodies and individuals to implement changing. They can help government ministries and departments, universities, colleges, schools, professional bodies, and communities interested in student success and well-being.

PAPER PRESENTATION

Learning about Controversial Issues in Museums: Visitors' Attitudes towards Conflicting Information

Doris Lewalter-Manhart, TUM, Germany; Wolfgang Schnotz, University of Landau, Germany; Inga Specht, TU Munich, Germany; Rahel Gruninger, University of Landau, Germany

Museums are nowadays oft confronted with the fact that science cannot provide clear answers to specific questions, because there are unsolved controversies based on conflicting evidence. A relevant research question is how the audience can cope with this kind of conflicting information. It is assumed that specific personality variables such as tolerance for ambiguity, epistemological beliefs, self-efficacy and topic-specific interest have an impact on processing of conflicting information. An empirical study was carried out which aimed at (1) identification of visitor profiles on the basis of these individual person variables, (2) assessing the domain specificity of these visitor profiles, and (3) assessing differences in the frequency of visitor profiles connected with the visitor's age, gender and habitual museum visits. A questionnaire was presented to 1002 visitors from two scientific and technological museums and two cultural and historical museums was conducted. A cluster analysis revealed seven different clusters, ranging from visitors who dislike ambiguity to visitors who can be described as "independent thinkers". Findings indicate domain-specific differences in the frequency of visitors allocated in the different clusters. Domain-specific differences were only identified for topic-specific interest and epistemological beliefs. The findings indicate also differences between clusters regarding gender and habitual museum visits, but not on age. The heterogeneity of visitors is a specific challenge for the design of exhibitions in museums as informal learning settings.

Theoretical background and research aims

Learning occurs at many different places. Besides formal learning settings such as schools or universities, informal learning settings can also be found at other places such as museums, which play an important role as sources of information for the general public. Visitor studies have shown that almost half of the German population can be reached by this learning context (Wersig & Graf 2000). Adult visitors of museums are not a homogenous group regarding learning relevant characteristics (cf. Gibbs, Sani & Thompson, 2006). They differ, for example, with regard to their professional qualification, life experience or personal affinities. Furthermore it has to be considered that museums are free choice learning settings which are used by the audience in an autonomous and self-regulated manner. That implies among other things that visitors stop paying attention to an exhibit if it does not appeal to them. Nowadays, museums are confronted with the task to present unsolved issues based on fragile or even conflicting evidence. Therefore museums have to meet the challenge to present fragile information to laypersons instead of well founded secure knowledge in an attractive and simulating manner.

But how does the audience cope with the fact that the presented information is fragile or even conflicting?

It is assumed that beneath situational factors (e.g. characteristics of information presentation) individual person variables of the visitors have an impact on information reception and the handling of divergent information. It is therefore an important aim of research to identify the individual factors that have an influence on the visitor's strategies in handling conflicting evidences in the domain of science and technology. To meet this aim, different visitor types need to be identified on the basis of individual person variables which are considered relevant for dealing with conflicting evidences. We assumed tolerance of ambiguity, epistemological beliefs, self-efficacy and topic-specific interest to be important personality characteristics that influence cognitive processing of conflicting information.

Ambiguity tolerance describes the ability to perceive ambiguity in information in a neutral and open way. It is assumed that tolerant individuals should perform well when confronted with contradicting information while intolerant individuals may tend to avoid or give up when encountering ambiguous information (e.g. Jonassen and Grabowski, 1993; Reis, 1997). Epistemological beliefs are fundamental assumptions about the nature of knowledge and learning as well as the limits, certainty, and criteria of knowing (e.g. Conley et al., 2004). They also focus on aspects to describe in which situations and from which sources knowledge can be obtained. Furthermore, they have an effect on the ways and results of learning processes by influencing the perceived credibility of information and its

source for example. Self-efficacy describes the belief in one's own ability to perform a task (e.g. Schwarzer & Jerusalem, 1999). It is important for the willingness to deal with demanding information. Finally topic-specific interest focuses on the motivation to engage with a certain topic (Hidi & Renninger, 2006). In order to assess domain specific aspects, museums of science and technology are contrasted with history museums.

In this study we focus on the following research aims:

- 1) Identification of visitor profiles on the basis of individual person variables relevant for the visitor's strategies in handling conflicting evidences
- 2) Assessing the domain specificity of these visitor profiles (natural science and technology vs. cultural history)
- 3) Assessing differences in the frequency of visitor profiles connected to the visitor's age, gender and habitual museum visits

Research design

To explore the individual background of the museum visitors we conducted a questionnaire study in four museums (two scientific and technological museums N=460: Deutsches Museum, Munich, and Technoseum, Mannheim, and two cultural and historical museums N=542: Germanisches Nationalmuseum, Nuremberg and Staatliches Museum für Völkerkunde, Munich). The overall sample size was 1002 visitors (48% male, average age M = 42,5 years).

For this study a questionnaire was developed which contained scales on the above mentioned individual person variables items about socio-demographic aspects, reasons for the museums visit and indicators to identify habitual museum visitors. Tolerance of ambiguity was measured by a scale adapted from Kruglanski et al. (1993) and Radant & Dalbert (2006); epistemological beliefs were assessed by three subscales focusing on sources, certainty and development, adapted from Conley et al. (2004); self-efficacy was investigated by three subscales focusing on general, natural science and conflict-orientated self-efficacy adapted from Schwarzer & Jerusalem (1999), Waltner (2007) and Krampen (1991); topic-specific interest was measured by a scale adapted from Frey and Schütte (2009).

Results and significance

To identify different visitor profiles a cluster analysis with ClustanGraphics was calculated. Seven clusters were identified in total. These clusters range from visitors who dislike ambiguity to visitors who can be described as "independent thinkers". Findings indicate domain-specific differences in the frequency of visitor allocated in the different clusters in both domains. Significant differences were identified for topic-specific interest. Regarding epistemological beliefs only the subscale focusing on the source of knowledge revealed significant domain-specific differences. No significant difference could be found for ambiguity tolerance. Furthermore the results indicate differences between the clusters regarding gender and habitual museum visits. However, we did not find age-related differences.

Our findings suggest that the museum visitors are heterogeneous with respect to personality variables relevant for cognitive processing of conflicting information. This heterogeneity is a special challenge for the design of exhibitions in museums that take into account the capabilities and individual characteristics of a majority of visitors in order to stimulate their learning.

Future studies on learning about conflicting issues in museums should focus on detailed analysis of information processing by museum visitors while dealing with conflicting information in an exhibition. Analyzing visitor profiles may help the designers of exhibitions in museums a clearer impression of the audience's most relevant characteristics.

PAPER PRESENTATION

Developing as Teacher in Higher Education: The relationship between Teaching Beliefs and Practice

Caroline Trautwein, Centre for Higher and Further Education, Germany

There is an ongoing discussion on how university teachers' beliefs or conceptions influence their teaching practice. Findings indicate that beliefs and practice are not related in a linear but rather in a dialectic more complex way. This relationship needs to be understood in order to gain insight into how university teachers learn to teach. This paper reports findings of the first stage of a research project investigating the development of eight university teachers attending a teaching development programme. It focuses on changes in teachers' beliefs and practice and how they relate to each other. Three different types of relationships are identified on a cross-case level: Changes in practice without a change of beliefs, changes in practice due to changed beliefs, changes in beliefs due to a changed practice.

On a case level it also becomes obvious that the same assumptions constituting ones beliefs about teaching determine ones strategies in developing as academic teacher. Conclusions for teaching development programmes in higher education are drawn.

Introduction

For a long time researchers are interested in what constitutes good teaching. In the 1970s research interests shifted with the cognitive revolution towards schoolteachers' knowledge and beliefs (Kane, Sandretto, & Heath, 2002; Thompson, 1992). The research on academic teachers' beliefs has educed a large body of literature on conceptions of university teaching (for reviews, see Kane et al., 2002; Kember, 1997). Usually different conceptions of teaching are described between the extreme categories of a teaching or content centred and a student or learning centred conception of teaching (N. Entwistle, Skinner, D. Entwistle, & Orr, 2000). It was recommended that teaching development initiatives should aim at changing teachers' conceptions in order to improve the quality of university teaching (McAlpine & Weston, 2000) and conceptual change programmes were introduced (Ho, 2000). Later instructional development programmes of university teachers were criticised as they lacked empirical proof of influence on daily teacher practice (Devlin, 2006; Stes, Coertjens, & Petegem, 2009). Devlin (2006) Kane et al. (2002) and Thompson (1997) supposed that conceptions of teaching are not related in a simple cause-and-effect way to instructional practice, rather a more complex, dialectic relationship should be expected and investigated. Shedding light on this relationship may lead to a better understanding of how university teachers learn to teach (Kane u. a., 2002).

This paper reports findings of a research project investigating the relationship between academic teachers' beliefs and changes in their teaching practice.

Theoretical Background

Research on (academic) teachers' beliefs has to deal with a confusing construct (Kane et al., 2002; Thompson, 1992). Different definitions of the terms beliefs and conceptions and their relationship will be discussed in this section. Reference to the theoretical framework of theories of action will be made (Argyris & Schön, 1974).

Method

We accompany eight university teachers who attend a two-year teaching-developing programme and examine their development as teachers. Teaching beliefs and practice are examined through semi-structured interviews, observations of teaching practice and documented reflection conducted at two different stages of the teaching-programme. As this paper reports findings from the first stage of our study we only draw upon experienced development from the teachers' perspective. At a later stage it will also be possible to refer to changes in beliefs and practice as perceived from the researchers perspective.

At this stage incidents of perceived development as university teacher were extracted from the interviews. In a grounded theory approach relationships between beliefs and practice concerning these incidents were categorised and different types of relationships were described across cases.

On a case level also beliefs about teaching and the perceived development as university teacher were related.

Outcomes

A) Types of relationships between teaching beliefs and practice concerning change

The following types of relationships between teaching beliefs and practice can be inferred from incidents of perceived development as university teacher:

- 1) Changes in practice without a change of beliefs: There are changes in practice, which seem not to involve changing beliefs. For example changes of order in an existing curriculum. These changes seem to be of minor extent.
- 2) Changes in practice due to changed beliefs: In this category two different types can be found:
 - a. Some changes in practice are linked to the fact that existing weaker or peripheral beliefs become stronger or more central (Green, 1971). E.g. one teacher says it always has mattered to him what competences students have acquired through his teaching. But now this question has become a central concern to him, which is reflected in his teaching practice.
 - b. Other changes in practice are connected to new beliefs. E.g. one teacher acquires the belief that teaching needs to activate students in order to foster learning processes through reflected experience, so she starts using learner-activating methods in her teaching.
- 3) Changes in beliefs due to a changed practice: Also change in practice can lead to changing beliefs e.g. when a new teaching method is given a try and has a positive outcome.

B) Relationship between teaching beliefs and perception of development as university teacher

On a case level it becomes obvious that the same assumptions that constitute one's beliefs about teaching underlie one's perception of development as academic teacher. For example one teacher feels urged to impress students by his scientific performance, as he perceives them as colleagues rather than learners. Consequently he strives to acquire further disciplinary knowledge and describes his development in teaching mainly as having a broader knowledge. These findings are in line with Åkerlind (2007) who identified different conceptions of developing as university teacher influencing development as teacher.

Conclusion

Findings confirm the stated influence academic teachers' beliefs have on teaching practice and on the development as teacher. Furthermore they shed light on the relationship between beliefs and practice concerning change. Implications for teaching development programmes in higher education will be described.

PAPER PRESENTATION

Threshold concepts and conceptual change in Dutch Ph.D. students

Marjon Fokkens-Bruinsma, University of Groningen, Netherlands; Marjolein Torenbeek, University of Groningen, Netherlands

This study focuses on identifying threshold concepts in Dutch Ph.D. students, which may interfere with their development of becoming a scientific researcher. In June 2010 five Ph.D. students and two Ph.D.s completed a questionnaire on their experience of threshold concepts in their doctoral research. First results show that all threshold concepts mentioned by Kiley (2009) were indicated by the (former) Ph.D. students. With respect to the type of conceptual change all Ph.D. students and Ph.D.s reported basic conceptual change and procedural conceptual change. Finally, they indicated which aspects they believed most contributed to the conceptual change during their doctoral research.

Objectives

How do Dutch Ph.D. students develop new levels of thinking and researching, and new ways of being a researcher? During their doctoral studies, Ph.D. students face the challenge of learning to become a researcher. They have to acquire the discourse of the educational research domain, and have to learn to become an educational researcher with the appropriate skills and knowledge to perform independent research. This can be a great challenge to Ph.D. students and may result in struggles, an exceeding of the formal duration of the doctoral research or even non-completion. This challenge of becoming a researcher can be viewed from the perspective of "threshold concepts" (Kiley, 2009; Kiley & Wisker, 2009; Trafford & Leshem, 2009), concepts that, according to Meyer and Land (2003, p.1), "lead to a transformed way of understanding, or viewing something that may represent how people 'think' in a particular discipline, or how they perceive, apprehend or experience particular phenomena within a discipline". This

study focuses on identifying threshold concepts in Dutch Ph.D. students. It will help us understand the difficulties Ph.D. students face in their becoming a researcher and identify the strategies supervisors might use to help them. As such it provides us with more insight in the problem of attrition and retention of Ph.D. students in the Netherlands. The following research questions will be answered: Which threshold concepts do Dutch Ph.D. students encounter in the four years of their Ph.D project? What type of conceptual change takes place in these Ph.D. students in terms of basic conceptual change, discipline conceptual change and procedural conceptual change? How can Ph.D. students be assisted in their transformation to a researcher?

Methodology

The data for this study was collected at the department of Pedagogy and Educational Sciences of a Dutch research university. A questionnaire composed of open questions on threshold concepts experienced during the doctoral research was completed in June 2010 by five Ph.D. students and two Ph.D.s in the Social Sciences. Data were analyzed with a coding scheme based on Kiley's (2009) study, which contains the following threshold concepts: argument/thesis, theory, framework, knowledge creation, analysis, and research paradigm. We used Davies and Mangan's (2007) scheme for describing the type of conceptual change that had taken place during the doctoral research. They describe threshold concepts from a conceptual change perspective, where a new concept emerges from reworking of prior understanding or restructuring existing naive knowledge. They suggested three types of conceptual change, namely profound or basic conceptual change which, concerns understanding of everyday experience, discipline conceptual change, that is, understanding of other subject discipline ideas, and procedural conceptual change that is the ability to construct discipline specific narratives and arguments transformed through acquisition of ways of practicing" (p. 715). Each of the answers of the Ph.D. students and Ph.D.s have been analyzed and coded independently by the two authors.

Findings

First results show that all threshold concepts mentioned by Kiley were indicated by the Ph.D. students and Ph.D.s. Knowledge creation was one of the most mentioned threshold concepts, whereas framework was the least mentioned threshold concept. It was interesting to see that one of the Ph.D.s mentioned all threshold concepts, whereas most Ph.D. students mentioned one or two types of threshold concepts. Some of the Ph.D. students mentioned some threshold concepts which were incompatible with Kiley's categorization. With respect to the type of conceptual change all Ph.D. students and Ph.D.s reported basic conceptual change and procedural conceptual change. Discipline conceptual change was only mentioned by the Ph.D.s who had experienced this discipline conceptual change after their Ph.D. To conclude, students indicated that learning on the job (learning by doing), presenting and publishing one's work, feedback or coaching from supervisors, interaction with and feedback from significant others and following courses were the aspects in the process of becoming a doctoral researcher that had most helped them in their understanding of scientific research.

Theoretical and educational significance

Our study has several practical and theoretical implications. More insight in the threshold concepts allows us to indicate the difficulties Ph.D. students experience. This will provide us with information on where to improve supervision and education of Ph.D. students. Our study contributes to the theoretical body of research on threshold concepts and conceptual change. It provides us with more information on how conceptual change may be best enhanced by the learning environment. Future research can, based on the insight into which threshold concepts are experienced by Ph.D. students acquired in our study, elaborate by examining, which the critical aspects of understanding of these threshold concepts are, similar to Taylor and Cope (2007) did in the Biology discipline. They indicated that threshold concepts have different aspects, and the degree to which the concept is understood is dependent on the understanding of these aspects. This will provide us with a more full understanding in the ideas of threshold concepts and conceptual change.

PAPER PRESENTATION

Multifaceted supervision: A response to the complexity of educating doctoral students

Ali Leijen, Tartu University, Estonia; Aivar Ots, University of Tartu, Estonia; Margus Pedaste, University of Tartu, Estonia; Karin Scager, Utrecht University, Netherlands

Successful completion of PhD studies depends on several aspects. The scope of the current study is PhD supervision. We aim to point out different factors that contribute to the quality of successful supervision. This research draws on previous research (Scager & Sonneveld, 2008) on multifaceted supervision carried out in the Netherlands and extends on previous findings with the data collected from Estonia. Scager & Sonneveld (2008) created a model of multifaceted supervision that consists of six qualities. They hypothesised that all six qualities are necessary in a successful supervision. The theoretical significance of the current research is mainly related to testing the hypothesis using the data from 90 doctoral students in Estonia. The educational significance relates to discussion on the pedagogy of supervision in doctoral studies. The major target group of this research is PhD students in education. As a control group data from PhD students from natural sciences was used. An additional aim of this study was to investigate how satisfied PhD students in educational sciences are with their supervisors in diverse domains of supervision, and which implications these findings would present for the development of study programmes. PhD studies in education have recently gained considerable attention in Estonia owing to the low graduation rates and concerns regarding the sustainability and development of the domain.

Introduction

Successful completion of PhD studies depends on several aspects. Ballantyne (2001), Hockey (1991), McCormack (2005), Sinclair (2004) point out different factors which can be organized under four categories: psychological features of a doctoral student, social-economical situation of the student, discipline and type of research, and supervision. The scope of the current study is PhD supervision. We aim to point out different factors that contribute to the quality of successful supervision. This research draws on previous research (Scager & Sonneveld, 2008) carried out in the Netherlands and extends on previous findings with the data collected from Estonia.

The literature review on the components and features of successful PhD supervision carried out by Scager & Sonneveld (2008) resulted in a model consisting of six qualities: subject knowledge of the supervisor, research expertise of a supervisor, interpersonal relations between the PhD student and supervisor, management of the PhD process, coaching of the PhD student, and supporting PhD students' socialisation and integration in a research community. Scager & Sonneveld (2008) reasoned, in line with Pearson & Kayrooz (2004) and Brown & Atkinson (1991), that supervising is a complex activity that requires supervisor's multifaceted engagement. They hypothesised that all the above-mentioned six qualities are necessary in a successful supervision. One aim of the current study is to test this hypothesis and find out whether a more versatile satisfaction with different aspects of supervision corresponds to PhD students' progression in their studies.

The main target group of this research are PhD students in education. PhD studies in education have recently gained more attention in Estonia owing to the low graduation rates and concerns regarding the sustainability and development of the domain. An additional aim of the current study was to investigate how satisfied PhD students in education are with their supervisors, and what would be the implications of these findings for the development of study programmes. Current research is part of a larger study planned for the period of 2009 – 2014.

Methods

Participants Data was collected from 90 PhD students from two universities in Estonia. In order to find out whether the situation regarding doctoral students in education is unique or similar to the situation in other fields, it was decided to collect data from two fields (education and natural sciences). 53 PhD students from the field of education (54% of the total population in Estonia) studying in two universities and 34 PhD students from the curriculum of Molecular and Cell biology and Ecology and Earth Sciences (22% of the total population in Estonia) studying in one university participated in the study. Doctoral students in education were better represented in this sample; however, students from natural sciences formed a relatively homogeneous group in several aspects and diverged from doctoral

students in education. Overall, different study years (1st, 2nd, 3rd, 4th) were reasonably represented, varying from 21% to 28%.

Data collection and analysis

Data about supervision was collected with the PhD student experience questionnaire (Scager & Sonneveld, 2008). The questionnaire consists of 56 items measuring PhD students' satisfaction with their supervisor in six areas of supervision (see introduction). In addition, the questionnaire consists of several open questions that allow exploring further different aspects related to supervising. The original questionnaire was translated to Estonian and back-translated to English. A native speaker who is an expert of doctoral studies compared the original and back-translation. He approved the quality of the translation. Scager & Sonneveld (2008) report high inner-reliability scores of the questionnaire's six scales. Similarly, inner-reliability scores of the scales were also high in our study (Cronbach α varying from 0,89 to 0,95).

Data about the progression in studies was measured based on students' collection of credit points. In Estonia, PhD studies consist of 240 ECTS credit points (180 credit points are reserved for PhD research and dissertation and 60 credit points for courses). On average, a student is expected to collect 60 credit points per year. The nominal period of a doctoral study is four years.

Data was collected during December 2009 - January 2010 with an online questionnaire on voluntary basis. No incentives were given to students for participation.

A T-test was used to examine whether PhD students in education and natural sciences differ in satisfaction rates with their supervisors. Qualitative content analysis (Bogdan & Bilken, 1992) and chi square tests were used to analyse the answers given to the open questions. Chi square tests were used to find out whether the multifaceted satisfaction with supervision is related to the progression in PhD studies.

Results

T-tests showed that natural sciences doctoral students' satisfaction with their supervisors was generally higher in comparison to the satisfaction of students in education. Regarding two areas of supervision, the difference was statistically significant. Doctoral students in education evaluated their supervisors significantly lower as 1) supporters of acculturation in research community ($t = -2.38$; $df = 74$; $p < 0.05$) and 2) experts in the PhD research domain ($t = -2.38$; $df = 77$; $p < 0.05$). Chi square test showed that among students with faster progression in studies were more often those who reported multifaceted satisfaction with their supervisor ($\chi^2 (1, N = 41) = 4.21$; $p < 0.05$) in comparison to students with slower progression in studies. Correspondence was also found between some singular aspects of supervision and progression in studies. However, a more versatile satisfaction with supervision seemed to be more clearly associated with the progression rates. The given result is theoretically significant since it appears in accord with the hypothesis of multifaceted supervision (Scager & Sonneveld, 2008). Multifaceted supervision seems to enhance the complex task of educating doctoral candidates and presents new prospects for the pedagogy of supervision. The latter illuminates the educational significance of the current study.

PAPER PRESENTATION

The undergraduate research journey: a cross-disciplinary examination of student experience

Kylie Shaw, The University of Newcastle, Australia

Interest in undergraduate research is gaining momentum in higher education globally. In particular, ways of integrating a capstone research project into undergraduate programs are being explored in light of the need to strengthen the output and quality of postgraduate research. In this study, student experience was explored across a range of fourth-year undergraduate programs in an Australian university, using visualisation as a reflective tool. The aim was to accurately describe the research journey in a way that would permit comparisons of types of journey within and between programs. The sample for the study was 162 fourth-year students across 14 different disciplines. A questionnaire was disseminated to participants, asking for general information and details of their research program. They were asked to draw a plot of their undergraduate research journey on the provided axis, labelling the high and low points of their experience. Commonalities and differences in the journeys were explored using a mix of quantitative and qualitative data analysis techniques. This study highlighted students' orientation to research through their understanding of the nature of the journey, experienced across different disciplinary contexts. It is through

providing a substantial early experience of research in undergraduate education that confidence in the capacity to carry out research can develop and, equally, potential research talent can be uncovered. Successful graduates then have the opportunity to 'fast-track' to a doctoral research degree and higher levels of professional standing within their discipline.

The undergraduate research journey: a cross-disciplinary examination of student experience

Rationale and relevance

Interest in undergraduate research is gaining momentum in higher education globally. In particular, ways of integrating a capstone research project into undergraduate programs are being explored in light of the need to strengthen the output and quality of postgraduate research and production of knowledge. The notion of 'journey' has been used to describe personal experiences of the doctorate (Batchelor & Di Napoli, 2006) and to map the terrain, providing a commonality of process which lies beneath disciplinary contexts (Miller & Brimicombe, 2003). Furthermore, there are increasing numbers of studies turning to metaphor and representation to try to elucidate the doctoral experience, for example, the intensity and emotive aspects of the individual's doctoral student experience have been compared to that of an emotional rollercoaster (Kearns, Gardiner, Marshall & Banytis, 2005). However, there has been no attempt to develop quantitative measures of journey plots that allow journeys to be compared across individuals and groups.

Aims, Research Methods and Design

In this study, student experience was explored across a range of fourth-year undergraduate programs in an Australian university through the concept of a research journey, using visualisation as a reflective tool. The aim was to accurately describe the research journey in a way that would permit comparisons of types of journey within and between programs. An instrument was developed which asked respondents at the end of their research project to plot their research journey, from the start of the project to the point of submission for examination, on an axis and to self-identify the highs and lows of their journey. The study was designed to concentrate on one site, and within the site to sample multiple programs. The site for the study was a regional university, chosen because of its spread of students across demographic groups and the range of disciplines that offered fourth-year research projects. Major areas included: Architecture & Construction Management; Arts & Social Studies; Economics; Education; Engineering; Law; Medicine & Health Sciences; Music; Nursing; Science and Mathematics. Information to student participants was disseminated through the academic coordinators for the discipline and participation was both voluntary and anonymous. The sample for the study was 162 fourth-year students across 14 different disciplines at the site. A questionnaire was disseminated to participants, asking for general information about the respondent and about the components of their research program. They were also asked to draw a plot of their undergraduate research journey on the provided axis, labelling the high and low points of their experience. Commonalities and differences in the journeys were explored using a mix of quantitative and qualitative data analysis techniques. The emergent methodology used to analyse aspects of the journey by transcribing, coding and recording text from the plot and measuring the coordinates of the visual representation is a new approach to exploring student experience. This method allowed for a depth of information about the research project previously not examined through a survey instrument, allowing for a comparison of student experience of research across different programs. These data provided insight into the impact of both personal and research-related tasks on the journey for students. A range of measures were developed based on the research plot including: student disposition at the beginning of the journey, the types of journey experienced, the milestones identified along the way and the extent of the highs and lows experienced.

Results and conclusions

The different shapes of the journey plots that were recorded suggested that there were large differences in student dispositions towards the research project. While each journey was highly individual, the grid allowed comparison in key areas: the start and finish positions, the nature of the items labelled, the number of positive and negative peaks and the overall pattern of peaks. The exploration of the research journey added a depth of detail previously uncovered in the literature about student experience. The data identified tasks in undergraduate research which pose challenges for students as a whole, and also compared the elements across programs. The value of this new measure lies in its capacity to make the process of research visible. This study highlights students' orientation to research through their understanding of the nature of the journey, and the highs and lows experienced across different disciplinary contexts. Overall the research suggests that the disposition of a student at the commencement of a project contributes to their preparedness to complete the research task and how they perceive research. The data suggests, from the student perspective, some of the places within the undergraduate research project where students become 'stuck' in the form of low episodes in their experience of research and from the journey plot we can visualise

how students then emerge from these stuck places to continue their journey and successfully master a new way of thinking within their discipline (Kiley & Wisker, 2009).

Significance

Increasingly, students across disciplines need incentives to pursue careers in research, and in academe, to sustain the on-going development of disciplines and to keep pace with the changing global emphasis on research. In the Australian context, the fourth year undergraduate research project is relatively unique in that students who excel are propelled directly into a doctoral research program. It is through providing a substantial early experience of research in undergraduate education that confidence in the capacity to carry out research can develop and, equally, potential research talent can be uncovered. Graduates then have the opportunity to 'fast-track' their way at an early age to doctoral research degrees and to higher levels of professional standing within their disciplines.

PAPER PRESENTATION

The motivations, characteristics, and practices of the highly productive research supervisor

Margaret Kiley, CEDAM, Australia

The aim of this research was to identify the various characteristics and practices of those research supervisors who, over their career and at any one time, supervise substantially more PhD candidates than is standard in Australian universities. Furthermore, the research aimed to identify and understand why these academics supervise so many candidates.

The research employed interviews that were subsequently transcribed, returned to the interviewee for confirmation, and then analysed using concept coding and categorisation.

The most common factor reported in the interviews was a love of teaching at the PhD level. Many reported that they enjoyed teaching, but not so much at the undergraduate level which tends to employ lectures and tutorials, but rather the one-to-one relationship developed in a supervisor/candidate relationship. In addition, interviewees reported the excitement they gained from intellectual engagement with candidates who were talented and interested in research, and their desire to imbue early career researchers with their own enthusiasm for research.

An examination of the literature on research supervision in Australia indicates a growing interest in the pedagogy of research supervision and the research reported here contributed to that pedagogical understanding with insights from highly productive supervisors.

Aims

The aim of this research was to identify the various characteristics and practices of those research supervisors who, over their career and at any one time, supervise substantially more PhD candidates than is standard in Australian universities. Furthermore, the research aimed to identify and understand why these academics supervise so many candidates.

Most universities in Australia recommend, and some enforce, that any one doctoral supervisor should have a maximum of four full-time equivalent doctoral candidates at any one time. The Australian doctoral education model involves supervisors in substantial hands-on supervision and even where co-supervisors are involved the bulk of the supervisory load tends to fall on one person. Therefore, the reason generally given for the limit on numbers is that to provide adequate time and attention to candidates and their projects substantial commitment and human resources are required.

In light of this general practice, this project set out to understand why, and how, some supervisors who are considered to be excellent, also manage to supervise anything up to eight or ten candidates at the one time and with considerable success. Methodology

The research employed interviews that were subsequently transcribed, returned to the interviewee for confirmation, and then analysed using concept coding and categorisation.

Deans of Graduate Studies in eight Australian universities (approximately 20% of the Australian total) were asked to nominate supervisors across a range of disciplines and who had a reputation for quality supervision, timely and successful completions and substantially more, in terms of numbers, than average. Interviews with 20 supervisors are reported in this paper.

The interviews addressed a number of issues including:

- Demographic e.g. how many students supervised?
- Motivational e.g. Why do you undertake such a substantial supervisory load?
- Philosophical e.g. How would describe your approach to supervision?
- Practical e.g. How do you manage such a large candidate load?

Findings

The most common factor reported in the interviews was a love of teaching at the PhD level. Many reported that they enjoyed teaching, but not so much at the undergraduate level but rather the one-to-one relationship developed in a supervisor/candidate relationship.

Following on from the 'teaching' theme reported by most of the interviewees was the excitement they gained from intellectual engagement with candidates who were talented and interested in research. A third characteristics related to the supervisors' love of research and the desire to imbue early career researchers with this enthusiasm Theoretical and educational significance of the research.

One critical aspect of doctoral education is the quality of, and candidates' levels of satisfaction with, research supervision. As Golde (2000) suggests one of the main reasons that candidates leave their doctoral program is that they have not been appropriately socialised into the discipline and institution. Lovitts and Nelson (2000, p. 49) further argue from their study that: 'The data suggest that the single most important factor in student decisions to continue or withdraw is the relationship with a faculty adviser.'

Satisfaction with the supervisory relationship is not only critical in candidates' decisions to stay or withdraw but the research suggests that the quality of supervision is a factor in timely completion of the PhD. For example de Valero (2001, p. 346) suggests that the following characteristics are those linked with timely completion: 'financial support, departmental orientation and advising, relationship between coursework and research skills, requiring significant results in the dissertation, student-committee relationship, student-advisor relationship, attitudes towards students, student participation, and peer support.

An examination of the literature on research supervision in Australia indicates a growing interest in the pedagogy of research supervision. 'One important consequence of the increasing scrutiny and intervention into the doctorate over the past decade or so has been the emergence of a set of practices concerned with doctoral education, focusing attention explicitly on the educative work involved in preparing doctoral graduates' (Boud & Lee 2009, p. 1).

The research reported here suggests that some supervisors can take on two or three times as many candidates as generally advised and still produce highly satisfied graduates who have completed successfully and in a timely fashion, the ways and means of this will be reported in detail in the conference presentation and paper.

PAPER PRESENTATION

Law teaching: true vocation or tribulation?

Gail Kotze, Tshwane University of Technology, South Africa; S Gravett, University of Johannesburg, South Africa

This paper reports on a study that examined the culture and identity of the legal academic as teacher. The study is based on three law teachers at a South African university. Using an ethnographic design type data was collected through observation during class visits, discussion about teaching in interviews and a review of teaching-related documents. The research revealed that participants' primary professional identity is created around their definition of themselves as teachers and not legal practitioners. Not only do they choose to teach but regard teaching as true vocation. As core of the nature of their teacher identities, participants express a significant emotional dimension shaped by their relationships with students.

This study originated from my need as educational advisor to increase my knowledge and understanding of legal academics and how they teach. It aims to contribute to our knowledge of the academic profession. There is evidence that the need to improve the understanding of the academic profession is shared by others (Becher and Trowler, 2001). Clark (1987:2) emphasises the need to study academics: "Of this we can be sure: the academic profession makes a difference. We can hardly know too much about it".

A literature search revealed that not much research has been conducted in this area. Although some attention has been given to the study of academics it has not focused extensively on legal academics in their teaching role (Taylor, 1999; Henkel, 2000; Becher and Trowler, 2001). In terms of teaching in particular, literature tends to tell academics what to do but what they actually do receives less attention. This while the choices that law teachers make about subjects and how they teach these influence generations of law students.

Until 2004, when Cownie published the first extended study exploring the everyday life of the United Kingdom law school, such studies were rare if not absent (Becher and Trowler, in Cownie, 2004). No evidence exists of any investigation of the culture of the legal academic as teacher within a South African context. Exploring the culture of a small number of South African legal academics as teachers will add a unique perspective to what is currently known and in so doing contribute to what Cownie (2004:47) calls "sustained qualitative examination" of legal academics.

Using an ethnographic design type I studied three purposefully selected legal academics at a South African university.

The study was guided by the following questions:

- What are legal academics' patterns of beliefs, behaviour, norms, attitudes and values about teaching the law?
- What constitute legal academics' identity as teacher?
- What shape/form legal academics as teachers?

Data was collected by three methods associated with qualitative research and an ethnographic design type; namely interviews, class observations and teaching-related documents. The transformation of data comprised three stages; namely description, analysis and interpretation. To realize the descriptive phase I made use of global analysis to search for main features or characteristics of each of the participants without chunking the data into smaller pieces but instead maintaining a holistic view of the data. This was followed by content analysis. Additionally, I conducted discourse analysis in extracts from all data sets. Word portraits were subsequently created around the core teaching characteristic of each of the participants. These main features portray the way in which they understand, experience and conduct themselves as teachers.

The principal findings suggest that participants' primary professional identity is created around their definition of themselves as teachers and not legal practitioners. As occupants of the teaching role participants reveal what Gee (2000:100) refers to as an "institution identity". Since an institution-identity is not given to an individual by nature or accomplished by individuals on their own it can be experienced as either a calling or an imposition. In fact in a world where work is sometimes equated with suffering and where people often do not regard their work as a true vocation (Palmer, 1998) it would be reasonable to argue that academia may be harbouring legal academics that would rather be exclusively practising law. However, in looking at participants' intention in making choices about their career path it is evident that they make a conscious choice to teach and do not regard it second best to being a legal practitioner. In making this choice participants illustrate a strong association with academic culture as opposed to the legal profession which has distinctive values and norms. This finding expands on the work of Cownie (2004) related to cultures and identities of legal academics, who found that law teachers regard academia a preferred career and true vocation.

A second feature of participants' primary identity as teacher is a display of emotion and passion in their teaching. The emotional side of teaching displayed is not unique and undisputed in literature (Hargreaves, 2000; Bellas, 1999). Teaching as emotional labour has been linked to the profession of university professor (Hochschild, 1979). Although Hargreaves (1998) confirms that teachers' relations with their students are often notably emotional in nature and what this study found therefore a mere reaffirmation of what is already known, the finding is significant because it relates to an aspect hardly touched on in studies similar to this one. Although Cownie (2004) in her study of the culture and identity of legal academics in the United Kingdom found that legal academics gain satisfaction from teaching, she did not explore their relationship with students further. As core of the nature of their teacher identities, participants value close contact with their students and embrace a caring notion toward them. The "emotional heart" of their teaching (Woods, 1996) underpins the values that shape them as teachers and as such emphasizes their strong association with teaching as true vocation.

PAPER PRESENTATION

Statistics anxiety: Relation to trait anxiety, learning behavior, and performance

Manuela Paechter, Karl-Franzens-University Graz, Austria; Daniel Macher, Karl-Franzens-University Graz, Austria; Ilona Papousek, Karl-Franzens-University Graz, Austria; Kai Ruggeri, Queen's University, Belfast, United Kingdom

Statistics anxiety can be described as the apprehension that occurs when an individual is exposed to statistics content, problems, instructional situations, or evaluative contexts. Statistics anxiety is situation-specific, inasmuch as the symptoms only emerge at a particular time and in a particular situation. It manifests itself by extensive worry, intrusive thoughts, mental disorganization, tension, and arousal in situations related to statistics. Generally, little is known about the underlying mechanisms of the relationship between statistics anxiety, its antecedents, students' learning behaviors, and their academic performance. Therefore, in the present investigation, the relationship between statistics anxiety, antecedents of statistics anxiety, learning behavior, and academic performance were investigated by means of structural equation modeling.

One-hundred forty-seven students enrolled in a statistics course in psychology filled in a questionnaire on statistics anxiety, trait anxiety, interest in statistics, skills in mathematics, learning strategies, and procrastination. Also, performance in the examination was recorded. Statistics anxiety receives a crucial role in the structural equation model. It is directly related to academic performance. Besides, statistics anxiety is related to inefficient learning behaviors such as procrastination. Statistics anxiety itself was related to antecedents such as skills in mathematics, gender, and trait anxiety. The results of the reported study do not only explain more of the mechanism how anxiety influences performance but are also important for instruction.

Introduction and aims of the research

A large proportion of students identify statistics courses as the most anxiety-inducing courses in their curriculum. Especially in subjects such as psychology, education, or sociology, statistics anxiety is widespread among students (Onwuegbuzie & Wilson, 2003). Statistics anxiety can be described as the apprehension that occurs when an individual is exposed to statistics content, problems, instructional situations, or evaluative contexts. Statistics anxiety is situation-specific, inasmuch as the symptoms only emerge at a particular time and in a particular situation. It manifests itself by extensive worry, intrusive thoughts, mental disorganization, tension, and arousal in situations related to statistics (Zeidner, 1991). The development of statistics anxiety can be influenced by an individual's experiences or skills in subjects such as mathematics, by traits such as anxiety, or by attitudes such as interest in statistics. There is evidence that statistics anxiety is related to general trait anxiety (Zeidner, 1991). Also, female students report higher levels of statistics anxiety than male students. Previous research suggest that students with a high level of statistics anxiety show lower academic achievements (Walsh & Ugumba-Agwonobi, 2002). Presently, it is not clear whether statistics anxiety exerts a direct influence in an examination, e.g., by worry and intrusive thoughts, or whether statistics-anxious students use inadequate learning strategies for achievement and are less prepared. Research points at a relationship between statistics anxiety and specific learning behaviors such as procrastination. Generally, little is known about the underlying mechanisms of the relationship between statistics anxiety, its antecedents, students' learning behaviors, and their academic performance. Therefore, in the present investigation, the relationship between statistics anxiety, antecedents of statistics anxiety, learning behavior, and academic performance are investigated by means of structural equation modeling.

Methodology

Participants were 147 undergraduate students enrolled in an introductory statistics lecture-based course offered for psychology undergraduates. In the study, 112 female students (76.19 %) and 35 male students (23.81 %) took part. The materials for this study include data gathered from questionnaires on statistics anxiety, trait anxiety, interest in statistics, skills in mathematics, the application of learning strategies, academic procrastination, and academic performance in the statistics examination. Questionnaire data were recorded one week prior to the examination. Additionally, the students' examination scores were recorded. FindingsA structural equation model on the relation between statistics anxiety, possible antecedents, learning behaviors, and academic performance was tested. The χ^2 test and descriptive fit indices provided by the software suggest a good fit of the model ($\chi^2 = 42.966$, $df = 30$, $p = .059$; $\chi^2/df = 1.43$; CFI = .97; RMSEA = .05; SRMR = .05). The model shows four antecedents that are related to statistics anxiety: Participants with higher levels of trait anxiety report higher levels of statistics anxiety ($\beta = .42$). Female students report higher levels of statistics anxiety ($\beta = -.32$). Skills in mathematics and interest in statistics are both negatively related to statistics anxiety ($\beta_1 = -.22$, $\beta_2 = -.31$). Both, trait anxiety and statistics anxiety are positively related to procrastination (higher levels of anxiety indicate a higher level of procrastination; $\beta_1 = .24$, $\beta_2 = .27$). Male students showed higher procrastination values than female students ($\beta = .37$). Several variables of the model influence academic performance: Statistics anxiety is negatively related to performance ($\beta = -.30$). Knowledge and skills in mathematics ($\beta = .16$) and interest in statistics ($\beta = .21$) have a positive influence on examination performance. Contrary to initial expectations, no significant relationship between procrastination or deep-level learning strategies and examination performance was found. Of the learning-related behaviors measured, only the frequency of the application of personal resource management strategies contributes positively to performance ($\beta = .16$). In the model, statistics anxiety is directly related to academic performance and is the strongest predictor of performance but it also has an indirect influence on academic performance via its relationship to procrastination.

Theoretical and educational significance

Statistics anxiety receives a crucial role in the structural equation model. It is directly related to performance in the examination. This relationship may be explained by the cognitive anxiety component. Statistics anxiety may lead to an adverse cognitive interference between examination-irrelevant thoughts such as worry and rumination and examination-relevant thoughts. Statistics anxiety is also related to procrastination and thus to less investment of personal resources in learning. Statistics anxious students spend less time for learning, show less concentration and effort, are less prepared for the examination, and consequently achieve less in the examination. The results of the reported study do not only explain more of the mechanism how anxiety influences performance but are also important for instruction. They suggest to support anxious students not only in the examination but also prior to the examination. In the examination, students profit from anxiety-reducing measures such as providing enough time for the examination or using humorous examination tasks (Onwuegbuzie & Wilson, 2003). Prior to the examination, instructors should support students in avoiding procrastination, for instance, by regularly providing opportunities for exercise and reflection of learning content. Instructors are advised to stimulate students' interest in statistics, perhaps by emphasizing the importance of statistics for the students' later vocation and for daily life. By such measures, students will be better prepared for the examination and experience less statistics anxiety.

PAPER PRESENTATION

Only connect? Being, knowing and communicating in the 21st century university.

Charles Anderson, Edinburgh University, United Kingdom; Velda McCune, University of Glasgow, United Kingdom

Abstract

To address the conference's main theme of 'Education for a Global Networked Society' would seem to require attention to be given to the interrelations between: the goals of education, the nature of our 'global networked society', its forms of communication and its pluralist knowledge practices. An influential characterisation of these interrelationships has been provided by Ron Barnett who has noted how 'Amid supercomplexity, the educational task [of universities] is primarily an ontological task. It is the task of enabling individuals to prosper amid supercomplexity, amid a situation in which there are no stable descriptions of the world' (2004, 252). This presentation examines a number of the challenge that students face in developing the forms of being and the orientations to knowledge associated with an age of supercomplexity. Attention centres on three interconnected areas of analysis. First, there is an examination of the types of commitments that may be required of both students and staff within learning communities in a 'global networked society'. The focus then moves to the question of how to conceptualise the knowledge practices that characterise current learning communities in higher education and the orientations towards knowledge that may be expected of students in an age of supercomplexity. This leads in turn to an examination of the nature of communication and the creation of meaning within learning communities that seeks to problematise the simplistic metaphors and models of communication that often underpin talk of global networking and 'knowledge transfer'.

PAPER PRESENTATION

Only connect? Being, knowing and communicating in the 21st century university.

Charles Anderson, University of Edinburgh; Velda McCune, University of Glasgow

Extended Summary

Introduction

This presentation examines a number of the challenge that students face in developing the forms of being and the orientations to knowledge associated with an age of supercomplexity. Attention centres on three interconnected areas of analysis. First, there is an examination of the types of commitments that may be required of both students and staff within learning communities in a 'global networked society'. The focus then moves to the question of how to conceptualise the knowledge practices that characterise current learning communities in higher education and the orientations towards knowledge that may be expected of students in an age of supercomplexity. This leads in turn to an examination of the nature of communication and the creation of meaning within learning communities that seeks to problematise the simplistic metaphors and models of communication that often underpin talk of global networking and 'knowledge transfer'.

The commitments and intentions displayed by students and lecturers

We begin by building on a feature of Wenger's (1998) account, considering how his depiction of learners' 'trajectories' in relation to communities of practice can inform our understanding of the commitments which learners may form as they come to identify with particular communities. A learner's trajectory is their sense of a path of development in relation to a particular community of practice. Where learners come to envisage a trajectory which brings closer identification with a particular community this can have a notably positive impact on their engagement with their studies (McCune, 2009). Thus Wenger's work signals the particular importance of those learning activities which encourage a sense of inbound trajectory among learners. This does, however, leave open the question of how to

support engagement among the many learners who will not intend to become full participants in a particular community but who may come nonetheless to value the practices of that community.

This question of trajectories is then considered in relation to Barnett's recent work (Barnett, 2007; Barnett and Coate, 2005) which can be seen to draw attention to the types of commitments that may be required of both students and staff if a learning community is to be engendered and the forms of being that may be demanded of students in such a community and in future transitions into and between work settings and cultural milieux.

Knowledge practices and orientations to knowledge

Attending to the forms of being demanded of students directs attention towards how meaning is negotiated within its social and cultural contexts (Lea, 2005), and to the knowledge practices that characterise learning communities in higher education and the orientations towards knowledge, (and towards discussions concerning knowledge), that are expected of students. In other words, consideration is given to the epistemological challenges associated with the ontological task identified by Barnett. Here we draw out implications for practice, shedding light on why even experienced learners often struggle with classroom discussion and assessed work as they work to negotiate the practices of particular communities, rather than reapplying generic skills; and introduce cautionary notes concerning the degree to which it is reasonable to expect students to move readily between the knowledge practices of different communities in a 'networked' society.

Communication and the construction of meaning: partial connection

This analysis of knowledge practices leads in turn to an examination of the nature of communication and the creation of meaning within and between learning communities in an age characterised by supercomplexity. Rommetveit's subtle account of how commonality of reference can be achieved to a degree (e.g. Rommetveit, 1992) against the background of 'a world we assume to be multifaceted, only partially shared' (Rommetveit, 1974, 34) offers valuable insights here. According to Rommetveit, a crucial matter for the coordination of attention and intention, is the sufficient sharing of perspectives on the matter that is under discussion (Rommetveit, 1974, 1990; Graumann, 1995). Implications of this emphasis on perspectivity for the fostering of learning communities are drawn out; and issues surrounding the relative power and authority of interactants, including their capacity to set the perspectives under which topics will be viewed, are examined. Building on this consideration of Rommetveit's work, a concluding section explores how Law's (2004, 62) advocacy of an ontology of the 'in-between', of partial connection, may be an appropriate way in which to frame our understanding of the challenges that university lecturers face in fostering communities of learners for a global, networked society.

Models of scientific thinking and connections to guidance and students' learning in university.

Hanna-Maija Liitos, University of Jyväskylä, Finland; Eeva Kallio, University of Jyväskylä, Finland

This paper investigates the complex nature of acquiring scientific thinking from three theoretical perspectives in students' learning in university context. Scientific thinking is defined to compose of thought operations, which include critical and logical thinking and judgment making skills based on evidence and awareness of one's epistemic assumptions. Students in this study represent two different faculties of sciences. Their models of thinking are studied in the beginning and in the middle phase of their studies and the relation to study guidance is explored. Research questions are following: 1) what kind of models of scientific thinking can be detected from students' thinking and 2) how these differences are related to students' experience of studies, including guidance of studies? Analysis of students' entrance examination essays, questionnaire and in-depth interviews were used to explore these questions. Preliminary results show that in the already beginning of their university studies relativism, i.e. ability to understand multiply perspectives on knowledge is present on student's thoughts. This form of thought is also present in the middle phase of studies, although some forms of integrative and evaluative thinking are emerging. Students present ambivalent thoughts on study guidance, part of them present positive attitudes and regard guidance as self-regulative tool, others have not used it, but instead formed independent plans for conducting their studies.

Theoretical framework

The purpose is to explore scientific thinking skills during university studies through three theoretical perspectives: dialectical thinking by Basseches (1984, 2005), Kuhn's (2002) model of epistemic understanding and Baxter Magolda's (2001) model of self-authorship. Three perspectives are used to understand the complex nature of acquiring scientific thinking skills. Scientific thinking is defined to comprise of thought operations, which include critical and logical thinking and judgment making skills based on evidence and awareness of one's epistemic assumptions. (Hofer & Pintrich, 2002; Kuhn, 2002; Commons & Pekker, 2004).

According to Perry (1968), students' patterns of reasoning develop through absolutistic/dualistic assumptions of knowing to relativism, and further to evaluative and integrative forms of knowing. In this study Basseches' model is used as a framework for adult thinking as continuous evolving process and movement to more evaluative and integrative forms of thought as organized on called 'schematic framework'. Secondly, Kuhn's model on development of epistemic understanding, reasoning and beliefs on knowledge was used, and also Baxter Magolda's model, which concentrates on building self-authorship in decision making. Models focus and emphasize different dimensions of scientific thinking. Guidance is defined according to social-constructive learning theory and is seen as horizon for action, where individuals choices are linked in cultural and social factors (Hodkinson & Sparks, 1997).

Mentioned models of scientific thinking are explored in different phases of study processes. Student's levels of thinking, learning experiences and experiences of guidance have been studied in the beginning and in the middle phase of their studies.

Major research questions are:

1. What kind of models of scientific thinking can be detected from student's thinking in the beginning and in the middle phase of university studies?
2. How these differences in the levels of thinking are related to student's significant learning experiences and experience of study guidance?

Methodology

60 student's entrance examination essays were analyzed using dialectical thinking schemata in the year 2006. Students' experiences of their study processes and thinking skills and guidance of studies were examined by study questionnaire in 2008. Questionnaire is based on integrative pedagogy and -thinking theories (Tynjälä & Kallio, 2010; Kallio, 2010) included questions about self-evaluation of thinking, of study processes, experiences of received guidance, personal study planning and amount and quality of guidance received during the studies.

In-depth interviews were conducted for a subgroup of students (N=27) in 2009-2010. Interviews included epistemic problem solving task called 'Livia war problem', Kuhn, *ibid.*), and semi-structured questions of students' own decision making and learning (Baxter Magolda, *ibid.*) during university studies. Interviews were tape recorded. To analyse the data both quantitative and qualitative methods were used.

Findings

Preliminary results indicate that dialectical thinking of the students in the beginning of their studies focus mainly on basic argumentation skills. This includes the understanding of relativistic nature of knowledge. Least present were

evaluation and integration of different perspectives. Preliminary results of epistemic understanding study show that students' thinking is predominantly on relativistic level in the middle phase of studies, although evaluativist levels are also present. From analysis of Baxter Magolda's model, student's present mainly relativistic and independent patterns of knowing.

Students' thoughts on guidance of studies and especially attitudes towards personal study plans were inquired in study questionnaire. Students were overall content with their study processes in university. The need for guidance differs during study processes, as student's needs for guidance is individual, although guidance is also needed in the middle phase of studies. Continuity and presence of guidance seem to be important issues for students. Question on personal study planning raised contradictory result: part of students (N=23) experiences personal study planning very important for success of their study processes, while same amount experiences that study planning has not influenced to their study processes; and last ones (N=17) had not formed opinion on matter. Students, who regarded personal study plan positively, used it for understanding and conversations and tool for planning of their studies. For those, who regarded it negatively, had not used personal study planning as a tool for their studies or had developed individual study plans.

Theoretical and educational significance

In sum, preliminary results indicate that university students show relativistic thinking forms already in the beginning of their university studies. This result is based on Basseches' model of dialectical thinking and it goes against to most of empirical results before: it has been claimed that in the beginning of their studies, students show absolutistic thinking, and relativistic thinking in the midst phase of their studies (see Perry, *ibid.*). However, because these are still preliminary results, no further conclusions can be made and final results have to be waited. The second main study question of the interconnections between development of thinking and learning-environment are under way and results of these interconnections will be discussed in the presentation.

PAPER PRESENTATION

Moving beyond academic procrastination by investigating procrastination in different life domains

Katrin Birte Jorke, Bielefeld University, Germany; Laura Meike Thau, Bielefeld University, Germany

The results of a variety of studies suggest that academic procrastination (chronic postponement of study related tasks) is detrimental to academic success. More and more universities offer counselling services for students suffering from academic procrastination. However, in order to support students effectively counsellors need to understand whether their clients' procrastination is solely an academic phenomenon or whether it occurs in other life domains as well. Hence, we need to move beyond the investigation of academic procrastination in order to understand procrastination comprehensively. In the present study on 203 students (mean age = 23.8) six different life domains (academic, daily duties, health, leisure, family, social contacts) were compared in regard to their occurrence and frequency of procrastination and in regard to the correlations of procrastination with other constructs (self-efficacy, stress, and life-

satisfaction). Results show that procrastination occurs in all domains investigated, that procrastination differs in frequency from one life domain to the other and that procrastination's correlations with self-efficacy, stress, and life-satisfaction vary in strength between domains. Interestingly, the academic domain was the domain displaying the highest procrastination frequency, while procrastination in the social contacts domain was correlated the highest of all domains with self-efficacy, stress, and life-satisfaction. The results deliver first hints for domain specificity of procrastination and will support the development of an instrument assessing the individual procrastination pattern across domains which, in turn, will support student counsellors in configuring their interventions for academic procrastination.

Theoretical Background and Aims

The results of a variety of studies suggest that academic procrastination (chronic postponement of study related tasks) is detrimental to academic success. More and more universities offer counselling services for students suffering from academic procrastination. However, in order to support students effectively counsellors need to understand whether their clients' procrastination is solely an academic phenomenon or whether it occurs in other life domains as well. Hence, we need to move beyond the investigation of academic procrastination in order to understand procrastination comprehensively. While previous procrastination research has focused on academic procrastination we adopt a holistic approach by examining procrastination in different domains. The purpose of the present study was to understand whether procrastination does occur in other domains but the academic, and if yes, whether procrastination differs in its characteristics (i.e. correlations with other constructs) between domains. We compared six different domains in regard to the occurrence and frequency of procrastination and in regard to the correlations of procrastination with other constructs. The domains (derived from a literature research and a qualitative study concerning commonly applied classifications of life domains) were: academic, daily duties, health, leisure, family, and social contacts. The constructs represent commonly assessed correlates of procrastination in procrastination research: self-efficacy, stress, and life-satisfaction.

Methods

Sample: Participants were 203 university students (mean age = 23.8, SD = 3.5), 83.7% of which were female. Participants were enrolled in different fields of study and had been studying for five semesters on average (M = 5.8, SD = 3.7). Participants were recruited via an online link on different social network websites. **Procedure:** The study was implemented via an online survey. Each domain's content was explained briefly before participants proceeded to fill out the survey which contained instruments for assessing the occurrence of procrastination in each domain (4-point scale, 1 item), the frequency of procrastination in each domain (adapted version of the Procrastination Scale for Students; Glöckner-Rist, Engberding, Hßcker & Rist, 2009; 6-point scale, 6 items each, .93 (family domain)

Results

First, for the grant majority of participants procrastination did occur in all domains (academic: n = 191, daily duties: n = 196, health: n = 195, leisure: n = 177, family: n = 180, social contact: n = 181). Secondly, results of multiple t-Tests (with Bonferroni correction) showed that all but two differences in procrastination frequency were significant (daily duties – health, family – social contacts). The domain displaying the highest frequency was the academic domain (M = 3.32; SD = .92). The domain displaying the lowest frequency was the leisure domain (M = 2.34; SD = .81). Correlations between procrastination frequency in different domains ranged from .39 (p p r = -.37 (p r = -.18 (p r = .32, p r = .19, p r = -.38 (p r = -.19 (p r = -.21, p r = .26, p r = -.24, p

Discussion

Results show that procrastination occurs in all domains investigated, that procrastination differs in frequency from one life domain to the other, and that procrastination's correlations with self-efficacy, stress, and life-satisfaction differ in strength between domains. Interestingly, procrastination in the social contacts domain seems to have the highest influence on stress and life-satisfaction, while procrastination in the academic domain, although being the domain displaying the highest procrastination frequency, is not as highly correlated with self-efficacy, stress, and life-satisfaction as one might have expected based on the general notion of academic procrastination as an impediment to academic success and subjective well-being. The results prove the approach taken in this study to be worthwhile in that it helps to understand procrastination more comprehensively. The differences in procrastination's character between domains can be seen as first hints for domain specificity of procrastination. The results support the demand for the development of an instrument assessing the individual procrastination pattern across domains. Such an instrument will support student counsellors in understanding their clients' academic procrastination in the broader context of procrastination in different domains which, in turn, will help to tailor interventions accordingly. Future studies should extend on these results by exploring the reasons for and consequences of procrastination in each domain on a more detailed level.

PAPER PRESENTATION

Promoting self-regulated learning in university education

Hideko Itoh, National Institute of Multimedia Education, Japan

Methods of promoting self-regulated learning in university education were investigated based on the quantitative and qualitative analyses of learning self-efficacy, self-evaluation of learning, and goal setting, as well as the usefulness of the learning and instructional activities. Participants were Japanese graduate students ($N = 36$) who alternatively took the role of instructor or learner. Participants completed the Learning Self-Efficacy and Self-Evaluation of Learning scales, which consisted of the following items: 1. Concentrate on the lecture, 2. Understand the lecture, 3. Identify key ideas, 4. Memorize the contents, 5. Acquire deep and wide knowledge, 6. Think by oneself, 7. Do one's best to solve problems, 8. Actively participate in collaborative work, 9. Actively participate in discussions, and 10. Ask questions. The correlation between the mean scores on the Self-Evaluation of Learning and Learning Self-Efficacy scales for a subsequent course indicated that higher levels of performance were correlated with higher self-efficacy ratings for subsequent learning. All the item scores on the Learning Self-Efficacy scale significantly increased after taking the course. These results are consistent with Bandura's theory of self-efficacy, which postulates that mastery experience is the most effective source of self-efficacy information. Learners also made proper efforts to achieve their goals. Furthermore, the mean degree of usefulness for lectures by students was high, suggesting that the goal of the course, active participation by students, was successfully attained. Reasons for the usefulness of lectures by students suggested the effects of multiple modeling. These findings indicate that self-regulated learning can improve university education.

Recent psychological and educational studies have focused on the self-directed functions of human nature, including the following:

Self-regulation and self-efficacy.

According to social cognitive theory, humans possess self-directive abilities that enable them to exercise control over their thoughts, feelings, and actions, based on the consequences of their actions. Therefore, psychological functioning is regulated by interaction between self-generated and external sources of influences (Bandura, 1986). Perceived self-efficacy refers to beliefs in one's capabilities to organize and execute the courses of action required to achieve goals.

Self-regulated learning.

The theory and practice of self-regulated learning focus on active aspects of learning, including self-efficacy, self-evaluation, and goal setting (Schunk and Zimmerman, 1998; Zimmerman and Schunk, 2001).

Modeling and multiple modeling.

Modeling or observational learning is defined as learning through observing others (Bandura, 1965; 1986). Multiple models displaying diverse patterns of behavior allows observers to exhibit novel responses representing amalgams of elements from the different models (Bandura et al., 1963).

Learning and instructional sciences. Itoh (2005) proposed the new field of "Learning and instructional sciences (LIS)" emphasizing the significance of self-investigation, which is a general term for finding out about the self. LIS can clarify learning and instructional phenomena and apply the outcome to human problem solving. A series of studies revealed that self-investigation can facilitate improvement in university education (Itoh, 2006; 2009).

The present study aimed to identify effective methods of promoting self-regulated learning in university education, based on the quantitative and qualitative analyses of learning self-efficacy, self-evaluation of learning, and goal setting, as well as the usefulness of the learning and instructional activities.

Method

Participants. Participants were 36 Japanese graduate students who were enrolled in courses given by the author from 2004 to 2008.

Course design. (a) Lecture by teacher: During approximately half of the sessions in each course, the teacher gave lectures. (b) Lecture by students: During the rest of the sessions, students took turns in the instructor's role and gave two lectures about their research topics, while the other students and the teacher took the role of learners.

Measures.

The Learning Self-Efficacy and Self-Evaluation of Learning scales consisted of the following items: 1. Concentrate on the lecture, 2. Understand the lecture, 3. Identify key ideas, 4. Memorize the contents, 5. Acquire deep and wide knowledge, 6. Think by oneself, 7. Do one's best to solve problems, 8. Actively participate in collaborative work, 9. Actively participate in discussions, and 10. Ask questions.

Procedures.

(a) Learning Self-Efficacy before the course: At the end of the orientation session, participants indicated their degree of confidence in their learning activities for the course on a scale of 0 to 10. After October 2006, participants also chose 5 items as progress goals from the 10 items. (b) Summative survey: In the final session of the course, participants completed a survey including the Evaluation of Teacher's Instruction by students and teacher, Self-Evaluation of Learning, Usefulness of Learning and Instructional Activities for Learning, Learning Self-Efficacy for a subsequent course, and free descriptions about the course. Except for the Self-Efficacy scale, participants' responses were given on a scale of 1 to 4.

Results and Discussion

After removing the effects of Learning Self-Efficacy before the course, a significant partial correlation coefficient was observed between the scores on Self-Evaluation of Learning and Learning Self-Efficacy for a subsequent course ($r = .634$, $p < .001$). This indicates that higher performance was correlated with higher self-efficacy ratings for subsequent learning. This finding is consistent with Bandura's theory of self-efficacy, which postulates that mastery experience is the most effective source of self-efficacy information. The correlation between the scores on Learning Self-Efficacy before the course and Learning Self-Efficacy for a subsequent course was significant ($r = .663$, $p < .001$). Higher self-efficacy was maintained in the ratings for subsequent learning activities.

Changes in Learning Self-Efficacy scores by item before and after the course analyzed with a 10×2 (Efficacy \times Periods) ANOVA showed significant interaction between Efficacy and Periods ($F(9, 297) = 2.72$, $p < .001$). Main effects were observed for Efficacy ($F(1, 297) = 9.95$, $p < .001$) and Periods ($F(1, 33) = 58.54$, $p < .001$). Post hoc analysis was conducted using Bonferroni's test. For Self-Efficacy before the course, the mean score for item 7 was higher than for items 2-6, 8, 9, and those for items 1, 5-9 were higher than for item 4. Whereas for Self-Efficacy after the course, mean scores for items 1-3, 5-10 were significantly higher than for item 4. A t test revealed significant changes in Learning Self-Efficacy scores on all the items. These findings suggest that achievement of the learning activities during the course effectively increased self-efficacy.

For progress goal items, significant correlations were observed between Self-Evaluation of Learning and Learning Self-Efficacy for a subsequent course ($r = .653$, $p < .001$). Learning Self-Efficacy before the course and Learning Self-Efficacy for a subsequent course ($r = .726$, $p < .001$, $N = 12$).

The most frequent items chosen as progress goals were items 5 ($n = 10$) and 6 ($n = 10$). The most frequent efforts for making progress were "Referring the related research materials" ($n = 6$) for item 5, while "Thinking by oneself to understand" ($n = 7$) for item 6, suggesting learners' proper efforts to achieve their goals.

The mean degree of Usefulness of Learning and Instructional Activities for Learning analyzed by ANOVA showed a significant effect for Activities ($F(6, 180) = 3.65$, $p < .001$). Post hoc analysis using Bonferroni's test revealed that lectures by students were rated higher than teacher's talks, a term paper, problem solving, and surveys on instruction. This suggests that the course successfully encouraged students' active participation.

Reasons for the usefulness of lectures by students included "Learned various research fields" ($n = 26$) and "Learned various instructional methods" ($n = 10$), suggesting the effects of multiple modeling both on contents and methods.

Conclusion

Self-efficacy, self-evaluation, goal setting, and multiple modeling during students' lectures effectively promote self-regulated learning in university education.

PAPER PRESENTATION

Elementary school students regulation of motivation and cognition in challenging learning situations

Jonna Malmberg, University of Oulu, Finland; Sanna Jarvela, University of Oulu, Finland; Hanna Jarvenoja, University of Oulu, Finland

At the school context, the students seldom recognize a need or opportunities to self-regulate their learning. When the task conditions become demanding and call for self-regulated learning, the students may give up since they don't know how to adapt their study techniques. However self-regulated learning is not a general process or trait that operates in a same fashion across learning situations. Rather, self-regulated learning is depended on the different features of current learning situation, such as context, task and various aspects of self that affects for the learning activities students choose to perform. The aim of this study is to examine how elementary school student use control strategies and maintain learning in challenging learning situations. In this study the elementary school students (N=19) aged 9 to 10 years participated in a science project for two months. The pedagogical structure aimed to promote self-regulated learning and included working with gStudy learning environment that prompted study technique use of the students. The students were divided in high and low achievers based on their learning result. The students' use of control strategies was coded from the interview data. Finally, the log file traces from the gStudy were divided in two categories, namely challenging and other gStudy sessions. The results suggest that successful use of control strategies enables the use of information processing strategies. However, when facing challenges, the high achievers did not change their prominent study technique. The low achievers instead switched into surface level strategies.

Summary

At the school context, the students seldom recognize a need or opportunities to self-regulate their learning. When the task conditions become demanding and call for self-regulated learning, the students may give up since they don't know or they don't want to adapt their study techniques (Winne & Hadwin, 2008). However, self-regulated learning is not a general process or trait that operates in a same fashion across learning situations. Rather, self-regulated learning activities are depended on the different features of current learning situation, such as context, task and various aspects of self (Wolters, 1998). That is why it is important to examine how elementary school students use control strategies and maintain learning in varying situations.

The aim of this study is to examine (a) How do the elementary school students use control strategies in challenging learning situations? (b) How the high and low achieving students' learning patterns are composed during the challenging and other learning situations?

Participants and methods

The elementary school students (N=19) aged 9 to 10 years participated in a science project for two months. The pedagogical structure aimed to promote self-regulated learning and included working with gStudy learning environment (Winne et al., 2006). The gStudy is multimedia learning environment that promotes use of study techniques with the assistance of cognitive tools. GStudy also records log file traces of students' use of these tools.

When the students logged in gStudy learning environment (f=172) they were prompted to fill in the "Motivation Scaffold sheet" where they explicate if they felt the learning situation challenging. The challenges were identified and categorized (Cohen's kappa .80) and the challenging gStudy sessions (f=46) were located from log file traces.

The students were asked to construct mind maps (F=28) about the topics before- and after the science project. The students' learning result was measured by analyzing these mind maps (Novak, 1998) by two independent researchers. After the last lesson the students were interviewed. The students were asked to describe the challenges they encountered and following control strategies. The control strategies (f=77) the students described using per challenge were identified from the interview data. The reliability analysis for the coding was conducted by an independent researcher (Cohen's kappa .72).

Analysis and results

K-means cluster analysis was used to establish two groups, namely high (n=7) and low achievers (n=12) based on the students learning result. This categorization was used as a basis for further analysis.

In respect of the first research question, the students reported using zero to three control strategies per challenge. Also, the high achievers reported using more control strategies, when confronting challenges (see Picture 1).

In respect of the second research question, the high and low achievers learning patterns in challenging and other gStudy sessions between the high and low achievers were investigated (see Table 1). Learning patterns refers to sequences about how cognitive tools are typically used in challenging and other gStudy sessions.

Table 1.

From the other gStudy sessions only one learning pattern emerged from the high and low achievers learning activity. Both groups pattern was similar and focused on making notes. From the high achievers challenging gStudy the same learning pattern emerged again. However, from the low achievers challenging gStudy sessions learning patterns ($F=88$) occurred (See table 1). These emerging learning patterns were composed of different types of highlights, notes and concept mapping.

Conclusions

The results of this study show that elementary school students are aware of using control strategies in challenging learning situations, but there are differences about how these control strategies are used. The students, who achieved the best learning result, reported having more choices of control strategies when confronting challenges, whereas the low achieving students gave up more easily.

These study suggest, that successful use of control strategies enables the use of information processing strategies (see also Rozendaal, Minnaerts & Boekaerts, 2001). Based on the theoretical models on self-regulated learning, challenges should lead to change or adaptation of study techniques (Winne & Hadwin, 2008). Yet, in this study the high achieving students maintain the same use of study techniques in challenging learning situations as they were engaged to use in other kind of learning situations.

The low achievers' study technique use, instead, become vague and experimental in challenging learning situations. This might indicate that the effort of carrying out a deeper learning strategy was too much for them, or they didn't recognize appropriate study technique. This study shows that even though the students are prompted to use different study techniques, they do not necessary change their prominent learning strategy. The study results suggest, that there should also be embedded prompts or hints for the students about the situations that call for changing the study technique, but also about the purposes that different study techniques can serve.

PAPER PRESENTATION

Self-regulation of motivation: Evaluation of a strategy knowledge test on motivation regulation

Hubertina Thillmann, Ruhr-University Bochum, Germany; Joachim Wirth, Ruhr-University Bochum, Germany

The purpose of this study was to evaluate a newly developed test for assessing students' strategy knowledge about motivation regulation during self-regulated learning (Wolters, 1998, 2003). 109 university students took part in a correlational study. Before reading a subjectively uninteresting text students were instructed to motivate themselves. Their motivation to read the text was assessed prior to and after the self-motivation phase. Students' conceptual knowledge about the respective text content was assessed by a multiple-choice test. Furthermore, students' strategy knowledge on motivation regulation was assessed by the newly developed strategy knowledge test on motivation regulation. The test has a specific format (cf. Artelt, Schiefele & Schneider, 2001) that presents sketches of learning situations with a specific motivational problem. Each situation is followed by a list of action alternatives that describe more or less useful motivation strategies. Students' task is to rate the usefulness of the action alternatives for each situation. A strategy knowledge score is calculated as the degree of correspondence between the individual's rating and a respective expert's rating. Results show acceptable reliability of the test as well as hints of validity. For example, positive correlations between students' strategy knowledge and their motivation after the self-motivation phase,

between students' motivation after the self-motivation phase and their learning outcome, and between students' strategy knowledge and their learning outcome suggest the expected mediation pattern. In sum, these first results are promising with respect to test quality.

Aims of the study:

Models of self-regulated learning assume that learners have to regulate their cognition as well as their motivation by appropriate strategies (e.g. Wolters, 1998). Furthermore, these models assume that learners' knowledge about strategies can be regarded as a prerequisite for their strategy use (e.g. Winne & Perry, 2000). Accordingly, Veenman, van Hout-Wolters and Afflerbach (2006) point out that for empirical research it is important to assess both, learners' strategy knowledge and their strategy use in order to be able to diagnose whether problems in self-regulated learning are due to a mediation deficiency, i.e. that learners have no strategy knowledge available, or to a production deficiency, i.e. that learners have strategy knowledge available but don't use it.

Empirical research on self-regulated learning has focused for a long time on the cognitive aspects of self-regulated learning (cf. Wolters, 2003) and the use of cognitive strategies (cf. Winne & Perry, 2000). Consequently, there exist various tests assessing cognitive strategy use. However, there is to our knowledge only one test available assessing strategy knowledge (Schlagmüller & Schneider, 2007). Furthermore, this test is restricted to knowledge about cognitive strategies.

Turning to the regulation of motivation within self-regulated learning, research has shown that learners report using motivation strategies, ranging from volitional strategies to extrinsic and intrinsic regulation strategies and that their use of motivation strategies seems to depend on the specific motivational problem, ranging from difficult tasks to unimportant or uninteresting tasks (Wolters, 1998). However, until now learners' knowledge about strategies for regulation of motivation has not been assessed. Against this background, the aim of this study was to develop and evaluate a new test that assesses learners' knowledge about strategies for regulating their motivation.

Methods:

Sample. 109 university students with a mean age of $M=24.1$ years ($SD=3.3$) and 74.3% female participated in this study.

Materials.

We developed two parallel versions of a strategy knowledge test on motivation regulation. The test included twelve situation sketches (each test version included six sketches). Each sketch was accompanied by four to six action alternatives. According to Wolters (1998), the situation sketches dealt with different motivational problems, namely uninteresting, difficult, or plenty learning material or an attractive distraction, and the action alternatives described different volitional and information processing strategies as well as extrinsic and intrinsic regulation strategies. Two science texts, two multiple-choice tests on conceptual knowledge and motivation ratings were taken from a training study run by Leutner, Barthel and Schreiber (2001).

Procedure.

The study was run with groups of about 15 persons per session, with each session taking about 60 minutes. First, students filled in the A version of the strategy knowledge test on motivation regulation (10 min.). Afterwards, students were instructed to read the abstracts of two different science texts and to rate their motivation to read the respective full text (10 min.). Then, they were given the text they previously rated as less interesting and were instructed to motivate themselves to read the text (3 min.). Subsequently, they wrote down how they had motivated themselves and rated again their motivation to read the text (5 min.). After reading the respective text (12 min.) students filled in a multiple-choice test on conceptual knowledge about the text content (8 min.). Finally, students filled in the B version of the strategy knowledge test on motivation regulation (10 min.).

Results:

The two versions of the strategy knowledge test on motivation regulation showed both medium difficulties and acceptable reliabilities in terms of internal consistency (version A: $M=.63$; $SD=.11$; $\alpha=.86$; version B: $M=.69$; $SD=.08$; $\alpha=.77$), and parallel-test-reliability ($r=.654$).

Furthermore, results revealed hints of validity of the strategy knowledge test on motivation regulation: First, we found a positive correlation between strategy knowledge (version A), and motivation after the self-motivation phase ($r=.198$;
p

Second, we found a significant difference between students' strategy knowledge on motivation regulation before the self-motivation phase (version A) compared to afterwards (version B) ($t(108)=7.51$; p

Discussion and Outlook:

In sum, results speak for a good test quality in terms of reliability and first hints of validity.

In order to further replicate and extend the results we are currently evaluating a test version for secondary school students. Results of this study will also be presented.

For future research we propose to assess learners' strategy knowledge and their actual strategy use of motivation regulation strategies in order to get a deeper insight into the mechanisms of motivation regulation and to be able to design adequate support for learners' regulation of motivation.

PAPER PRESENTATION

Readers' ability attributions in dealing with scientific Internet information

Dorothe Kienhues, Institute of Psychology, Germany; Rainer Bromme, Universitat Muenster, Germany

The Internet has become an important source for laypeople searching for (scientific) information. During Internet search, they easily come across conflicting or preliminary information. We assume that being confronted with such information evokes a need to explain why conflicts occur, and that people may (partly) attribute the problem of making sense of conflicting information to their own limits to understand the information and to deal with it properly. This study investigates readers' ability attributions in dealing with conflicting and consistent Internet information. Different variables were considered: situational ability reasoning, a global competence self-concept measure, decisional conflict, satisfaction with the decision made, and knowledge gained during Internet search. Sixty-four participants were asked to search the Internet for information on cholesterol to support a fictitious friend in making a treatment decision. Participants were either provided with 15 preselected conflicting websites (conflict group, $n = 30$) or 15 preselected consistent websites (consistency group, $n = 34$). Results show that dealing with conflicting or consistent information did not differentially influence participants' situational ability reasoning, decisional conflict, satisfaction with the decision made or knowledge gained during Internet search. However, regression results revealed that in dealing with conflicting information, questioning one's ability was a reaction to the problems encountered and did not derive from the general competence self-concept. Dependent on features of the information, participants either referred to a trait-like concept of own competencies in their situational ability reasoning or not.

The Internet has become an important source for laypeople searching for (scientific) information. While searching the Internet, they easily come across conflicting or preliminary information provided by experts of all kinds. When confronted with conflicting information on the Internet, it might be unclear for laypersons whether there is a 'real' contradiction or whether their lack of understanding causes the impression of a conflict. In latter case, a reader would assume that more knowledge on his/her side could resolve the conflict or at least make it possible to find out which view is right or wrong (we will call this an ability attribution). We assume that people may (partly) attribute the problem of making sense of conflicting information to their own limits to understand the information and to deal with

it properly (even though they usually do not lack self-confidence). This study investigates ability attributions in dealing with conflicting and consistent Internet information. Precisely, we wished to investigate whether participants show different ability attributions depending on the kind of information dealt with.

We hypothesized that participants dealing with conflicting information would question their ability to deal with the task at hand more than participants dealing with consistent information. To explore ability attributions in further detail, we additionally took into account participants' general self-concept of own competencies. We assumed that the global self-concept measure should only be a reliable predictor for participants' task-specific ability reasoning in the case of consistent information, but that the predictive power of the general variable should be lessened in the case of conflicting information, due to the specific influence of this kind of information. Furthermore, we considered potential differences in decisional conflict and satisfaction with decision, assuming that participants dealing with conflicting information would experience more conflict and would be less satisfied with their decision than participants dealing with consistent information. In our study ($N = 64$), participants searched the Internet for cholesterol information to advise a fictitious friend about treatment. Participants were randomly assigned to two conditions: a group provided with 15 preselected websites with conflicting contents (conflict group, $n = 30$) and a group provided with 15 preselected websites with consistent contents (consistency group, $n = 34$). We applied a scale of a global competence self-concept measure (FKK) before the Internet search. After the Internet search, we applied a scale retrospectively assessing participants' ability reasoning during Internet search, e.g. in how far participants had thoughts of insufficiency concerning their knowledge for dealing with the specific task. Participants furthermore answered the Decisional Conflict Scale, the Satisfaction with Decision Scale and a post-search knowledge test on cholesterol to control for learning effects (no significant difference between the groups, $t[62] = -.46$, $p > .20$). Results indicate that the two groups did not differ significantly in the scores gained on the ability reasoning scale, $t[62] = -.95$, $p > .20$. Contrary to our suggestions, all participants equally estimated their situational ability as "mediocre". We then conducted a hierarchical moderated regression analysis. Dependent variable was ability reasoning. Predictor variables were general competence self-concept (as measured with the FKK; the two groups did not differ significantly in this measure, $t[62] = 1.31$, $p = .19$), the kind of information dealt with (conflicting information vs. consistent information), and the interaction of the FKK and kind of information dealt with.

Results reveal that a model including the interaction term accounted for 52% of the variance and contributed to an increment of explained variance over the variance contributed by a model without the interaction term, $R^3 = .52$, $F(1, 61) = 7.26$, $p < .09$. A moderating effect was identified by a significant beta weight for the interaction term ($b = -.26$; $p > .10$; consistency condition: $b = .73$; $p < .05$, $t[62] = .59$, $p > .20$, nor in satisfaction with decision, $t[62] = .09$, $p > .20$). Correlation analyses reveal that participants who believe more in their abilities during online search were more certain in their decision and vice versa, $r = .58$, $p < .05$, $r = .62$, $p < .05$, $r = .14$, ns. Our results underline the role of ability aspects in dealing with conflicting scientific (Internet) information. Regression results reveal that participants attribute the problem of making sense of conflicting information to their own limits to understand the information and to deal with it properly, even though they usually do not lack self-confidence. These results suggest that questioning one's own competence to deal with conflicting information is an interpretative answer to the difficulties encountered when it comes to making sense of such information. In general, dealing with information on the Internet seems to require an optimistic and self-confident view of one's own abilities to deal with the information accessed. This subjective assessment seems to determine more how people react in the specific situation than an objective measure of ability, e.g. a knowledge measure. Therefore, it is important to encourage consumers' information literacy. The role of laypeople's beliefs about their abilities for dealing with scientific information, on the Internet and in general, will be further highlighted in the full paper.

PAPER PRESENTATION

Toward a dynamic approach to the study of self-efficacy: the impact of its evolution on motivation

nadia leroy, UNIVERSITE DE GRENOBLE LSE, France; Gwenaëlle Joet, Université Pierre Mendès France, France; Pascal Bressoux, Université Pierre Mendès-France, France

The influence of students' self-efficacy on their academic motivation has largely been documented. However, studies having addressed the effects of self-efficacy fluctuations over time on motivation remain relatively absent from international literature.

A longitudinal approach was used to examine growth trajectory in self-efficacy during the first year of middle school as well as the impact of its changes on academic.

A total of 915 students completed a questionnaire at four occasions during their 6th grade year. Using the multilevel model for change technique (Singer & Willett, 2003)

The results revealed that student's self-efficacy gradually declines over the school year.

Having proposed a model for intra individual changes we then wanted to examine the relationship between self-efficacy growth patterns and academic motivation. Growth parameters extracted from the intra individual model were introduced as covariates in a regression model aiming at explaining interindividual differences in academic motivation.

Concerning the relationship between self-efficacy changes and academic motivation they indicated that fluctuations in self-efficacy impact student motivation.

Theoretical implications of such a dynamic approach with regard to academic motivation will be discussed

Theoretical framework

The first year of middle high school is a transitional period that puts students in face of new demands that force them to adapt to a variety of situations. With a larger responsibility left to them, the way in which they feel able to cope with these many challenges seems to play a key role for their school adaptation.

Another factor that plays a particularly important role with regard to school achievement is academic motivation (for review, see Gottfried et al., 2009) especially among students who demonstrate self-determined forms of motivation.

Studies conducted by Albert Bandura (1977, 1982, 1997) have shown that evaluations that students formulate about their capacities to achieve a given task (i.e., their self efficacy beliefs) can be considered as powerful motivational resources.

According to the socio-cognitive theory, self-efficacy determine the level of effort and perseverance that individual deploy when confronted with difficulties (Bandura, 1989 ; Bandura & Cervone, 1983). As a consequence, self-efficacy can be considered as a factor that indirectly affects school performance (e.g., Bandura, 1997; Pajares, 1996; Schunk, 1995) via academic motivation.

However if these theoretical contributions seem to indicate that self-efficacy play a central role in the cognitive regulation of motivational processes few studies had effectively been conducted to empirically analyze their relationships.

In addition another issue that needs to be considered in empirical studies concerns the evolutionary nature of self-efficacy.

Theoretically admitted as a dynamic variable that tend to decrease over the school years, self efficacy and its effect on motivation are in fact systematically apprehended in a static way. Little is known about its pattern of change across time and even less about the effects of self-efficacy fluctuations on academic motivation.

Objective and hypothesis

The aim of the present research is precisely to examine the relationship between self-efficacy and academic motivation according to a dynamic approach by analyzing how self efficacy changes impact on academic motivation.

In terms of the direction of self efficacy change trajectory, we had a priori hypothesis for a decrease over time. Concerning the impact of self-efficacy changes on academic motivation we hypothesized that academic motivation would be positively influenced by the beliefs student develop about their capacities to achieve a given task and that the fluctuations of these beliefs can account for a significant part of motivation variance.

Method

Participants

Students registered in French middle high schools in the Grenoble area participated in the present study. The original sample consisted of 1082 students (boys, n=543; girls, n = 538) from 47 classes of 15 schools in a large French city.

The data collection took place for 4 consecutive times. The students were sampled few weeks after the beginning of the year and then at the end of each quarter. Thus, in total four measures were taken. 915 students completed the questionnaires on all occasions.

Measures

Academic motivation

We used the academic self regulation questionnaire, developed by Ryan and Connell (1989), to evaluate why students do various school related behaviors. This questionnaire assesses the reasons why students do various school related behaviors in a Likert scale format from 1 (strongly disagree) to 5 (strongly agree).

Self efficacy beliefs

The scale aiming at measuring this variable was inspired by a scale extracted from the Motivated Strategies for Learning Questionnaire (MSLQ) by Pintrich and De Groot (1990).

Analysis technique

To model self-efficacy growth trajectory and to test this impact of its evolution on academic motivation we used the multilevel model for change technique (Singer & Willett, 2003) and fitted longitudinal models using SAS PROC MIXED with Full Maximum Likelihood parameters estimation method to handle the presence of any missing data

Results

The analysis had two parts.

The first part examined the growth trajectory of self-efficacy beliefs. The second part aimed to ascertain whether self-efficacy beliefs fluctuations could account for the variation in academic motivation.

Firstly, to identify fluctuations occurring in each student self efficacy pattern, a simple longitudinal model equation has been fitted.

Results indicate that this simple longitudinal model equation describes negative self-efficacy development over the first year of middle high school with a mean decrease of 0.07 point in self-efficacy score from one measurement occasion to another.

In this second part of the analysis that consist on analyzing the impact of self-efficacy changes we introduced in a multilevel of academic motivation the growth parameters factor reflecting self-efficacy intraindividual fluctuations. In other words, academic motivation score was regressed on growth parameters extracted from the self-efficacy growth trajectory just fitted above

The results summarize a number of important findings with respect to the predictive capabilities of self efficacy dynamic on academic motivation.

First, initial mean level of self-efficacy significantly predicted academic motivation score at the end of the school year beyond the influence of initial level of performance and motivation, indicating that, on average, student who had higher scores on academic motivation score had significantly higher initial values on self-efficacy scores.

Second, self efficacy rate of change over the school year also significantly predicted the level of academic motivation at the end of the year after controlling self-efficacy mean level at the beginning of the year .

This result indicates that, on average, children whose self-efficacy rate of change is the faster have significantly higher values of academic motivation.

To briefly conclude we can say that ths study present the advantage to clarify our understanding about the effects of self-efficacy dynamics on academic motivation during the first year of middle high school insofar as they reveal that the impact of self efficacy on motivation is not limited to the value taken by this variable at a given point in time but that it also extends at its rate of change throughout the school year. By better understanding the relationship between these two key processes it would be possible to improve the predictive power of models of motivation and as a consequence to better apprehend the processes involved in school achievement differences

PAPER PRESENTATION

Teachers' Source Evaluation Self-Efficacy Predicts Their Use of Relevant Web Source Features

Ivar Braten, University of Oslo, Norway; Rune Andreassen, Ostfold University College, Norway

The study investigates the relationship between teachers' beliefs about their capability to evaluate the trustworthiness of sources and their reliance on relevant source features when searching the Internet to learn about special educational needs (SEN). To answer the research questions about this relationship 263 in-service teachers from 40 elementary schools responded to a 30-items digital questionnaire including questions about domain knowledge, experience in searching for information and participants' beliefs about their capability to evaluate the trustworthiness of Web-based information on SEN. Two hierarchical multiple regression analyses were performed, one with emphasis on source features related to the product of a Web site as DV, and the other with emphasis on source features related to the producers of a Web site as DV. The analyses showed that teachers' source evaluation self-efficacy beliefs predicted their use of both source feature dimensions independent of other individual difference variables. This study contributes to the literature of source evaluation within both reading and information literacy by exploring the role of teachers' self-related belief.

Aim

The main aim of this study was to investigate the relationship between teachers' beliefs about their capability to evaluate the trustworthiness of sources and their reliance on relevant source features when searching the Internet to learn about special educational needs (SEN).

Theoretical framework

Learners' demanding, yet necessary source evaluation, presents not only students but also professionals and seasoned learners great challenges. Thus far, few studies have investigated in-service teachers' use of source features to evaluate Web-based information. However, Williams and Coles (2007) found that many teachers recognized the need to make quality judgments about research evidence but did not feel confident that they were able to do so.

Bråten et al. (2009) and Rouet et al. (1996) demonstrate that domain knowledge plays a role in source evaluation. Also, learners' experience in searching for and evaluating information is likely to contribute to their sourcing skills (Rouet et al., 1997). Another relevant but less researched individual difference variable in this context concerns learners' self-efficacy beliefs (Bandura, 1997), specifically their beliefs in their capability to evaluate the trustworthiness of Internet sources. In the present study, we therefore created a new measure to assess teachers' source evaluation self-efficacy and used the scores on this measure to predict their use of relevant source features when evaluating source trustworthiness. Specifically, we hypothesized that teachers' source evaluation self-efficacy would uniquely predict their reliance on relevant source features when judging the trustworthiness of Web-based sources on SEN after variance related to gender, age, domain knowledge, and experience in relevant Internet use had been accounted for.

Method

263 in-service teachers from 40 elementary schools responded to a 30-items digital questionnaire.

Predictors.

A mix of Likert scale and multiple choice questions were asking for participants' gender, age, domain knowledge related to SEN, and experience in using the Internet in search for SEN information during the current school year. They were also asked to indicate which SEN topics they had most frequently been in search of. To assess participants' beliefs about their capability to evaluate the trustworthiness of Web-based information on special education, we developed the Source Evaluation Self-Efficacy Scale (SESES) by combining questions.

Dependent variables.

The outcome variables were based on participants' responses to five 5-point Likert scale items concerning to what extent they emphasized the source features of layout, Web-address, author, content, and date of publication, respectively, when judging the trustworthiness of Web sites on SEN. Principal component analysis of the five items yielded two factors with high loadings and no overlap for any item. Because the first factor seemed to be concerned with the product of a Web site (its content and the layout and timeliness of this content), we labeled this factor Emphasis on Product. Because the second factor seemed to be more concerned with the producer of a Web site (Web-address and author), we labeled that factor Emphasis on Producer.

Results

Two hierarchical multiple regression analyses were performed, one with emphasis on product as DV, and the other with emphasis on producer as DV. In each analysis, gender and age were entered into the equation in step one, and

indicators of domain knowledge and experience in searching the Internet for SEN information were entered in step two. In the third step, we included scores on the measure of SESES.

First analysis.

In step one, both gender and age were statistically significant predictors, indicating that female teachers were more likely than male teachers and younger teachers more likely than older to emphasize the product when evaluating source trustworthiness. In step two, experience in searching the Internet were a statistically significant predictor in addition to age. Finally, in step three, the SESES was the only statistically significant predictor in addition to gender, indicating that the higher confidence the teachers had in their ability to evaluate the trustworthiness of sources, the more they emphasized product features of the site.

Second analysis.

In step one and two, no significant increment in the explained variance was observed. However, when participants' SESES scores were entered in step three, this resulted in a statistically significant increment in the explained variance. In this step, the SESES was a strong positive predictor of Emphasis on Producer.

Conclusions

This study contributes to the burgeoning literature on source evaluation within both reading and information literacy in several ways. First, few other studies have explored the role of teachers' self-efficacy beliefs for educational use of information technology (Hoy & Davis, 2006). Second, this study developed a new measure of self-efficacy beliefs specifically addressing beliefs about source evaluation when using the Internet in a particular domain and provided preliminary reliability and validity information about this measure. Third, the study provided the first empirical evidence about the underlying structure of learners' use of source features when evaluating sources, indicating that emphasis on product and emphasis on producer may form separate dimensions. Fourth, the study showed that teachers' source evaluation self-efficacy beliefs predicted their use of both source feature dimensions independent of other individual difference variables, suggesting that teachers' critical evaluation of Web-based resources is not only a matter of domain knowledge and technological skills but also of self-related beliefs.

PAPER PRESENTATION

Domestic and international students: readiness, course experiences and achievement

Ellen Jansen, University of Groningen, Netherlands; Cor Suhre, University of Groningen, Netherlands

Higher education institutions all over the world have received international students with open arms. A case study in Economics and Business at a Dutch research university shows that international students need less time-to-degree, have higher marks and need less re-sits compared to domestic students. Data from the REQ (Readiness and Expectations Questionnaire) and CEQ (Course Experience Questionnaire) point at differences between the different groups of students. In the study we discerned domestic students, European students and Asian students. It seems that international students have another approach to the study and another study experience than Dutch students.

Introduction

International degree programmes attract a lot of students from different regions. These students represent a heterogeneous group. Regions that are best represented in the Netherlands are Asia and European countries with German as the medium. To be able to enhance foreign students' chances of graduating and to offer them a

satisfactory study experience the management needs specific information on students' readiness, expectations and study performance.

In particular we draw attention to differences between students in their study aspirations, their study skills, the course experiences and study progress. This information can be used to provide prospective students with accurate information on study skills required to succeed and to offer students from different regions any additional support they need the most.

Research Questions

There are three questions we wish to address in our presentation:

1. Which differences in study preparation and course experiences exist between students from different regions in the world in a typical degree programme at a Dutch university?
2. Which differences in achievement profiles exist between students from different regions in the world in a typical degree programme at a Dutch university?
3. Does the participation in international degree programmes have advantages for domestic students?

Theoretical background

Research on study success departs from a student-centred theory of college completion (see for example Stage & Hossler, 2000). They start their model from student background, via school experiences, intentions and engagement, college entry through completion or drop out. In an adapted form for our programme the model can schematically designed as:

Student Background experience	School	Higher experiences	Degree education	completion
SES	learning	choice	persistence	
GPA	experience	motivation	drop out	
Gender		involvement	skills acquisition	

The model shows that outcome not only depends on the higher education experience, but it is also influenced by student background characteristics, experiences in secondary education and experiences, motivation and involvement in higher education. Bandura and Locke (2003) showed that perceived self efficacy and personal goals enhance motivation and performance attainment. This is based on social cognitive theory which indicates that people regulate themselves in an anticipative, purposive and evaluating manner. Efficacy beliefs contribute to the level of motivation and performance. If students belief that their self efficacy is high, they will use more efficient problem solving strategies and achieve higher intellectual performance (Bouffard-Bouchard, 1990 in : Bandura 2003, p.88). Academic self-efficacy is also related to students' approaches to learning and their use of study and learning strategies (Simmons, 1996).

As an elaboration on Tinto's interactionalist theory with the central concepts of academic and social integration (Tinto, 1975, 1993) Kuh and Love (2000) added the cultural perspective and this can be seen as one of the main problems first-year students encounter commencing in higher education. Drop-out in the first year of higher education is a global theme (Krause, 2005; McInnis & James, 2004; Yorke, 1999) and reasons to drop out can according to Yorke and Longden (2004) be classified in four groups among others unsatisfactory experience at university and difficulties in coping with the programme demands. It seems that first-year students are not clear about what is expected of them in terms of more generic foundation skills, and that they have unclear expectations about what is going to happen starting their study (Pitkethly & Prosser, 2001).

Research design

Two cohorts of students from Dutch as well as international degree programmes in Economics and Business at a Dutch university are followed during their first year.

At the very begin of their study they filled out the Readiness and Expectations Questionnaire (Jansen & van der Meer, 2007; Van der Meer & Jansen, 2008; Jansen & van der Meer, forthcoming) and midway their first year an adapted version of the Course Experience Questionnaire (McInnis et al, 2001; Ramsden, 1991; Wilson et al, 1997). The results of these questionnaires are merged with data on student characteristics and student progress/ success data. For triangulation purposes interviews with students and focus groups were organised.

Results

The results from cohort 2009 show that students from different nationality groups do differ in their expectations and preparedness for university. Students from Asia were to a higher extent unsure if they were well-prepared for university. They scored lower on their self-perceived command of English and on the preparedness scales on time-management, information processing, writing and working in small groups. On the other hand Asian students expect to a higher extent than the other nationality groups to be involved in research activities in the first year and to be inducted in the new programme. European students (German, Bulgarian, Romanian) have the highest expectation that they will need time-management skills and overall they scored highest on the readiness scales.

Also the course experiences differ for the different groups. The European international students were the most satisfied with the degree programme, but the teaching quality was the least appreciated. They identified the workload in the programme as appropriate.

We had students rate their study behaviour against two standard 30 hours time per week and more than 75 % tutorial attendance on a five point scale. The average score are given in the next table. This table shows that the study behaviour of the three groups differ strongly. Most European and Asian students easily comply with these standards, while many Dutch students don't.

A LISREL analysis indicated the importance of the expectations on degree programme satisfaction, which leads to a better study behaviour and actually to higher study success.

Also the perceived readiness in information processing affects the course experience and via the course experience affects the degree programme satisfaction.

PAPER PRESENTATION

Reciprocal Effects of Spelling and Reading Comprehension

Olaf Koeller, Leibniz Institute for Science and Mathematics Education, Germany

A repeated measurement study was carried out to analyze reciprocal effects of reading comprehension and spelling. Recent training studies have suggested that transfer effects across skills can be observed. To test whether these effects can be found in a school setting, we analyzed two-wave data ($n = 1.143$, 49,7% female) from junior high schools. The first measurement point (T1) was at the beginning of grade 5, the second at the beginning of grade 7 (T2). Students worked on spelling and reading tests. Multi-level analyses supported a reciprocal effects model. The effect of T1-reading on T2-spelling ($b = .216$, $p < .001$), however, was stronger than from T1-Spelling on T2-reading ($b = .060$, $p < .05$). These effects were stable even after controlling for psychometric intelligence and type of secondary school. Educational implications are discussed.

Background and Aims of the Study

Reading and Spelling skills are very important for a successful school and vocational career. Therefore, educators put much emphasis on teaching both skills in primary and in secondary education and much research has been carried out identifying antecedents of successful spelling and reading. In the field of educational research, several studies have been conducted investigating the relationship between reading and spelling skills in early years of primary school (Ehri, 2005). Here, major findings support a reciprocal effects model, meaning that early reading skills (fluency when reading single words) promote spelling and vice versa. Authors like Ehri (2005) have argued, that this relationship is based on common cognitive processes during reading and writing. In older ages, however, the relationship between reading and spelling is less clear. Stanovich and Cunningham (1992) analyzed data from a sample of university students and found a correlation of $r = .57$ between reading comprehension and spelling. Such a strong association may be understood in terms of individual differences in the underlying verbal ability. However, reading and spelling may also be causally interconnected in their development.

Based on this research we were interested in the relationship between reading comprehension and spelling in early high school years. We thus carried out a repeated-measurement study with time points at the beginning of high school (grade 5) and two years later (beginning of grade 7). We predicted stronger effects from reading on spelling than vice versa. Since the German high school system is highly selected, meaning that bright students attend high-achieving schools preparing for university (in German: Gymnasium) while the rest of the students attend schools

preparing for vocational education, we were also interested in whether school-type contributes to change in spelling and reading skills.

Materials and Method

A repeated measurement study with data collections at the beginning of grade 5 (T1) and the beginning of grade 7 (T2) was carried out. A total of $n = 1.143$ German high school students (49,7 % female; 31% non-German students) worked on spelling and reading comprehension tests at both measurement points. Students came from two different types of junior high schools, i.e., 27 percent attended Gymnasium, while the remaining 77 percent attended schools preparing students for vocational education.

Reading comprehension was measured with tests that have been developed in the context of large-scale studies. Items mainly focus on students' skills to form a broad and general understanding of the texts and to retrieve information from the texts. Means of test linking using an anchor item design were applied to obtain a common scale for T1 and T2. Using IRT methods weighted likelihood estimates (WLE) were computed as students' reading scores. The WLE-reliabilities of the reading tests were sufficient ($> .80$ at T1 and T2).

Spelling was measured at both time points by means of a text consisting of 307 words, of which 31 were written incorrectly. Students were instructed to mark the incorrect words. The test score was defined by computing the squared number of identified mistakes divided by the total number of words marked by the student. Reliability was also quite high at both time points ($> .80$).

Validity of both the reading and the spelling test was investigated by linking test results to school marks (in German as the first language) in the last report card. The correlation coefficients were $r = .39$ ($p < .001$, T1) and $r = .43$ ($p < .001$, T2) for spelling and $r = .38$ ($p < .001$, T1 and T2) for reading, indicating a sufficient degree of validity.

Due to the hierarchical character of the data (students nested within classes) multi-level analyses using HLM 6.0 were conducted. To ease interpretations of the HLM-output, all measures were standardized at T1 ($M = 0$, $SD = 1$). T2 measures were standardized with respect to T1 means and standard deviations, so that differences in all measures could be interpreted as change over time.

Results

Longitudinal multi-level path analyses were conducted to test the reciprocal effects model of spelling and reading comprehension. The findings provide evidence for a substantial effect of T1-reading on change in spelling ($b = .22$), while the corresponding effect from T1-spelling on T2-reading was substantially smaller ($b = .06$) but still significant. Furthermore change in both constructs was significantly affected by school-type, i.e., students at Gymnasium outperformed all other students, and intelligence. Note that more than 70 percent of the variance in T2-spelling and T2-reading was explained by T1-measures.

Discussion and Educational Implications

The major hypothesis predicting a stronger effect of reading on change in spelling than from spelling on change in reading was supported. This finding highlights the important role reading experiences play for the development of spelling skills. Reading activities do not only enhance reading comprehension but also increase the lexical and orthographic memory of students. Accurate spelling is thus strongly based on specific word knowledge that students receive from reading.

With respect to school-type, the results provide evidence for the important role learning environments play. Curricula on spelling vary among schools and particularly the German Gymnasium has a strong tradition promoting students' spelling skills. This tradition was clearly reflected by the findings.

Concerning educational practice the findings strongly suggest that teachers providing learning opportunities in reading will also improve spelling skills of their students. Our findings should also motivate parents to foster their children's reading activities at home.

PAPER PRESENTATION

Literacy skills and psychosocial competence in Primary school children

Asimina Ralli, University of Athens, Greece; Electra Andaraki, University of Athens, Greece

Literacy skills and psychosocial competence are very important parameters for children in the school setting. Most of the relevant studies have focused only on the relationship between reading difficulties and externalizing behavior problems, without considering other aspects of literacy, such as writing skills, as well as other aspects of psychosocial competence such as school competence.

The aim of the present study is to explore the possible associations between literacy skills (reading and writing) and psychosocial competence (school, social and emotional competence as well as behavior problems) in the Greek mainstream classroom. The sample consisted of 90 primary school children, aged 9-12 years. Children were individually assessed in their literacy skills and data were also collected regarding their psychosocial competence. According to the results, performance in both reading and writing were related with children's social and school competence. Furthermore significant correlations were found between writing skills and school competence as well as between restitution of unstructured text and emotional competence. The findings are discussed in relation to other relevant evidence. Finally, strengths and limitations of the current study are described, and implications for interventions are suggested.

Theoretical background:

The link between reading performance and psychosocial competence has been well documented in the literature. Most of the studies have mainly focused on reading difficulties and behavioral, social and emotional problems in childhood (Pearl, 2002; Wehby et al., 2003).

Reading difficulties have been linked with a range of specific social, emotional, and psychosocial problems, including low self-esteem, depression, anxiety, loneliness, and aggression (Gorman, 2001; Grigorenko, 2001; Snowling 2002; Carroll et al., 2005; Nowicki, 2003).

Impulsivity, hyperactivity, and attention problems have also consistently been associated with reading difficulties (Fleming et al., 2004), with scores on reading achievement tests in elementary school predictive of these behavioral symptoms. Teachers have been found to tend rating students with reading difficulties as having lower social competence and more psychosocial problems than their peers (Pearl, 2002; Nowicki, 2003).

The relationship between reading difficulties and behavior problems increases as students progress through school (Roeser & Eccles, 2000; Morrison et al., 2001; Fleming et al., 2004; Nelson et al., 2004). Also, both reading difficulties and psychosocial problems are strongly predictive of difficulties in adolescence (Hinshaw, 1992; Maughan, 1995).

Adolescents with reading difficulties display higher school drop-out rates, higher levels of inattention, and more delinquent behaviors (including violence and substance abuse) in comparison to controls (Wehby, et al., 2003; Arnold et al., 2005).

Although a great deal of research has demonstrated an association between reading difficulties and psychosocial problems, little is known about the early development, underlying causal mechanisms, or the causal direction of this link (Hughes et. al. Dunn, 2000). Which came first? Do problems in academics lead to problems in behavior? Do problems in behavior lead to problems in academics?

There are two pathways to the above question: According to the social behavior deficit model, social skills problems may lead to academic problems (Dishion et.al. 1995; Wehby et. al. 2003). On the other hand, according to the academic skills deficit model, academic problems may lead to behavior problems (Lee et al., 1999; Roberts et al.2001). Mackintosh's study (2008) demonstrated that deficits in either area were independent risk factors which support the idea for both pathways. Alternatively, the spoken and written language impairment may have a shared underlying etiology with the behavior problems.

In contrast to the voluminous literature on the relation between externalizing behavior problems and reading difficulties, little has been written about:

- a. possible associations between different levels of literacy skills and psychosocial competence (social, emotional, school competence and behavior problems) in the mainstream classroom which may include both typically developing children and children with learning difficulties.
- b. possible associations between literacy skills and internalizing behavior problems.
- c. possible associations between writing skills and psycho-social competence.
- d. data in other languages and cultures than English. Such data could offer a further insight along this line of research.

Previous studies have mostly used curriculum-based measurements of oral reading fluency and children's school attainments in reading. The present study attempts to address the above issues using recently devised psychometric tools which cover more than one aspect of reading performance including apart from fluency- as most of the studies do-, decoding, syntax, morphology and reading comprehension. The present study also includes assessments of children's writing skills. Furthermore, while other studies have used office discipline referrals (ODRs), children's self-reports and rating scales for assessing children's psycho-social competence, the present study uses a test for psychosocial competence completed by the teachers.

Aims:

The aim of the current correlational study is to explore the relationships between literacy skills (reading and writing) and psycho-social competence using cross-sectional data from primary school children in Greece by applying psychometric assessments recently standardized in the Greek population. The above tests measure not only reading fluency as most of the previous studies but also decoding, syntax and comprehension. Also writing measures which have not been included in previous studies will be employed in the present study. Regarding children's psychosocial competence new variables will be measured such as school competence apart from social and emotional competence and behavior problems.

Methodology:

Ninety primary school children from three age groups (10, 11, and 12 years old) took part in the study. Children's reading performance was assessed with the tool Test-A for reading (Panteliadou and Antoniou, 2008). The above test examines decoding, reading fluency, syntax and comprehension. The writing skills were assessed with the test of writing difficulties (Porpodas et. al. 2008). The particular test assesses spelling accuracy, text structure, as well as restitution of unstructured sentence and text. Children were assessed individually during those two assessments. Children's psychosocial competence was assessed with the test for psychosocial competence (Ηatzichristou et. al. 2008) which was completed by the teachers. The above test includes questions for social competence, school competence, emotional competence and behavior problems.

Findings:

In general, developmental patterns were found in children's performance both in literacy skills and psychosocial competence. Particularly, children's reading performance varied by age range mainly in reading fluency and comprehension. Children's writing performance varied also by age mainly for spelling accuracy as well as for restitution of unstructured sentence and text. Regarding psychosocial competence, older children performed better in social and emotional competence than their younger counterparts.

Children's performance in both reading and writing was found to be related with their social and school competence. Particularly, children with high performance in reading decoding and fluency, morphology-syntax and comprehension had also scored in high levels for school and social competence. Furthermore, significant correlations were found between writing skills and school competence as well as between restitution of unstructured text and emotional competence.

Theoretical and Educational significance:

The present research demonstrates that competence in literacy skills is a foundation for psycho-social competence. Thus, is very important, children with poor literacy skills who are therefore at risk for psychosocial problems to be identified efficiently during the first grades of the primary school. Interventions should be also devised for promoting literacy skills, or both literacy skills and psychosocial competence. Future studies could also focus on the particular factors underlying this complex link between literacy skills and psychosocial competence in children.

PAPER PRESENTATION

Development and validation of COAT: measuring linguistic performance across children groups

Michalis Michaelides, University of Cyprus, Cyprus; Maria Kambanaros, University of Cyprus, Cyprus; Kleanthes Grohmann, University of Cyprus, Cyprus

The aims of this paper are to describe the development of a language-specific scale to measure object and action word retrieval for use with Greek-Cypriot children and present validity evidence for the measurements derived from this scale using data collected from various children groups. The adapted scale was originally administered to typically developed first-graders, and subsequently to younger children, monolingual and bilingual groups with specific language impairment, as well as typically developed bilingual children. Results confirm the difference in favour of nouns compared to verbs across the various samples, as well as the positive relationships of linguistic performance with a battery of scales administered to some of the participants. Group differences are also examined. Beyond the practical usefulness of developing an original, language-specific instrument with validity documentation in a language that has not been studied, this research is important for improving theoretical understanding of language acquisition in Greek-Cypriots, as well as for clinical purposes to identify special populations.

THEORETICAL BACKGROUND – PURPOSE

The study of language acquisition and linguistic development in a globalised society is becoming quite important in recent years. One aspect of this developmental process that has received little attention is lexical access of nouns and verbs, despite an increasing appreciation for the role of the lexicon in language development (Tomblin & Zhang, 2006), the acquisition of literacy skills (Messer, Dockrell & Murphy, 2004), and for communication and psycho-social well-being (Tomblin, 2008). Linguistic development in special populations such as children with specific language impairment (SLI), or dyslexia, and the increasing numbers of bilingual students in European schools pose additional challenges for the field.

Research suggests that verbs appear to be a more problematic category compared to nouns in various languages and across different groups of language users, including normal elderly adults and young bilingual adults (e.g., Bogka et al., 2003). Similar findings emerge for special populations, such as children with word-finding difficulties and/or SLI (Dockrell, Messer & George, 2001; authors, 2010) as well as for monolingual and/or bilingual adults with acquired language disorders.

The purpose of this paper is to (a) describe the development of a language-specific scale to measure object (noun) and action (verb) word retrieval for use with Greek-Cypriot children; (b) present validity evidence for the measurements derived from this scale across typically developing children and children with specific language impairment, whether monolingual or bilingual; and (c) report comparative results on verb and noun access from these groups. Beyond the practical usefulness of developing a unique language-specific instrument in a language that has not been studied, this research is important for improving theoretical understanding of language acquisition in Greek-Cypriots, as well as for clinical purposes to identify special populations.

METHODOLOGY

Cypriot Greek is a dialect of Modern Greek. The COAT (Cypriot Object and Action Test) was adapted for use with young children from the Greek Object and Action Test (author, 2003) which is used to assess verb and noun retrieval in Greek. Children are asked to name picture stimuli; answers are scored, noting the types of errors made by the children. Thirty typically developing (TD) monolingual first-grade children, between 6;0 and 6;11 years of age were tested with the COAT. They were recruited randomly from three urban public schools. Subsequent testing was conducted with 14 monolingual children with SLI (aged between 5;5 – 9;9 years), and 10 TD children of younger age (between 3;05-5;2 years of age). Two smaller groups were also included: 4 bilingual children with SLI, 6 TD bilingual children.

For the adaptation of the test, word frequency, syllable length as well as adult ratings were taken for each test item regarding the age of acquisition, picture complexity and picture imageability. A test battery was administered in addition to the COAT, which included measurements of nonverbal performance with the Raven's Coloured Progressive Matrices, linguistic abilities with the Developmental Language IQ Test, receptive vocabulary with the Greek version of the Peabody Picture Vocabulary Test, and the Picture Naming Test.

FINDINGS

The GOAT consists of 42 nouns and 42 verbs. Based on the adult ratings on the age of acquisition, a number of words with estimated mean age of acquisition above 6 years of age were deleted from the test. The adapted version of the

COAT consists of pictures of 35 nouns and 39 verbs. The object and action words did not differ significantly on word frequency ($z=-0.569$, $p=0.569$), syllable length ($z=-0.404$, $p=0.687$) or age of acquisition ($z=-0.401$, $p=0.688$). Nouns were however rated as more imageable ($z=-4.047$, $p<0.001$) and more easily recognizable ($z=-2.644$, $p<0.01$) than verbs. Multiple linear regression models revealed that mean age of acquisition of a word was the most significant predictor of correct lexical access, both for nouns and verbs.

Correlation coefficients between performance on the COAT (both on the verb and the noun subtests) and the rest of the measures administered in the test battery were positive in almost all cases and in all children groups, as expected; small sample sizes however did not allow many significant correlations to emerge (detailed results will be presented in the full paper).

MANOVA tests were employed to compare performance on the verb and noun components of the COAT for the three largest groups. Monolingual TD children performed significantly better than the other groups on both noun and verb accuracy, and the monolingual SLI performed better than the younger TD children only on nouns.

Children in all groups did better on nouns than on verbs. Wilcoxon signed rank tests within each group showed that this difference was significant for the TD ($z=-3.55$, $p<0.001$) and the monolingual SLI children ($z=-2.42$, $p=0.016$).

RESEARCH SIGNIFICANCE

Measures appropriate for use with particular groups and documented validity evidence are necessary for the assessment of language development in typical as well as special populations. The current research describes the development of such an instrument in Cyprus where similar measures have not yet been developed. The clinical relevance of the COAT for identifying children with developmental difficulties is obvious. Further data collection will lead to the establishment of norms for various special groups, such as children with SLI and bilinguals. This will enable more accurate evaluation and design of timely interventions. Moreover, the study findings contribute to the theoretical discussion on language development, and the linguistic differences between special populations.

PAPER PRESENTATION

The Testing Effect: Applied to Primary School Children Learning Vocabulary

Nicole Goossens, Erasmus University Rotterdam, Netherlands; Gino Camp, Erasmus University Rotterdam, Netherlands; Rolf Zwaan, Erasmus University Rotterdam, Netherlands

Vocabulary learning is an important factor in primary school education. Lack of vocabulary has a negative impact on subjects like reading comprehension, geography and math. The current study investigated whether vocabulary learning can be stimulated by using a cognitive memory principle, such as the testing effect. The testing effect refers to the phenomenon that tests enhance long term retention more than additional study of course material (Roediger & Karpicke, 2006). The testing effect has been investigated primarily in adults, using word pairs, texts, pictures, and foreign words as study materials. This study is the first to investigate the testing effect in children learning new vocabulary. In the current study, the value of the testing effect for learning 16 new words was examined in grade 3. After an initial study phase, children were presented with extra study trials, test trials, or a combination of extra study and test trials. After five minutes, all children made a final test. This test was repeated after a retention interval of one week. The children showed a testing effect in learning new words. The children who had received extra study trials forgot significantly more of the words than the children who received test trials or a combination of extra study and test trials. These results show that testing may be a powerful means of improving word learning for children.

Extending the vocabulary of primary school children is important, because a small vocabulary has a negative impact on subjects like reading comprehension, geography and even math (Vermeer, 1998). Children with small vocabulary sizes even have more difficulties in extending their vocabulary than children with big vocabulary sizes (Stanovich, 1986). There is a high need for instructional designs that are optimal for remembering new words and their meaning for the long term. The current study investigated whether providing children with test trials after initial learning can help children to learn new words. This instructional guideline is based on the testing effect. This phenomenon, stemming from cognitive psychology, refers to the finding that tests enhance long term retention more than additional study (Roediger & Karpicke, 2006). Research on the testing effect has used texts and pictures, but most experiments on the testing effect have been conducted in verbal learning using independent word lists as study material (e.g. Tulving, 1967; Wheeler, Ewers, & Buonanno, 2003). Also, the testing effect has primarily been investigated in adults. Only Gates (1917) and Spitzer (1939) have investigated the testing effect with primary school children.

The current study is the first to use new vocabulary as study material in the testing effect procedure and is also one of the first to investigate the testing effect in children. The value of the testing effect for learning 16 new words was examined in grade 3. The hypothesis was that children would forget more of the new words after one week in the restudy condition than in the testing condition. We expected that even less forgetting would occur in the condition that consisted of a combination of restudy and test trials, because the children could restudy what they did not know during the test trials. We also investigated whether vocabulary size influences the size of the forgetting effect.

Method

Subjects Eighty-two children (44 boys, 38 girls), aged 8-10 (grade 3) participated individually in this study.

Materials & Design

The children read a story from a grammar book of grade 5 with 16 new difficult words to learn. The words to learn were presented by E-Prime 2.0 on a laptop computer. A 3 x 2 mixed design was used. Subjects learned 16 words under one of three conditions (S = study, T = test): repeated study (SSSS), repeated test (STTT), or a combination of studying and testing (STST). All the subjects were given an immediate test (after a retention interval of 5 minutes) and a delayed test (after 1 week).

Procedure

The children's vocabulary size was assessed prior to the experiment (Verhoeven & Vermeer, 1996). All the children learned the words individually, together with the experimenter. In the initial study phase, all children listened to the story twice and were then told the meaning of the new words. The children also had to read the words aloud twice. After a short break, the children either restudied the words (SSSS), were tested on the words (STTT), or were given a combination of restudy and test trials (STST). The children were given a final test after five minutes. This test was repeated after a retention interval of one week.

Results

The mean percentages of words recalled by the subjects on the final test after 5 minutes and on the final test after 1 week are presented in Table 1. The mean differences in recall between the two tests are also presented. Table 1 Mean recall percentage of studied words (with standard deviations in parentheses) on the final test after a 5-min and a 1-week retention interval as a function of learning condition (SSSS, STTT, STST).

Final Test Condition

	Immediate (5 minutes)	Delayed (1 week)	Differences
SSSS (N = 27)	55.32 (16.87)	43.29 (17.50)	12.04 (13.86)
STTT (N = 27)	50.93 (18.81)	46.30 (20.53)	4.63 (8.05)
STST (N = 28)	53.35 (16.09)	49.33 (17.71)	4.02 (8.71)

Before we analyzed the results we examined if there was a relationship between the vocabulary size and the difference in recall between the two tests. Vocabulary size did not correlate significantly with difference in recall between the two tests ($r = -.19$, $p = .089$). Therefore, we did not include vocabulary size as factor in our analysis. There was a significant interaction between condition and final test moment ($F(2,79) = 4.91$, $p = .010$, $\eta^2 = .11$). Thus, the children displayed a testing effect. The children in the SSSS condition displayed a larger forgetting effect between the immediate test and the delayed test than the children in the STTT or STST condition. Post hoc analyses confirmed these observations. Children in the SSSS condition forgot significantly more of the words after one week compared to the children in the STTT condition ($p = .034$) and compared to the children in the STST condition ($p = .018$). There was no difference in forgetting between the STST condition and the STTT condition ($p = 1.00$).

Conclusion

The current study is the first one to investigate the value of the testing effect procedure in learning new vocabulary in primary school children. The children showed a testing effect in learning new words independent of their vocabulary size. Children who had received extra study trials forgot significantly more of the words than the children who had received test trials or a combination of extra study and test trials after one week. A combination of extra study and test trials does not reduce forgetting more than only extra test trials. These results show that testing may be a powerful means of reducing forgetting in word learning for children.

In conclusion, the procedure of testing can successfully be applied to an educational setting with educationally relevant materials for vocabulary learning in children. If children make tests while learning vocabulary, they will forget fewer words on the long term retention than if they restudy the words.

PAPER PRESENTATION

Peer-Feedback and Feed-Forward in academic writing: Effects on revision performance

Susanne Narciss, Technische Universitat Dresden, Germany; Jan-Willem Strijbos, Ludwig-Maximilians-Universitat, Germany

Peer-feedback content is a core component of peer assessment, but the impact of various contents of feedback is hardly studied. Participants in this study were 140 graduate students who were assigned to six experimental and a control group. Experimental groups received a scenario with feed-forward (FF) or without feed-forward (no-FF) in combination with concise general (CGF) or elaborated specific (ESF) feedback or no feedback (no-FB). The study consisted of a pretest-treatment-posttest design. We used the same material as in the study by Strijbos et al. (2010). In each phase participants were asked to revise a text containing various errors in view of text comprehension criteria (i.e., simplicity, structure, conciseness, stimulating). Students were asked to first detect and label these errors (error-detection; ED) and subsequently suggest corrections for them (error-correction; EC). We computed a revision performance score by adding the z-score ED and z-score of the EC-measure and divided the resulting revision score by time-on-task. There were no significant differences during the pretest. An ANOVA for the treatment phase revealed a significant interaction for feedback and feed-forward. No significant effects were found for the posttest. These findings reveal that less treatment is sometimes more. Students with feed-forward achieved lower levels of revision performance if they were also provided with ESF. If students are not provided with feedback, feed-forward was beneficial for their performance. There was no difference in performance for students with CGF.

The shift towards student-centered learning emphasises that students assume responsibility for their learning. In the context of peer assessment the role of feedback is stressed but the evidence for peer feedback effects are scarce. A recent study by Strijbos, Narciss and Dÿnnebier (2010) investigated the impact of peer-feedback content (concise general (CGF) vs. elaborated specific (ESF) and of sender's competence level (low vs. high) on peer-feedback perceptions and revision performance. Concerning revision performance, the groups receiving feedback did not outperform the control group. Strijbos et al. (2010) hypothesised that the lack of differences might be due to the scenarios providing a type of feed-forward (FF) to all groups, because they included the text comprehension criteria on which the students could rely during the revision of the treatment and posttest text. Based on feedback models stressing the role of internal feedback loops (e.g., Butler & Winne, 1995; Narciss, 2008) the question can be raised whether students in the control group achieved the same level of performance as the feedback groups due to the feed-forward information.

Purpose and research questions

This study aims at clarifying if the feed-forward provided by the peer-feedback scenarios accounts for the lack of missing differences between the feedback groups and the no-feedback group. To meet this aim we conducted a follow-up experimental study in which the effects of (a) contents of peer-feedback (CGF vs. ESF vs. no-FB) and (b) the availability of feed-forward (FF vs. no-FF) on error-detection (ED) and error-correction (EC) performance were investigated.

Method

Participants. The participants were 140 teacher education students at Dresden University of which 38 were male and 102 female. Their age ranged between 20 and 39 years (mean = 24.6). Most of the participants were in the third or fourth year of their studies (75%).

Design, materials and procedure.

A three feedback (CGF vs. ESF vs. no-FB) by two feed-forward (FF vs. no-FF) pretest-treatment-posttest design was conducted. Students were randomly assigned to the six experimental conditions. A seventh condition (ESF with no-FF) containing the same information as the FF, served to investigate the mere impact of the FF information. We used the same material as in the study by Strijbos et al. (2010). During each phase (pretest, treatment, posttest) participants were asked to revise a text containing various errors in view of text comprehension criteria (i.e., simplicity, structure, conciseness, stimulating): pretest 13, treatment 24 and posttest 29 errors. In the treatment phase students studied a scenario consisting of a text revised by a fictional student and the feedback that this fictional student received by the fictional peer. Participants in the FF scenarios were provided with a description of the text comprehension criteria. In CGF-scenarios the peer-feedback consisted of short and general comments (e.g. "The text is complex and hard to understand"). The peer-feedback in ESF-scenarios consisted of knowledge of mistakes (location and error-type) and implicit knowledge on how to proceed (e.g., "An introduction is missing"). The experiment lasted ninety minutes (30 min. per phase) and was embedded in the context of 'academic writing'.

Measures:

Error-detection (ED), error-correction (EC) and time-on-task. During each phase students had to revise a text containing typical errors with regard to text comprehension criteria. Students were asked to first detect and label these errors and subsequently suggest corrections for them. Rooted in signal detection theory, ED was operationalised by the difference of the standardized number of hits and false alarms. EC was measured by the number of correct correction suggestions. In each phase students manually recorded when they started and stopped on a revision task: time-on-task (in min.).

Results

Preliminary analyses revealed that the elaborated feedback group receiving the same information as the feed-forward information spent significantly less time-on-task in all phases than the other groups. Hence, it was excluded in further analyses. Correlational analyses revealed significant correlations for time-on-task and EC, as well as for ED and EC measures in each phase. Therefore, we computed a revision performance score by adding the z-score ED and z-score of the EC-measure and divided the resulting revision score by time-on-task. Table 1 shows the Mean and SE's for time-on-task and the revision performance by time-on-task for the six experimental conditions.

Table 1. Mean and standard errors of time-on-task, and revision performance by time-on-task for the 6 experimental conditions by phase.

A preliminary ANOVA for the pretest-score of the revision performance by time-on-task revealed that there were no significant differences among the experimental conditions. Furthermore, a correlational analysis showed no significant correlation between treatment and posttest revision performance, but a significant correlation between pretest and posttest revision performance ($r = .24$, $p = .005$). Thus, we first conducted an ANOVA for the treatment revision performance by time-on-task score. This ANOVA revealed no significant main effects but a significant interaction for feedback and feed-forward $F(2, 117) = 4.03$, $p = .02$, $\eta^2 = .06$.

As shown in Figure 1 the no-FB group achieved a significant better revision performance with FF, than without FF, whereas for the ESF-group it was the reverse. There is no difference for the CGF-group.

Figure 1: Interaction between feedback content and feedforward for treatment revision performance.

We subsequently conducted an ANOVA for the posttest revision performance by time-on-task. This reveals neither significant main effects for the feedback or feed-forward conditions nor a significant interaction.

Significance of the study

This study investigated the effects of combining feedback and feed-forward in a peer-feedback scenario in the context of an academic writing revision task. The findings reveal that less treatment is sometimes more. Students receiving feed-forward achieved lower levels of revision performance if they were also provided with ESF. If students were not provided with feedback, feed-forward was beneficial for their performance. There was no difference in performance for students with CGF.

PAPER PRESENTATION

Collaborative Revision: An Investigation Into How L2 Language Learners Collaboratively Revise

Elke VanSteendam, HUB (University College Brussels), Belgium; Gert Rijlaarsdam, University of Amsterdam, Netherlands; Huub Van den Bergh, University of Utrecht, Netherlands

A large majority of the studies on L2 collaborative revision are empirical studies which study the effect of students commenting on and revising each others' writing (peer response e.g. De Guerrero & Villamil, 1994; Liu & Hansen, 2002). Studies on the collaborative revision process of two students revising an L2 text which neither of them has written are scarce (Van Steendam, Rijlaarsdam, Sercu, & Van den Bergh, 2010). In this study we analyse the collaborative revision process of dyads revising other students' writing both with and without instruction. To that end, 90 Belgian undergraduates, university students of English as a second language, were randomly assigned to two conditions in which they had to collaboratively revise L2 essays. In a first condition, prior to the dyadic revision session, students watched two models illustrate two different approaches to L2 revision: a global approach in which a reviser improved structure and content of L2 writing and a local approach in which a second reviser edited a text in a linear manner. In a second condition dyads revised collaboratively without any instruction. Both product and process data were collected and the data were analysed using a triangular approach. Analyses of the product data (revision quality) confirm results of previous studies on modelling and cognitive strategy instruction: dyads in the modelling condition revised more global problems than dyads in the control condition (Van Steendam et al., 2010). To completely understand why some dyads revised more and better than other dyadic groups, the quantitative product results were completed with qualitative analyses of revision processes and interaction in the dyads.

Studies on revision in a second language (L2) are relatively scarce (Chenoweth & Hayes, 2001; Hall, 1990; Lindgren & Sullivan, 2006; Stevenson, Schoonen, & De Glopper, 2006, Sullivan, Lindgren, & Spelman Miller, 2008). The majority of these studies compare the L2 revision process to L1 revision. Relatively few studies on L2 revision investigate collaborative revision. A large majority of the studies on collaborative revision are empirical studies which investigate the effect of students commenting on and revising each others' writing (peer response e.g. De Guerrero & Villamil, 1994; Liu & Hansen, 2002). Studies on the collaborative revision process of two students revising an L2 text which neither of them has written are scarce (Van Steendam, Rijlaarsdam, Sercu, & Van den Bergh, 2010). The objective of the present study is twofold.

A first aim is to analyse the collaborative revision process of dyads revising other students' writing both with and without support and/or instruction. The instructional method under review is strategy instruction through modelling, which according to a number of empirical studies is one of the more effective instructional methods for both individual and dyadic revision (Graham & Perin, 2007; Van Steendam et al., 2010). Our second objective is to study the relationship between the collaborative revision process and its resulting revision product. To that end, 90 Belgian undergraduates, university students of English as a second language enrolled in an English composition course, were randomly assigned to a dyad to collaboratively revise an essay. The essays the 1-year university students had to revise were selected from a corpus of 1-year university L2 writing and were thus a good representation of participants' typical problem areas in writing in English. To counter the criticism that students would be at a loss to revise the essays without any additional instruction or training (Liu & Hanssen, 2002; Min, 2006; Zhu, 1995), we had half of the

students watch two models of text revision prior to the collaborative revision session. The students in this randomly formed condition thus observed a first model demonstrate a global revision strategy and a second model illustrate a local revision approach. The design, inspired by both Wallace & Hayes (1996) and by Rijlaarsdam et al. (2008), enabled us to both study authentic collaborative revision processes (control condition) and dyadic revision after instruction (strategy modelling condition).

Both product data (revision tests) and process data (collaborative revision process and interaction) were collected. Process data were collected with both screen capture software and audio software. Multilevel results of product data in previous studies on modelling collaborative revision (Van Steendam et al., 2010) showed that dyads in a modelling condition outperformed dyads in so-called practising conditions without a model for revision quality. Multilevel analyses of the product data in this study confirm these findings. Dyads in the modelling condition revised more global text problems than dyads in the control condition. However, to completely understand why some dyads revised more and better than other dyadic groups, the quantitative product results should be completed with qualitative analyses of revision processes and interaction in the dyads (data triangulation). Studies on modelling (e.g. Braaksma, Rijlaarsdam, Van den Bergh, & Hout-Wolters, 2004) show that observation has a significant impact on students' writing processes: students engage in more metacognitive activities and meta-analytic activities such as rereading and analysing text compared to writers in a practising-only condition.

A preliminary analysis of the process data in the study under review confirm that modelling a revision strategy has a significant impact on the orchestration of writing processes, in this particular case the dyadic revision process. The results are interpreted in the broader theoretical framework of revision in both L1 and L2 on the one hand and on observational learning and cognitive strategy instruction in revision on the one hand.

PAPER PRESENTATION

Individual and school-level predictors of progress in writing

Kane Meissel, University of Auckland, New Zealand; Judy M. Parr, University of Auckland, Faculty of Education, New Zealand

Student achievement profiles of many countries in the OECD exhibit considerable disparity based on socio-economic and ethnic groupings (OECD, 2001; 2005). The investigations detailed in this paper draw on longitudinal data collected from a large national project aimed at raising achievement and decreasing disparities in literacy among students in Years 4-8; gains were substantial. The current paper aims to examine various predictors of student writing progress within this intervention. Since the intervention has been demonstrably successful using typical Educational measures, further analyses provide an interesting profile of where the shift occurs and for whom. Possible predictors were investigated using multiple linear regression, with progress as the dependent variable. Baseline achievement was the best predictor of growth (both in terms of significance and magnitude), with lower starting points predicting greater progress, suggesting that the intervention was more effective with lower achieving students. Factors related to socio-economic status, gender and ethnicity were also important, with students in typically disadvantaged groups progressing more slowly, after taking into account the variance predicted by starting point.

The student achievement profiles of most countries in the OECD exhibit considerable disparity based on socio-economic and ethnic groupings (OECD, 2001; 2005). Efforts to reduce these disparities have increasingly focused on school reforms, including (re-)educating and developing teachers, since teachers have the most impact on student achievement at the system-level (Alton-Lee, 2003; Nye, Konstantopoulos & Hedges, 2004).

The investigations detailed in this paper draw on longitudinal data collected from a large national project aimed at raising achievement in literacy. The project involved expert facilitators working with school leaders and teachers and had a large effect on student achievement, with an average Cohen's effect size of .38 above expected maturational progress for each of the two years of the project (almost three times the usual rate of progress). The gain was markedly higher among lower achieving groups, with average effect sizes of 1.0 above expectation each year. The large gains in achievement are credited to coherence within and between the multiple levels of the schooling and administration systems developing educational partnerships, alongside a focus on evidence-informed inquiry into effectiveness at each level of the system (Author, 2007; 2010).

The current paper examines various predictors of student progress within this intervention using multiple linear regression. Since it has been demonstrably successful using typical Educational measures, further analyses provide an interesting profile of where the shift occurs and for whom.

Two cohorts of students in Years 4-8 are included in the regression model ($n=6,801$); the first started the intervention at the beginning of 2006, while the second began at the start of 2008. Each cohort was involved in the project for two years. The dependent variable was progress over the two years as measured by aSTTle writing, a standardised assessment tool (technical data available at http://www.tki.org.nz/r/asttle/user-manual_e.php).

Factors investigated included baseline achievement, gender, ethnicity, decile (a measure of the average socio-economic standing within a school's zone), school size, school type (full primary, contributing or intermediate), and year level. Gender, ethnicity and school type were entered as either dichotomous or polytomous dummy variables. This process is outlined and justified in a number of publications (e.g. Brambor, Clark & Golder, 2006; Fox, 2008). Various interactions were also considered to investigate moderating effects.

Stepwise regression and incremental sums of squares methodologies were used to investigate the relevance of individual factors and their higher order interactions. Stepwise regression is sometimes criticised as being analogous to data dredging due to the possibility of over-fitting of a model, meaning that the apparent relationships may only be valid within the specific data set, and have little generalisability (Rencher & Pun, 1980; Copas, 1983). However, due to the large number of students, as well as the inclusion of two cohorts within the model, this issue is largely circumvented since any findings are based on generalisation across two large cohorts (Tabachnik & Fidell, 2001).

Interestingly, the most parsimonious model was the best in terms of predictive validity, very low levels of multicollinearity and interpretability. Although the initial stepwise model suggested some evidence of interaction effects, subsequent models, testing these against models with only lower order factors using incremental sums of squares, showed no loss of predictive validity as a result of their exclusion. The initial model with all variables predicted around 37% of the variance in progress, as did the final, parsimonious model where only significant lower order variables were included. A Kolmogorov-Smirnov test for normality confirmed that the residuals were normally distributed.

By far the best predictor of growth (both in terms of significance and magnitude) was initial achievement, with lower starting points predicting greater progress. Decile was also important, with students in lower deciles progressing less than those in higher decile schools, after taking into account the variance predicted by starting point. In other words,

students with similar starting points were more likely to have greater progress if they were in a school drawing on a higher socio-economic area. Female students and students in intermediate schools also tended to have higher levels of progress than other students, while Maori and Pasifika students typically progressed more slowly than other students (largely NZ European and Asian students) with similar starting points.

The regression model provides important insight into the deeper structure of shift among students within a successful intervention. The project aimed to enhance teacher content knowledge of writing and to transfer this learning to practice. The finding that starting point is the major predictor suggests that teachers were more successful in accelerating the performance of lower achieving students; that the knowledge they built of writing and writing practice was best suited to the nature of learning and instruction effective with such students. Perhaps, also the complexity of the act of writing means that a high level of knowledge is needed to assist those higher achievers to progress. Of concern are findings regarding the influence of socio-economic factors and of ethnicity; while the intervention had been demonstrably successful for all, these analyses show it to be most successful for underachievers from groups that are traditionally advantaged.

PAPER PRESENTATION

Didactic Instruction or Cognitive Conflict in preschool children's invented spelling?

Tiago Almeida, ISPA, Portugal; Ana Cristina Conceicao Silva, ISPA, Portugal

The goal of this work was understand the differences between didactic instruction and cognitive conflict in the development of invented spelling. The participants were 60 preschool children (5-to-6) divided in two experimental groups (n=20) and a control group (n=20). All children were pre-syllabics, equivalent in intelligence level, phonological awareness and they were capable of naming the same letters. In Experimental Group 1 we used a didactic instruction of the sound of the letters; in Experimental Group 2 we used a constructivist approach inducing the children to think about and try to discover the sound of the letters using metalinguistics strategies of reflection. All children of experimental groups faced a pre test, an intervention and a post-test. In the pre and pos test we asked children to write a set of 40 words to evaluate the number of correct phonetizations. The results show that the participants of experimental group 2 (discovery of the sound) had better results in the pos-test than the participants of experimental group 1 (didactic instruction). Participants of both experimental groups evolve more that the control group. These results indicate that when children are induced to reflect about the phonological structure of words they generalize more to other situations than when they are instructed to do so.

Recent studies (Sporer, Brunsteim & Kieschke, 2009; Nie & Lau, 2010) retake the discussion concerning the highest or lowest efficiency of constructivist strategies of instruction – adult-child interaction inductive of cognitive conflict – comparatively with didactic instruction – adult-child interaction centred in adult knowledge transmission – at cognitive, academic and motivational achievements of children. These studies (2009, 2010) show that the constructivist strategies were more efficient e produced more lasting results that didactic instruction. Ferreiro and Teberosky (1979) introduced constructivist principles in the study of written language early acquisition. Currently the Psychogenetic Perspective (op. cit. 1979) has a main role on the analyses of children early conceptualizations and ideas about written language. The work of Ferreiro and Teberosky (1979) was continuously developed and improve for

the authors (Ferreiro, 2004) and by other works with European Portuguese (Alves Martins, 1994; Silva, 2003; Alves Martins & Silva, 2006). Alves Martins and Silva (2006) demonstrated how the specific interaction adult-child could facilitate the discovery of written language and alphabetic principle. The results show that it's the nature of adult-child interaction – facilitator of cognitive conflict – and the children needs of solve the problem alone that promote the conceptual evolution of children think and knowledge about written language.

Even so, some authors (Ball & Blachman, 1991; Byrne & Fielding-Barnsley, 1991) argue that is more efficient the utilization of explicit methodologies with systematic and direct instructions. However, concerning the early acquisition of written language and the evolve of invented spelling, the lack of studies and data comparing these two methodologies of intervention program (one based in constructivist approach and other based in a more directive and didactic instruction) lead us to the following problem: is more efficient use a didactic instruction or a constructivist instruction to evolve preschool children invented spelling and to promote a better appropriation of the alphabetic principle? Thus our goal was to analyze what intervention methodology (didactic instruction versus. constructivist interaction) is more facilitator of metalinguistics reflection strategies and more effective to infantile evolution of phonetized writings.

Methodology:

Participants selection: the participants were selected previously concerning the conceptions on the writing (pre-syllabic), number of letters known, level of intelligence, phonological awareness and pedagogical practice of the educator. Phases of pre and pos test: the participants were requested to write 40 real words initiated for consonants b, d, p, t, v, f, m, n (4 of each letter) and r (8) to analyze if exist generalizations for letters not worked. The protocols were analyzed considering the conceptual level of the writings and the number of letters correctly phonetized.

Programs of writing:

The writing programs had the duration of 6 sessions. The studies of Alves Martins and Silva (2006) show that this number of sessions is enough for the evolution of children invented spelling to a more evolved conceptual level. Still in accordance with the works of the authors (op. cit.) these sessions will be destined to take children to use conventional letters to represent the initial consonant of the words. The used words in the programs will be always different of the used in pre and pos test. In the two experimental groups, in each session, participants were asked who to write a word, as he or she knows. After that, the same word, written for a hypothetical child of another school, was used correct letters to represent the syllables. The confrontation writings will appear with a structure CV, CC in alternating. In each session were used 10 words all initiated with the consonants P or T (1? and 2? sessions, words initiated with consonant P; 3? and 4? sessions, words initiated with consonant T; 5? and 6? session, half of the words initiated with consonant P and the other half with consonant T).

Experimental Group 1: The methodology of this group implies that the intervention sessions will be carried through individually. The instruction was given in a didactic way after children write the words. The confrontation writing will be carried through by the experimenter and in accordance with the experimental condition the instruction will be guided for sound of the letter. Thus, in experimental condition 1 the following instruction will be given: "The sound of the first letter is P?", "You ear two bits (stand for syllables), so you write two letters"

Experimental Group 2: The sessions will be carried through individually and the changeable instruction was given to help children think and discover the sound of the first letter. It was asked for after his writings he compares the writings of the other child with their one and that try to think which were the best form to write and why. In experimental conditions 2 was requested to children that in the analysis of the words, attempt against to the sound of the first letter, being given the following instruction to them: "You are capable to say which is the sound of the first letter in the word that you find it is better written?", "Why do you think it is better written?", "What is the first sound you eared?", "How many bits (stand for syllables) do you eared?", "How many bits the other boy wrote?", "Witch one do you think is more correct? You or the other boy? Why?"

Control Group:

The participants of control group were doing draws while the participants of experimental groups were in individual sessions.

Results:

Our results show that when children are induced to think about the words they are able to generalized more efficiently to other words. In experimental group two all children evolve to syllabic or syllabic-alphabetic writes while in experimental group one just half of the children evolve to more advanced levels of conceptualization. Concerning to the number of phonetizations, experimental group 2 had a significant higher number of corrects letters mobilized that

experimental group 1 ($p < 0,01$). Both groups performed better than the control group in the number of correct phonetizations and conceptual evolution.

Discussion:

Probably these results appear because the kind of cognitive strategies utilized in the interventions programs. While in experimental group 1 the main strategy utilized by children when learning by didactic instruction in experimental group 2 children develop a more appropriate knowledge about the alphabetic principle because they are conducted to think and reflect about the relation between written words and oral language (Silva, 2003). Other conclusion that we can retreat is that some kind of written language initiation is better than none. This kind of studies can help us to understand how to initiate children in written language before the formal learning, improving the success of future readers and writers.

PAPER PRESENTATION

Organizing teachers' knowledge about networked learning in concept-maps

Celeste Meijs, Open University, Netherlands; Maarten de Laat, Open University, Netherlands; Bieke Schreurs, Ruud de Moor Centrum Open Universiteit, Netherlands

Networked learning is an important form of professional development of teachers that complies with the rapidly changing culture, technology and complexity of the profession of the teacher. However, the formation of teacher networks is a often difficult process. In the current presentation, an instrument that can be used to support the formation of the networks by the teachers is described: the construction of a concept-map that constitutes of the knowledge, skills, beliefs and values of teachers regarding networked learning. This map gives insights in the position of the teachers regarding networked learning, which in turn should give them support in acting accordingly in the formation of the networks.

Background:

Professional development of teachers has traditionally been organised in static courses or seminars (Lieberman & Wood, 2002a). Since the emergence of sophisticated internet tools for online connections between people and the rapid demographical and socioeconomic changes, networks to support learning arose (Goodyear, Banks, Hodgson, & McConnel, 2004; Harasim, Hiltz, Teles, & Turoff, 1995; Lieberman & Wood, 2002a). Additionally, recent studies indicate that learning from other teachers is a powerful way to enhance professional development (Dresner, Worley, & E., 2006; Lieberman & Wood, 2002a, 2002b) and that teacher networks provide large opportunities for professional development (de Bruijn, 2008; Gellert, 2003; Lieberman & Wood, 2002b). Therefore, it would be a missed opportunity not to stimulate the formation of teacher networks.

Aims:

The formation of teacher networks is a difficult process because, amongst other things, it needs a switch in thinking about teacher professional development programs (Meijs & De Laat, in prep). Networked learning stimulates a personal driven informal perspective on professional development, starting with a critical, reflective and active attitude from the teacher. An aid to help teachers in the formation of teacher networks is giving teachers insight in their skills, knowledge, beliefs, and values regarding networked learning. With this metacognitive knowledge, teachers should be able to establish their own position regarding networked learning, which in turn, should lead to more support during the formation of teacher networks. We establish this insight by constructing concept-maps, which have previously been described as a useful manner to organise and structure knowledge (Amer, 1994; Zanting, Verloop, & Vermunt, 2003).

Methods participants:

We developed an interview framework that included the formation of a concept-map about the skills/knowledge/beliefs/values of the teacher regarding networked learning. The interview was administered by 12 teachers of primary and secondary schools.

Methods procedure:

The interview took about 1,5 hour. These conversations formed the base for the construction of a concept-map, in which the teachers connected the core concepts mentioned during the interview.

Methods instrument:

The rationale behind the formation of concept-maps was founded by the epistemic frameworks theory described by Shaffer et al. (2009). However, in a different context, the method of structuring knowledge is applicable for other topics as well. Shaffer et al. describe five levels of information of which we make use of the levels skills, knowledge, beliefs and values. The core elements of the interview framework were: (a) The core concepts of networked learning according to the teachers, (b) previous experiences and contacts related to networked learning, (c) skills needed for networked learning and estimation of their own skills, (d) characteristics of a good teacher network and estimation of their own network, and (e) to make associations between the concepts mentioned during the interview by means of connecting the concepts in the concept-map.

Methods statistics:

Several measures were calculated for the quantitative data-analyses including social network analysis measurements (Hawe & Ghali, 2008; Wang & Li, 2007), which were applied to the concept-map, to analyse the overall density of the concept map, followed by measurements to detect which key topics were closely connected, and if there were clusters and isolates. The content of the concepts was used for qualitative analyses. Also

Results:

The density of the concept-map, which is the percentage of connections made / all possible connections is a useful measure for comparison between subjects. On average, the teachers connected 14.3% of all possible connections (sd = 9.2; range 6.2 – 37.9). Mean number of connections per concept is 2.3 (sd = 9.1; range 1.3 – 4). Future studies should explore whether these measures correlate with other factors such as experience with networked learning or overall position regarding networked learning based on the results of the network-learning quiz (Meijs & De Laat, in prep).

The concept-maps reveal, per teacher or overall, what he or she finds the most important value, what the most important actions or skills are to reach the aim and what they need to know about this. For instance, overall, the maps show that the teachers aim to learn from and with each other, that they need to work together and need to give and take in order to reach this aim and that this requires an open attitude.

Discussion:

The concept-maps show that the teachers are aware of how they want that their professional development regarding to networked learning is designed, what they need to do and what their attitude regarding networked learning is. This should give them support in acting accordingly.

Subjectively, the participating teachers mentioned that they felt enlightened about their vision on networked learning after the completion of the interview framework and the concept-map, because the most important concepts according to them (and mostly had the highest number of connections) stood out of the map.

Theoretical implications:

There is a lot of research on the effects of social networks, to some extent as well within professional development. However current research lacks insight about the strategies people develop and apply when engaged in these activities. What makes a good networker/networked learner? This study is an attempt to uncover the behavioural aspects of networked learning to build further theory to frame social learning in networked environments by means of the construction of concept-maps.

Practical implications:

The interview framework with the formation of the concept-map is a useful instrument for the support of teachers in the formation of teacher networks.

PAPER PRESENTATION

Theoretically and empirically developed test-instruments for teachers' professional knowledge

Melanie Juttner, University of Munich (LMU), Germany; Birgit Neuhaus, University of Munich (LMU), Germany

Due to the fact, that students' learning outcome was not as high as expected in international studies like PISA or TIMSS, research on teachers' professional knowledge and the role of teachers concerning teaching effectiveness increased (Johnson, Kahle & Fargo, 2007). In spite of everything, research on teachers' professional knowledge and the relationship between this knowledge and their students' learning outcome is still at the beginning (Baumert et al., 2010). The here presented part of the project, ProwiN (professional knowledge in science education), is a first step towards closing this gap for science education. In the study the pedagogical content knowledge, the content

knowledge and the pedagogical knowledge of science teachers' is evaluated by using paper-and-pencil tests as well as videotaping lessons combined with students' achievement tests. These data will be used for the calculation of correlations between teachers' professional knowledge and students' learning outcome. This project is realized by a co-operation of the Universities of Munich, Duisburg-Essen and Bochum. In the presentation, the theoretically and empirically based developed PCK- and CK-items for biology as well as the results of the pilot phase will be demonstrated.

1. Theory

The effectiveness of instruction is defined in many ways with different focal points (Seidel & Shavelson, 2007). All in all the theoretical models indirectly postulate that the professional knowledge of the teacher influences the effectiveness of instruction and therefore the students' outcome (Johnson, Kahle & Fargo, 2007). But research on this relation is just at the beginning and only several studies like COACTIV (Cognitive Activation in the Classroom; Baumert et al., 2010) analyzed it by combining mathematical teachers' knowledge tests to students' results of PISA. Research on other subjects than maths – like science – is still rare (Abell, 2007). The here presented project is a first step to close this gap concerning biology.

Research on professional knowledge exists since decades (Abell, 2007). The original definition of professional knowledge was given by Shulman (1987). All current empirical studies and theories on professional knowledge have different foci and interpret teachers' professional knowledge in different ways, but often based on Shulman's idea. Currently, there are three major categories used in most of the studies: content knowledge (CK), pedagogical content knowledge (PCK) and pedagogical knowledge (PK) (Baumert et al., 2010).

PCK is an important category not only for teachers, but also for science educators, so it will be pointed out in this paper. According to Shulman (1987), ProwiN (professional knowledge of science education; Borowski et al., in press) - and therefore the here presented part of this project - defines the PCK as knowledge of structuring the content and preparing the subject matter, making it comprehensible for students (Borowski et al., sub.).

The model of the PCK-test has three dimensions: knowledge (declarative, procedural and conditional), facets (models, experiments and students cognition) and topics (neurobiology, plants and vertebrates) (Tepner et al., in progress). According to the professional knowledge and especially to the PCK, the following objectives of the research project reported here are:

- (1) development of a reliable and valid assessment test to measure biology teachers' PCK,
- (2) analysis of the correlations between the three types of knowledge and
- (3) to scrutinize the influence of different types of knowledge for teachers of different school types: secondary school and secondary modern school.

2. Study design

The PCK-items, all in all 27 open-ended items, were developed based on the theoretical model. Some of these PCK-items were based on an empirical pilot-study that was conducted to learn more about students' errors (Jýttner & Neuhaus, 2010).

In the pilot phase, the PCK-questionnaire was first of all given to 24 biology teachers (58% female; 42% male) of different secondary school types. First results concerning quality criteria will be presented: For calculating the reliability the standardized cronbach's alpha was taken, because of different variances of the items (Field, 2009). The ICC (IntraClassCorrelation) was used to analyze the objectivity. For this calculation, the two-way mixed model and the absolute agreement was taken (Shrout & Fleiss, 1979). The validity of the test was computed by the t-test.

3. Findings

The 27 PCK-items were uniformly distributed over the theoretical model. For all facets the reliability is computed and presented in table 1 (see appendix). The inter-rater reliability of two independent raters is ICC (3,2) = .87 (F 503,503 = 15.43; p

The t-test of the mean test score of biology teachers working in secondary school versus other school types is not significant for the PCK-test (T = - 1.24; p = .30; N = 24).

4. Discussion and contribution to teaching of science

Nearly all quality criteria of tests are achieved: The reliability, measured through the standardized cronbach's alpha for each subscale is satisfying (Field, 2009). The objectivity, measured by the singled measure ICC, demonstrates another

satisfying result (Garson, 2010). In future the validity of the test should be analyzed again and optimized. Therefore the pilot phase is still going on for becoming a bigger sample size ($N = 60$).

In a nutshell, the PCK-items for biology teachers seem to be useful, reliable and objective items. Additionally, both instruments, the PCK-test for teachers and the students' achievement tests, could be combined to collect data on the relationship of both. This could be seen as a first step forwards in the research on teaching effectiveness.

Until summer 2011 the results of the main study with a sample size of $N = 300$ biology teachers and the final version of the test-items will be presented.

PAPER PRESENTATION

What can novice teachers learn from experienced teachers – and vice versa? A collaboration scenario

Kati Makitalo-Siegl, University of Jyväskylä, Germany; Anna-Maria Mekota, University of Munich, Germany; Joachim Kahlert, University of Munich, Germany; Frank Fischer, Universität München, Germany

There is a notion about the importance of collegial support and pedagogical discussions in teacher's profession. However, only few studies have been investigating learning among teachers directly in their workplace, although this setting would be the most natural place for learning, because collegial expertise is available. So far we know that in order to collaborate successfully, a certain degree of support is necessary.

This study aims to investigate how to structure teacher groups in order to optimise teacher collaboration and how to support teachers to bring their expertise into the group. Twelve novice and experienced teachers from primary- and secondary school levels participated in this study and their intergenerational collaboration was guided by a collaboration script. Both quantitative and qualitative approaches were utilised in the analysis of the interviews and the log diaries.

The results show that the teacher-pairs utilised the given collaboration script in their meetings and found it to be useful regardless of the school level. Novice teachers received advices and support from experienced teachers and experienced teachers got new perspectives and the opportunity to share their knowledge. Both novice and experienced teachers self-reported more about changes in their knowledge as well as beliefs and emotions than changes in teaching practices. The possibilities and the challenges of the collaboration scenario and also the role of technology will be further discussed.

PAPER PRESENTATION

Does the Lesson Study Work? A Systematic Review on the Effects of Lesson Study and Learning Study

Wai Ming CHEUNG, University of Hong Kong, Hong Kong

Purpose:

There has been a rapid proliferation of lesson study and learning study all over the world. Do they really work in teachers' professional development and student learning? This paper reviewed studies from 2000 to 2010 on lesson study and learning study with a view to unraveling their benefits on teachers and students.

Methods:

A total of 74 articles were extracted from relevant electronic databases and 9 articles were screened in the systematic review to examine the effect of lesson study and learning study.

Results:

8 studies reported that lesson study or learning study was beneficial to teachers while only 6 stated beneficial to students. This supported the benefits of both as a powerful tool to help teachers examine their practices and enhance student learning.

Conclusion:

All nine reviewed studies showed that they work with positive effects on teaching, learning or both. However the outcome measures and study designs with varied a lot which made comparison of results difficult. We recommend that more well-controlled studies with validated outcome measures be conducted in the future to address the short and long-term effects of lesson study approach on students, teachers and school level.

Significance:

This review is the first of its kind which unveils the positive effects on teaching and learning which shed light on the linkage between teachers' professional development and student learning. Future directions of lesson study and learning study are recommended.

Since 1999, Stigler and Hiebert commended the use of lesson study (Fernandez & Chokshi, 2002; Lewis & Tsuchida, 1998) as a teacher professional development approach to improve teaching and student learning, the movement for classroom-based research has become prominent among teachers and educators for the past decade. A related basic approach called "learning study" was developed from the ideas about lesson study by Marton (Marton & Morris, 2002; Marton & Pang, 2003; Marton & Tsui, 2004). Lesson study and learning study which share the basic elements are used worldwide nowadays in the United States, Sweden, Australia, the United Kingdom, Hong Kong, Japan, and Singapore to improve teachers' teaching and quality of student learning. Both approaches combine collaboration, reflection, and professional development into a structured experience that allow them to construe new meanings about instructional practices.

There has been however a lack of systematic review that focuses on its effectiveness available in the literature. Our point of departure is to answer the question "Does the lesson study work", "How it works?" and "What kind of evidences we find". This paper aimed to respond to this question with present findings on this aspect based on a systematic review of relevant studies from 2000 to 2010. This systematic review covered literature from 2000 because there was lack of studies about lesson study and learning study before 2000. Although lesson study has widely been used in Japan, most lesson studies were not yet well-documented, fidelity and spread standards were problematic. The evidence we reported here are the evidences that are the best we can find.

A comprehensive literature search was performed for the period from January 2000 to March 2010, on computerized electronic databases. Studies were further filtered by visual examination to avoid duplication of articles across different databases. A study was included if: (i) the theme was mainly on identifying the effectiveness of "lesson study" or "learning study"; (ii) it was an empirical study; and (iii) the targeted subjects were teachers or students. The study was excluded if it was a review. A total of 74 articles (21 from ProQuest, 27 from JSTOR, 24 from Springer-Link, 2 from Sage Journals) were extracted from the electronic databases. According to the inclusion criteria, 20 articles in full texts were selected for a detailed review. After screening, 9 articles were included in the systematic review.

All of the reviewed studies (N=9) reported positive effects on either students or teachers, or both. Six studies reported that lesson study or learning study had positive effects on students (Cheung, 2009; Lo et al., 2006; Marton & Pang, 2006; Matoba et al., 2007; Pang, 2009; Pang & Marton, 2003). Among them, three studies reported that the positive effects on students were statistically significant (Cheung, 2009; Marton & Pang, 2006; Pang, 2009). Two studies found that learning study outperformed lesson study on enhancing students' learning outcomes (Pang, 2009; Pang & Marton, 2003). Eight studies reported that lesson study or learning study had positive effects on teachers or teaching (Cheung, 2009; Lo et al., 2006; Marton & Pang, 2006; Pang & Marton, 2003; Marble, 2007; Matoba et al., 2007; Perry

& Lewis, 2009; Stewart & Brendefur, 2005). Among these lesson studies, one study reported positive effects on both teachers and students (Matoba et al., 2007). Four learning studies reported positive effects on both students and teachers. The positive effects on teaching from learning study were the light shed by the comparative analysis of what happened in the classrooms that related differences in the students' capabilities in handling the object of learning to differences in how the object of learning was handled in the classrooms.

As the main aim of lesson study is to enhance teacher's professional development to improve students achievement (Matoba et al., 2007) and learning study is to enhance the learning outcomes of students (Kullberg, 2010), so it is more beneficial if the linkage between teaching and learning is made clear to the audiences (Kennedy, 1999). What has been missing is a theory that could explain the effects of teachers' actions on student learning in a useful way though there have been many attempts to explain teaching-learning relationships (Nuthall, 2004). In the reviewed learning studies, teaching and student learning is explored by means of a framework called variation theory (Marton & Booth, 1997; Marton & Tsui, 2004; Marton & Pang, 2006). The framework makes it possible to analyze teaching and learning in commensurable terms, which implies that "what the teacher intends the students to learn", "what is made possible to learn in a lesson" and "what the students learn" are connected and describe in similar ways. The reviewed studies (Cheung, 2009; Lo et al., 2006; Marton & Pang, 2006; Pang & Marton, 2003) showed the use of variation theory to explain differences in students' possibilities to learn with reference to the differences in handling how the object of learning was handled in the classroom. In this sense, learning studies will be transferable or may be replicable to other teachers and students if the new teachers tried to help the students to discern the critical features of the object of learning. It would be valuable to education if more research could also highlight the significant effects of lesson study and learning study on teaching and student learning.

Our review identified some positive evidence supporting the educational benefits of lesson study and learning study. There is however still a lack of high-quality and well controlled studies in this field. The majority of the existing trials have small sample size. Further trials should be conducted with more representative samples to confirm the effectiveness of lesson study and learning study. Proper randomization techniques need to be used, clearly described, and fully reported. This review did not intend to make a conclusive remark on the effect of lesson study and learning study. On the other hand, we attempted to summarize findings of respective research in the past decade so as to shed light on the direction of future research on this modality.

PAPER PRESENTATION

Is teacher expertise reflected in talking about classroom situations?

Katharina Rosenberger, University College of Teacher Education Vienna/Krems, Austria

The conference paper aims to present the reconstruction of pedagogical knowledge through picture und text vignettes. The vignettes have been used to show teacher students' – and in comparison expert teachers' – way of seeing and interpreting a given classroom situation. The central aim is to investigate the changes in the students' pedagogically directed perception, in their skills of interpretation and their knowledge of action at the beginning and at the end of their studies.

The sample comprises 273 teacher students. In addition to these two data sets, 60 experienced teachers also took part as a comparison group. Using the vignettes we analyse and assess the texts written in their response mainly with qualitative research techniques: How do the respondents comment on the pedagogical situation described in the text vignette or shown in the picture? What do they articulate and how do they articulate it?

At the conference the results of the expert-novice-comparison will be presented. A comparison of the students' answers with those of experienced teachers illustrates to a certain extent differences – for instance the 'teacher's eye' of the expert teachers as a symptom of professional identity or the 'student's heart' by focusing on how pupils feel. The analysis also reveals the range of interpretative perspectives of any particular situation and indicates in which way initial teacher training could address this issue.

The debate about teacher expertise is highly related to the question of professional knowledge and its acquisition in formal and informal ways. To cope with pedagogical-practical challenges requires on one hand conceptualized knowledge (acquired through formal training) and on the other hand embodied practical knowledge (acquired by doing). (cf. Polanyi 1958 and Neuweg 2004) Professional knowledge has to manifest itself in successful practise. Teacher education institutions are therefore facing various challenges. Their curriculum and actual training serves

primarily as a structure for the direction of teaching, but it cannot determine it. Thus, these institutions need to find effective ways how it is possible to support the acquisition of practical knowledge.

A key approach in initial teacher training in various European countries is observation, analysis and (verbal) reflection of teaching – either one's own practice or others persons teaching, which became especially popular with Schoen's distinction between reflection-in-action and reflection-on-action. While the first is integrated in action serves the second as a form of retrospective deliberation on action. "Through reflection, he [the practitioner] can surface and criticize the 'taken-for-granted assumptions' that have grown up around the repetitive experiences of a specialized practice, and can make new sense of the situations of uncertainty or uniqueness which may allow himself to experience." (Schoen 1983, 61) Although Schoen does not follow the classical Cartesian model of rational subject, he doesn't reflect the concept of reflection. On the contrary he recognises the reflection of concrete situations as a form of creating or refining professional wisdom.

The conference paper aims to present the reconstruction of pedagogical knowledge through picture und text vignettes. The vignettes have been used to show teacher students' – and in comparison expert teachers' – way of seeing and interpreting a given classroom situation. Both vignettes are embedded in a broader multi-method research design of the perennial research project "Competency development of students in teaching degrees, using the example of the ability to differentiate as one of the prerequisites for handling heterogeneous student groups competently" that is carried on from 2009-2012 at a University College of Teacher Training in Vienna. The project follows two basic tracks of research: on one hand the description of actions taken in the classroom by students in teaching degrees (through reconstructive methodologies) and on the other hand an explorative study and an analysis of professional concepts that generate such interpretations. A central aim of the project is to investigate the changes in the students' pedagogically directed perception, in their skills of interpretation and their knowledge of action at the beginning and at the end of their studies.

The sample comprises 273 Austrian teacher students. At the very beginning of their training in 2008 they were asked to take part at the vignette study and they will be asked again shortly before the completion of their course in 2011. In addition to these two data sets, 60 experienced teachers also took part as a comparison group. Using the vignettes we analyse and assess the texts written in their response: How do the respondents comment on the pedagogical situation described in the text vignette or shown in the picture? What do they articulate and how do they articulate it?

The codifying system consists of inductive as well as deductive codes – mainly with descriptive and structural categories. In the process of analysing the material we mainly used qualitative research techniques (criteria-related text analysis). Additionally, some quantitative calculations were also done to allow a comparative analysis in order to find special types and correlations. These types were interpreted in case studies and linked with other empirical methods in the research project.

At the conference the results of the expert-novice-comparison will be presented. A comparison of the students' answers with those of experienced teachers illustrates to a certain extent differences – for instance the 'teacher's eye' of the expert teachers as a symptom of professional identity or the 'student's heart' by focusing on how pupils feel. The analysis also reveals the range of interpretative perspectives of any particular situation and indicates in which way initial teacher training could address this issue. The distinction between experts and students is much smaller than was assumed by teacher trainers interviewed for the study. Therefore we might have to rethink our assumptions about the role that verbal reflections on teaching play in teacher training and find innovative ways how reflecting can be used in order to improve the students' repertoire of strategies.

PAPER PRESENTATION

Extending understandings: Teacher expectations across time

Christine Rubie-Davies, University of Auckland, New Zealand; Rhona Weinstein, University of California at Berkeley, United States; Phil Cowan, University of California at Berkeley, United States; Carolyn Cowan, University of California at Berkeley, United States

This study sought to empirically examine long-term teacher expectation effects in relation to student outcomes. Many studies have investigated what we defined as contemporary effects (teacher expectation effects that occur across one year) but few have studied longer-term effects. We examined enduring effects (distal effects of one teacher across more than one year) which have occasionally been reported and compounded effects (the additive effects of different teacher expectations across several years) which to our knowledge have not previously been reported. The participants (110 students) were tracked from pre-school through Grade 4. Teacher expectations were measured in Fall and student achievement in Spring. Relationships were found between teacher expectations and student achievement across one year (contemporary effects) and more distally across two or more years. Compounded teacher expectation effects were examined in two ways, firstly by using structural equation modelling to predict student achievement and secondly, by examining long-term outcomes when students had successive teachers with correspondingly high or low expectations for their achievement. Data from the path model showed that by end of Grade 4 the longer term expectancy effect advantage translated to a score of 61.5% correct on a test versus a score of 39.5% - a substantial difference. There was a direct linear relationship by end of Grade 4 between numbers of teachers a student had with high (or low) expectations and student achievement. The study advances understandings of longer-term relationships between teacher expectations and student outcomes, particularly by including the compounded effect of expectations across time.

Despite the voluminous teacher expectation research, little is known about relationships beyond one year between teacher expectations and student outcomes. There is clear evidence of teacher expectation effects in naturalistic settings across one year (defined as contemporary effects). Further, a few researchers have considered the enduring effect of teacher expectations (i.e. whether teacher expectation effects of an original perceiver are sustained across several years). For example, Alviderez and Weinstein (1999) showed that Kindergarten teachers' over- and under-estimates of intelligence relative to IQ predicted grade-point average 14 years later. Despite using different expectation measures, various studies have reported that controlling for initial achievement, earlier teacher expectations have a durable effect on later outcomes as diverse as achievement, courses taken and test-taking for college admission. However, the role of an initial and then subsequent perceivers and additive effects across a number of years should also be considered. We define the separate but cumulative effects of multiple teachers across time as compounded effects of teacher expectations. Brophy (1983) suggested that even if effects of within-year expectations were small, the effects could increase substantially as they accrued across several years. To our knowledge, this has not been investigated previously.

Research aims

Our aims were to a) examine contemporary effects of teachers' expectations on student achievement across one year, b) investigate enduring effects of a single teacher's individual expectations on students' achievement beyond the year students were with the original perceiver, c) consider the compounding of each succeeding teacher expectancy effect from Kindergarten through fourth grade and d) explore effects on fourth-grade achievement of multiple years of having a teacher with high versus low expectations.

Method

The participants were 110 students tracked from pre-K to Grade 4. This study used data from the Schoolchildren and their Families Project (Cowan, Cowan, Ablow, Johnson, & Measelle, 2005) to examine teacher expectation effects across time (at Kindergarten, Grade 1 and Grade 4). The 'intelligence' subscale of the Child Adaptive Behavior Inventory (CABI) (Cowan, Cowan, Heming, & Miller, 1995) was used as a measure of teachers' expectations. In Fall, at Kindergarten, Grade 1 and Grade 4, teachers provided expectation data for the target and other students in their classes. Standardized measures of verbal ability and achievement were obtained at pre-school using the Peabody Picture Vocabulary Test (PPVT) and then the Peabody Individual Achievement Test (PIAT) in Spring.

Results

At the three grade levels across a one-year period, controlling for the most proximal end of year achievement, three hierarchical regressions were performed to predict end of year achievement at Kindergarten, Grade 1 and Grade 4. At each grade level, teacher expectations predicted student achievement.

We examined enduring effects of teacher expectations, after controlling for PPVT scores, and found significant and sustained effects of early teacher expectations past one year. Beyond the Kindergarten year, we found evidence of rising teacher expectation effects in the following year and diminishing effects four years later. With regard to the predictive role of Grade 1 teacher expectations, there was evidence of an increased effect of expectations on Grade 4 achievement three years later compared to the within-year effect which was smaller.

The question of the compounding of teacher expectancy effects was explored in two ways. First, we examined the additive effects of successive teacher expectancy effects in predicting fourth-grade achievement by using a path model. The compounded result of the teacher expectancy effect at Kindergarten, Grade 1 and Grade 4 was almost a quarter of a standard deviation or the difference between scoring 61.5% and 39.5% on a test. The combined effect across four years of previous and current teacher expectations was more substantial than the within-grade effects or the enduring effects across more than one year. Second, we used a median split at each grade level to assign students to high or low teacher expectation groups. Controlling for achievement, the more teachers students had with high expectations, the greater their mean achievement at Grade 4 and conversely, the more teachers students had with low expectations, the lower was their mean achievement. Numbers of high (or low) expectation teachers significantly predicted achievement at Grade 4.

Discussion

The current study conceptualized three different long-term teacher expectancy effects: contemporary, enduring and compounded. The contemporary teacher expectancy effects confirmed results of other studies (e.g., Kuklinski and Weinstein, 2001). While the effects were small, early teacher expectations had an independent relationship with student outcomes at the end of the current year, above what might be anticipated based on prior achievement, and beginning in the Kindergarten year. Evidence of the enduring effects of teacher expectations on student achievement also confirmed previous work (e.g., de Boer, Bosker, & Van der Werf, 2010). The remarkably consistent evidence for the enduring relationship between earlier teacher expectations and later student achievement is an important finding in its own right, since it indicates an extension of teacher expectancy effects beyond the year in which the expectations were formed. Our findings of compounded effects across multiple years, occurring at both positive and negative poles of expectations, underscores the increased and cumulative effects that Brophy (1983) hypothesized – small effects can become sizeable over time.

This study shifts the debate from single teachers whose expectations endure to compounding effects across multiple teachers over time. The interesting question, however, is not whether long term effects of teacher expectations exist but rather what the conditions are in relation to teachers and students whereby expectancy effects are intensified and accrue more or less across a child's schooling. Further, given consistent findings about teacher qualities or practices that moderate teacher expectancy effects, it is critical to pursue the role of teacher differences in studying longitudinal effects. We know relatively little about teacher qualities, beliefs, and school environments that moderate beliefs about what teachers can expect of students and how they actualize these beliefs in practice. Developing a more holistic view of students within the schooling context offers many opportunities to advance knowledge about expectancy processes and positively contribute to enhanced and equitable outcomes for all students.

PAPER PRESENTATION

Beliefs about teaching: persistent or malleable?

Erika Lofstrom, University of Helsinki, Finland; Katrin Poom-Valickis, Tallinn University, Estonia

The paper describes a follow-up study focusing on change in Estonian university students' beliefs about the teacher role. The beliefs were investigated through metaphors, and analysed applying the dimensions of the teacher identity model developed by Beijaard, Verloop and Vermunt (2000). The method of analysis was thus deductive, theory-driven content analysis. The number of students was 68, resulting in 136 metaphors collected two years apart. A third of the students changed the type of metaphor between the two sets of data collection. The finding indicated that beliefs about teaching are fairly persistent. However, when there were changes, the views expressed were broader including additional elements reflecting a more developed and expanded view. The finding supports the notion that it is important to provide university students opportunities to reflect on their experiences of the university teaching–learning environment as this may allow the students to broaden their conceptions. This is particularly vital in programmes that follow a consecutive (3+2) teacher education model and in contexts in which there is a lack of prospective teachers in certain subject areas. Now that we have an understanding of the positive nature of the changes, the next step is to look into factors facilitating change in the beliefs.

Introduction

This paper describes a follow-up study focusing on change in Estonian university students' beliefs about the teacher role. The beliefs were investigated through metaphors about the teacher role. Beliefs are often unconscious, yet they serve as a filter through which the student responds to teacher education. Prospective teachers enter the university with existing conceptions and beliefs about teachers and teaching (Calderhead 1996). Preconceptions have demonstrated resistance to change (Joram & Gabriele 1998). However, beliefs can change as a result of reflection on

classroom experiences, and the changes can be expressed through metaphors (Alger 2009). Metaphors can serve as a tool in making implicit beliefs explicit (Leavy & al. 2007) helping the student to connect personal beliefs and educational theories.

The Interpretative Framework

We have analysed metaphors using the dimensions of the teacher identity model by Beijaard, Verloop and Vermunt (2000) identifying different knowledge bases that characterise teacher identities. According to Beijaard & al., teacher expertise can be based on subject matter expertise, pedagogical knowledge, and didactics expertise. The knowledge base that the teacher primarily relies on has implications for the teaching. In addition to the subject area knowledge teachers need an understanding of how to teach the content to enhance learning, i.e. knowledge of didactics, and it is discipline- and subject specific in nature. Focus is on the creation of learning environments that support the learning processes. Further, the understanding of human learning, behaviour, and communication are essential elements and form the pedagogical knowledge with an emphasis on relationship, values, and the moral and emotional aspects of development.

Method

The research questions were: How stable are students' beliefs about teacher role? Can changes be identified, and if so, how have the beliefs changed? The number of students was 68, resulting in 136 metaphors collected two years apart; in the first and the third study year. The students were asked to provide a metaphor characterising the teacher role. They were prompted by the statement "A teacher is like...", which they were to finish, and provide a brief explanation. The metaphors together with the explanations formed the units of analysis. The metaphors were categorised through deductive, theory-driven content analysis according to the dimensions in the Beijaard et al. model. The agreement for the categorisations between two independent raters on 85% of the metaphors was high with an agreement rate of 97%.

Findings

The pedagogical metaphors were generally related to mother or leader, or other living entity. By contrast, the subject metaphors were mostly related to static, non-living objects, typically book. The didactical metaphors typically expressed something active, strong or powerful, e.g. brick oven, ice-breaking ship, steam engine, a snowflake starting an avalanche. The metaphors expressing teacher/work characteristics represented both static objects and living entities, but the explanations described work environment or personal characteristics.

In the first data set, 19 metaphors were categorised as expressing a belief about the teacher as a pedagogue, 7 expressing subject expertise, and 9 expressing didactics expertise. Twenty-one metaphors were hybrids of these categories, and 12 did not fall into these categories expressing teacher characteristics or characteristics of the teacher's work rather than its knowledge base. In the second data set, 27 metaphors were grouped into the Pedagogue, 13 in the Subject expert, and 7 in the Didactics expert category. Thirteen metaphors were hybrids, and 8 expressed teacher/teacher work characteristics. The metaphors changed in twenty-four cases (32%). In twenty cases (29%) some element was added to the initial idea expressing an expanded view of the teacher role.

The relevance of the research

The data showed that metaphors tended to be more persistent than malleable. However, when there was change, the metaphors expressed a broader view of the teacher role indicating development of beliefs. The expanded perspectives may be related to own experiences in the university teaching-learning environment, which emphasises the importance of offering the students opportunities to reflect on their learning experiences. The next step is to look into students' experiences of their study environments to find out the factors that are related to change in the beliefs. Our interest in prospective teachers arises from the fact that a large number of students who have a foundation degree in a subject choose careers other than teaching. School teaching staff in Estonia is growing older and there is a lack of school teachers in certain subject areas (Riigikontrolli...2004). Research (Rots & al. 2007) indicates that non-integrated teacher education, which also Estonian subject teachers follow, is a negative predictor of graduates' entrance into the teaching profession. At the point at which the Estonian university students are to choose entry into subject teacher studies at the Master's level, their likelihood of entering teacher education is at the lowest point (Lõfström & al. 2010). By investigating the students' beliefs about teaching and the changes in those beliefs during their Bachelor's degree studies (i.e. prior to entering teacher education) we can better understand the possibilities teacher educators have in identifying and working with teacher potential already during the Bachelor's studies.

PAPER PRESENTATION

A meta-analysis on teacher judgment accuracy

Anna Suedkamp, University of Kiel, Germany; Johanna Kaiser, University of Kiel, Germany; Jens Moller, University of Kiel, Germany

This meta-analysis summarizes empirical results on the correspondence between teachers' judgments of students' academic achievement and students' actual performance. Drawing on a heuristic model of teacher-based judgments on students' academic performance, we further investigated theoretically and methodologically relevant moderators of the correlation between the two measures. Overall, 75 studies reporting correlational data on the relationship between teachers' judgments of students' academic ability and students' test performance were analyzed, including studies focusing on different school types, grade levels, and subject areas. The overall mean effect size was found to be .61. The effect sizes were moderated by use of direct versus indirect teacher judgments, with use of direct judgments leading to a higher correspondence between teachers' judgments and students' academic achievement.

Introduction

The ability to accurately assess students' achievement is considered to be an important professional skill of teachers. Often, teacher judgments are the primary source of information on students' academic achievement. Indeed, teacher judgments can have consequences for their instructional practice (Alvidrez & Weinstein, 1999; Clark & Peterson, 1986; Hoge, 1983, Hoge & Coladarci, 1989), the further evaluation of students' performances (Begeny, Eckert, Montarello, and Storie, 2008; Feinberg & Shapiro, 2003), and placement decisions—and can crucially influence individual students' academic careers and self-concepts (Mßller, Pohlmann, Kßller, & Marsh, 2009).

A review of literature by Hoge & Coladarci (1989) summarized the results of 16 studies presenting data on the relationship between teachers' judgments of students' achievement and the students' actual performance on an independent criterion of achievement. Hoge and Coladarci reported a range of correlations from .28 to .92 and a median correlation of .66. Additionally, they examined how different methodological study characteristics were related to the correspondence between teachers' judgments and students' achievement. They also sought to identify moderator variables influencing the size of the correlation between the two measures. Because only 16 studies were included in the review, the sample sizes for studying the different effects were small. As such, only descriptive analyses could be presented.

Since the publication of the Hoge and Coladarci review in 1989, numerous further studies have reported data on teachers' judgment accuracy. In order to overcome the limitations of their narrative review and to draw a clear picture of current findings on teacher judgment accuracy, we therefore present a comprehensive meta-analysis. Beyond the statistical synthesis of study results, the meta-analysis evaluates whether potential moderators influence the size of the correlation between teacher judgments and students' actual academic performance.

Method

We identified relevant studies by applying a multimodal search strategy involving both electronic and manual searches.

For this meta-analysis, we coded not only study outcomes, but also several study characteristics as variables with the potential to explain differences in study outcomes (e.g., the students' grade level, the use of direct or indirect teacher judgments).

To account for the hierarchical structure of the meta-analytic data (subjects within studies at the first level, and studies at the second level), we applied a multilevel approach (Hox, 2002; Kalaian & Kassim, 2008). The analyses were performed with HLM6 (Raudenbush, Byrk, Cheong, & Congdon, 2004) using the HLM2 option, in which restricted maximum likelihood estimation is applied.

Results

Overall, $k = 75$ studies were included in the analysis of effect sizes. In a first step, we applied an unconditional multilevel model to the data to estimate the overall mean effect size and to examine heterogeneity in the primary study effects. The overall mean effect size was .61 ($SE = .03$) and significantly different from zero. A large and highly significant chi-square test ($\chi^2 = 827.09$, $df = 74$) indicated that the effect sizes are heterogeneous, indicating that there is a need to include explanatory variables in the model to explain the variance in the effect sizes. The Fisher's Z-transformed correlations ranged between -.03 and 1.18.

Next, we computed several conditional multilevel models in which the explanatory predictor variables were entered separately. For each model, only those studies reporting data on the predictor variable of interest were included in the analysis; all others were excluded. Therefore, the sample size varied across the models. In this summary, an excerpt of the most relevant and significant findings is presented.

First, most studies asked teachers to judge students' performance indirectly (90%); only 10% effect sizes related to direct judgments. We found a significant negative effect ($-.25^{**}[1]$) of direct vs. indirect teacher judgments on teacher judgment accuracy, indicating higher correlations between students' academic achievement and direct teacher judgments (mean effect size = .86) than indirect teacher judgments (.61).

Second, most studies addressed the domain of language arts (59.4% of effect sizes), followed by mathematics (34.9%), music (2.8%), science (0.9%), social sciences (0.9%), and sports (0.9%). In comparison to language arts (reference category), the only statistically significant effects to emerge were those for sports (.40*[2]) and music (-.26*). The mean effect size for the study focusing on sports was 1.033, significantly higher than for studies focusing on language arts (.63). The effect size for music was .33, significantly lower than the mean effect for studies addressing language arts.

Third, according to our coding procedure, the domain specificity of the achievement test and the teacher rating was congruent for 64.9% of the effect sizes reported in this analysis and incongruent for 35.1%. We found a significant negative effect on teacher judgment accuracy (-.11*). As expected, larger effect sizes were observed for studies in which the domain specificity of the achievement test and the rating task was congruent (.66) than for studies in which it was not (0.56).

Discussion

On the basis of a heuristic model of teacher judgment accuracy, we statistically summarized empirical research findings in a meta-analysis. In addition, we examined the role played by theoretically and methodologically relevant moderators in explaining the variation in findings across studies.

The results of our meta-analysis indicate that teachers' judgment accuracy—defined as the correlation between teachers' judgments of students' performance and students' actual test performance—is positive and fairly high (.61). Nevertheless, this result shows that teacher judgments are far from perfect, and that there is plenty of room for improvement.

Our meta-analysis revealed substantial variation in effect sizes across studies. Three important moderators of teacher judgment accuracy were identified: one judgment characteristic, one test characteristics, and one characteristic based on the interaction between judgment and test characteristics.

In summary, this meta-analysis has important theoretical and methodological implications for research on teacher judgment accuracy. It highlights the various methodological aspects that need to be considered when conducting studies on teacher judgment accuracy. The differentiation between teacher characteristics, student characteristics, judgment characteristics, and test characteristics was fruitful in this analysis, as these factors proved to constitute judgment accuracy.

SYMPOSIUM

SIG FUTURE & VISION

Jean-Luc Patry, Universitat Salzburg, Austria; Dimitris Pnevmatikos, University of Western Macedonia, Greece; Anna Tapola, Linnaeus University, Sweden; Wiel Veugelers, University of Amsterdam, Netherlands; Kirsi Tirri, University of Helsinki, Finland; Lena Fritzen, Vaxjo university, Sweden

Within SIG 13, two international projects performed by several institutions across Europe are among the main activities. The aims and future activities of these two projects are presented and discussed.

The first project, the Linnaeus International Project on Integrative Approaches within Teacher Education (TLP), was initiated 2009 by Linnaeus University, Sweden, and has seven partners. TLP aims to analyse the preconditions for integrative approaches in teacher education, where morality and democratic aspects, and subject matter, are integrated into new entreties. The topics to be addressed in teacher education deal with various contemporary challenges related to threats against humanity and human living conditions. The aim includes a broad distinction of the concept of democracy, i.e., studies within TLP aim to study the preconditions for practicing democracy on a daily basis, as fostered though teacher education.

The project has now been running for two years, and in this session we report on our progress, common research, and future plans. The second project is a network called "Education for Democratic Intercultural Citizenship" (EDIC) with eight partners. The main focus is to establish a platform for educators and researchers from different parts of Europe to work and learn together. Creating networks of educational professionals that are the same time flexible (bridging) and give a sense of community (bonding) is very important for future educational change. Educating a new generation of young educational researchers that is linked to elder generations is important for education, for universities and for the young scholars own career and well-being.

Within SIG 13, two international projects performed by several institutions across Europe are among the main activities. The aims and future activities of these two projects are presented and discussed. The first project, The Linnaeus International Project on Integrative Approaches within Teacher Education (TLP), was initiated 2009 by Linnaeus University, Sweden. The invitation to join the project was met with considerable interest from the SIG 13 community.

TLP aims to analyse the preconditions for integrative approaches in teacher education, where morality and democratic aspects, and subject matter, are integrated into new entreties. The topics to be addressed in teacher education deal with various contemporary challenges related to threats against humanity and human living conditions. The aim includes a broad distinction of the concept of democracy, i.e., studies within TLP aim to study the preconditions for practicing democracy on a daily basis.

Various contemporary challenges related to threats against humanity and human living conditions, constitute the targets addressed within TLP. For example, a common research object is called Food Security (including issues related to lack of clean fresh water, and polluted agricultural land, etcetera). Another research object concerns risks related to modern genetics and gene technology (including issues related to human nature, human dignity, and threats against genetic diversity among people etcetera). Within TLP it is assumed that some ways out of the challenges may be found within education, especially in terms of Education for a Global Networked Society. However, since contemporary global challenges most likely need to be addressed in political arenas, and not least through human behaviour and human action, it is not sufficient to merely rely on various types of subject matter education. Therefore, we are interested in examining what potentials that might exist in integrative approaches where subject matter education, and moral and democratic education, are integrated. In addition, since all formal education in schools ought to involve professional teachers, TLP focuses on preconditions for integrative approaches within teacher education where moral and/or democratic aspects and subject matter are integrated into new entreties.

Within the TLP network we address such demanding research objects by creating an international research milieu that: (i) is permeated by interdisciplinarity; (ii) offers an arena that provides opportunities to explore, scrutinise, analyse, and evaluate the potentials that may be inherent in the integration of subject matter, and moral and political aspects; (iii) enables and supports extensive research collaboration between different groups of scholars; (iv) facilitates comparative studies between different countries; (v) includes a variety of research traditions (e.g. emanating from educational science, psychology, science, philosophy, etcetera), which supplement each other in order to shed light on common research objects; and, (vi) provides an international critical mass.

The project has now been running for two years, and in this session we report on our progress, common research, and future plans.

The second project to be presented and discussed is a network called "Education for Democratic Intercultural Citizenship" (EDIC). The main focus is to establish a platform for educators and researchers from different parts of Europe to work and learn together. The participating universities are Barcelona, Brighton, Helsinki, Prague, Thessaloniki, Fribourg, Kibbutzim College Tel Aviv, and Humanistics Utrecht.

Modern societies need citizens who can cope with differences and together constitute a democracy. More than ever democracy can be seen as what Dewey called 'a way of life'. It deals with how to live with cultural differences, to develop a common moral foundation, to get everyone involved, to live with change and uncertainties, and to develop new joint initiatives. Living in a modern democratic and intercultural society requires people, and in particular young people, who are reflective, moral, dialogical and social competent and are willing to behave in these ways. Education, both in formal and informal institutions, has an important role in most societies in creating this kind of citizens. Creating networks of educational professionals that are the same time flexible (bridging) and give a sense of community (bonding) is very important for future educational change. Educating a new generation of young educational researchers that is linked to elder generations is important for education, for universities and for the young scholars own career and well-being.

After several joint research seminars the network now created an annual intensive programme for young and senior researchers to enter in a dialogue with each other about research, concepts and practices and to collaborate.

SYMPOSIUM

SIG FUTURE & VISION

Wim Van Dooren, K.U. Leuven, Belgium; Michael Schneider, ETH Zurich, Switzerland; Xenia Vamvakoussi, , Greece

Conceptual change has influential in cognitive psychology and educational research for more than 20 years. Throughout its lifespan, the SIG on Conceptual Change has been under continuous development, in terms of theoretical assumptions, methodology, and content-domains. Input of pre-appointed discussants will trigger a discussion on several topics that are of interest to the SIG.

A first topic is how conceptual change is viewed nowadays the field. This topic can stimulate discussion on the various theoretical approaches used to studying conceptual change, their similarities and differences, and the potential impact of taking various stances.

A second issue relates to the curricular domains in which conceptual change research is conducted. Besides research in the past in the domains of physics, biology and history, focus is now also on other domains, such as mathematics. What does the field gain by these extensions? Is conceptual change similar across domains?

Third, there is interest in the role of motivation, emotions, and personal epistemologies in learning. This topic is of particular interest, since it can stimulate fruitful exchange between members of different SIGs within the EARLI community.

A fourth element are the methodological tools that are being used in our field. These are also under continuous development, and include besides questionnaires, task-based interviews, and a variety of qualitative approaches and intervention studies, also eye-movement technology, reactiontime measurements and phenomenographic methods. Finally, there are the instructional implications derived from conceptual change research. What do nowadays' conceptual change approaches to learning have to offer in relation to instruction, and what empirical evidence is there available?

Conceptual change has been an influential topic in cognitive psychology and educational research for more than 20 years. Throughout its lifespan, the Special Interest Group on Conceptual Change has been under continuous development, in terms of theoretical assumptions, methodology, and content domains. Given this continuous development, it seems useful to close the EARLI Conference with an open discussion, where all SIG members and interested non-members can discuss a variety of new developments, and the impact they have, should have, or could have on our Special Interest Group.

The Future and Vision session will start with some input of pre-appointed discussants who will briefly share their experiences and insights on what they saw and heard during the conference that might be of interest to the SIG members. Afterwards, the audience will be invited to participate in the exchange. There are four potential topics on which the Future and Vision session could focus.

A first topic is how conceptual change is viewed nowadays by researchers in the field, which can stimulate discussion on the various theoretical approaches that are used to studying conceptual change. Indeed, under the common denominator of the conceptual change approach to learning, several distinct theoretical assumptions have served as a source of hypotheses and have guided rich and fruitful research agendas. One can think of the potential impact of taking a sociocultural stance towards conceptual change, a 'knowledge in pieces view', a phenomenographic approach, or a framework theory approach. The discussion might focus on the differences and commonalities of these various approaches, and their impact on the field of conceptual change. To what extent are they compatible? How can each of the approaches enrich the research field?

A second issue that deserves attention relates to the curricular domains in which conceptual change research is conducted. In the past decades, research on conceptual change has provided detailed descriptions and explanations of students' difficulties in diverse areas, such as physics, biology and history. Since some years, the scope is being expanded towards new curricular domains such as mathematics and economy, and towards societal topics that can be considered "controversial" (e.g. global warming, evolution theory). Topics for discussion could be what the field of conceptual change gains by its extension to new curricular domains, and whether (and why) this extension needs our explicit attention. Reflections could also be made on whether conceptual change is similar in these different curricular domains, or whether (and why) the processes involved are actually different.

A third element for discussion is the methodological tools that are being used in our field. These tools are also under continuous development, and the toolkit available to nowadays' conceptual change researchers is extensive. Besides questionnaires, task-based interviews, and a variety of qualitative approaches and intervention studies, research has made use of eye movement technology, reaction time measurements and phenomenographic computer tools. Reflections could be made on each of these methods' usefulness in conceptual change research, on their validity, and on the need for new or improved methods to study the phenomena that we are interested in.

Fourth, there is a considerable interest among researchers in the Special Interest Group in the role that motivation, emotions, and personal epistemology play in the way processes of conceptual change take place. The discussion could therefore focus on the impact of this "warming trend", on the progress being made in this direction and on the future directions of it.

Finally, an ever-present interest of the Special Interest Group is the instructional implications that derive from research on conceptual change. Cognitive conflict has been –and possibly, still is – typically recognized as a conceptual change teaching practice. Effective as cognitive conflict may be in certain contexts, it became subject to severe criticism as its limitations emerged and were pointed out. It is an urging question however, what nowadays' conceptual change approaches to learning have to offer in relation to instruction, and what empirical evidence there is available for these instructional implications.

PAPER PRESENTATION

Seeking relevance: an evaluation of student learning and assessment in postgraduate accountancy

Jane Hughes, Open University, United Kingdom

Does assessment help students develop an appropriate 'form of competence' (Wenger 1998: 53) for a 'professional life', beyond higher education?

Taking a sociocultural perspective (Lave and Wenger 1991), this study explored the influence of assessment (accountancy examination) on postgraduate accountancy students' learning trajectories, the transformational journey of a learner, as they became a member of a higher education accountancy practice. The learning trajectory and associated identity development of seven case study students were explained using 'modes of belonging': engagement, imagination and alignment, (Wenger 1998: 174). The explanation considered students' prior experiences, as well as their future expectations, in relation to their accountancy studies.

While student success relied on having appropriate accountancy-related study-strategies, the most successful students, in terms of pass marks, were those who were able to combine appropriate accountancy-related study-

strategies with a sense of imagination of how they might use accountancy in the future and were aligned with accountancy, which they could relate to a 'professional life'. The findings suggest that, when designing assessment, higher education accountancy practitioners could consider how to encourage students to see the 'use value' (Lave and Wenger 1998: 112) of their accountancy studies, with the aim of moving students away from a narrower focus on accountancy-related study strategies.

This research took place in the business school department of a post-1992 UK university. The research subjects (postgraduate students) studied accountancy as a core (mandatory) module, Accounting for Managers (AFM), on a generic postgraduate business studies degree. Quantitative analysis showed that for students who entered postgraduate studies with higher-level prior qualifications, the pass rate was 87.5 %, compared to a pass rate of 68.46% for those with lower-level prior qualifications, (n = 345). Log-linear analysis indicated that the prior level of qualification had a stronger effect on pass rates than other factors: seminar attendance, prior knowledge of accountancy ($\chi^2 = 15.963$, df 1, p

This research aimed to explore the relationship between AFM student prior experiences and AFM student outcomes (pass rates). From a sociocultural perspective, the learning trajectory provides evidence of the transformation, or a change in identity, as students become members of an HE accountancy practice; identity is a 'form of competence' (Wenger 1998: 53). This study explored the learning trajectories, undertaken by the AFM students, using the 'community of practice' model of Wenger (1998). While difficulties arise in establishing a 'community of practice' in institutionalised education (for example, Roth and Lee 2006: 33), the concept of identity is useful in exploring learning development (Sfard and Prusak 2005: 18). Tobell et al. (2010: 277) see investigating identity as a way to analyse educational transition in an HE 'practice'.

Assessment, in particular, signals what is valued in the 'practice'. Differences arising between teachers' perceptions and students' perceptions of assessment, and the subsequent response from students, seen in students' use of study strategies, have been explored in HE (for example, Entwistle and Wilson 1977). Reconciling the requirement of a 'professional practice' with an HE 'academic practice' in accountancy is problematic, both for assessment and for curricula (Lin et al. 2004). Boud and Falchikov (2006) highlight the drawbacks of HE assessment for preparation for life beyond university; HE assessment, inevitably, takes place in an institution that mimics a 'professional life' experience. This study used the sociocultural perspective of Wenger (1998) to explore the question:

How do students' perceptions of their assessment (accountancy examination) affect their learning and outcomes (pass marks) as they engage in the AFM practice?

A sociocultural, or situated, view of learning contrasts the 'use value' of what is learnt, whereby learning contributes to becoming a 'knowledgeable person' in a practice, with the 'exchange value' of what is learnt, whereby learning is exchanged for a 'reward', such as, examination success (Lave and Wenger 1991: 112).

Methodology and methods

This research took a case study approach (Yin 2003). Student case studies (seven students), with a range of prior HE qualifications and study experiences, were the main analytical focus. In-depth semi-structured interviews with students, before and after the examination, provided 'narrative' data, following Sfard and Prusak (2005). 'Practice' data, following Wenger (1998), came from students' examination answers, revision and class notes. Pass mark data provided evidence of examination outcomes. 'Narrative' and 'practice' data were analysed using the 'modes of belonging' (ways of learning): engagement in practice, imagination and alignment (Wenger 1998: 174)

Findings

These case study students perceived the HE accountancy practice, in which they were engaged, to be an 'examination practice'; having appropriate, accountancy-related study strategies was the key to accountancy examination success. Students who were conscious of the need to develop appropriate study strategies, had better outcomes (higher pass marks) than those who were not so aware.

The most successful students, in terms of pass marks, were those who were able to combine appropriate accountancy-related study-strategies with a sense of imagination of how they might use accountancy in the future and were aligned with accountancy, which they could relate to a 'professional life'. The latter students saw the 'use value' (Lave and Wenger 1991: 112) of their studies, and drew on their prior experiences and future ambitions to do so. While the use of appropriate accountancy-related study-strategies appeared necessary for success in this 'examination practice', the use of study strategies (engagement in practice) was only part of the story of student success. This research suggests that imagination and alignment have a role to play in student learning.

The findings suggest that, when designing assessment, HE accountancy practitioners could consider how to encourage students to see the 'use value' of their accountancy studies, with the aim of moving students away from a narrower focus on accountancy-related study strategies. Harnessing students' prior experiences and future expectations in order to develop ways to help students see the relevance of their accountancy studies for their future ('professional life') may improve students' experience and performance. The limitations of this study arise from the small sample, albeit an approach which offered the opportunity for fine-grained analysis. Further research using the 'modes of belonging' (Wenger 1998: 174) to explore student experiences and outcomes in other business school disciplines is ongoing.

PAPER PRESENTATION

The quality and importance of thesis 'contribution'

Sid Bourke, University of Newcastle, Australia; Allyson Holbrook, SORTI, The University of Newcastle, Australia

One of the key components of examiner comment on the theses they examine is the contribution the thesis makes to the discipline and its literature. Universities normally request specific comment from examiners on the significance and 'contribution' of the thesis. We asked PhD and research masters degree examiners to rate the thesis they had just examined on 12 quality criteria, including three thesis contribution indicators, and indicators covering the literature review, thesis approach/method, analysis/ results and presentation. The criteria were developed from an archive of examiner reports. We also asked how important each criterion was. Although the means for contribution quality items were between Moderate/high and High, they were lower than those for the other quality indicators, indicating the examiners considered thesis contribution was of lower quality than the other indicators. This was particularly so for examiners of masters theses. However, the contribution indicators had among the highest correlations with the overall normative measure of thesis quality, emphasising their importance. Research candidate enrolments and outputs are vital to national advancement, and involve a considerable financial investment, both nationally and individually. Universities must articulate clear standards within and between research degrees. There is clear benefit for all stakeholders – candidates, universities, employers and research funding agencies – nationally and internationally.

Aims

One of the key components of examiner comment concerns the contribution the thesis makes to the discipline and its literature. Although advice to examiners differs considerably between universities, one common component is a request to indicate the significance and 'contribution' of the thesis. The main aims of this paper are to: Identify the relative and absolute importance and quality of three indicators of thesis 'contribution' Identify any differences between PhD and masters theses in examiner judgments about importance and quality of thesis 'contribution' Establish the relative importance and quality of 'contribution' compared with the other nine indicators of thesis quality for both PhD and masters theses. Brief review Concerns about thesis outcomes range from the nature of skills development through to where the bar is set in doctoral work, and how this differs between doctoral and masters theses (Scott et al. 2004). Researchers have noted the need for, but a lack of consensus about, doctoral standards and evince doubts about consistency, clarity and rigour in thesis assessment and the criteria applied (see, eg, Denicolo 2003, Morley et al. 2002, Powell & McCauley 2003). Interviews, surveys, observed examination proceedings, and collection of examiner reports, have elicited what examiners look for in a thesis (eg, Pitkethly & Prosser 1995, Delamont et al. 1997, Mullins & Kiley 2002, Winter et al. 2000, Trafford 2003). Many are single institution studies, but

the most extensive study focusing purely on examination was that of Tinkler and Jackson (2004) which spanned 20 institutions. In a study of 8 institutions' PhD examinations across all disciplines, the authors found that examiners utilise a common framework of criteria in PhD examination (Bourke et al. 2004) and are, on the whole, consistent in their application (Holbrook et al. 2005). The focus in this new study is one major aspect of the criteria they use – the contribution of the thesis.

Methodology

We have expanded our research into PhD thesis assessment to include masters degrees. Archived examiner reports were accessed to identify links between what examiners wrote and their recommendations. We developed a set of 12 criteria, across five areas, that captured the essence of what examiners were doing when assessing thesis quality and deciding their recommendation. This was an iterative process, involving regular return to the examiner reports to confirm or alter the criteria identified. The five areas within which these 12 criteria nested were Contribution, Literature review, Approach/methods, Analysis/results and Presentation. Three of these area are entirely consistent with the components of a dissertation identified by Lovitts (2007, pp.53-58). For Stage 2 we collected a new sample of 621 PhD thesis examiners, and an initial sample of 170 masters examiners. The research protocol requested the examiners to perform two additional tasks: rate the overall quality of the thesis, and subsequently complete a questionnaire. At the time of examination, examiners rated the thesis on a 5-point normative scale. The questionnaire Shortly after the examination, the examiners completed a questionnaire, first asking them to rate the quality of the thesis on each of the 12 identified criteria. A 6-point scale was used with categories ranging from Exceptional quality to Fundamentally flawed. Examiners were also asked how important each of the 12 criteria was for thesis quality generally (not for the thesis just examined), with response categories from Exceptionally important to Not at all important. The results now summarised in this paper focus on the three indicators of thesis contribution identified: Originality of the contribution, Substantive contribution to the discipline, and Advance(s) in new knowledge/ theory/ skills.

Findings

Importance

Originality was considered more important by examiners of both PhD and masters theses than the other two contribution indicators, Substantive nature was second and advancement of knowledge third. The means of the three contribution indicators were 6th, 8th and 9th among the 12 criteria used for PhDs and 7th, 8th and 11th for masters theses. It was notable that the importance of approach/methods and analysis/results were rated above contribution at both degree levels.

Quality

A similar pattern was evident for thesis quality at both degree levels, in that originality was of higher quality than substantive nature and advancement of knowledge. The means for quality across all PhD examiners were between moderately high and high quality for all contribution measures. As might be expected, the means for thesis contribution were lower for masters' examiners. When compared with the other nine indicators, the three contribution ranks were 8th, 11th and 12th for PhD theses and 10th, 11th and 12th for masters theses. Although still in the moderate/high to high range, clearly examiners were least satisfied with contribution quality. When the assessment of the 12 individual indicators was related to the overall PhD thesis quality measure, the contribution indicators had, along with literature review use, the highest correlations (all between 0.70 and 0.74). However, as might be expected, these indicators had lower correlations with overall masters thesis quality (between 0.56 and 0.64), while literature coverage (0.68) and analysis/results being appropriate (0.66) had higher correlations.

Theoretical and educational significance

Research candidate outcomes are vital to national advancement, and involve considerable national and individual financial investments. Research, particularly PhD projects, requires a highly complex and integrated set of outcomes, however, currently the measurement of outcomes is primarily limited to degree completions, because the criteria by which theses are judged and standards are applied do not translate easily into an assessment scale. It is very important that the universities articulate clear standards within and between research degrees. There is clear benefit for all stakeholders – candidates, universities, employers and research funding agencies – to have a clear idea of the quality of research and how it is assessed. The empirical research necessary to identify 'quality' and differentiate between theses is still in its infancy. This is a yawning gap at a time when sustained attention is focussed, internationally, on the quality of research.

PAPER PRESENTATION

The pattern and style of formative feedback presented by PhD examiners in their reports

Allyson Holbrook, SORTI, The University of Newcastle, Australia; Sid Bourke, University of Newcastle, Australia

Drawing on a mixed methods approach this paper will report on the pattern and style of formative comment employed by examiners of PhD theses and will look at these qualities in conjunction with examiner recommendations and specific ratings of quality. The problems facing weaker students are highlighted. There is strong evidence of examiners wanting to assist the student to complete the task, but even more pronounced attention to encouraging the student to dig deeper intellectually and embed their work more firmly in the scholarly literature. Such motivations are closely aligned with development of scholarly identity, disciplinary immersion and innovation.

Aims

There is still a great deal to learn about assessment in higher education, from the approaches used through to effectiveness. The researchers have drawn on PhD examiner reports to investigate the standards in play and the criteria used to determine different levels of doctoral quality. This paper will report on the pattern and style of formative feedback employed by examiners and will look at these qualities in conjunction with examiner recommendations and specific ratings of quality. PhD examination has often been compared to peer review. In the normal course of manuscript peer review reviewers tend to identify features of a manuscript that show deeper flaws that may lead to rejection. Another function of peer review is to provide feedback that can assist in the development of the writer and move the manuscript toward higher quality. These functions also exist in doctoral examination. Each examiner report addresses a range of content. What examiners focus on tells a great deal about what they are seeking from a thesis. Questions addressed in this paper explore how examiners address the weaknesses they perceive that cannot be corrected in a simple and straightforward manner. In our previous study the latter are identified as prescriptive instruction where an examiner tells the candidate exactly what they need to do. In formative comment the examiners identify the problem, engage with it and offer direction. This process lends itself to further learning by the candidate. Bearing in mind that formative feedback in this context has already been coded by this definition and includes all three characteristics, questions that move the analysis forward are: What is the distribution of content emphasis in formative instructive comment? How is this distribution related to examiner recommendation and a thesis quality measure? Does the nature and tone of the comment vary for: content areas, field of study, and recommendation? A further and final question pertains to developments in recent literature. Pryor and Croussard (2010) identify three different levels of engagement evident in formative feedback to doctoral students during candidature: concrete/procedural; reflective discursive and discursive existential. This framework captures some of the complexity connected to learning, especially at doctoral level where new knowledge production and disciplinary immersion are transformative both intellectually and personally. This prompts the further question: 4. Are there different levels of assessor or peer engagement communicated in the formative comments in doctoral thesis reports?

Method

The approach used is a mixed methods sequential design with an equal emphasis on qualitative and quantitative elements applied in two separate studies at different points in time. A total of 2121 examination reports from study 1 and another 600 from study two were collected from a total of 9 Australian universities (representative of the sector in Australia and all fields of study) in de-identified format. These were scanned, transferred into a standard template and then coded and entered into QSR N6. They were coded at 29 categories that identified dialogic elements, content area and evaluation types (e.g. summative, formative, prescriptive instructive, instructive commentary and other evaluative) (Lovat et al., 2008). These categories represent the core codes. Since establishing and testing those categories, the team have been systematically exploring substantive sections of text in depth. This paper reports on an analysis of what is, on average, the largest section of evaluative text. Two-thirds of all reports have some formative comment. The analysis involves using the intersect function in N6 to identify the proportions of formative comment associated with each broad category of thesis content (e.g., contribution, analysis, literature review coverage, etc.). We have the full data set at present only for study 1 and those results are presented in this abstract, but will be combined with a further 600 reports from study 2 in the final paper. After coding, the data are transferred into SPSS to examine relationships with recommendation, a separate quality rating, and field of study.

Findings

Findings are interim at this stage and are limited to questions 1 and 2. The landscape of formative comment as a sub-section differs from the core landscape of examiner report text. The category 'analysis and reporting' is dominant in both, but the emphasis on coverage and use of literature becomes much more pronounced when only formative comment is examined. 'Communicative competence' has a slightly higher profile, whereas significance and contribution less so. Most of the formative comment is about analysis and reporting (more than 40%) and the literature (about 30%) compared to 37 and 9 percent of the total text units. Examiner recommendations were divided into four levels from highest to lowest. The lower groups had consistently more intersected text than the higher groups, and the differences were significant. For only one area (coverage of the literature) were all groups discrete, but in other cases the two lower groups had significantly more intersected text than the two higher groups.

SignificanceThe most interesting questions (3 and 4) have yet to be addressed and further coding will be required but, to this point, it is clear examiners focus on two areas of the thesis or subsequent publication that would benefit from closer attention and extended comment. There is strong evidence of examiners wanting to assist the student to complete the task, but an even more pronounced attention to encouraging the student to dig deeper intellectually and embed their work more firmly in the scholarly literature. Such motivations are closely aligned with development of scholarly identity, disciplinary immersion and innovation (Crossouard & Pryor, 2009). Formative feedback in higher education, the way peer assessors reach decisions on quality (Lamont, 2009), and a great many aspects about doing and completing doctoral degrees (Lee and Boud, 2009) are now substantial areas of study in the higher education literature. When completed, this work will contribute not only to a deeper understanding of the nature of assessment at doctoral level, but will reveal how the act of formative assessment is directed at multiple and integrated facets of learning to address the needs, and perpetuate the activity, of knowledge creation.

PAPER PRESENTATION

Evaluation of a Theoretical Structure of Model Competence using Multiple-Choice Items

Eva Terzer, Humboldt-Universität zu Berlin, Germany; Annette Upmeyer zu Belzen, Humboldt-Universität, Germany

Model competence functions as a "door-opener" for an elaborated understanding of the nature of science and leads to advanced qualities of scientific thinking and problem solving (Leisner, 2005). Therefore, it is a profound part of scientific literacy (Driver et al., 1996; Gilbert & Boulter, 2000). Yet, various studies (e. g. Grosslight et al., 1991; Treagust et al., 2002) have identified that students are not aware of the role of models in an epistemological process and focus on descriptive aspects of models, perceiving them as depicting miniatures of real-life objects.

On the basis of the view of models in philosophy of science (e. g. Giere, 2004; Mahr, 2008), Upmeyer zu Belzen and Krueger (2010) used various studies evaluating students' and teachers' comprehension of models and modelling (e. g. Grosslight et al., 1991; Justi & Gilbert, 2003; Crawford & Cullin, 2005) to develop a theoretical structure of model competence. However, it still has to be tested empirically. In this study, 45 multiple-choice items are used to evaluate the theoretical structure of model competence (Upmeyer zu Belzen & Krueger, 2010) empirically (N ≈ 2000) by structural equation models, by variance analyses and by Rasch models. The results of a pilot study (66 items, N = 270) suggest a unidimensional structure of model competence. They indicate that level 1 can be separated from level 2 (.002**) and 3 (.008**). The latter cannot yet be split up empirically.

Relevance

Going along with a stronger focus on the outcomes of the German educational system, educational objectives are operationalized in terms of competence (Klieme et al., 2008). The implemented German educational standards and curricula defining learning outcome for 16 years olds particularly include model competence (KMK, 2005). Model competence functions as a "door-opener" for an elaborated understanding of the nature of science (Leisner, 2005). Therefore, it is a profound part of scientific literacy (Driver et al., 1996; Gilbert & Boulter, 2000). Yet, various studies have identified that students are not aware of the role of models in an epistemological process and focus on descriptive aspects of models (e. g. Grosslight et al., 1991; Treagust et al., 2002).

The precondition for the diagnosis of model competence in biology education is the development of a diagnostic instrument based on an empirically tested theoretical structure of model competence suited to this domain (cp. Schecker & Parchmann, 2006) – a gap that needs to be filled. Upmeyer zu Belzen and Krueger (2010) used various studies dealing with students' and teachers' comprehension of models and modelling (e. g. Grosslight et al., 1991; Justi & Gilbert, 2003; Crawford & Cullin, 2005) to develop a theoretical structure of model competence that identifies two cognitive dimensions of model competence differentiated into three levels with increasing degrees of reflection. This structure still has to be validated empirically.

Theoretical Background

In our research, model competence relates to Weinert's (2001) general definition of competence as a specialized, domain-specific competence referring to cognitive, motivational and volitional prerequisites to coping with a specific range of situations. In this project, only the cognitive dimensions will be examined (cp. Hartig & Klieme, 2006).

Aims and Research questions

The aims of this study are the operationalization and the empirical evaluation of the theoretical structure of model competence (Upmeyer zu Belzen & Krueger, 2010).

The main resulting research questions associated with the operationalization are:

- Do the items have suitable psychometric properties?
- Are these items content valid?

A further research question is linked with the empirical validity of the theoretical structure:

- Does the data support the theoretical structure?
- In which way is model competence related to other theoretical constructs?

In addition to the information gained on the validity of the theoretical structure, students' answers will allow a cross-sectional description of their model competence.

- Are there differences in model competence between different grades (grade 7 to 10) and different school types (Sekundarschule and Gymnasium)?

Further studies in our research group examine whether the theoretical structure of model competence provides a basis for a differentiated facilitation of students' model competence.

Methods

In the first step, the theoretical structure is operationalized in multiple-choice items with a standardized question for each combination of aspect and level. Students' conceptions of models and modelling and their impact on model competence (Trier & Upmeyer zu Belzen, 2009) serve as background information for the construction of the items. These items are calibrated and validated in pre-tests. In a second step, a selection of content validated items will be used in a main study with the aim to evaluate the theoretical structure empirically.

Experienced teachers develop items with reference to actual school practice. The response options are generated on the basis of students' answers to an open-response version of the items to allow the use of a wording close to students' one and to construct valid items.

The item pool is distributed in overlapping test-booklets (multi-matrix-design), reduced and calibrated by theoretical criteria (e. g. grade of difficulty, selectivity, contents and contexts). Each item will be answered by \approx 50 students per group (grade 7-10, Sekundarschule and Gymnasium), totalling \approx 2000 students in the main study.

A first study with 66 items was conducted with 60-70 students per item ($N = 270$ students). The internal validity is evaluated using IRT (Rasch) models (ConQuest; Wu et al., 1997) in order to test if the theoretical structure consists of discrete dimensions and categories (s. a.; Hartig, 2008). Variance analyses provide information about the relations between components and the levels of model competence, with the dependant variable representing the difficulty of the items. Analysing the data of the main study, we will additionally use confirmatory factor analyses (Mplus, Muthén & Muthén, 2007) to evaluate the theoretical structure. The model-fit of competing psychometric operationalizations will be tested (Carroll, 1993).

The main study is designed as a cross-sectional cohort study (grade 7 to grade 10, Realschule and Gymnasium, \approx 2000 students). In addition to analyses concerning the internal validity, the influence of the control variables subject matter knowledge and intelligence as well as a comparison to open-ended tasks (Gruenkorn et al., 2009) are considered.

Findings

According to the results of the first study (66 items, $N = 270$), the operationalization led to 22 items with adequate psychometric properties. These data suggest a unidimensional structure of model competence. They indicate that level 1 can be separated from level 2 (.002**) and 3 (.008**). The latter cannot yet be split up empirically. A second pretest (22 selected items of the first study, 28 new items, $N = 396$) is currently analyzed. A selection of 45 items tested in these studies will form the item pool of the subsequent main study. Final findings regarding the empirical validity will be available in spring 2011.

PAPER PRESENTATION

Measuring change when there is a changing criterion: the case of digital literacy

John Ainley, Australian Council for Educational Research, Australia; Julian Fraillon, ACER, Australia; Christopher Freeman, ACER, Australia; Wolfram Schulz, ACER, Australia

It has been a long-standing principle in the measurement of change not to change the measure. However, it is now accepted that changes are necessary for assessments to remain relevant. This is especially the case when studying the

digital literacy of students. This paper is based on computer-based assessments of digital literacy in Australia conducted in 2005 and 2008. It reports the methods used for equating those assessments and measuring change over that three-year period. The assessments involved large nationally representative samples in primary and secondary schools and included the creation of digital products. The assessment tool was based on sets of thematic modules in a rotated design with some modules used to link the two assessments. There was a significant increase between 2005 and 2008 in the mean digital literacy score for Grade 6 students, and shift in the distribution, but that no significant increase for Grade 10.

Introduction

It has been a long-standing principle for the measurement of change to not change the measure. However, it is now accepted that changes in methods and content are necessary for assessments to remain relevant (von Davier & Mazzeo 2009). This is especially the case when studying changes in the digital literacy of students (called ICT literacy in Australia and Computer and Information Literacy by the IEA). This paper reports a computer-based assessment of digital Literacy in Australia conducted in 2005 and 2008, methods for equating those assessments and the measurement of change over that three-year period (MCEETYA, 2007). Digital Literacy is seen as a set of generalisable and transferable knowledge, skills and understandings concerned with the use of computer technology to investigate, create and communicate information in a variety of contexts (Catts & Lau, 2007; ETS, 2002, European Commission, 2006)).

Assessment design

The assessment of digital literacy in Australia was computer-based and combined the performance of specific software functions with the creation of digital products in a rotated set of thematic modules. It made use of purpose-designed software that included simulated and live applications. Some tasks were automatically scored and others were captured for marking by assessors. Tasks involved collecting and appraising, synthesising and reframing information. A number of thematically-linked modules were used in a rotated design to ensure that the instrument assessed what was common to ICT Literacy across a range of contexts.

In 2005 each student completed three of the seven modules generating more than 200 score points. In 2008 the appearance of material was identical and the method of response was the same as in 2005. The 2008 assessment included three modules from 2005 plus four new modules. Each student completed two of the trend modules and two of the new modules. The 2008 tasks included new software contexts but relied on the same fundamental ICT receptive, productive and evaluative processes as the 2005 tasks. In both 2005 and 2008 students completed a questionnaire about their use of ICT at school and at home. For the 2008 cycle some innovations in delivery methods were introduced without altering the assessment experience.

Data

The assessments of digital literacy in Australia were conducted in Grades 6 and 10 with large nationally representative samples. The 2008 sample included almost 11,000 students from 591 schools and the 2005 sample consisted of 7,400 students from 517 schools. The samples were selected by cluster sampling methods from a stratified sampling frame to ensure that the results accurately represented the Australian population of Year 6 and Year 10 students. Trained test administrators supervised the assessment in schools.

Analysis

IRT methods (Rasch scaling) were used to analyse the student responses and generate a scale for locating items from each module and reporting student achievement. For each cycle these methods were used to analyse the student responses and generate a scale for locating items from each module and reporting student achievement. The scale was one-dimensional and reliable (0.93). The logit scale was transformed to a reporting scale which was set to a mean score of 400 and a standard deviation 100 for Grade 6 students in 2005. The scale was characterised by descriptions of proficiency levels based on item difficulties. A proficient standard for each Grade was established by a panel of ICT education experts.

Thirty-seven items were used to compare the relative performance of the Grade 6 and Grade 10 students and 39 items from the trend modules were used to link the 2008 results to those from 2005. The comparisons of achievement over time in such a rapidly developing field were made possible through instruments that reflect relevant technological changes and maintain integrity to the core processes of the ICT Literacy construct.

Results and conclusions

An important conclusion, consistent with the argument of Kolen (1999), was that it was possible to introduce change in the assessment but still provide measures of change in the underlying construct with a core set of common items. There was a statistically significant increase between 2005 and 2008 in the mean score for Grade 6 students from 400 to 419 scale points. For Grade 10 the increase from 551 to 560 scale points was not statistically significant. The difference between Grade 6 and Grade 10 did not change significantly being 141 points in 2008 and 151 points in 2005. In 2005 49% of Year 6 and 61 % of Year 10 students attained the relevant proficient standard, in 2008 this increased to 57% of Year 6 and 66% of Year 10 students. The associations with student characteristics were the same in 2008 as in 2005. There were significant differences in digital literacy associated with socioeconomic background, Indigenous status and remote geographic locations. Frequency of computer use (especially school utilities) was also associated with digital literacy in each cycle and there had been an increase in computer use at home and school between the two cycles.

PAPER PRESENTATION

Two strategies to measure Cognitive Load

Melina Pichler, Ulm University, Germany; Tina Seufert, Ulm University, Germany

Despite the extensive use of concepts from Cognitive Load Theory, the problem of how to assess cognitive load, especially the intrinsic, extraneous and germane load aspects remains still unsolved. We developed two strategies to measure cognitive load: (1) First, we trained a group of learners in differentiating the three concepts before rating (informed rating). (2) Second, we developed a questionnaire with different items for each type of cognitive load (differential rating). The question was how valid, reliable and how comparable the two instruments are. In an experimental study (n=51) with 21 tasks each varying in one aspect of cognitive load learners of both groups had to rate the three types of load and additionally the overall amount of load. To analyse the reliability of the two instruments we calculated the overall internal consistency and for the differential rating additionally the internal consistency per load type. The validity was analyzed by comparing the ratings of the learners with the theoretically expected outcomes. Both instruments turned out to be valid, except the germane load scale of the differential rating. The overall internal consistency of the informed rating was weak, indicating that may be better for differential than overall load ratings. The overall and specific reliability of the differential rating instrument was good. In many tasks we found differences between the two instruments due to more distinct values of the informed rating group. Overall, especially the informed rating seems to be a promising strategy to assess different aspects of cognitive load.

Introduction and Theoretical Background One of the most powerful and most criticized research frameworks in educational research of the last decades is the Cognitive Load Theory (CLT; Chandler & Sweller, 1991). Powerful because the concept is extensively used for evaluating learning environments or interpreting empirical results. Criticized, because there is at least one main problem that is still not solved adequately: how to measure cognitive load (Moreno, 2010). Almost all studies on multimedia learning assess cognitive load by using one item for rating the perceived invested mental effort (Paas, 1992). Some other studies used objective techniques like dual task measures or physiological parameters. However, there is no appropriate instrument to measure the three conceptual parts of CLT, the intrinsic, extraneous and germane cognitive load. In the present study we investigated two different strategies for assessing these different parts of cognitive load: (1) First, we trained a group of learners in differentiating the three concepts before rating (informed rating). (2) Second, we developed a questionnaire with different items for each type of cognitive load (differential rating). The question was whether the two instruments were reliable and valid and whether they lead to comparable ratings of cognitive load when the same tasks had to be evaluated.

Method

In the experimental study 51 students took part and were randomly assigned to one of the two experimental groups. The informed rating group got a short introduction into cognitive load, especially the three different types of cognitive

load, whereas the differential rating group didn't get any instruction. Then every learner had to evaluate 21 tasks where the three types of cognitive load had been varied based on theoretical assumptions and empirical findings: (a) For intrinsic cognitive load (ICL) the element-interactivity of a task had been varied, e.g. "the day after tomorrow will be Saturday. Which day was yesterday" versus "Three days after yesterday was Friday. Which day will be five days before tomorrow?" (b) For extraneous load (ECL) we showed learning environments with an integrated format of text and picture versus a separated format etc. (c) For germane load (GCL) we asked to rate different instructional settings which should either induce germane load, like "every 20 minute a teacher gives you time to think of examples you can find for the topic" versus tasks without such an activation. We created pairs or groups of tasks with the same content type, only varying in the amount of ICL, ECL or GCL. Students had to rate the three types of load in a questionnaire. The informed rating group had to answer one item per load type, the differential rating group got 2 respective 3 items for each load type: For ICL we asked for example how complex the task was. For ECL learners should rate whether it was exhausting to find the relevant information. For GCL we asked learners to rate whether this task animates to think intensively about the given topic. In both questionnaires learners additionally had to rate the overall amount of perceived cognitive load on a 7-point-likert-scale from very low to very high mental effort, which was adapted from Paas (1992). To analyse the reliability of the two instruments we calculated the overall internal consistency for each task. For the differential rating test with more than one item per load type we also analyzed the internal consistency per task for each type of cognitive load. The validity was analyzed by comparing the ratings of the learners with the theoretically expected outcomes, i.e. the theoretically defined oppositional tasks should be rated significantly different in the respective type of load.

Results

The reliability of the informed rating test was highly varying for the different tasks: for almost half of the tasks the internal consistency was not sufficient. The differential rating test on the other hand had good to excellent values of an overall from .67 to .96. For the different load types the internal consistency was also good (with the exception of 1 to 2 tasks) with a values about .80. The validity test revealed significantly different ratings for the oppositional groups of tasks (extraneous load: $F(1,7) = 68.89$, $p=.00$, $\eta^2=.92$, germane load: $F(1,20) = 20.31$, $p=.00$, $\eta^2=.62$, intrinsic load: $F(1,19) = 131.74$, $p=.00$, $\eta^2=.88$). The differential rating test also differentiated very good for differences in extraneous load ($F(1,9) = 21.87$, $p=.00$, $\eta^2=.73$) and intrinsic load ($F(1,17) = 106.19$, $p=.00$, $\eta^2=.87$), but not that good for differences in germane load ($F(1,21) = 0.27$, $p=.61$, $\eta^2=.01$). Moreover we analyzed whether there are differences between the ratings of the two groups. For ECL the two instruments were comparable for 62% of the tasks, for ICL only for 52% and for GCL the ratings were comparable only for 33% of the tasks. However, in all those cases where there are differences between the two groups, the informed rating group rated the load type of the task more distinct, e.g. for a low germane load task the germane load rating is much lower than in the differential rating group.

Summary and Discussion

The informed rating turned out to be a valid measure for the three types of cognitive load. However, the overall reliability was not sufficient, indicating that it is much better to make differential ratings instead of calculating an overall amount of cognitive load. Nevertheless, other reliability measures like retests should be considered. The differential rating instrument also was valid for ECL and ICL, but for GCL the items should be revised. The great differences between the two questionnaires are due to the more distinct ratings of the informed rating group. Overall, especially the informed rating seems to be a promising strategy to assess different aspects of cognitive load.

PAPER PRESENTATION

A Framework for validation of Competence Assessment Programs

Saskia Wools, Cito, Netherlands; Theo Eggen, Cito / Twente University, Netherlands

One of the current trends in education is the shift towards more competence-based education. An implication of this change in educational emphasis is an increased use of competence assessments such as performance assessments, situational judgement tests, portfolio assessments. These competence assessments are often combined into a competence assessment program (CAP) that is aligned with the competence-based curriculum (Baartman, et al., 2007). Within a context of competence-based education CAPs are used for high stake decisions on students. It is

therefore important that the quality of these CAPs is ensured. An important aspect of the quality of assessments is validity. But while validity is a very important quality criterion for any form of assessment, it has thus far been operationalized mainly around the use of standardized tests. Nevertheless, validity is just as important for competence assessments and CAPs. This paper exemplifies the use of the Argument-based Approach (Kane, 1992) to validity for a single competence-based performance assessment. Furthermore, the Argument-based Approach to validity is extended for the validation of competence assessment programs (CAPs) where separate tests or assessments contribute to one decision.

Introduction

One of the current trends in education is the shift towards more competence-based education (Baartman, Bastiaens, Kirschner & Van der Vleuten, 2007). In the Netherlands, for example, the ministry of education decided that all vocational education institutes must formulate their curriculum according to principles of competence-based education which has led to concomitant changes in learning outcomes. One of the implications of this change in educational emphasis is an increased use of competence assessments such as performance assessments, situational judgement tests, and portfolio assessments (Baartman, Bastiaens, Kirschner & Van der Vleuten, 2006). These competence assessments are often combined into a competence assessment program (CAP) that is aligned with the competence-based curriculum. Within a context of competence-based education CAPs are used for high stake decisions on students. It is therefore important that the quality of these CAPs is ensured. An important aspect of the quality of assessments is validity. But while validity is a very important quality criterion for any form of assessment, it has thus far been operationalized mainly around the use of standardized tests. Nevertheless, validity is just as important for competence assessments (Messick, 1994). Recently, Wools, Eggen, and Sanders (2010) presented criteria that can be used for the evaluation of validity of competence assessments. These new criteria are developed for use alongside the Argument-based Approach to validity as described by Kane (2004; 2006). The proposed paper exemplifies the use of the Argument-based Approach to validity for a competence-based performance assessment. Furthermore, the Argument-based Approach to validity is extended for the validation of CAPs where separate tests or assessments contribute to a single decision.

Argument-based Approach to validity

Validity is basically about the interpretations assigned to test scores rather than the scores themselves (Kane, 1992). Interpreting a test score concerns explaining the meaning of a score and making the implications of the scores explicit. The process of evaluating the appropriateness of these interpretations is called validation. Validating an interpretation or use of test scores concerns a critical evaluation of the claims being made. This requires a clear description of the claims that accompany the proposed interpretation and uses. Also, this critical evaluation requires a somewhat objective attitude from the researcher involved. However, as Kane (2006) comments, 'most validation research is conducted by tests developers and tends to have a confirmationist bias.' (p. 22). In consideration of this tendency Kane (1992) suggests the Argument-Based Approach (ABA) to validation which provides guidance in the validation process.

This guidance is provided by a framework for gathering evidence to support intended interpretations and uses of test scores (Llosa, 2008). The argument-based approach (Kane, 1992; 2004; 2006) consists of two phases: the development stage in which an assessment is developed and an appraisal stage in which the claims being made in the development stage are critically evaluated. During the development stage, inferences and assumptions inherent to the proposed interpretation of assessment results are specified within an interpretive argument. When the assessment is fully developed and the interpretive argument is specified, a critical evaluation of the claims being made within the interpretive argument should be made. This critical evaluation takes place in the appraisal stage during which the assumptions stated in the development stage are validated in a validity argument that includes both analytical and empirical evidence. Validation of a competence-based performance assessmentIn the proposed paper both the interpretive argument as the validity argument are presented for a competence-based performance assessment. The validation of this assessment serves as illustration of the Argument-based Approach to validity for competence assessments. It is demonstrated which assumptions and inferences are made for this assessment and furthermore, validity evidence is structured into a validity argument to complete the validation. Validation of a competence assessment program (CAP)In the second part of the paper the Argument-based Approach is extended to the validate a combination of multiple tests that lead to one decision, specifically a CAP. It is demonstrated how the inferences and assumptions underlying different tests can be combined into one interpretive argument. Furthermore, it is demonstrated what validity evidence should be gathered to form a validity argument that supports the interpretive argument.

To summarize, the proposed paper will present the use of the Argument-based Approach to validity for the validation of a single competence assessment. Furthermore, the approach will be extended for the validation of a combination of multiple assessments in a CAP.

PAPER PRESENTATION

Assessment of fraction competencies on the basis of a two-dimensional competency-model

Lenka Schnaubert, TU Dresden, Germany; Susanne Narciss, Technische Universität Dresden, Germany

The assessment of competencies is a strongly discussed issue in educational psychology. Criterion-oriented testing requires an appropriate theoretical basis. Therefore Eichelmann, Narciss, Faulhaber and Melis (2008) created a two-dimensional competency-model for the domain of fractions. Based on Anderson and Krathwohl's revision of Bloom's taxonomy of educational objectives (Anderson et al., 2001), it contains a cognitive process-dimension while differentiating conceptual and procedural fraction knowledge. On the basis of this two-dimensional view on fraction competencies, two sets of fraction tasks (A and B) were created – each containing 35 items – and given to 293 6th and 7th graders, who each worked on one of the sets for 30 min. 237 pupils were re-tested after one week where they worked on the other set. Data-analysis showed that the item difficulties (integrating both sets and assessment times) ranged from .03 to .88 (.01 to .91 if only considering results without pre-testing) – with the conceptual items being slightly more difficult than the procedural items. The difficulties were normally distributed for each set with a mean of .45 (A) or .41 (B). For each set the mean discriminatory index was .31 (ranging from -.25 to .61) – considering the two-dimensional basis, this was appropriate. A closer look at each item revealed that some tasks were rather difficult, did only correlate negligibly with other test-items and therefore had no (or even negative) discriminatory power. Reliability-analysis showed a Cronbach's α of .73 for version A and .80 for version B.

Introduction and purpose

The domain of fractions is said to be one of the most difficult mathematical domains for students. Many authors stress the importance of this domain for educational and everyday purposes, especially when considering the amount of errors students make when handling fractions (e.g. Brown & Quinn, 2006) and the conceptual deficits students have regarding fractions (e.g. Chan, Leu & Chen, 2007). Although these problems are well-known to teachers and researchers around the globe, a valid diagnostic instrument providing information about the level of competence of students as well as information vital to treatment adaption is overdue.

The assessment of competencies is a strongly discussed issue in educational psychology. As criterion-oriented testing requires an appropriate theoretical basis, national and international comparative studies like PISA use theoretical frameworks to create tasks for assessment purposes. The critique is that these frameworks lack the precision to deduce guidelines for the generation of adequate assessment tasks and tools (Eichelmann, Narciss, Faulhaber, & Melis, 2008).

Therefore, Eichelmann et al. (2008) developed a competency-model for the domain of fractions which represents competencies as pairs of knowledge and a cognitive process. This two-dimensional representation of competencies is rooted in Anderson and Krathwohl's revision of Bloom's taxonomy of educational objectives (Anderson et al., 2001). The cognitive process dimension of this two-dimensional competency-model includes the processes Remember, Represent, Compare, Compute, Communicate, Model and Meta-cognition, the knowledge dimension includes

conceptual knowledge ("knowing what") and procedural knowledge ("knowing how"). It was explicitly developed to be used as a rationale for developing fraction tasks, which address competencies in the fraction curriculum (Eichmann et al., 2008). The present study aims at developing and evaluating such tasks.

Methodology

Based on Eichmann and colleagues' (2008) two-dimensional view on mathematics and the spadework of Berger (2009), two sets of fraction tasks (version A and version B) were created – each containing 35 items. Each set covered all of the suggested processes and knowledge types and their combinations (except for the combination of Metacognition and conceptual knowledge).

To allow economic assessment but still to address the full range of competencies described, the sets contained multiple-choice items as well as other answering formats (e.g. calculating was required as well as sketching, see figure 1). To allow a detailed look on students' performance in dealing with fractions, tasks were created to account for typical errors in the fraction domain as well (see figure 2).

The two sets of fraction tasks were given to 293 6th and 7th graders including the full range of traditional German school types. The students were randomly assigned to one of the two different sets and worked on it for 30 minutes. 237 pupils were re-tested after one week where they again worked 30 minutes but on the other set.

Results

Data-analysis showed that the item difficulties (integrating both sets and assessment times) ranged from .03 to .88 (.01 to .91 if only considering results without pre-testing) – with the conceptual items being slightly more difficult than the procedural items, although this difference was not significant. The difficulties were normally distributed for each set with a mean of .45 (version A) or .41 (version B). For each set of tasks the mean discriminatory index was .31 (ranging from -.25 to .61). Considering the two-dimensional basis, this can be regarded as appropriate, even if items with a significant negative item-test-correlation should be reconsidered. A closer look at each item revealed that some tasks were rather difficult, did only correlate negligible with other test items and therefore had no (or in one case for each version even significant negative) discriminatory power. Reliability-analysis showed a Cronbach's α of .73 for set A and .80 for set B, containing only results of pupils who worked on every task. Due to the restricted time frame, this was only true for NA = 64 or NB = 56.

Theoretical and educational significance

As mentioned above, fraction learning is a difficult subject for students. To effectively support learners, interventions (instructional designs, feedback, learning and teaching methods) have to be adapted to the learners' level of competence. Therefore we need to get a detailed look on how students perform, what kind of errors they make and we need instruments that enable us to draw conclusions regarding the students' competencies. Given the opportunity provided by computer-supported learning, such an instrument would allow the implementation of adaptive feedback and adaptive instructional designs to support students according to their competencies. The presented generation and first evaluation of two theoretically designed fraction tests provide a basis for future work. Even if further evaluations, revisions and the implementation of a computer-based version are still to be done, this work shows how criterion-based fraction tasks and tests can be designed and what can be accomplished by using specific competency-models as a theoretical basis for constructing diagnostic instruments.

PAPER PRESENTATION

Different Identities as Tools in Social Science Learning

Karin Ehrlen, Sodertorn University, Sweden

The aim of this study is to investigate how knowledge is constructed in dialogue. The focus is on a dialogue in the form of a discussion between two young adult students about an international political conflict. The discussion is video recorded, transcribed and analyzed. The immigrant experiences in the families of the discussing persons contribute to the construction of knowledge by making it possible for the participants to move among a variety of perspectives related to different identities. This helps them in their efforts to understand the conflict. This indicates the usefulness to study cultural diverse settings at school from a dialogical perspective. The educational significance of the study is the importance for teachers to realise the use that can be made of different identities as new perspectives on subjects at school.

Aims

According to Bakhtin (1984), seeking knowledge in dialogue is the opposite of finding truth in authoritative monologism. The knowledge in dialogue is the opposite of a ready-made truth, which is possible to possess. In dialogue, the knowledge is to be found between people. The aim of this study is to investigate how knowledge is constructed in dialogue. Theoretical framework and research questions
The prerequisite for a dialogue is that there is more than one voice (Bakhtin, 1981). That an utterance is directed toward a listener means that it is directed toward the specific conceptual system of the listener. Voice is understood as perspective on topics. This means that one person may express several voices and many individuals can express the same voice. One way for speakers in a dialogue to express personal will is in the choice of speech genre (Bakhtin, 1986). Speech genres acknowledge the tradition of how we speak about certain subjects. In addition to the connection to typical themes, speech genres depend on the situation in which they are used, the social position of the speaker, and the relations between the speakers in the dialogue. In this study the focus is on a dialogue in the form of a discussion between two young adult students about an international political conflict. The research questions are: What voices are heard? From what national, ethnic or religious position do the participants speak? What times, places and conflicts are actualized in the utterances?

Methodology

A first course in social sciences at upper secondary for adults in Sweden is object of the research. The first part of the course concerns the Swedish parliamentary system. Here a group of five students is followed. The last part of the course is about international relations. Here two girls in their early 20s, who had been followed during the first part of the course, volunteer to go on letting their work being recorded for research purpose. A task given by the teacher, in this part of the course, is to choose an international conflict and, after working on the subject, present an essay. The two participants would present a common essay. One of them has immigrated to Sweden, and the other girl's parents have immigrated to Sweden. The conflict the girls choose to work on is the Israeli – Palestinian conflict. They are video recorded on four occasions, while they are working. This, however, is not all of the work that the girls put into the project. The researcher interviews them about their work and is told that they also discuss the subject over the telephone and read and write about it when they are not together. About four hours of video-recorded work is transcribed. The character of the content is to a big deal work with facts. The students collect data about for example the history of the region and about economics. The final essay is mainly based on this kind of material. There is also content that can be described as procedural questions about how to write the essay. Other material has no connection to the task given by the teacher. The data that is selected for further analysis is material, where the discussions concern the girls' efforts to understand the Israeli - Palestinian conflict. Utterances are analyzed as actions and interactions. This is because when we consider utterances as actions, we take notice of intentions and this means that we study the individual and the historical, cultural, and institutional environment of the actions and of the individual together (Halldén et al. 2007; Wertsch, 1991).

Findings

Not only the students take part in the discussions. Other voices enter the discussions from TV programs and material from the Internet. The girls find themselves forced to enter a dialogue with these voices from "outside" and to take religious and ethnic positions vis-à-vis these voices from "outside". The immigrant experiences in the families of the discussing persons contribute to the construction of knowledge by making it possible for the participants to move among a variety of perspectives related to different identities as well as between times and places. Other factors contributing to the knowledge construction are that the girls have common experiences (they are from immigrant families) and different experiences (they are of different ethnicities and have knowledge of different geographical areas). These conditions make it possible for the students to move between voices of non-migrants and migrants, between voices of Swedes and voices of Arabs or Pakistanis. In time, the dialogue alternates between old religious

history, the Second World War, and present time. Conflicts that are actualized in the dialogue are between Israel and Palestine, Hitler and Jews, non-migrants and immigrants, the Swedish speaking minority in Finland and immigrants in Sweden, Pakistan and India. In the enterprise of understanding the conflict, the students appear to favour a human rights speech genre over a genre with explanations from political history or religious history. This means that the students describe the conflict from the perspective of an individual human being rather than from the perspective of larger political structures. Although the participants choose to understand the conflict in the same speech genre (a human rights genre), they express two different voices in this genre. One student is of the opinion that how long you have been living in a country is grounds for your right to remain, while the other girl appears to give ethnicity or culture priority or at least can understand it as reasonable. Conclusion The students' capacity to position themselves in different identities helps them in their efforts to understand the conflict that is the theme of the essay.

Theoretical and educational significance

Theoretically this study indicates the usefulness to study cultural diverse settings at school from a dialogical perspective. The educational significance of the study is the importance for teachers to realise the use that can be made of different identities as new perspectives on subjects at school.

PAPER PRESENTATION

Emerging intercultural interactions at university: Agency and identities within and across contexts

Simone Volet, Murdoch University, Australia; Farida Fozdar, Murdoch University, Australia

The paucity of intercultural interactions among students from diverse cultural backgrounds on university campuses is well documented. Recent research has revealed troubling patterns in students' attitudes towards learning and interacting in culturally diverse groups, and evidence that culturally homogeneous groups are firmly established within the first year of study, with limited change in later years. In light of tangible educational, social and economic benefits expected from intercultural learning during university study, it is argued that early establishment of systemic in-group favouritism needs to be avoided. The study reported in this paper tries to capture first year students' initial expectations and evolving experiences of intercultural interactions by exploring the mediating role of individual and situational dimensions within and across contexts of study. This research departs from prior research by focusing on positive intercultural experiences and exploring the emerging nature of interactions in situated contexts. Data consists of two questionnaires from 321 students and two interviews with a sub-sample of 34 students during their first seven months at university. Preliminary findings, analysed from a combination of cognitive-situative perspective, identity theory and multiple contexts as activity systems perspective, provide evidence of institutional and instructional influences but also stress the criticality of agency, personal identities and interdependency within and across contexts.

Introduction and Aims

The challenges of cultural diversity in higher education have been extensively researched in countries hosting large numbers of international students, most of them also having a diverse domestic student population (e.g. Harrison & Peacock, 2009; Groeppel-Klein, Germelmann, & Glaum, 2010; Levin, Van Laar & Foote, 2006; Sakurai, McCall-Wolf, & Kashima, 2010; Summers & Volet, 2008). This research has documented the societal, situational and personal variables that can inhibit the emergence and maintenance of productive interactions between students from diverse cultural backgrounds in learning and social university contexts.

What have received less attention, however, are the nature, origin and development of intercultural experiences and interactions taking place through learning activities, and which lead to positive outcomes. Adopting a positive psychology lens (Linley, Joseph, Harrington & Wood, 2006) to examine this phenomenon is viewed as imperative to identify the process by which intercultural interactions and confidence emerge and intercultural learning takes place, thus the educational conditions and practices that should be considered when designing learning activities. The study presented in this paper aimed to address this gap.

The aim of the paper is a) to present and interpret first year students' initial expectations and evolving experiences of intercultural interactions with peers, in relation to personal and contextual dimensions, and b) to examine the mediating role of individual and situational aspects on interactions that have lead to positive outcomes in the context of learning activities.

The research, framed in combined cognitive-situative (McCaslin, 2008; Volet 2001) and activity (Engestrom, 1993; Nardi, 1997) theory perspectives, targets students' expectations, metacognitive reflection and personal interpretations of actual experiences taking place in learning contexts that are conceptualised as dynamic social systems made of interdependent participants. The conceptual lens of identity theory is added with a view to capture

the significance on emerging intercultural peer interactions of multiple, endorsed, assigned and negotiated personal, social, ethnic or cultural identities (e.g. Sidanius, Levine, Sears & Van Laar, 2008).

Methodology

Consistent with the multiple theoretical grounding, a multi-method approach is adopted for the study. It combines questionnaires from a large sample of first year students (n=331) with in-depth interviews with a sub-sample (n=34). The questionnaire data (beginning and end of first semester) provides data on a range of evolving individual and perceived situational dimensions within distinct contexts of study. They include measures of intercultural disposition, motivation to mix, social goals, expectations of intercultural interactions, prior, current and anticipated experiences, as well as open-ended questions about self-identified ethnicity(ies).

The two sets of interview data (4-5 months apart) explore students' cultural, linguistic and educational backgrounds, expectations, and emerging experiences of positive intercultural interactions in learning activities and broader social contexts, alongside reflections on the importance and impact of personal ethnic and/or cultural identity(ies). Using original process-based stimulus materials (construction of personal and situational identity maps), the second interview teases out the significance of identity(ies), agency and situated opportunities and constraints in students' cognitive and affective interpretations of actual experiences of positive intercultural interactions.

Questionnaire data analysis reported in this paper includes both a variable-oriented approach (e.g. multiple analyses of variance with repeated measures, regressions) as well as a person-oriented approach (e.g. cluster analysis), in an attempt to identify patterns of individual and situational variables and their relationships, as well as entry profiles of groups of students based on selected dimensions, and the evolution over one semester at university of target variables not used in the cluster groupings.

The interview data selected for presentation is from the second interview. The process-based stimulus materials used for data collection will be presented alongside the method of analysis (still being refined).

Findings

Preliminary findings reveal interaction effects for course of study by time in students' ratings of their behaviours and (meta)cognitions related to intercultural interactions and experiences, a pattern which parallels interaction effects for course of study by time in perceptions of teacher practices that capitalize on cultural diversity – the patterns in both instances highlighting evidence of less positive cognitions and practices after one semester, with some differences across courses. These findings can partly be related to differences in perceptions of the importance of cultural understanding in the respective course of study and future profession as well as the diversity student profile of each course. The significance of self-assigned identities and bi/multi-lingualism on students' intercultural dispositions and perceptions of the importance of fostering intercultural interactions at university is also highlighted. The interview analyses suggest some ambivalence among students regarding intercultural interactions, which includes a general positivity towards the idea but at the same time some reticence to make a personal effort to take up the opportunities, even when learning activities are structured such as group work. The analyses of positive intercultural interactions, using the identity maps and an activity theory perspective, provide illustrations of 'reluctant agency' and peers interdependency, alongside the significance of personal multiple, but also assigned and negotiated identities on emerging intercultural interactions. The implications of these findings for the design of learning activities and instructional practices that foster intercultural learning as an integral part of university education are discussed.

PAPER PRESENTATION

Do All-Day Schools offer better participatory opportunities for parents with migration background?

Christine Steiner, German Youth Institute, Germany; Bettina Arnoldt, Deutsches Jugendinstitut, Germany

High and far-reaching expectations have been placed on the German all-day schools: One of them is the inclusion of the subject of migration in the schools, and the integration within the school of the children and youth with a migration background. Therefore, one step is to improve the cooperation between school and parents, especially parents with migration background or a lower social status. All-day schools are able to provide more possibilities for parental participation.

The willingness of parents to commit oneself for school interests is seen as an essential factor for improving school quality. Several studies verified a strong connection between parental participation and personality development of students. The lecture will answer the question, whether all-day schools succeed in including parents that are in general under-represented on participation. The empirical basis of the presentation is the nationwide "Study of the

Development of All-day Schools" (StEG) for which those who teach in all-day schools, as well as pupils and their parents were interviewed three times. The results show that parents with migration background participate significantly more in extra-curricular activities than parents without migration background. Moreover, the analysis shows, that the probability for parental participation increases if parental collaboration is established in the school concept. This is an important result, because in this point head masters and teachers have opportunity for action.

For a long time Germany has been a country in which school typically ended around noon. This has only begun to change in the last few years, during which time more and more schools, especially grade schools, have become all-day schools. Just between 2002 and 2006 the numbers doubled. Despite this dramatic growth, at the moment only one third of all schools offer all-day places. High and far-reaching expectations have been placed on the all-day schools: The diverse educational, free-time and care offerings that run through the day and are linked with the educational plan are meant to achieve a clear improvement in the educational quality, as well as offering the parents a chance to balance work and family. In addition, by opening the school to those in the region who have no direct connection to schools, the school can be placed in the context of the pupils' lives, and offer not only a better, but a different way to learn. This applies as well to the inclusion of the subject of migration in the schools, and the integration within the school of the children and youth with a migration background.

The goals of improving integration and reducing social inequality in educational attainment are strongly connected with all-day schools. Therefore, one step is to improve the cooperation between school and parents, especially parents with migration background or a lower social status. All-day schools are able to provide more possibilities for parental participation. Besides participating in conventional committees for parents, they can support the additional learning time, for example to foster homework, give support at lunchtime or offer extra-curricular activities.

The willingness of parents to commit oneself for school interests is seen as an essential factor for improving school quality. Several studies verified a strong connection between parental participation and personality development of students. This result can be explained by a number of reasons: parental commitment functions as an example for their children, parents get more information from school and at the same time, they have the chance to influence school decisions. However, it is known that in general it is parents with higher income and higher education, who look after their interests.

The lecture will answer the question, whether all-day schools succeed in including parents that are in general under-represented on participation, because of their wider possibilities of participation and because of their focus on (social) integration. The empirical basis of the presentation is the nationwide "Study of the Development of All-day Schools" (StEG) for which those who teach in all-day schools, as well as pupils and their parents were interviewed three times. The third survey took place in 2009 in 357 primary and secondary schools. The longitudinal approach from StEG allows to understand better how schools establish a new learning culture, because changes across time could be investigated. The study is conducted jointly by three institutes: German Institute for International Educational Research (DIPF), German Youth Institute (DJI) and Institute for School Development Research (IFS).

The question was examined by analyzing the data with regression analysis. Because of the fact, that the new possibilities of participating in all-day schools are yet not wide spread, the calculations were checked with a rare-event-regression. Firstly, the results show that also in all-day schools parents with a lower social status, lower education or migration background participate less in parental committees. Secondly, parental involvement in extra-curricular activities in general is at a low level. Thirdly, parents with migration background participate significantly more in extra-curricular activities than parents without migration background. Moreover, the analysis shows, that the probability for parental participation increases if their children are users of extra-curricular activities. Another crucial factor is that parental collaboration is established in the school concept. This is an important result, because not only individual factors influence parental participation, but school characteristics. In this point head masters and teachers have opportunity for action.

PAPER PRESENTATION

"Doing science" through multimodal interactions in the early childhood classroom

Charles Max, University of Luxembourg, Luxembourg; Chris Siry, University of Luxembourg, Luxembourg

In this paper we will share findings as evidence of the spontaneous ways children describe, explain, interconnect and reason about phenomena related to the natural, physical and chemical properties of water. Drawing from a longitudinal corpus of classroom interactions (200 h), this research is part of a larger three-year study (2008 - 2011)

conducted in five pre-school and elementary schools. The data were collected in the academic year 2009-2010 via participatory observation, video and document analysis, interviews with teachers and pupils.

The aim of this research is to explore the nature of 4 to 8 year-old children's science learning as a social phenomenon that is interactively achieved, discursively bound and contextually mediated. A particular concern in this multicultural context are the multiple resources, which young learners bring from socio-cultural, institutional and historical contexts and, which they use within interactive practices and multimodal talk-in-interaction to co-create make meaning about water phenomena.

The multi-dimensional framework of the study combines cultural-historical, sociocultural, interactional and micro-ethnographic perspectives in order to frame „doing science" as a cultural enactment in collaborative inquiry activities. The outcomes stress changes in children's knowing related to water phenomena as a mutual redistribution between individual resources as regards thinking and speaking on the one hand and external means of inquiring on the other hand (intentionally introduced or jointly created within the learning activity). This presentation provides insights in this dialectical process of scientific learning and meaning making.

Subject/ Problem

In order to shed light on the learning processes of young children as they accomplish joint activities in elementary science, this study emphasises the interactive practices of children when "doing science" around the exploration of water in early childhood classrooms with a complex multilingual background. More specifically, the present paper analyses the mutual accomplishment of the particular inquiry context through children's joint acting with material equipment and their multimodal interactions about the natural, physical and chemical properties of water.

The mutual dynamics between processes of personal scientific inquiry and collective knowledge creation (Paavola and Hakkarainen, 2005) are central to "doing science" as deployed in the present research. Specifically, we conceive science learning as an interactional achievement, one that encompasses the enactment of elementary science as culture and as a cultural accomplishment. This enactment unfolds through a dynamic, non-linear and creative combination of culturally given tools and the children's specific linguistic repertoires and discourse formats that they develop across multiple contexts.

Rationale

The rationale behind this research is to explore the nature of young children's science learning as a social phenomenon that is interactively achieved, discursively bound and contextually mediated. A further issue of this study concerns the multiple resources of young learners, which they use to make meaning about water phenomena through interactive practices and multimodal talk-in-interaction. To that end, the following questions are guiding the research work:

- How do 4 to 6 year-old children display their understanding about water phenomena?
- How does the multimodal nature of children's ways of doing, arguing, reasoning, imagining, re-presenting and talking about water phenomena allow to construct a collaborative framework for exploring the specific science phenomena?
- How does the context-sensitive organization of talk and multimodal interactions of the children shape promising opportunities for science learning in an early education class?

Multi-method framework

As we explore what young children value in science activities, we elaborate on the empirically tangible and systematically analyzed ways in which they construct science as their gradually emergent accomplishment, which - at first sight - might not be considered (relevant) 'canonical Science'. However, children's discursive practices are framed as enactments of elaborate science, demonstrating representations of science concepts but also the conditions of such science accomplishments. A specific emphasis concerns the available multimodal resources and the diversified multilingual practices brought into the situated science classroom setting.

The study is framed by a multi-dimensional approach based on a thorough combination of different research perspectives. In particular, these perspectives include cultural historical frameworks of human activity (Daniels et al., 2010), sociocultural approaches on learning as cultural enactment (Goodwin, 2007), conversational analytic perspectives on learning as an interactional achievement (Melander & Sahlström, 2009) and micro-ethnographical discourse analyses to conceptualizing "doing science" as a cultural accomplishment (e.g., Schlieben-Lange, 1983).

Within these perspectives, we acknowledge that learning science is both individual as well as collective, as participants construct science in interaction with others (Fleer & Robbins, 2003). Issues of learning, participation and change within open science workshops can be addressed from a micro-sequential approach to interaction, which we see as layering well with sociocultural approaches (Robbins 2005). Whereas the sociocultural understandings of participation

tend to deal with long-term processes occurring within specific communities, a CA approach understands participation as "a micro phenomenon, accomplished in the complex, situated moment-by-moment constitution of human sociality ... participation is in constant flux, and what is of interest to CA is the organization of this flexible phenomenon" (Sahlström 2009, p.108).

Research design/context

Drawing from a longitudinal corpus of classroom interactions (age 4-8), this excerpt is part of a larger three-year study (2008 - 2011) conducted in five pre-school and elementary schools. By working in collaboration with early childhood classroom teachers, this project systematically documents the emergence of practices through which children co-construct science as a discursive accomplishment, while simultaneously supporting teachers in implementing science activities and expanding inquiry-based approaches. Classroom interactions were audio and video recorded by children and researchers. Researchers intervened as participant observers as children investigated a variety of water-related concepts. Children acted as co-researchers and recorded prominent moments of their inquiries via handheld devices during and after the classroom sessions. The recorded core moments of the inquiry process in form of pictures, drawings, audio or video recordings mediated the subsequent teacher-initiated talk and interactions between the children as well. All the recordings (200 hours) have been organised within a searchable database using Transana, an open-source software (Woods, 2007). They serve as the main data source for the current analytic work. Key episodes are being transcribed in relation to the core research questions. The transcripts serve to analyse the dynamics of speech while children interact (1) in small groups during inquiry activities, and (2) during classroom talk, teacher initiated.

Findings / Analysis

The project has generated tangible outcomes about the multimodal and discursive ways of young children when enacting knowledge and reasoning as regards elementary science topics. In considering the ways in which children develop shared meanings, the research draws attention to a genuine feature of knowledge building through participating in emerging multimodal and multilingual discourses. In our case, multilingual children develop their multimodal frameworks (understood as enrichment or reorganization processes) while participating in spontaneous scientific discourse – featuring both specific conceptual content and scientific inquiring – through discourse competencies that are enacted during multilayered interaction.

In this presentation we will share findings as evidence of the spontaneous ways children describe, explain, interconnect and reason about phenomena related to the natural, physical and chemical characteristics of water. By tracking changes in children's knowing as a mutual redistribution between individual resources as regards thinking and speaking on the one hand and external means of inquiring on the other hand (intentionally introduced or jointly created within the learning activity) the project provided insights on the dialectical process of scientific meaning making.

PAPER PRESENTATION

Progressive reflection – fostering conceptual understanding in chemistry

Sascha Schanze, Leibniz Universität Hannover, Germany; Thomas Gruess-Niehaus, Leibniz Universität Hannover, Germany; Sarah Hundertmark, Leibniz Universität Hannover, Germany

Research results report difficulties in teaching chemical concepts like the solution concept because students often have resistant alternative conceptions of the processes, formed in everyday life experiences. It is assumed that the process of externalising concepts, reflecting on the externalizations progressively and also communicating them in a group can support the awareness of misconceptions and also to overcome them. In a study 297 13 to 15 year old students, learning chemistry in a context based curriculum, use computer based concept mapping or a monitoring worksheet method as progressive reflecting tools. Additionally the condition reflecting in pairs or alone is altered. Results show an advantage of the mapping method for students reflecting alone. No differences between the methods were found when reflecting in pairs.

Introduction

Modern chemistry curricula are learner-oriented and provide opportunities for meaningful inquiry. But they also put demands on the student because of complex and sometimes open-ended environments and on the teacher to monitor and scaffold students' individual learning progress. Land & Zembal-Saul (2003) describe tools and perspectives to progressively deepen and refine meaning as fruitful and supportive. Our research focuses on supporting students' understanding chemistry concepts, by using tools that foster students to first externalize their ideas in their own language and then to continually reflect on their understanding (progressive reflection), on their artefacts. The study compared computer-based concept mapping and a monitoring worksheet as two progressive

reflections methods. We also compare individual learning with collaborative learning settings where students discuss in pairs about their individual artefacts (peer interaction).

Theoretical background

Progressive Reflection: We understand progressive reflection comparable to Liu (2002) as a process of ongoing revision, meaning that revision takes place in an isochronous way. Students need methods or tools that foster them to make their thinking visible (Linn, 2000) and to build up a coherent knowledge structure. These self constructed external representations are partly snap-shots of their understanding or idea of the relating concept. To reflect on theses artefacts after a new learning period give the students the chance to identify inconsistencies or add new ideas. In this study we compare two methods, a monitoring worksheet method and computer-based concept mapping. Because of its absent linear structure a concept map can easily be augmented or refined; creating new or deleting incorrect propositions does not entail as many problems as correcting a text. So we assume concept mapping to be more supportive for understanding the underlying chemical concept.

Peer interaction: In order to stimulate the procedure of reassessing one's initial explanation, peer interaction can be one means that students actually recognise the reason for rethinking and reassessing their prior understanding (e.g. Havu-Nuutinen, 2005). So, we assume, that if students reflect on their concepts progressively and collaboratively, comprehension of the addressed concept can be fostered in a wider and deeper way.

Research question

- To what extend does students' understanding of a basic concept depend on the used reflection method and the social setting?

Based on the presented theoretical background, we hypothesise that

- the concept mapping method outclasses the monitoring worksheet method with regard to foster student's understanding of the respective concept.
- students reflecting collaboratively will gain a better understanding of the addressed concept than those students reflecting alone.

Methodology

Participants: 297 13 to 15 years old students (51% female, seventh grade, 10 classes, three German schools). The variable "social arrangement" was altered between the classes whereas the variable "reflection method" was altered within the classes. The participants were assigned to the four experimental groups (fig. 1) with regard to gender as well as verbal and spatial intelligence. During the teaching unit (20 lessons), the dissolution concept was developed by investigating chocolate and its ingredients whereas brewing and sweetening tea was the context of three reflection phases. In order to measure learning progress and long term effects about the content of the teaching unit, the German version of the solution concept test (SCT, Uzuntiryaki & Geban, 2005) was used (pre-, post-, and follow-up-test; 14 items). Gender, domain specific self-concept and verbal and spatial intelligence were surveyed.

see appendix

Figure 1: 2x2 design of the study

Analysis and results

The raw data as well as z-values of the SCT's overall scale are displayed in figure 2.

see appendix

Figure 2: Raw data and z-values of the SCT

Figure 2 indicates the fact, that at the beginning of the teaching unit the knowledge base of the 4 experimental groups cannot be characterised as comparable; the pair working classes showed greater previous knowledge than the single working classes (difference: $M = 1.08$, $t(244) = -3.805$, $p = .000$). As a consequence, the previous knowledge is considered as a covariate while analysing the learning progress of the 4 experimental groups. A repeated measures analysis of variance (ANOVA) shows a significant difference which can be traced back to the extreme enhancement of the single working concept mapping group ($F(2,444) = 2.171$, $p = .046$, partial $\eta^2 = .029$; weak effect, following (Cohen 1988)). Looking at the pair working groups no difference could be found between the two methods (more detailed results will be presented).

Discussion

The different learning outcomes of the single working classes can be traced back to the fact, that in a concept map the individual understanding of the respective learner becomes immediately obvious whilst a text rather is unclear and

confusing. In order to understand the content of a concept map, the students have (a) to recognise and (b) to find suitable association to every single concept and relation. If the goal is to understand a text there is a right chance to lose sight of inadequate concepts - such faulty terms and ideas are not noticed as frequently as in the case of a concept map. The findings of the peer interaction groups go along with a meta-analysis of collaborative concept mapping activities, conducted by Gao et al. (2007). One reason which is possibly essential for the effectiveness of peer interaction can be seen in different cognitive preferences of the group members. Furthermore the students might learn predominantly by discussing with their partners and not by collaboratively revising their externalizations so that no dependence of the applied method can be detected. These findings implicate extra scaffolds in the peer interaction period that foster the revision of the externalizations. For this reason, we currently analyse the video-typed conversation.

PAPER PRESENTATION

Using non-integrated and/or integrated instruction to develop understanding of the nature of science

Rena Heap, The University of Auckland, New Zealand

The importance of an understanding of the nature of science (NOS) as one of the crucial educational components of scientific literacy is well argued in literature (e.g. Lederman, 2007) and is clearly reflected globally in science education documents and reform initiatives, including our New Zealand curriculum document. Young people need to see science as relevant to the identities they are building or wish to build for their future selves and they need to develop this insight against an international backdrop of global issues and concerns. Hodson (2009) argues for a curriculum aimed at far reaching social change through critical considerations of socio-scientific issues. It is of critical importance to research effective ways for pre-service teachers to develop their own understanding of NOS in order to plan to teach NOS in a transformed school science programme which engages and retains students' interest in science. This study examines the effectiveness of the use of structured reflection and generic science-content-free activities to develop understandings about the nature of science (NOS). The research participants were pre-service primary teachers (n=38) enrolled in the Graduate Diploma (Primary) University degree programme. Data was collected using open-ended questionnaires, selected items from the Views on Science-Technology-Society (VOSTS) questionnaire (Aikenhead & Ryan, 1992) and the preservice teachers' regular reflective journal writing. Analysis of the data obtained showed a considerable shift in students' NOS views and showed a relationship between these shifts and the use of the structured reflection and generic science-content-free activities.

Aim

Improving nature of science (NOS) understandings is complex and requires an approach that addresses conceptual change. Therefore, the research design for this study incorporated an explicit reflective approach and consistently provided opportunities for reflection and reflective writing. The generic science-content-free activities were strategically embedded throughout the course so that the pre-service teachers could approach them as decontextualised NOS activities (a non-integrated approach) or could relate the generic NOS activity to the science content being covered at the time, as contextualised activities, if they made those connections (an integrated approach). The research aim was to identify the existing NOS understandings and to map shifts in these understandings over the duration of a science course.

Two factors were examined in facilitating shifts in NOS understandings;

- 1) The use of structured reflection
- 2) The use of both an integrated and a non-integrated approach, utilising generic science-content-free NOS activities.

Methodology

Within this research study the researcher was both the instructor of the course and the researcher. The research was embedded in critical social science methodology as underpinning both critical social science and the educational goal of scientific literacy and NOS is the emphasis they place on transformation, emancipation and change. The research participants were students (n=38) enrolled in the Graduate Diploma (Primary) University degree programme. The design of this research study provided the opportunity for both integrated and non-integrated instruction. Data was collected using; 1) open-ended questionnaires, 2) selected items from the Views on Science-Technology-Society (VOSTS) questionnaire (Aikenhead & Ryan, 1992) and 3) the students' regular reflective journal writing. Data was analysed both qualitatively and quantitatively using a content analysis of all the sets of data collected. A NOS framework was developed to further analyse data gathered. Findings Only one small section of quantitative data, from the students' reflective journals, will be introduced in this preview. A comprehensive data analysis, both qualitative and quantitative, is presented in the final presentation and paper. All entries in the students' regular reflective journal writing were coded for the articulation of NOS tenets. Table 1 shows the quantitative results of this analysis. This table shows the number of students who expressed a NOS tenet in their reflective journal writing for that topic or NOS activity. Columns A and B are a chronological overview of the course. Column C shows the number of students who, based on activities of the topic or in the generic NOS activity, expressed at least one NOS tenet in their journal writing. Columns D-H identify which NOS tenets were explicitly articulated in the students' journals. Multiple references to the same NOS tenet by each student will only score as one since the analysis is to show how many students articulated each tenet, not how many times the tenet was expressed. The total number of comments in each topic or generic activity will usually exceed the number of students who expressed NOS tenet/s as the students may have articulated more than one tenet. The shading of the cells (columns D-H) indicates the tenets which were explicitly covered during the topic or activity. Within any of the topics covered, it would have been possible to see each of the NOS tenets, but those shaded were specifically addressed.

Significance

Quantitative data analysis shows a shift in NOS understanding. Qualitative analysis of the data shows that the students moved backwards and forwards between approaching the generic activities as stand-alone activities to deepen their NOS understanding (non-integrated) or relating the activity to the science content being covered (integrated approach). This was considered to be of critical importance in structuring a course to develop NOS understanding. The full presentation will examine this data and approach in depth, with regard to the theories of conceptual change and cognitive load. It is of critical importance to research effective ways for pre-service teachers to develop NOS understanding in order to teach NOS in a transformed school science programme which engages and retains students' interests in science. If teachers translate into classroom practice such contemporary understandings, this could be a critical factor in the development of the scientific literacy required by our students in order for them to fully realise the benefits of and participate in an increasingly scientific society. PAPER PRESENTATION

Using self-generated analogies in teaching of thermodynamics

Fredrik Jeppsson, FontD, Sweden; Jesper Haglund, Linköping University, Sweden, Sweden

Using self-generated analogies has been proposed as a method for students to learn about a new subject, by use of what they previously know. We report on a group exercise on using self-generated analogies to make sense of two thermodynamic processes, reversible adiabatic expansion and free expansion of an ideal gas, particularly regarding the entropy concept. The participants (N = 8) were physics teacher students at the fourth year of the teacher education program. In all, the students brought up 27 analogies, all of which used microscopic models, and during the group exercises a number of challenges were encountered, which provided a ground for discussions. In the present study, we show that the use of self-generated analogies is a possible way to make students assume ownership of their learning, by engagement in group work. Due to this ownership, self-generated analogies tend to be elaborated into a greater structural depth than teacher-generated analogies.

Introduction

Many concepts in thermodynamics are considered to be abstract and difficult for novices to grasp and this is particularly the case for the concept of entropy. One common approach to introduce abstract concepts in science education is to use analogies. Gentner's Structure Mapping Theory (1983) has been used extensively in science education research to account for the nature of analogical reasoning. The purpose of teaching with analogies is that the students are going to learn about a new domain by comparison with another, more familiar domain. Conclusions are made with regards to the familiar context and transferred to the taught context. However, it is not always clear that the more familiar domain is familiar to all listeners and therefore students may draw wrong conclusions. The failure to recognise structural relations in taught analogies may seem as a paradox since individuals frequently use spontaneous analogical reasoning in daily life. Blanchette and Dunbar (2000) explain this discrepancy by contrasting a reception paradigm with a production paradigm. In the reception paradigm, learners are supposed to receive an already existing analogy and interpret and use it in an intended way. This brings along two challenges: firstly, that the subjects are supposed to have in depth knowledge of the source domain, and secondly; that they have to identify the similarity of the domains. In the production paradigm, on the other hand, the learner him- or herself creates or generates analogies in order to organise what is known about a studied phenomenon. By default, the source domain and how it is linked to the target is grasped by the learner, otherwise it would not be considered as useful. In this study we regard spontaneous analogy as the use of analogy when exploring a new area spontaneously, without being cued by a teacher or researcher. Self-generated analogy is the generation of a new analogy, by request from a teacher or researcher. Aim In the present study, we aim to: Explore how the use of self-generated analogies may be used to express and develop the understanding of thermal phenomena. Describe different challenges, which were identified from group work on the generation of own analogies for two thermodynamic processes

Methodology

The participants were eight teacher students ($N = 8$), specialising in mathematics and physics teaching at upper secondary school, at the fourth year of the teacher education program at a Swedish university. The participants were given a short introduction by the researchers on the use of analogies in teaching and on two thermal processes: reversible, adiabatic expansion of an ideal gas, and; free, adiabatic expansion of an ideal gas. The participants were divided in two groups of four in each and asked to generate own analogies for the two processes. The audio records were transcribed and the coding and analysis was managed by using the MAXQDA software. We followed the approach of Blanchette and Dunbar (2000) in analysing the following dimensions of the generated analogies:

Degree of similarity · Structural depth ·

The explicitness In addition, we analysed the challenges that the groups encountered during the exercises. Findings Overall, the discussions in the two groups went on well and the teacher students came up with many analogies for the two processes, out of which 27 were analysed. In spite of the primarily macroscopic approach of a thermodynamics course the teacher students had just participated in, all analogies used microscopic models, comparing particles to for example people or angry bees. A majority of the analogies were originated by the groups themselves, but 10 of them were taken from previous teaching. Interestingly, however, the groups elaborated the new, own analogies more than the previously known analogies, as seen in Table 1 in the larger amount of concepts covered, the qualitatively deeper structural level and the considerably larger amount of statements.

As hypothesised, it was challenging for the teacher students to account for the constant entropy during reversible, adiabatic expansion, since their conception of microstates was limited to spatial configuration, ignoring the energy contribution. In addition, it was challenging to grasp the constant temperature in free, adiabatic expansion, partly by influence from known reversible processes. However, by the end of the exercise, the students had managed to come to terms with the challenges and make sense of the processes.

Educational significance

We show that the use of self-generated analogies is a possible way to make students assume ownership of their learning, by engagement in group work (Enghag, Gustafsson, & Jonsson, 2009). Specifically, self-generated analogies tend to be elaborated into a greater structural depth than teacher-generated analogies. As opposed to Blanchette and Dunbar (2000), however, we claim that this is not due to the student teachers not realising the structural relations of the teacher-generated analogies, but on the assumption that these analogies are unproblematic. Self-generated analogies, on the other hand, have to be explicitly elaborated and scrutinized in order to see where they break down. In this respect, we adhere to the view of Heywood and Parker (1997) that richness of the discussions is one of the main objectives of the exercise, rather than finding the analogy with the perfect match between the source and target domains.

As a conclusion, student-generated analogies may provide both a useful instructional tactic for encouraging students to 'talk physics' and as a research tool for identification of conceptions. A particularly promising result of the exercise was that the groups by themselves and with brief input from the researchers managed to make sense of and resolve most of the encountered challenges.

PAPER PRESENTATION

Mediating disciplinary practice to understand a complex aquatic ecosystem

Cognitive Development, Computer supported Learning Environments, Science Education; Catherine Eberbach, Rutgers University, United States; Cindy Hmelo-Silver, Rutgers University, United States; Rebecca Jordan, Rutgers University, United States; Julia Svoboda, Georgia Institute of Technology, United States

This study explored how computer, teacher, and student use of questions mediated middle school student understanding of a complex aquatic ecosystem. Adopting a case study approach, we closely examined three groups of middle school students in a U.S. school as they interacted with computer tools. More specifically, we focused on questions as a critical mechanism for supporting complex observational reasoning. Our findings suggest ways in which questioning may support learning about complex systems in technology rich learning environments.

Introduction

Learning about complex systems is challenging when even experts find systems difficult to understand and predict. Understanding complex systems necessitates reasoning about multiple, interdependent levels, non-linear causality, and emergence. Yet, novices tend to focus on observable structures and simple linear relationships without perceiving systemic and dynamic patterns (e.g., Ben-Zvi Assaraf & Orion, 2010; Hmelo-Silver, et al., 2007). That is, students focus on easily perceptible structures and behaviors without associating these with their functions or micro-level structures and processes. The ability to observe scientifically meaningful patterns is critical to generating new knowledge. Much more than simply sensing phenomena, observation is a complex scientific practice that requires the coordination of disciplinary knowledge, theory, and habits of attention (Eberbach & Crowley, 2009). Computer tools can support the development of such perceptions.

This study focuses on the use of questions as a critical aspect of scientific observation and how asking questions mediates student observations and understanding of an aquatic ecosystem. Asking what, how, and why questions is a powerful heuristic of expert observational practice. Doing so filters complexity and stimulates iterative cycles of noticing recurring patterns and asking new questions (Smith & Reiser, 2005). Research suggests why and how questions are associated with deeper levels of reasoning and what questions with more superficial reasoning (e.g., Graesser & Person, 1994). However, Hmelo-Silver and Barrows (2006) found that so-called superficial what questions could serve important functions, such as focusing and orienting students towards important aspects of a task and helping them to develop appropriate problem representations.

Methods and analysis

Working from a framework in which knowledge is socially constructed (De Jong & Joolingen, 1998; Palincsar, 1998), this case study examines how teacher and peer interventions mediated middle school students' observations of an aquatic ecosystem. This research is situated in a technologically rich learning environment where instruction was organized around facilitating student understanding of structures (what), behaviors (how) and functions (why). Collaborative student groups accessed hypermedia organized around these questions and used simulation models to explore the system's macro- and micro-levels. One challenging task involved identifying what the simulation objects represented and discerning their behavior. Finally, students generated a structure-behavior-function model using the Aquarium Construction Toolkit (Goel et al., 2010).

Data sources consist of video-recordings and student-generated models. We used an iterative deductive and inductive approach in which we initially viewed the video with certain expectations but were open to unanticipated

phenomena and interactions. We examined student and teacher discourse, with a particular interest in the role of questions.

Findings

The findings demonstrate the importance of questions in mediating students' developing understanding of complex systems. But the nature of those questions was unexpected: asking "what is it" questions productively cultivated iterative observations of the same phenomena—a key practice of scientists that is difficult to motivate students to do. Asking questions about structure eventually led to noticing and documenting relations between the system's structures and behaviors. In particular, when the students or the teacher asked "what is it" questions in reference to abstract representations, it led to iterative close observation of the representation's behavior, which in turn, afforded new opportunities to notice and incorporate information from data outputs and graphs to interpret and identify the object.

Throughout, students generated field notes, discussed what the simulation's structures represented, and often hypothesized what the functions and behaviors of these structures were. For instance, when working with one computer simulation that included only abstract representations, students were able to notice and to coordinate a range of evidence to reason about the identity of each structure based upon its behaviors. However, when asked to create a model after interacting with these simulations, these ideas did not appear in the student-generated models. Instead, students used their models to document their understanding rather than as a tool for reasoning. Finally, by asking focused questions that explicitly considered timing, behavior of the representation, and relations between different phenomenon, the teacher played a key role in facilitating the development of students' observational practices.

Theoretical and educational significance

In this study, we expected that asking questions would be an important strategy for mediating productive observations and learning about complex systems. Our analysis suggested that asking simple what questions were scientifically valuable and initiated a line of inquiry that supported complex observational reasoning. We noted how asking "what is it" questions led students to iteratively observe phenomena, to purposefully notice recurring behavioral patterns, and to reason about complex and dynamic relationships across the system's macro and micro levels. We suspect that certain design features (e.g., abstract forms used in the simulations) necessitated that students closely observe their behavior in conjunction with the graphs in order to identify the structures.

Although research suggests that use of how and why questions that emphasize behavior and function are more scientifically valuable than simple what questions that emphasize identification of structural components, in this case, the use of what questions also appeared to effectively stimulate productive observations and complex reasoning. It was probably critical that the teacher balanced identification questions with more conceptual questions. Pursuing explanations about why the fish are dying seemed necessary for observing complex relationships, and finding connections between the different levels of systems. Finally, the kinds of questions used by the teacher played a key role in the kinds of questions students also asked and their ability to observe phenomena in ways that begin to distinguish scientific from everyday practice. Thus, in sum, this paper adds to our understanding of how systems understanding develops, and how instruction can support it.

PAPER PRESENTATION

Analyzing students' learning pathways to better understand processes of mental model development

Sibylle Reinfried, University of Teacher Education Central Switzerland Lucerne, Switzerland; Sebastian Tempelmann, University of Teacher Education Central Switzerland Lucerne, Switzerland

An analysis of 13-year old middle school students' learning pathways concerning their mental model development of the greenhouse effect and global warming was conducted to better understand mental model construction processes in learners and the difficulties related to them. An explanatory in-depth investigation based on the case study method was employed. An instructional sequence embedded in a pre-posttest design provided quantitative and qualitative data. The instruction used a constructivist learning environment that focused on model evolution and conceptual change and included worksheets, a model experiment, phases of co-construction and one-on-one tutoring interviews. The transcripts of the videotaped student-student and student-teacher co-constructions, students' annotated drawings, their answers to the questions in the questionnaire and the tutoring interviews served as the database. The learning and teaching processes as revealed in this database were depicted in diagrammatic representations that allowed the analysis of the interaction patterns used by the learners to build successive intermediate mental models within the model evolution process. The diagrams demonstrate that during their conceptual change process the

students used prior knowledge as well as sources of ideas based on individual experience, contributions from the learning material and from the tutor. These findings give evidence that mental model evolution can be seen as an interactionist way of learning. Because teachers play a key role in the mental model development process these results are of great importance for teacher education and their professional development.

Background

Prior research has indicated that students of all ages show little understanding of the greenhouse effect and global warming. Detailed inquiry of students' understanding of the greenhouse effect revealed specific alternative conceptions that have proven to be largely resistant to instruction (Reinfried, 2010). Many attempts that have been made to teach the complex concepts of the greenhouse effect and to change learners' pre-instructional ideas were not satisfactory (Kirkeby Hansen, 2010). Based on the principles of constructivist learning theory (e.g. Vosniadou, 2008) and conceptual change theory (e.g. Posner et al., 1992) we developed a constructivist learning environment aimed at inducing a lasting conceptual change. In a quantitative longitudinal study including 289 middle school students, this learning environment caused a relatively persistent knowledge gain in comparison to conventional instruction and proved to lead to a better understanding of the greenhouse effect (Reinfried, 2010).

To better understand (1) how students construct their knowledge and (2) what their difficulties are in understanding the complex greenhouse effect concept, we subsequently conducted a learning process study in which we explored students' learning pathways when studying our constructivist learning environment. We embedded this learning environment into an approach of mental model co-construction, which is, according to Clement & Rea-Ramirez (2008), central to understand how students construct meaning in science. This approach, called 'model evolution approach', includes student-teacher co-construction that builds on students-generated as well as teacher-generated model elements and can be described as functioning within a cycle of model generation, evaluation, and revision.

Research questions

The following research questions were addressed:

- What processes are involved in the construction of mental models concerning the greenhouse effect and global warming?
- What kind of intermediate mental models are constructed?
- What are teachers' and students' contributions to the co-construction process?

Methods

The learning pathways of fourteen students of the 7th grade (Mage = 13 years, 8 boys, 6 girls from a Swiss suburban middle school) were explored in an explanatory in-depth investigation. The case study employed an instructional sequence embedded in a pre-posttest design, providing quantitative and qualitative data. The students' knowledge and mental models of the greenhouse effect before and after the instruction were explored using a questionnaire that included 24 knowledge questions and a request to draw an annotated sketch of how they understood the greenhouse effect. During an instructional session, which took 60 minutes, two students, working in pairs, were guided through the learning process by a tutor. The students worked with worksheets and a model experiment. The instructional techniques included analogies and observations, phases of student-student and student-teacher co-construction and a one-on-one tutoring interview with each learner after the research session. The entire session was videotaped. The transcripts of the videotaped student-student and student-teacher co-constructions, students' annotated drawings, their answers to the questions in the questionnaires and the tutoring interviews served as database. Following the different steps of qualitative content analysis (Mayring, 2008), the video transcripts and students' drawings were interpreted and systematically categorized.

Results

The categorized transcripts and drawings allowed the identification of model evolution phases, discrepant events and the use of analogies, and thereby the observation of each student's model evolution process. The learning and teaching processes involved were depicted in diagrammatic representations. These convey each individual's model construction process and illustrate how a student-teacher co-construction process leads to a model that could explain why carbon dioxide is responsible for the natural greenhouse effect and why increasing carbon dioxide emissions must lead to global warming. As a result of the co-construction process, the students made progress towards scientific ideas but not by replacing or removing their pre-instructional conceptions. They did however integrate new knowledge, construct simple relationships between physical processes relevant to the greenhouse effect and successively add variables to their models, which resulted in evolved and enriched mental models compared with what they had expressed at the outset of the learning process. The diagrams of the learning process provide a view on the interaction patterns that were used to build successive intermediate models within the model evolution process. The diagrams reveal that during their conceptual change process the students used prior knowledge as well as sources

of ideas based on individual experience, contributions from the learning material and from the instructor. Based on these results and in accordance with Clement & Rea-Ramirez (2008) we state that mental model evolution is to be seen as an interactionist way of learning that is an empirically constrained, creative process requiring scaffolding students' reasoning via teacher-student co-construction.

Implications

The results of this study are of great significance for pre- and in-service teacher education. Teachers play a key role during the teacher-student co-construction process by constantly diagnosing students' ideas and encouraging the students to disconfirm, recombine, restructure or tune their ideas and to generate successive intermediate mental models. As a consequence, teaching for deep understanding involves (1) analyzing students' alternative conceptions developed both before and during instruction and (2) finding and coordinating sequences of analogies and dissonance producing events that take these alternative conceptions into account (Clement & Rea-Ramirez, 2008). If teachers learn how to make use of mental model evolution strategies, their teaching for meaningful conceptual change will be more effective.

PAPER PRESENTATION

Number sense in infancy: Individual differences in number discrimination

Annelies Ceulemans, Ghent University, Belgium; Annemie Desoete, Ghent University, Belgium; Sofie Rousseau, Catholic University of Louvain, Belgium; Cecile Guerin, Catholic University of Louvain, Belgium

Number discrimination is considered to be a basic form of number sense. Therefore, number discrimination performances in infants at age 8-11 months and 24 months are explored to detect early differentiation between children. A number discrimination task with different number sets was used. Both group and individual performances as well as the relation between the different performances were of interest.

First, infants completed a habituation task (1 versus 3, 1 versus 4, or 4 versus 8): children saw a number of dots until they were habituated after which the same and a new number were shown in alternation in the test phase. Stimuli were controlled for continuous variables (e.g., total occupied area; individual dot size) and an eye-tracker recorded the children's eye-gazes. Second, a manual search task was given at 24 months, with the same number set as in the habituation task. A researcher hid balls in a opaque box. Children were allowed to retrieve the balls, but in a second trial some balls were surreptitious taken away. Respectively, longer looking and searching at the new number indicates successful discrimination.

The group results of the first moment show that infants discriminate small numbers as well as a small from a large number, but not large numbers. Furthermore, poor performers for each set support the existence of individual differences on number discrimination performances in infancy. Data from the second moment will be available at the conference. Implications and future challenges will be outlined.

Background: Individual differences in number sense are considered to differentiate with respect to mathematical achievement. Although number sense is mostly investigated in preschoolers it is assumed to be present earlier in the form of number discrimination. Individual differences may thus occur from infancy on. Because studies on number discrimination, however, mainly focus on group results, research needs to explore individual differences. This study explored performances of children at the age of respectively 8-11 months and 24 months on number discrimination tasks. Possible number sets were drawn from previous research to cover the full range of possibilities. As such a number set with only small numbers (1 versus 3), one with a small and a large number (1 versus 4) and one with only large numbers (4 versus 8) were selected for this research. The number discrimination tasks were age-appropriate for both research moments. Group performance as well individual performances on the number discrimination tasks were of interest. Furthermore, it was questioned whether a relation exists between the performances at the different

ages. It is hypothesized that poor performers at the age of 8-11 months are still performing poor at the age of 24 months.

Method:

At the age of 8-11-month-olds infants completed one of the three number discrimination tasks according to the habituation paradigm (1 versus 3: $N = 48$; 1 versus 4: $N = 37$; 4 versus 8: $N = 51$). Children saw a number of dots until they were habituated to it. Afterwards, in the test phase they saw in alternating order the same (three trials) and a new number (three trials). This resulted in three test trial pairs including the old and a new number of dots. Longer looking at the novel number is considered to be an indication of a successful discrimination between the presented numbers of stimuli. Stimuli were controlled for continuous variables (e.g., total occupied area; individual dot size). Habit X 1.0 generated the task and an eye-tracking system, Tobii T60, recorded the children's eye-gazes. At the age of 24 months infants received the same number set as they did on the previous research moment. This time a researcher hid balls in a opaque box according to the manual search paradigm. First, children were allowed to retrieve the balls. In a second trial some balls were surreptitiously taken away. A longer searching time after these kind of trials (compared with the first trials) indicates differentiation between the two numbers. The manual search tasks was adjusted to each specific number set.

Results:

Data from the first research moment show a successful discrimination (at group level) for the number sets 1 versus 3 ($F(1,45.669) = 5.182, p = .028$) and 1 versus 4 ($F(1,36) = 1.940, p = .002$) but not for the number set 4 versus 8 ($F(1,50) = 0.107, p = 0.745$) during the habituation paradigm. These findings indicate that infants in this study can discriminate small numbers from each other as well as a small from a large number, but not large numbers. Poor performers (being the children who looked longer at the old number during all test pairs) can be identified for all sets. Data from the second research moment are currently being collected and will be available at the conference.

Conclusions: The identification of poor performers clearly supports the existence of individual differences on number discrimination performances in infancy. Since these individual differences thus occur from infancy on and number discrimination is considered as a basic form of number sense it will be interesting for future research to explore the relationship between these individual performances and later performances on components of number sense which have already been found to be predictive to further mathematical outcome. More specifically, these differences in number sense may be related to individual mathematical differences between children later on. Furthermore, the group results show the importance of exploring the whole possible number range. For each number range poor performers are identified besides non-poor performances indicating that infants do vary in their ability to discriminate each number set.

PAPER PRESENTATION

English elementary school children's beliefs about knowledge

Ruth Kershner, University of Cambridge, United Kingdom; Linda Hargreaves, University of Cambridge, United Kingdom; Sue Bingham, University of Cambridge, England, United Kingdom; Rocio Garcia, University of Barcelona, Spain

This paper presents evidence from a small-scale study of children's epistemic beliefs across the English primary (elementary) school age range (5-11 years). The study aimed to gain a better understanding of developmental change in children's personal epistemology; to pilot and refine a productive dialogic methodology; and to test the application of relevant conceptual frameworks to young children's epistemic beliefs. The premise is that effective, inclusive learning and teaching in school depends on the types of knowledge created and valued in school, home and community. The study draws on existing frameworks of personal epistemology including Schommer-Aikins's (2004) multidimensional belief system. Semi-structured interviews were conducted with groups of 3-5 children from each of seven classes (UK: Reception to Year 6). Data were recorded, analysed and coded inductively. Emerging categories were then compared to existing conceptual frameworks. Preliminary analysis suggests that the 5-11 year old children in this study do identify different forms and sources of knowledge in the school, home, community and beyond. There is evidence of age-related change between year groups. The study has theoretical significance for the extension of existing conceptual frameworks to accommodate children's references to the functions, purposes and values of knowledge, and to different ways to learn. In educational terms, it raises key points concerning the relevance of family and community contexts, and teachers' awareness of their own and their pupils' epistemic beliefs.

Aims and background

This paper presents evidence from a small-scale study of children's epistemic beliefs across the English primary (elementary) school age range (5-11 years). The study aimed to gain a better understanding of developmental change

in children's personal epistemology; to pilot and refine a productive dialogic methodology; and to test the application of relevant conceptual frameworks to young children's epistemic beliefs. The premise is that effective, inclusive learning and teaching in school depends on the types of knowledge created and valued in school, home and community. Children's sources of knowledge beyond the school may be either incorporated or dismissed in formal education, with associated implications for educational achievement. Research on personal epistemology has highlighted the educational relevance of students' beliefs about knowledge and knowing (Bendixen and Feucht, 2010). Our theoretical analysis of English children's epistemic beliefs draws on three conceptual frameworks: Schommer-Aikins's (2004) multidimensional belief system; Hofer and Pintrich's (1997) epistemological theories (noted to have potential connections to conceptual change learning); and Hammer and Elby's (2002) epistemological resources in specific subject domains and contexts.

Methodology

Exploratory research question: How far do children aged 5-11 years in an English primary school identify, describe and value different forms of knowledge in the school, home, community and beyond?

Design and procedure:

The study was carried out in one rural primary school in Eastern England. Written parental consent was gained for the children's participation, within a wider ethical framework (BERA, 2004). A group interview approach was used, drawing on a general sociocultural understanding of how knowledge and epistemic beliefs are created and incorporating elements of Bronfenbrenner's ecological systems theory.

Small groups of 3-5 children from each of seven classes (UK: Reception to Year 6) participated the following: group discussion focusing on 'what children know' in different contexts. The children's ideas were recorded collectively. Further group discussion of knowledge and knowing prompted by a semi-structured interview schedule. Individual activity in which children used a personal systems diagram to record their own ideas about their knowledge in different contexts and how important they think this knowledge is.

The data consisted of taped group discussions and the children's individual and group work (i.e. their writing and drawing). These data were first coded inductively with attention to age-related changes and individual differences within the seven year groups. Emerging categories were then compared to the three conceptual frameworks outlined above for further theoretical consideration.

Findings

Preliminary analysis suggests that the 5-11 year old children in this study do identify different forms of knowledge in the school, home, community and beyond. They express a wide range of epistemic beliefs relating to different types of human experience, domains and contexts, and affective aspects. There is evidence of age-related change between year groups, notably relating to distinctions made between stable 'facts' and more abstract or questioning beliefs about the nature of knowledge in different contexts.

With regard to the theoretical conceptualisation of personal epistemology, we found that the children's statements and conversation called up elements of each model mentioned above and, in turn, potentially extended them. For instance, Schommer-Aikins' framework can be used to map many of the children's espoused beliefs. However her specific belief dimensions of stability of knowledge, source of knowledge, speed of learning and ability to learn were more strongly represented in all the children's talk than was knowledge structure. Hofer and Pintrich's framework similarly applied in relation to the children's ideas about the certainty and the internal/external sources of knowledge, with some evidence of age-related change. Yet little was said about the dimension of simplicity of knowledge and only occasional reference was made to the justification procedures of knowledge (e.g. how knowledge is demonstrated and proved). Both of these frameworks may usefully be extended by the children's references to the functions, purposes and values of knowledge, and to different ways to learn. However further research is needed to gather systematic evidence across all these dimensions, including developmental change.

With regard to Hammer and Elby's framework, the current study was not solely or directly focused on learning specific subjects. Yet the children did offer relevant epistemological activities (such as the value of play) and forms (e.g. information versus knowledge), within their wider discussions of the nature and sources of knowledge in different contexts. Explicit epistemological stances, such as acceptance, puzzlement, and so on, were less evident, although most of the children exhibited a wondering interest in talking about knowledge and knowing in this way. Knowledge resources in different contexts were clearly evident in comparing school and home.

Conclusions

This study provides substantive findings about young children's epistemological beliefs, together with certain methodological and theoretical insights. In particular, it has theoretical significance for the further elaboration of

existing conceptual frameworks. In educational terms, it raises key points concerning the relevance of family and community contexts, and teachers' awareness of their own and their pupils' epistemic beliefs.

PAPER PRESENTATION

Application of Skill Theory to compare scientific reasoning of young children in different tasks

Heidi Meindertsma, Rijksuniversiteit Groningen, Netherlands; Marijn van Dijk, Rijksuniversiteit Groningen, Netherlands; Paul van Geert, Rijksuniversiteit Groningen, Netherlands

In order to study the development of scientific reasoning in children, it is necessary and also challenging to compare performance of children over different tasks and/or situations. In the present study, Skill Theory (Fischer, 1980) is used as a framework for comparative description of the reasoning of children during and between different scientific tasks in a guided interaction with an adult. Fifteen 4- and 5-years old children performed four different tasks (floating/sinking, linked syringes, marble track, balance scale) with four different adults. Two variables were used to record the performance of the children: the correctness of the predictions and the cognitive complexity levels of the given explanations. Results indicate that children show high variability in cognitive complexity level between tasks but also within a task. Although the older children were not significantly better in making predictions, complexity levels were higher in 5 year olds than in 4 year olds. Only in the floating/sinking task, a meaningful relationship was found between prediction and complexity level. Our results demonstrate the importance of the dynamics of the interaction between child, adult and task. Coding the explanations of the children using skill theory can be seen as a good first step in unraveling these dynamics.

Introduction:

In recent years, there has been an increased interest in science education in preschoolers. In order to study the development of scientific reasoning and the effects of science education, the researcher faces the difficult task of comparing performance of children in different tasks and situations. In the present study, Skill Theory is used as a framework of comparative description of young children's scientific reasoning in scientific tasks with an adult. Already in 1930, Piaget described the conceptions of children about physical causality and many other science related concepts. Since then, much attention has been given to the approaches and strategies children use in solving or explaining scientific tasks. For example, Siegler and Chen (1998) and later Jansen and Van der Maas (2002) focused on rule learning in children solving balance scale problems. Tytler and Peterson (2004) characterized the approaches children use in explorative situations by several dimensions, such as nature of exploration and depth of processing. However, these systems are rather specific and thus not always suitable to compare across tasks and conditions. Skill Theory (Fischer, 1980) promises to be a good general framework to classify the explanations of the children (Rappolt-Schlichtmann, Tenenbaum, Koepke, & Fischer, 2007), and thus enables comparison of the competence level of children across tasks and children (Fischer, 1980).

The complexity level is divided into three different tiers: sensory-motor, representations and abstractions (Fischer & Bidell, 2006). Each tier consists of three different levels: single, mapping and system. The highest tier, abstractions, has an additional level called principles. The highest levels will not be reached until early adulthood. As part of its dynamic approach to scientific reasoning, Skill Theory emphasizes the importance of context on the performance level. Also, the performance of children is assumed to be highly fluctuating, leading to high inter- and intra-individual variability in competence (Van Geert & Van Dijk, 2002). In the Netherlands, the educational project 'Curious minds' claims that children in the age of three to six years of age have natural talents in the Science, Technology and Mathematics (STEM)- disciplines: they ask questions, are creative, explore and want to know how something works. The project aims at describing and stimulating the talents of young children in the STEM-disciplines. The importance of context is emphasized by stating that talent can be seen as a process that emerges during real time interactions between child, task and adult, but only if the situation is sufficiently talent-eliciting, open and supportive ((Steenbeek & Uittenbogaard, 2009, p.45). In a previous study, we have argued that the task protocol (specifically, the way this is 'open' or rather 'strict') possibly influences the level of the scientific reasoning.

The present study aims at contributing to unraveling this dynamics by answering the following questions:-

How can the reasoning of children during and between different scientific tasks be characterized?

- What complexity level do 4- and 5-year old children reach in their explanations?
- o How good are the predictions made by these children? o Are there differences in age for complexity level and percentage of correct predictions?
- o How does the complexity level relate to percentage of correct predictions? - How variable is the performance of these children?
- o How variable is the performance between children?
- o How variable is the performance between tasks and conditions?

- o How variable is the performance within sessions?

Method:

Fifteen 4- and 5-years old children performed four different tasks (floating/sinking, linked syringes, marble track, balance scale) in four different conditions; varying from a very strict (test) protocol to no specific instructions (Meindertsma, Van Dijk, & Van Geert, 2010). Two variables were used to record the performance of the children: the correctness of the predictions and the complexity levels of the given explanations. All explanation will be coded as level 3 (sensimotor system). When the child explains one element of the explanatory principles of the task, this is coded as representational/single. Two or more given principles are coded as representational/mapping and a complete explanation is coded as representational/system. The third tier, abstractions, is only reached when a statement about a general rule is made.

Results:

In our study, fourteen children explained at least once at single representational level, although six of them never came higher than this level. Five of them gave an explanation at the level of representational mapping whereas three children reached the first level at the abstraction tier in the floating/sinking task in combination with the strictest protocol. Only one child never made it to the second (representational) tier. Variability was high between and within tasks. Nine children differed more than one level in maximum complexity level between tasks. Only one child reached the same maximal level in all four tasks. Also within a task there was a high fluctuation of performance. The percentage of correct predictions showed the same pattern as complexity level: there was a high variability between children as well as between and within tasks. Although the older children were not significantly better in making predictions, complexity levels were higher in 5 year olds than in 4 year olds ($t = 2.312$, $p = 0.04$). There seems to be clear differences between the conditions/tasks: most children used explanations of higher complexity in the strictest condition (the floating/sinking task) and only here a significant correlation was found between correct percentage predictions and complexity level ($r = 0.707$, $p = .003$).

Conclusion:

These results support the notion of high intra- and inter-variability as predicted by skill theory (Fischer & Bidell, 2006; Van Geert & Van Dijk, 2002). The influence of the context – adult and task – could account for this variability. Many children used explanations of different complexity level, indicating that children do not only proceed through skill levels with age, but can also show short-term progressions within a task, as Fischer and co-workers have claimed (Fischer and Bidell, 2006). Our future efforts will focus on the dynamics of this interaction. Coding the explanations of the children using Skill Theory can be seen as a good first step in unraveling these dynamics.

PAPER PRESENTATION

Different perspectives on the effectiveness of private tutoring in Germany

Karin Guill, TU Dortmund University, Germany; Wilfried Bos, TU Dortmund University, Germany

Parallel to the mainstream education system many students make use of private tutoring to improve their academic achievement. However, evidence about the effectiveness of private tutoring to do so is rare and contradictory. Effects of private tutoring seem, at least partly, to depend on the understanding of academic success. As private tutoring focuses on success in the mainstream education system, positive effects on marks are expected. Positive effects on the broader achievement tests are less likely. These hypotheses are tested in the presented analyses. The data originates from the German longitudinal study KESS ("Competencies and Attitudes of Students") at the beginning of grade 7 and at the end of grade 8. The effect of private tutoring is evaluated on multiple criteria: The majority of the parents ($N = 447$) as well as of the students ($N = 618$) states that private tutoring improved the students' mathematics achievement. In contrast, there is neither a significant improvement of maths marks of tutored compared to non-tutored students (ANOVA with repeated measures, $N = 4701$) nor an improvement in maths achievement test results due to private tutoring when controlling for prior knowledge and school level effects (HLM, $N = 4701$). Effects of private tutoring on the different criteria will be compared and related to the main activities during the tutoring lessons.

Research aim

Parallel to the mainstream education system many students make use of private tutoring. Private tutoring is defined as tutoring in academic subjects in addition to the provision by mainstream schooling (Bray, 1999). While there is growing research about the extension and use of private tutoring there are few empirical findings about the effectiveness of private tutoring to improve academic achievement. In addition, results are contradictory. In a German context, parents and students mostly state their satisfaction with the effects of private tutoring (Abele & Liebau,

1998). Results from a quasi-experimental design are indicating an improvement of marks in school due to private tutoring (Mischo & Haag, 2002). In contrast, regression analyses show that private tutoring has a small but negative effect on the results of a mathematics achievement test (Guill & Bensen, 2010). Internationally, there is evidence for positive (Ireson & Rushforth, 2005; Kulpoo, 1998) as well as for negative (Cheo & Quah, 2005) or even for contradictory effects of private tutoring within the same study (Kenny & Faunce, 2004). The aim of this paper is to clarify the mixed results from earlier studies and to answer the following research question: Does the effectiveness of private tutoring depend on the operationalization of academic success? Do effective and non-effective tutoring lessons differ regarding the main activities during the tutoring lessons? As private tutoring focuses on success in the mainstream education system, positive effects on marks are expected. Positive effects on the broader achievement tests are less likely.

Methodology

The analysed data originates from the Hamburg panel study KESS ("Competencies and Attitudes of Pupils") at the beginning of grade 7 and at the end of grade 8. Missing values are partly imputed. Students stated whether they currently were taking part in private tutoring in mathematics; 13.2 % were doing so at the end of grade 8. Parents stated whether their child had taken part in tutoring during the past two years, which additionally 11.4 % did. Students described how often they did different activities like doing homework or practicing study techniques during the tutoring lessons.

The effectiveness of private tutoring is evaluated based on four criteria:

- 1) the parents' statement about its effectiveness
- 2) the students' statement about its effectiveness
- 3) improvement of maths marks at the end of grade 8
- 4) better results of tutored compared to non-tutored students in the KESS 8 mathematics achievement test.

Findings

76.7 % of the parents agree that private tutoring improved their child's performance in mathematics, 23.3 % disagree (N = 447). Students with effective and non-effective private tutoring report no significant differences regarding the main activities during the private tutoring lessons (N = 296 to 317, t test). 80.4 % of the students agree that private tutoring improved their performance in mathematics, 19.6 % disagree (N = 618). Students with effective private tutoring report repetition of earlier lessons, preparing tests and debriefing previous tests, and checking of their homework during the private tutoring lessons significantly more often than students with non-effective private tutoring (N = 386 to 416, t test, *p). Improvement in math marks due to private tutoring are analysed by group comparisons between students with and without private tutoring. In a two-way ANOVA with repeated measures (within subject: Term 1 vs. term 2 in grade 8; between subject: tutoring vs. no tutoring) the interaction term *tutoring is not significant (p = .058) when controlling for motivational covariates as interest, self concept, and anxiety (N = 4701). 18.6 % of the tutored students improved their mark, 81.4 % did not improve their mark (N = 618). Students with effective and non-effective private tutoring report no significant differences regarding the main activities during the private tutoring lessons (N = 386 to 416, t test). When analyzing effects of private tutoring on achievement test results, controlling for prior knowledge, socioeconomic status, gender, and especially for school level characteristics is important as tutored and non-tutored students differ systematically in these characteristics and are unequally allotted between different school tracks. Therefore, hierarchical regression analysis (HLM) are used. Even then, the main effect of private tutoring is negative (N = 4701). Further analyses are in preparation.

Theoretical and educational significance

Students' and parents' satisfaction with the effects of private tutoring stands in obvious contrast to the absent effects of private tutoring on the more objective criteria marks and especially test results. There are two possible explanations: Firstly, activities such as checking the students' homework and debriefing previous tests might give the students an illusion of competence without a real improvement in situations without the tutor's assistance. Secondly, general achievement tests as well as marks might be too vague a measure to capture small improvements in achievement by private tutoring. For further analyses, more detailed information about teaching and learning processes during the tutoring lessons should be taken into account, for example by analysing teacher-student dialogues. A more detailed diagnosis of the students' achievement development is desirable. For educational practice, these findings indicate that private tutoring often not succeeds in solving school achievement problems. Parents and students opting for private tutoring should be advised to evaluate its success critical, if possible on objective criteria, instead of relying on a general impression that it seems to help.

PAPER PRESENTATION

School Curriculum Development to Improve Students' Strategy Use: Focusing on Diagrams Use in Math

Emmanuel Manalo, Waseda University, Japan; Maiko Takahashi, The University of Tokyo, Japan; Ryuji Mine, Hitachi, Ltd., Japan; Atsushi Maki, Hitachi, Ltd., Japan; Yuri Uesaka, The University of Tokyo, Japan

Although many studies have indicated that using diagrams is a powerful strategy for problem solving, research and educational practices have revealed that students do not use this strategy spontaneously despite frequently receiving instructions with the use of diagrams in class. This lack of spontaneity means that many students do not obtain the benefits of diagrams use that have been demonstrated in previous research. There are studies that have proposed teaching methods to address this problem, but these methods are not fully integrated within the school curriculum. This paper reports on the development of an instruction and support program to promote students' spontaneous use of diagrams as part of a school curriculum. The program (2 days, 2 x 50mins in each day) was provided to first grade students of a public junior high school (n=34) in Japan as a part of math course. Teaching approaches that previous studies have found as effective in promoting spontaneous diagrams use were employed in the program. Other students in the same grade (n=72) took other equivalent instructional programs dealing with other skills. To evaluate the effect of the program, pre-tests and post-tests were conducted 3 months before and after the program respectively. The results showed that improvement in spontaneity of diagrams use was significantly higher among students in the first group compared to the other groups. This finding indicates that teaching approaches to promote spontaneity in students' strategy use, that have been developed through experimental studies, can successfully be implemented in ecologically valid contexts.

Introduction

Many previous studies have demonstrated that diagrams are powerful strategies for problem solving (e.g., Cheng, 2002; Larkin & Simon, 1987; Mayer, 2003). However, studies relating to educational practices have suggested that students do not use diagrams effectively as teachers and researchers do. One of the main problems is lack of spontaneity: many students try to solve problems in their head and do not construct diagrams spontaneously, despite the fact that they frequently receive instructions with the use of diagrams in class. Recent studies examining students' behaviors when solving math word problems (e.g., Uesaka, Manalo, & Ichikawa, 2007; Uesaka, Kiyokawa, & Ichikawa, 2010) have confirmed this tendency, suggesting that many students do not obtain the benefits of diagrams use that have been demonstrated in previous research. To address this problem, some studies have examined factors influencing, and teaching approaches for promoting, students' use of diagrams. For example, Uesaka et al. (2007) found that students tend not to use diagrams because they perceive diagrams as "tools for teachers' instruction" rather than "their own tools for problem solving". In addition, Uesaka, Manalo, and Ichikawa (2010) demonstrated that a combination of teacher explicit instruction about the efficacy of diagrams use, and practice in constructing diagrams, promoted students' spontaneous use of diagrams because these manipulations enhanced perceptions about the usefulness of diagrams as their own tools, and diagram construction skills, respectively. Uesaka and Manalo (2007, 2008) provided another perspective: that setting a learning circumstance, where students collaboratively communicate with diagrams and experience peer teaching in a small group, increases the subsequent spontaneous use of diagrams. As most of the studies described above have been undertaken in the context of psychology or diagrams research, these have had little influence on real day-to-day instructional practices in schools. However,

incorporating the effective approaches that previous studies have revealed into the school curriculum would seem desirable as that would likely result in benefits to student development of learning skills. The present study, therefore, attempted to develop a program to improve students' spontaneous use of diagrams in a school setting.

Method

The program was provided to first grade students of a public junior high school ($n=34$) in Japan as a part of math course. The program consisted of 2 days, with 2 x 50-minute lessons in each day. Other students ($n=72$) in the same grade of this school took equivalent instructional programs dealing with other skills. The authors developed the instructions provided on the basis of findings from previous studies. For example, based on the findings by Uesaka et al. (2010), teaching approaches that enhance perceptions of the efficacy of diagrams use and diagram construction skills were both included. Moreover, based on the findings of Uesaka and Manalo (2007, 2008), the classes provided ample opportunities for students to experience peer teaching with diagrams in small groups. The two days proceeded as follows. The first day focused mainly on enhancing students' views about the efficacy that results from incorporating diagrams as tools within their own personal repertoire of learning strategies. The instructor demonstrated the efficacy of diagram use in solving a math word problem. To promote deeper understanding of this efficacy, the instructor provided other problems for the students to solve with and without using diagrams. Finally, working in small groups, the students were provided three other math word problems and asked to find the most effective diagrams for solving them. Diagrams proposed within the groups were shared in the class. On the second day, the purpose was to develop diagram drawing skills as well as to continue enhancing perceptions of the efficacy of diagrams use. Horizontal bar charts were focused on as these are popularly used in Asian countries for solving algebraic problems (e.g., Koedinger & Terao, 2002) but many students find them difficult to use. Firstly, the instructor demonstrated how to draw and use horizontal bar charts when solving algebraic problems. Secondly, the students were asked to solve similar problems in small groups. Finally, the instructor provided a task, in which the students were asked to make a new math problem which can be solved with the use of a horizontal bar chart. Pre- and post-instruction assessments were administered 3 months before and after the program. In these assessments, the participants were asked to solve math word problems. As one of the main objectives of the assessments was to gauge students' spontaneity in using diagrams, the teacher did not say anything that could influence the approaches that they used in attempting to solve the problems.

Results and Discussion

The students' responses to each of the problems given during the pre- and post-instruction assessments were coded. Firstly, they were coded according to whether a "diagram was used (1)" or "no diagram was used (0)". Secondly, the quality of the diagrams the students produced were coded according to a rubric whether appropriate diagrams to use in solving each of the problems were used. To examine differences between the programs provided to the students, a covariant analysis of variance (ANCOVA) (with the numbers of problems in which diagrams were used at pre-instruction as the covariant) was carried out on the numbers of problems in which students used diagrams at post-instruction. The results showed that the improvement in spontaneous use of diagrams among the students who took the diagrams-related program was significantly higher than other students ($F(1, 104) = 3.96$, $p = 0.048$, $p = 0.002$). These findings indicate that teaching approaches which have been revealed as effective in promoting spontaneity in students' strategy use through experimental studies can successfully be implemented in ecologically valid contexts.

PAPER PRESENTATION

Effects of instructions on economics students' critical thinking

Anita Heijltjes, Avans Hogeschool, University of applied sciences, Netherlands; Tamara Van Gog, Erasmus University Rotterdam, Netherlands; Fred Paas, Institute of Psychology, Erasmus University Rotterdam, The Netherlands, Netherlands

Although critical thinking (CT) is considered to be a central goal in economics education, it is rarely explicitly taught and educators are often unsure how to foster CT throughout the curriculum. An experimental study will be presented investigating the impact of CT instructions on economics students' CT development. CT development was operationalized as gains in inductive and deductive reasoning skills. Participants ($N=183$) were exposed to one of four conditions: CT instruction, CT instruction combined with self-explanation prompts, CT instruction combined with activation prompts and a control condition (irrelevant instruction). Results show that participants exposed to the CT instructions gained more from the pre-test to the immediate post-test than participants in the control condition. This effect lasted on the delayed posttest with inductive reasoning skills but not with deductive reasoning skills. There were also differences between the experimental conditions: Participants in the self-explanation condition significantly outperformed participants in the CT instruction condition on inductive reasoning on the immediate test, although this effect disappeared on the delayed test. CT dispositions, especially actively open-minded thinking, correlated positively with all tests scores, and with CT development in inductive reasoning skills.

Introduction

Against the background of complex and rapidly changing business environments, economics students are expected to become critical thinkers (Chonko, 1993; Klebba & Hamilton, 2007; Smith, 2003). Critical thinking (CT) enables students to make sound logical and unbiased decisions and often leads to better learning and transfer outcomes (e.g. Facione, 2009; Halpern, 1998; Helsdingen, Van Gog, & Van Merriënboer, in press). It is therefore surprising that CT is rarely explicitly taught (Jones, 2007). The existing CT literature is predominantly descriptive and pays limited attention to the effectiveness of CT instructions (Abrami, et al., 2008; Wolcott, et al., 2002). Hence the present study aims to empirically examine the effects of CT instructions on economics students' CT.

During reasoning, two thinking systems, referred to as system 1 and system 2, can be at work (Evans, 2003; Stanovich, 2009). System 1 has a rapid, automatic nature and requires little reflection, while system 2 is slow in nature and requires the exclusion of attention to other matters. Using system 1 reasoning might result in thinking errors, unless system 2 overrules these automatic responses by explicit reasoning efforts like CT. These reasoning efforts are presumably affected by dispositions (West, Toplak, & Stanovich, 2008), and may have to be explicitly taught (Abrami, et al., 2008). The teaching method used here consists of CT instructions and subsequent application of these instructions to domain content, either with or without prompts. We hypothesized that 1) CT instruction with prompts (either self-explanation or activation prompts) would foster acquisition of CT skills compared to CT instruction without prompts, which would be better than no CT instruction at all, and that 2) participants with higher scores on dispositions (actively open-minded thinking and need for cognition) would score better on CT development than participants with lower scores on these dispositions. CT development was operationalized as pre-test to posttest learning gains on inductive reasoning skills and deductive reasoning skills.

Method

Students (N=183), from an economics department within a Dutch University of Applied Sciences, were randomly assigned to 4 conditions: control (n= 40), instruction (n=46), instruction plus self-explanation prompts (n=47), instruction plus activation prompts (n=50). CT was measured by a pre-test, an immediate post-test and a delayed post-test. All tests consisted of deductive and inductive reasoning tasks selected for their heuristic tendency (adapted from e.g. Tversky, A., & Kahneman, D.; West, et al., 2008). After the pre-test participants completed a dispositions test consisting of a Dutch translation of the Actively Open-Minded Thinking Scale (Stanovich & West, 2007) and the Need for Cognition Scale (Cacioppo, et al., 1996). Thereafter participants in the experimental conditions were exposed to a 15 minutes CT instruction, while the control group watched a short film unrelated to CT. Then all participants worked on a business case that allowed them to practise some of the instructed heuristic reasoning skills; participants in the prompting conditions were asked to self-explain how they arrived at the answer, or their memory of the instructions was activated by hints about relevant task aspects. Subsequently participants performed a post-test comparable to the pre-test. After three weeks they completed a similar delayed post-test (n=76). CT learning gains were measured by subtracting pre-tests scores on inductive and deductive reasoning skills from the immediate and delayed post-test scores.

Findings

In line with our first hypothesis, on the inductive reasoning skills, an ANOVA showed an effect for instructional interventions on learning gains in both post-tests (immediate post-test $F(3,179) = 20.52$, $p = .000$, delayed post-test $F(3,72) = 5.03$, $p = .003$). Post-hoc tests showed that participants exposed to the instruction significantly outperformed the control group on both post-tests. Moreover, participants in the 'instruction plus self-explanation prompts' condition outperformed participants in the instruction only condition on gains in inductive skills on the immediate test. This effect was extinguished on the delayed test however. On deductive skills, learning gains were also significantly higher for all instructional conditions compared to the control group on the immediate post-test ($F(3,179) = 6.81$, $p = .000$). However, this effect was not found on the delayed post-test ($F(3,72) = 1.75$, $p = .164$). Moreover, we did not find any effects of prompting on deductive reasoning skills.

In line with our second hypothesis participants with lower (+1 SD) scores on actively open-minded thinking differed significantly on learning gains on the immediate post-test ($T(84) = -.220$, $p = .031$) and the delayed post-test ($T(19) = -2.46$, $p = .024$), in favour of the higher achievers. Dispositions, especially the actively open-minded thinking scores, significantly correlated with the CT pre-test scores and post-test scores (pre-test $r = .31$, immediate post-test $r = .40$ and delayed post-test $r = .33$).

Additional analyses showed that instructed and practised skills led to significantly better results than instructed but not practised skills, in inductive and deductive reasoning on both post-tests (note that not all skills were practised on the business case).

Discussion

Although participants in all instruction conditions benefited from the CT instructions, these only had a lasting (i.e., > 3 weeks) impact on inductive skill development, not on deductive skill development. Possibly, the business case allowed for practicing inductive skills more than deductive skills. Adding self-explanation prompts to the instruction only yielded better inductive reasoning results, and only on short term. Because the prompts were given during the business case, this might also be a consequence of the case, which probably allowed more for practicing inductive rather than deductive skills. The lack of longer-term effects may be due to the short exposure to the prompts. Adding activation prompts which focused attention on task relevant factors and inhibited attention to irrelevant factors did not show additional benefits on gains compared to CT instruction only, which is rather surprising. Participants' dispositions, especially actively open-minded thinking were correlated positively with CT and gains in CT. Also brief explicit CT instructions on heuristic inductive and deductive reasoning have positive effects. Future research might unravel why effects of CT instruction differ on inductive and deductive (heuristic) reasoning tasks, to what extent additional practise might be necessary, and whether dispositions as actively open-minded thinking could be affected by instructions, especially for students scoring lower on these dispositions.

PAPER PRESENTATION

The Development of Inductive Reasoning Skills from Grade 1 to Grade 11

Gyongyver Molnar, University of Szeged, Hungary; Beno Csapo, University of Szeged, Hungary

In educational assessment growing attention has been paid to the developmental perspective of cognitive abilities, however, most of the measurements still focus on single measurement points. Inductive reasoning is such ability. In the past years, we carried out several cross sectional assessments to study the development of inductive reasoning. This paper synthesizes the results of these assessments and outlines the developmental tendencies and student level differences of inductive reasoning. Altogether, nine age groups from grade 1 to 11 were assessed by means of several inductive reasoning tests containing a large number of common anchor items that allows the transfer of all results to the same scale. Rasch-model was used for scaling the data. Large differences were found at individual and cohort level as well, while the developmental speed is relatively slow, at about one quarter standard deviation per year. The fitted logistic curves indicated a rapid change around grade 7; then the speed of development got slower. The differences at student level in the same grade are getting larger when older age-groups are considered. At the end of compulsory schooling the difference is more than threefold of what is computed at school entrance. Findings support the views that there exist differences equivalent with several years of development within the same age groups in the field of a general cognitive ability.

Theoretical framework

In new educational assessment models and projects growing attention has been paid to the assessment of cognitive skills and competencies and to the comparison of different aged students' achievement by bringing their results to a common scale (sees Lazer, Mazzeo, D. Way, S. Twing, Camara, and Sweeney, 2010). A broad age range can only be covered with different tests, containing a number of common anchor items. IRT models offer the possibility to express all test results on the same scale.

Inductive reasoning is one of the basic components of thinking (Csapo, 1997). Several studies have focused on inductive reasoning from different perspectives, with different techniques, with different contexts (Tomic, & Kingma, 1998), but usually in laboratory conditions and not in developmental perspective regarding a wider age range.

Aims

The crucial questions that arise when we look at the assessment of inductive reasoning include how students' inductive reasoning develop over time during compulsory schooling and what kind of developmental differences occur between students in the same cohort.

In this paper we

- (1) synthesize the results of the cross-sectional studies carried out on a nationally representative sample;
- (2) place the scaling into a developmental context, by expressing the achievements of the different age groups on the same scale;
- (3) express the competency level differences between students in the same cohort in developmental years.

Methodology

This paper synthesizes studies aiming at different cohorts regarding inductive reasoning. Every sample involved in these analyses is representative for the school population of Hungary. The sample for the studies was drawn from 1st and 4-to-11 grade students (age 6 to age 17). The total number of participants is about 75 000.

The instruments of the studies were pencil and paper tests that varied by grade. The different tests were connected by common anchor items. Test for first graders was developed directly for young learners; i. e. special attention was paid to the non-verbal character of the test. The tests for higher graders are comprised of letter series, number analogies, verbal analogies and number series tasks altogether. Regarding the item types, each test comprised both open-ended and multiple-choice items, altogether 109 items.

The Rasch-model was used for scaling the data and plausible values (PV) and weighted likelihood estimation (WLE) were computed to compare the achievements of the age groups and to obtain individual level point estimates. Besides the Item Response Theory, several means of Classical Test Theory were computed and logistic curve estimation was made to predict the point of inflection and the growth rate.

Educational and scientific importance

Most of the researches on inductive reasoning focused on one measurement point; however, skills and competencies can be studied from a developmental perspective as well. Therefore, we decided to develop a test battery for a broader age-range, from age 6 to 17, that is applicable in educational context. Data allows the construction of inductive reasoning competency scales for a broad age range that describes students' development during the years of compulsory schooling and indicates student level differences in the same grade.

Analysis and results

The reliability indexes (Cronbach- α) for the inductive reasoning tests are between .86 and .94. The item difficulty parameters vary from -2.30 to 3.78, while the mean person parameters are between -1.16 (sd=1.19 for grade 1) and 1.37 (sd=1.17 for grade 11). The difficulty level of the items fit most students' ability level. This item bank is appropriate and valid to measure student's inductive reasoning level from grade 1 to grade 11 in an educational context.

Across all grades, development of inductive reasoning is obvious; however, the developmental speed is relatively slow, at about one quarter standard deviation per year and changing between different grades (see Figure 1). The slowest development (.12) is noticeable from grade 9 to 10 (age 16). The fastest development (both .5) happens from grade 6 to 7 and 9 to 10; it is more than twofold of what is computed in average from school entrance to school leaving. According to the fitted logistic curves the point of inflexion is at the age of 12.9, meaning that a significant change in growing occurs in grade 7, the accelerating growing slows down in this competence field.

The differences at student level in the same grade are getting larger when older age-groups are considered, at the end of compulsory schooling there are more than threefold differences of what is computed at school entrance. Students with the highest ability level differences are 10th graders, where the average difference between the 10% of the lowest and the highest achiever is 7.74 logit. If we assume that 2.53 logit development happens within the analysed period of 10 years in average, this difference corresponds to 30 year developmental log between the highest and the lowest achievers in this age group.

There are first grade students with inductive reasoning ability level of higher achiever 11 graders and on the other way round, there are 11 graders with reasoning skill level of a lower achiever first grader. The difference between students with the lowest ability level (-5.55) and the highest ability level (6.70) in the sample is more than four times higher than the differences between the mean achievers in grade 1 and grade 11. The standard deviations regarding different age groups do not change over time.

Findings of the present paper do support the views that claim that there exist differences measurable in several years within the same age groups in the field of a general cognitive ability and the development is expressible and comparable on the same developmental scale.

PAPER PRESENTATION

Reading and reasoning about uncertain science issue: An eye-movement analysis

Fang-Ying Yang, National Taiwan Normal University, Taiwan, Province of China; Meng-Lung Lai, National Chiayi University, Taiwan, Province of China; Meng-Jung Tsai, National Taiwan University of Science & Technology, Taiwan, Province of China

The objective of the study is to explore the reading and reasoning behaviors of university students when they encounter a news report concerning the issue of earthquake prediction. We employ the eye tracking method to record subjects' visual attentions on different parts of a news report which show the components of scientific argumentation including claim, warrant, data and theory (Tulmin, 1958). By comparing the visual attentions with subsequent reasoning modes, we hope to obtain a more in-depth picture about how the online cognitive processes and text comprehensions may interfere the practice of argument skills. The study is still in progress. Currently, 14 eye-movement samples have been collected. More eye movement data and reasoning analysis will be presented in the conference. Some preliminary findings are summarized as follows. First, the data of average fixation durations show that participants distributed much of their reading time to statements regarding Data (mean=0.35s). Warrant, Backing and Rebuttal (0.27s) received less time. Statements regarding Claim (0.21s) did not gain too much attention. Second, according to Table 1, LBK students seemed to pay more attention on the data and rebuttal statements. Third, the saccade durations (i.e. total time not fixed) of LBK students were significantly higher, which suggested that LBK subjects were more likely to be disoriented when reading unfamiliar texts. Moreover, it was found that those who changed their positions after reading the news report showed significantly higher fixation durations on Data. The average fixation duration on Rebuttal was higher too.

Objective

The objective of the study is to explore the reading and reasoning behaviors of university students when they encounter a news report concerning the issue of earthquake prediction.

Background rationale

The improvement of argument skills is a central goal of science education (Duschl & Osborne, 2002). Studies investigating students' argument skills have reported that the practice of argument skills is mediated by domain-specific background knowledge and personal epistemological beliefs (e.g. Duschl & Osborne, 2002; Kuhn et al., 2008; Yang & Tsai, 2010; Zimman, 2000). According to the problem-solving paradigm, background knowledge affects the construction of the problem representation (Newell & Simon, 1972). Therefore, to study peoples' argument skills, it is necessary to disclose how they perceive the problem/issue to be argued.

As far as representing the encountered problem is concerned, it has a lot to do with individual's reading and comprehension when the problem and associated information are written in texts. As Gee (2000) pointed out, readers construct mental representations of texts in accordance with the surface structure of the text, readers' prior knowledge, and the concurrent experiences in the sociocultural context. Different problem representations will lead to different problem solving outcomes. In literature related to the reading of science texts, most studies focus on discussing text structures (e.g., Broek & Kendeou, 2008; Kendeou & Broek, 2007), the effects of psychological factors (e.g., Quian & Alvermann, 1995; Lehman et al., 2007) and associations with academic performance (e.g., Reilly & McNammar, 2007). Nevertheless, no study probed how different ways of text reading and comprehension would affect reasoning when people encounter problems or issues in newspapers, magazines or on-line resources.

Thus, in the study, an attempt is made to explore the interaction between reading and reasoning behaviors displayed by university students when they encounter an uncertain science issue in newspapers. We employ the eye tracking method to record subjects' visual attentions on different parts of a news report which show the components of scientific argumentation, including claim, warrant, data and theory (Toulmin, 1958). By comparing the visual attentions with subsequent reasoning modes, we hope to obtain a more in-depth picture about how the online cognitive processes and text comprehensions may interfere the practice of argument skills.

Methodology

Subject

Participants of the study are 25 university students who are in science related majors. About half of them in earth science major are assigned to High Background Knowledge (HBK) group because the target issue is earthquake prediction. The rest belong to the Low Background Knowledge (LBK) group.

Instrument

This study employs FaceLAB 4 eye tracking system developed by Seeing Machines Company, Australia. This apparatus is a non-intrusive and fully automated eye and head tracking instrument. The data rate is 60Hz.

Reading material

A news report concerning whether earthquakes are predictable was selected from the data base of a renowned news media in Taiwan, Chinatimes, as the reading material. The report contains two contrary viewpoints held by different expert groups. One group of experts claimed that some certain kind of fish can predict earthquakes, while the other group argued that the predication is impossible even in next 20 or even 30 years. Both groups provide data and explanations to their arguments. To facilitate reading, the whole issue is divided into 5 on-screen pages. Each page consists of no more than 230 Chinese characters. For the purpose of examining readers' attentions on different parts of text, the reading material is divided into several 'Lookzones' (i.e. areas of interest) that indicate 'Claim,' 'Data,' 'Warrant,' 'Backing,' and 'Rebuttle.' Two coders deciphered the reading material and the inter-coder agreement is over 0.9. The remained difference was solved through discussions.

Interview

To probe students' reasoning modes, participants receive interviews before and after the eye-movement investigation. They are asked to take sides between two different expert groups and provide reasons for their choice.

Data analysis

The eye-movement data are analyzed by the GazeTracker software also provided by Seeing Machines. The outputs of the GazeTracker analysis include number of fixations, total reading time, average fixation duration, saccade duration (time spent during two adjacent fixations), fixation positions and durations in a LookZone, etc. Figure 1 shows two examples of eye movement paths. In the figure, the black circles indicate fixation positions and the rectangle areas are the Lookzones.

Students' interview responses are analyzed through the content analysis. The ability of coordinating theory and evidence as well as reflective reasoning are the main coding targets.

Procedure

The study is carried out mainly by the FaceLAB system. Participants are asked to read the material displayed on the computer screen according to their own pace. The FaceLAB records concurrently eye movements during reading. Before and after reading the issue, students are interviewed to probe their thoughts about the target issue.

Result and discussion

The study is still in progress. Currently, 14 eye-movement samples have been collected. The average fixation duration for HBK was 0.27sec while LBK 0.30. The average numbers of fixation count for HBK and LBK were 139.75 and 130.5 respectively. The average fixation duration for HBK students was 0.28 second and 0.30 for LBK subjects. Some preliminary findings are summarized as follows. First, the data of average fixation durations show that participants distributed much of their reading time to statements regarding Data (mean=0.35s). Warrant, Backing and Rebuttal (0.27s) received less time. Statements regarding Claim (0.21s) did not gain too much attention. Second, according to Table 1, LBK students seemed to pay more attention on the data and rebuttal statements. Third, the saccade durations (i.e. total time not fixed) of LBK students were significantly higher, which suggested that LBK subjects were more likely to be disoriented when reading unfamiliar texts. Moreover, it was found that those who changed their positions after reading the news report showed significantly higher fixation durations on Data. The average fixation duration on Rebuttal was higher too.

Conclusion

According to the eye-movement collected at this far, university students showed different cognitive approaches to process the uncertain science information. The approaches were apparently related to their knowledge background. The study is in progress. More eye-movement data and the analysis on students' reasoning modes and will be presented in the conference.

Note: Complete references will be included in the full paper.

PAPER PRESENTATION

Taking a Reader's Perspective Improves Argumentation in Students' Writing

Kristin Schmidt, University of Freiburg, Germany; Matthias Nuckles, University of Freiburg, Germany

The aim of this study was to investigate how writing can facilitate critical thinking. Following Kuhn (1992), we defined critical thinking as "internal argumentation". As people tend to exhibit a "my-side" bias and avoid considering different points of view, we asked participants to imagine specific audiences during writing in order to distance themselves from their own point of view and to consider an alternative position. Using this instruction, we expected to help students reach a higher quality of argumentation. We asked 80 participants to write an argumentative text either to

(1) themselves, (2) pupils, (3) peers, or (4) experts and to take the perspective of their assumed readers. Thus, we varied the expertise-level of the fictional audience. Participants received detailed instructions on how to write an argumentative text. Results showed that writing for different audiences had an effect on the quality and quantity of arguments and their integration into an evidence-based final conclusion. Differences between a writer's and the imagined reader's level of knowledge facilitated the generation of different arguments. A high expertise of the imagined audience promoted the integration of different arguments and counterarguments into a final conclusion. This study showed that a rather minimal instructional aid, that is, the task of imagining a specific audience during writing, improved the quality of a written argumentation.

Theoretical background

The ability to think critically is important for an active participation in a pluralistic and rapidly changing society wherein people have to deal with conflicting information. Critical thinking involves the illumination of conflicting information with the help of argumentative support and contradiction. Thus, the essence of critical thinking is argumentation. Unfortunately, even adults rarely achieve the normative ideal of argumentation (Nussbaum & Schraw, 2007). They tend to interpret all information in a way that fits their preexisting beliefs and expectations (Nickerson, 1998), a phenomenon that is called "my-side bias". Instructions which are designed to support the generation of alternative arguments and counterarguments, for example diagrams, have a small effect on argumentation skills. These instructions rather provide memorization aids for important elements of argumentation than help to distance from preexisting beliefs. By contrast, taking a specific perspective seems to be a process that invites people to distance themselves from their existing mental models and to modify them. The exploration of a topic from another point of view may help people acknowledge previously neglected facets of an issue. Hence perspective-taking can reduce "my-side bias" and thereby improve argumentation. Accordingly, new ideas could become part of the writer's mental model. In our study, we investigated the effect of an imagined reader's level of expertise during writing and its effect on the facilitation of argumentative writing.

We hypothesized that

- (1) perspective-taking is more effective for written argumentation when the writer and the imagined reader are dissimilar because a different point of view is more likely to stimulate the construction of more varied arguments.
- (2) the greater the knowledge level of the imagined audience, the more complex the integration of arguments and counterarguments will be, since integration is an indicator for expertise. As the expertise level of the writer is stable, the expertise level of the reader is suspected to have an influence.

Methodology

Eighty preservice teachers with an average age of 23.1 years ($SD = 2.82$) were assigned to one of four conditions: writing an argumentative text either to (1) themselves, (2) pupils, (3) peers, or (4) experts. As the audience was fictional, the students had to imagine the potential readers and their attributes based on their prior knowledge and personal experiences. The task was to write about possible causes for conduct disorders. The students first received written instructions on how to write an argumentative text. They were encouraged to develop arguments and counterarguments in order to explore the issue and to develop a final conclusion. In each condition they had one hour to plan and develop their texts.

The data analysis was based on the argumentative texts. All texts were rated by two independent raters ($ICC = .92$). The expressed argumentation skills of the students were the dependent variables in the study. The number of primary claims (opinions on the main issue), arguments (claims supported with evidence) and counterarguments (arguments that refute others) and the integration of the different arguments into a final conclusion were analyzed. The final conclusion is a result of weighing different arguments. It was rated on a 5-point Likert-Scale based on Kuhn's epistemological theory (Kuhn, 1991). The lowest score indicates that alternative arguments were assimilated in an absolutist way suggesting that only one detectable, correct answer exists. The highest score indicates an evaluative stance with multiple alternative arguments judged reflectively by consideration of situational aspects.

Results

Participants were motivated to engage in the topic. All of them produced some ideas as to what aspects can cause conduct disorder. The average text length was 3686 signs ($SD = 1407$). Text length was a statistically significant predictor of the number of primary claims, $F(1, 75) = 15.85$, $p F(1, 75) = 22.18$, p

To test the first hypothesis, namely the positive effect of an imagined, dissimilar reader, on the construction of different arguments, we conducted a contrast analysis (Rosenthal & Rosnow, 1985) with number of signs as a covariate. The contrast weights of the experimental conditions were assigned as follows: self: -1; pupils: 1; peers: -1; experts 1 (with positive values indicating a higher degree of dissimilarity between writer and imagined reader). The tests proved to be statistically significant for primary claims, $F(1, 75) = 6.30$, $p F(1, 75) = 6.58$, $p F(1, 75) = 0.36$, n.s.,

partial $\eta^2 = .01$. We can conclude that perspective-taking was more effective for argumentation when writer and imagined reader were dissimilar.

To investigate the second hypothesis, the influence of the imagined reader's knowledge level on argument integration was examined. As we expected argument integration should increase with imagined reader's level of knowledge, we computed a linear trend contrast with the following contrast weights: pupils: -1; peers: 0; experts 1. The test of this contrast proved to be significant, $F(1, 76) = 4.83$, p

Conclusion

Writing to different audiences had an effect on the quality of argumentation, the essence of critical thinking. As predicted, the greater the difference between the knowledge level of the writers and their presumed readers, the greater the number of different arguments writers produced on the issue at hand. It can be speculated that taking the perspective of an imagined dissimilar reader supported the writer in "perceiving" arguments that would otherwise have been neglected when looking at the topic only from one's own point of view. The greater number of different arguments thus suggests that perspective taking counteracted the "my-side bias". The results indicated that students were able to integrate arguments and counterarguments depending on the imagined audience, although previous research found that students often fail in integration tasks. Our study showed that a small instructional add-on, the disclosure of an audience, was able to influence the performance on an argumentative writing task.

PAPER PRESENTATION

The development of students' logical operations and deductive patterns between grades 5 and 9

Tibor Vidakovich, University of Szeged, Hungary

The aims of the research were (1) to construct tests for the evaluation of logical operations and deductive patterns of students; (2) to diagnose the status of these logical structures among grade 5, 7 and 9 students; and (3) to examine the influence of the development of logical operations on the development of deductive patterns. For the assessment of the most frequent logical operations and deductive patterns of students, two parallel tests were constructed. The tests were administered to about 5,100 students. Improvements in the means of logical operations were significant between grades 5 and 7, and lower, but still significant between grades 7 and 9. The results of conjunction were the best, while those of disjunctive operations were lower. The most problematic operation is the conditional. The development of deductive patterns showed similar tendencies. Students' performances were the best in the tasks of modus ponens and modus tollens. The results of disjunctive syllogism were lower, and those of transitive syllogism were the lowest. The correlations between operational and deductive tasks were significant in most cases. For grade 5 and 7 students, higher correlation values were found in the cells of the exclusive-or and disjunction, while for grade 9 students, correlation values were higher in the cells of biconditional and conditional. The analysis of developmental processes revealed some parallel tendencies in the development of logical operations and deductive patterns. But the influence of the development of logical operations on the functioning of deductive patterns could not be unambiguously verified.

Objectives

A crucial question concerning students' deductive reasoning is how they understand logical operations and deductive patterns in textbooks and in teachers' oral explanations. Difficulties in understanding logical structures can hinder students' learning, and their academic progress, in general. The aims of our investigation were: (1) to construct tests for the evaluation of the most frequent logical operations and deductive patterns; (2) to diagnose the status of these logical structures in three groups of students (in grades 5, 7 and 9); and (3) to examine the hypothesis that the development of logical operations has a significant influence on the development of deductive patterns.

Theoretical background

Research on students' logical structures has been popular for decades, not only in psychology, but also in educational research. Since Piaget's works, operations of propositional logic have been playing an important role in the research of deductive reasoning (Inhelder and Piaget, 1958). Investigations focused primarily on conditionals (Wason and Johnson-Laird, 1972), though a small number of studies have been conducted on the development of the whole system of two-variable logical operations, as well (Johnson-Laird and Byrne, 1991). The main directions of research included the development of logical operations, typical errors when interpreting logical structures (e.g. Johnson-Laird, 2005). The relevant publications of the 2000's suggest that the interpretation of quantifiers may play an important role in syllogistic reasoning (e.g. Roberts, Newstead and Griggs, 2001). Context and content factors, prior knowledge and beliefs have significant effects on deductive reasoning (Evans and Feeney, 2004). These factors can profoundly influence the functioning of several components of deductive reasoning, e.g. that of conditionals (Dieussaert, Schaeken and d'Ydewalle, 2002) and quantifiers (Newstead and Coventry, 2000). Empirical research in this field has

concentrated on logical operations and deductive patterns. But there have been only few large-scale assessments conducted to map the development of the components of deductive reasoning (Vidákovich, 2005), although the information on developmental tendencies is important in fostering deductive reasoning.

Methods

Two parallel tests were constructed for assessing students' logical operations and deductive patterns. Each one included three subtests, one for assessing frequently used operations of propositional logic (conjunction, exclusive-or, disjunction, biconditional and conditional), and two for assessing frequently used deductive patterns of propositional and predicate logic (modus ponens, modus tollens, disjunctive syllogism, transitive syllogism). The tasks of logical operations contained a complex statement, with one of the logical operations, and four pairs of facts, representing the truth table of the operation. Students had to circle the letter of those pairs that matched the complex statement (Vidákovich, 2005). The tasks of deductive patterns contained two complex statements (premises), and the first part of a third complex statement (conclusion). Students had to finish the third statement so that the conclusion should be valid. The tests were administered to about 5,100 students; 2,100 from grade 5, 500 from grade 7 and 2,500 from grade 9. Although students were selected from volunteering schools, the sample sizes allow us to draw generalizable conclusions. The reliability parameters of the tests were fairly good for all sub-samples (Cronbach's alphas about or above 0.9). The task types in the two test versions were the same, and their results were also very similar.

Results

Improvements in the means of the logical operations were significant between grades 5 and 7 (p). The performances in the individual tasks reflected the same tendency, except for the task of conjunction. The results of this operation were relatively high (91%) already in the grade 5 sub-sample. The results of disjunctive operations were lower, especially in grade 5. In grade 9, achievements of disjunctive operations were much better. The most problematic operation was the conditional. Students' achievements in the conditional task were poor (50%, 55% and 58% for the three sub-samples). These results show that the development of this operation is slower than that of other operations. These results are concordant with the results of previous studies (Vidákovich, 2005). The development of deductive patterns seems to follow the tendencies found in the tasks of logical operations. Significant development takes place both between grades 5 and 7 (p). Students' performances in individual tasks followed similar tendencies, with significant differences. The results were the highest in the tasks of modus ponens and modus tollens (between 77% and 94%), the achievements in propositional tasks were better than those of predicate tasks (p). The correlations between operational and deductive tasks were significant (p). EDUCATIONAL RELEVANCE According to our results, the most significant development of logical operations and deductive patterns takes place before adolescence. The analysis demonstrated that there are some parallel tendencies in the development of logical operations and deductive patterns. There were significant, but not striking correlations between the development of logical operations and that of deductive patterns. In spite of these, our hypothesis, that the development of basic logical operations influences the results of deductive patterns, can not be unambiguously verified on the basis of the results.

PAPER PRESENTATION

Development in relations between time perspectives, delay of gratification and learning environment

Thea Peetsma, University of Amsterdam, Netherlands; Jaap Schuitema, University of Amsterdam, Netherlands; Ineke van der Veen, University of Amsterdam, Netherlands

After they start secondary school (at age 12 in the Netherlands), students' time perspectives on school and professional career and their self-regulated learning decrease, while their time perspectives on leisure increase. Some schools have implemented innovative learning environments to enhance motivation and learning. Possibly in schools with an innovative education concept, where learning is more related to students' experience and the relevance for themselves, the developments in time perspectives and learning are different. In this study we aimed to investigate the relations in the developments in time perspectives and delay of gratification in the first two years of secondary education. In addition, the dependence of these relationships on students' perceptions of the relevance of their learning was investigated. Also differences in academic school level, and gender were included in the analyses.

648 students participated in the study. A self-report questionnaire for time perspectives, on short and long term, academic delay of gratification, and students' perceptions of the learning environment was administered four times: at the start and after six months of the first and second school year. The results indicate that students' short term perspective on school and professional career was positively related to developments in students' delay of gratification and students' long term perspective on leisure was negatively related to delay of gratification. We also found a positive relationship between students' perceptions of the learning environment and the development of their future time perspective and delay of gratification.

Aim

Time perspectives are regarded as predictors of students' learning behaviour (e.g. Lens, 1986; Peetsma & Van der Veen, in press). Time perspectives on a school and professional career showed positive relations with their learning behaviour, as students' delay of gratification (Bembenutty & Karabenick, 1998), while future time perspectives on leisure showed negative relations.

Unfortunately, a decline in school motivation of young adolescents is a well-known phenomenon. This decline came across in various countries (Peetsma, et al, 2005). The phenomenon was a reason for some schools to implement innovative learning environments to enhance motivation and learning (Waslander, 2004). It was expected that schools where learning is more related to students' experience and the relevance for themselves, the developments in time perspectives and learning are different, but little longitudinal research is known.

In this study we aimed to investigate the relations in the developments in time perspectives and delay of gratification in the first two years of secondary education in the Netherlands (students of age 12-14). In addition, the dependence of the relationships between time perspectives and delay of gratification on students' perceptions of the learning environment was investigated. Also differences in school year, academic school level, and gender were taken into consideration. Understanding of the interrelations might be helpful preventing declines in motivation for school.

Theoretical background

The decline in motivation from the start of secondary school has been explained by a lack of 'person-environment fit', that is a poor integration of young adolescents in the school environment (Midgley et al., 1989; Roeser et al., 2000). Also developments in future time perspectives might be of influence (Peetsma, 1997; Peetsma & Van der Veen, in press). Students' time perspective on school and professional career became less important while future time perspective on leisure time did grow in importance. Future time perspective is generally described as a representation or conceptualization of a particular life domain in terms of time, characterized by "extension" and "valence" (see, e.g., Gjesme, 1996; Husman & Lens, 1999). Extension indicates the degree of remoteness of the representation in time. For students, "the time after finishing school" and "the current school year" seems to be meaningful long and short terms in time. The valence of the future time perspective indicates the value ascribed to a life domain in the future. The appreciation expressed by a person with respect to a certain life domain in the future plays an essential role in defining the concept of future time perspective as a motivational variable. Peetsma (1992) included an affective component in the concept of time perspective. She conceptualized time perspective in terms of three components (i.e., affect, cognition, and behavioural intention) aimed at a certain life domain. Cognition consists of ideas or expectations with regard to the future, and of knowledge of social realities. Affect is conceived of as an expression of feeling or general affect towards a particular life domain in the future, whereas the targeted behaviour in the future as behavioural intention.

Academic delay of gratification is regarded as an indicator of students' learning behaviour. The concept refers to students' postponement of immediately available opportunities to satisfy impulses in favor of pursuing chosen important academic rewards or goals that are temporally remote but ostensibly more valuable (Bembenutty & Karabenick, 1998).

A main characteristics of innovative learning environments proved to be the relatedness of learning to the students' worlds (Oostdam, et al, 2006). If students perceive what is being learned as relevant to their own lives, it might reduce the lack of fit between them and their schools. It seems important for teachers to help students understand the relevance of learning tasks to themselves and to relate the content to their prior knowledge. Possibly, in schools where learning is more related to students' experience and the relevance for themselves, the developments in time perspectives and learning behaviour are different.

Method

648 students in secondary education participated in the study. The students were from all academic levels of secondary education and at the start of the study the students were on average 12 years old.

A self-report questionnaire was administered four times: The first at the start of secondary education, the second half way through the first year, the third measurement at the beginning of the second year and the fourth half way through second year. All items in the questionnaire were rated on 5-point Likert scales.

Time perspectives on a school and professional career, and leisure time on short and long term were measured with four scales (24 items) of the TPQ (Peetsma, 1992). To measure the emphasis given by teachers to the relevance of what is being learned we combined three items from the TASC (Belmont, Skinner, Wellborn & Connell, 1988) with three items of a scale measuring 'connection to students' worlds' adapted from Thoonen, Slegers, Peetsma and Oort (2010). All scales showed sufficient to good reliabilities in this study.

The data were analysed using multivariate Latent Growth Curve Analyses (LGCA) with Mplus (Muthén & Muthén, 2007). The rate and level of growth of the five variables were examined and related to each other. To investigate differences in the rate and level of growth of the different variables and whether the relationships of the level of growth in the variables in the model differed between groups, a multi-group LGCA was performed with groups being students in school year 1 vs 2, traditional vs innovative schools, three academic levels of secondary education and boys vs. girls.

Results

The data of the first two measurements in the first year of secondary education have been analysed. The results indicate that students' short term perspective on school and professional career was positively related to developments in students' delay of gratification. Students' long term perspective on leisure was negatively related to delay of gratification. We also found a positive relationship between students' perceptions of the learning environment and the development of their time perspectives and delay of gratification. In the paper we include the analyses of the third and fourth measurement.

PAPER PRESENTATION

Determining Factors Influencing Attitudes Regarding Sciences : Case Study of Quebec Youth

Ghislain Samson, Université du Québec à Trois-Rivières, Canada

Youth interest and motivation regarding science and technology is both a political and academic concern. As a result, we have endeavored to examine these concerns from our students' perspectives. First, preliminary results are presented. An inquiry based on questionnaires and interviews has been conducted over a two-year span, involving various schools in Québec. Supporting Osborn, Simon and Collins (2003) and Toussaint (2004), our preliminary results seem to demonstrate that interest and motivation decrease in certain cases during the transition from elementary to high school. In other cases, interest and motivation remain high until adulthood. Secondly, we compare our results from Quebec with other countries. These comparisons will take gender differences into account. Thirdly, we provide various suggestions to encourage students at all levels to pursue science and technology (S&T). More importantly, we encourage students to continue to pursue their post-secondary schooling and training. Many Canadian and American projects suggest that interdisciplinary methods contribute to heightening motivation and interest regarding science and technology for both students and teachers.

Problem –

The science and technology (S&T) courses in high schools aim to develop a basic techno-scientific culture in all students. This is not the reality. Many inquiries and reports, such as PISA (2007), expose various difficulties regarding S&T learning among students. In Canada, the view on scientific culture is based upon four main principles. The fourth one specifically addresses attitudes. In response to this lack of student interest regarding science (Versailles, 2003), it seems that this motivation decreases as the students progress in school (Osborne, Simon et Collins, 2003; Toussaint, 2004).

In a knowledge-based economy where science and technology are being implemented in schools, students' attitudes regarding techno-scientific disciplines becomes an important question throughout their schooling.

Aims/Objectives -

This study's general objective aims to better understand the determining factors, particularly the attitudes (concept considered vague and complex in the literature) that encourage or discourage our youth in choosing S&T pathways. Specifically, two goals are pursued: 1) Document, based on a literature review, the concept of attitudes in science with students, from elementary school to college; 2) Determine, using validated tools, the representations, interests and attitudes of students towards science.

Methodology –

The participants are from schools in the Mauricie and Centre-du-Québec (Canada) area. (Two schools P, two schools S, and two schools C). These establishments were chosen based on their proximity and/or previous relations in other current projects. Using computerized research instruments such as databases, we did a literature review pertaining to the attitude concept, particularly in the context related to science and technology courses from elementary school onward (Obj.1). Also, we established a description of the interests and attitudes of Québec students enrolled in schools in these two regions (Obj.2).

Data collection –

In an exploratory descriptive study (Van der Maren, 1995), we used two methods to collect our data: 1) questionnaires (Thibert, 1980; Menis, 1989; Karsenti, 1998; Toussaint, 2004); and 2) focus groups. The questionnaires had open-ended and multiple-choice questions allowing us to collect information on different aspects: P, S and C were used to evaluate students' representations, interests and attitudes (Toussaint, 2004) regarding science and technology. At least 150 students participated. To better describe and understand the factors influencing the students' attitudes towards techno-sciences and to complement the data retrieved in the questionnaires, group interviews were conducted. Based on previous work on focus groups (Greenbaum, 2000; Krueger and Casey, 2000), interviews with three groups were scheduled to explore in greater detail aspects of the questionnaires. Each group included six to ten participants (one in elementary school, one in high school and one in college - Obj.2). The questions comprised in the focus group protocol are based on the results from the questionnaire. All discussions were taped and transcribed for analysis.

Data analyses –

Data from the multiple-choice questions was quantitatively analyzed (descriptive statistics, correlations and factor analysis). Data from the open-ended questions, from questionnaires and focus groups, was analyzed, using both quantitative and qualitative techniques (Larose et Lenoir, 1995; Scelles, 1997), as well as content analysis methods (Bardin, 2001; Paillé et Mucchielli, 2003). Students' attitudes towards science and technology in school as well as in their daily lives, including career orientation, were particularly considered during the analyses.

Results –

The repercussions of this study are of different natures. First, an update of the research related to attitudes directly associated with the interest towards science and are indirectly associated with the techno-scientific culture. This study also allows us to better understand how students perceive techno-sciences, and how it is perceived with regards to their future schooling or even career in science. Our preliminary results regarding self-efficacy, proactive learning strategies, scientific learning values, goals related to school performance and academic achievement as well as a stimulating environment for learning, confirm these results, such as those of Osborne, Simon et Collins (2003) and Toussaint (2004). Some, however, are more nuanced. Finally, among the other repercussions of this project, the instruments used (questionnaires and focus-group protocols) can be reused in other projects.

Discussion and Conclusion- In the United States, the GREEN (Global Rivers Environmental Education Networks) project contributes to integrated problem solving in real and current situations. Therefore, some authors, such as Stapp (2000), consider interdisciplinarity as a motivational source since it increases student interest as well as teacher interest. Also, interdisciplinarity helps create links and reinforces relevance in learning. What if schools could contribute in making S&T learning more relevant in a dynamic and realistic context where students would be proactive?

PAPER PRESENTATION

To Keep the Golden Mean - Curvilinear Relationship between Interest and Physics Performance

Konstanze Jenderek, Goethe-University Frankfurt, Germany; Regina Vollmeyer, Goethe-Universität, Germany;
Anita Puttmann, Goethe-University Frankfurt, Germany

Deci and Ryan (2000) suggested the more topic-related input given by an instruction the more interest will be evoked. So we hypothesize firstly that an instructional manipulation would have an influence on interest. Furthermore researchers (e.g., Denissen, Zarrett, & Eccles, 2007; Tobias, 1994) have repeatedly tested a linear relationship

between performance and interest. However, Heckhausen (1989) presumed a curvilinear relationship between motivation and performance. So we hypothesize secondly a quadratic relationship between interest and performance. In our school experiment (N=94) we created three groups by inducing low, middle and high interest, by giving three different instructions and presenting different numbers of pictures with text. As a manipulation check we used the FAM-interest scale (Rheinberg, Vollmeyer, & Burns, 2001). Students studied a learning programme on torque lasting thirty minutes. Performance was measured through a knowledge test. The manipulation was not effective. Univariate variance analysis indicated that the manipulation did not affect interest, $F(2, 92) = .99$; $p = .38$. Though, interest impacted performance as we will show by discussing the second hypothesis. Results of a curve regression confirmed the quadratic relationship between interest and performance. First, we regressed performance on interest in a quadratic model explaining 11% of the variance ($p = .0030$). Second, we regressed performance on interest in a linear model not explaining significantly amounts of variance ($R^2 = .02$, $p = .23$). We found a reverse U-shaped relationship between interest and performance ($b = -1.32$, $p = .0030$), middle interest predicts highest performance, low and high interest predict lower performance. Further results and implications will be discussed.

Deci and Ryan (2000) suggested the more topic-related input is given by an instruction the more interest will be evoked. Therefore we expected in our first hypothesis that presenting more relevant information would have an influence on induced interest as well as on performance. Furthermore, researchers (e.g., Denissen, Zarrett, & Eccles, 2007; Randler, & Bogner, 2007; Schiefele, & Schreyer, 1994; Tobias, 1994) have repeatedly expected and found a linear relationship between learning performance and interest. However, Heckhausen (1989) presumed there could be a curvilinear relationship between motivation and performance. And therefore we predicted that working on a computer learning task in the context of three different levels of interest-inducing instructions would lead to a quadratic relationship between interest and learning performance, taking into account that interest is conceptualized as a component of motivation.

In our second hypothesis we expected a curvilinear relationship between interest and learning performance. We conducted an experiment comprising N=94 students from six classes of the 10th high school level. First, we created three experimental groups inducing (1) high, (2) middle and (3) low interest levels. We manipulated interest by presenting three different sets of instructions and showing different number of coloured, topic relevant pictures (zero versus four versus eighteen pictures) as well as topic relevant text. To test manipulation we used the FAM-interest scale (Rheinberg, Vollmeyer, & Burns, 2001). Other variables like previous knowledge, age and gender were controlled. In the main part of the experiment students studied a computer based learning programme on torque that lasted thirty minutes. Performance was measured using a knowledge test afterwards. First of all we checked whether the manipulation was effective. However, it did not work as it neither affected the FAM-interest, $F(2, 92) = .99$; $p = .38$, nor performance in the knowledge test, $F(2, 92) = .53$; $p = .59$. Only descriptive data supported weakly the expectations regarding the manipulation. As expected students receiving high level interest instruction showed greater interest ($M = 3.14$, $SD = 1.00$) than students under middle ($M = 3.01$, $SD = 1.27$) as well as under low ($M = 2.75$, $SD = 1.11$) interest instruction. To test the second hypothesis we employed curve regression analysis, which then was confirmed. First, we regressed physics performance on interest in a quadratic model, which explained 11% of the variance, $F(2, 92) = 5.41$, $p = .0030$. Second, we regressed the physics performance on interest in a linear model, which did not significantly explain enough of the variance ($R^2 = .02$, $F(1, 93) = 1.45$, $p = .23$). Furthermore the negative beta coefficient revealed that the relationship between interest and performance is reverse U-shaped ($b = -1.32$, $p = .0030$). We learned through this that average interest correlated highest to the physics performance, while low and high interest correlated with lower physics performance.

The results of this study are considered to be important for science as well as practically. Our first hypothesis has to be rejected. There was no support for Deci and Ryan's (2000) suggestion to manipulate interest through number of relevant information. Nevertheless, results confirmed the second hypothesis. Our findings question the traditional view of the relationship between interest and performance which is commonly thought to be linear. This research hopes, therefore, to provide an alternative perspective.

Future research should continue examining this curvilinear relationship e.g., to replicate this quadratic model on the one hand or to reject it on the other hand. Furthermore, the results have implications for education taking into account the effects of written instructions as they obviously have an impact on students' interest. By understanding the factors that may lead to an improved or poor student performance, teachers could improve their results by keeping to the golden mean. This means teachers could improve students' learning ability by not under or over motivating them. Nevertheless, the reasons why high interest leads to poorer performance than average interest remain unanswered. As yet, we do not understand what happens cognitively to cause this decline in performance when interest is high. Further results and implications will be discussed.

PAPER PRESENTATION

A quantitative and qualitative perspective for characterize the attitudes of primary school students

Orit Ben Zvi -Assaraf, Ben Gurion University of the Negev, Israel, Israel; Chagit Tishler, Ben Gurion University of the Negev, Israel; Shoshana Agranovich, Ben-Gurion University of the Negev, Beer Sheva, Israel., Israel

This study examines attitudes to school science classes amongst primary school children. Data was collected through a combination of quantitative and qualitative research tools, joined together to form a picture that draws on the benefits of both. 1298 primary school students in grades 4-6 were given a Likert-type questionnaire and asked to provide verbal explanations for their agreement/disagreement with each item. The items were divided into three "clusters," representing three central influences on student attitudes: "motivational factors", "locus of control" and "relevance". Our results revealed such things as the extent to which students value class discussion as a motivation to learn science, the importance of self-efficacy in determining how students' perceive their mastery of the material, and the role curiosity and a feeling that the material is relevant plays in students' willingness to learn it.

Theoretical Background

Science today is an integral part of the Western world and its culture. Unfortunately, the rising importance of science in students' lives is not necessarily reflected in their awareness of it, or in their desire to learn. To date, only a relatively small body of work has been devoted to assessing these attitudes amongst students still in primary school. However, as early as three decades ago researchers showed that age 8-13 is a crucial period in the development of attitudes towards science. Further research showed that a positive attitude to learning science has extensive ramifications for motivation to learn science. Attitudes towards learning science developed in primary school, it seems, influence the choices and decisions made by students later in their life.

Research Goals and Questions

This study aims to characterize the attitudes of primary school students towards learning science. The study offers a new perspective of the attitudes of elementary school students, combining quantitative and qualitative research tools to form a picture that draws on the benefits of both. We ask the following about students' attitudes towards science: Which motivational factors influence them?

2. How does locus of control impact them?
3. How do students assess the relevance of their science studies?

Population

1298 primary school students in grades 4-6, from twenty primary schools throughout Israel, representing different lifestyles (town, village, agricultural).

Research Tools

A questionnaire beginning with 12 Likert-type items, with the answers to each item also being explained in free writing. The second part included 8 semi-structured items relating to the same topics, designed to obtain additional data written by the children themselves. On the one hand, the qualitative tools provide in-depth data about the personal perceptions of every individual student. On the other, the size of the population and the data produced by the questionnaires provide a large sample that more accurately indicates which characteristics are more important to the population, and which explanations of their attitudes recur most frequently.

Results

The results are divided into three "clusters," corresponding to the three factors addressed in the research questions.

1. Motivational factors.

Data for this cluster was drawn from the following items in the questionnaire:

- 1* I enjoy science classes because we have interesting discussions about science-related topics.
- 2* I enjoy science classes because the teacher and students do experiments
- 3* I'm not really interested in the science we learn in class
- 4* I do not enjoy science classes, because I don't like class discussions
- 5* Science topics we learn in class are usually very interesting to me

Results showed that most students see class discussion as interesting (49.8% agreed with statement 1). The most common explanation for this was "because it is a funner way to study science." Nevertheless, it is noteworthy that only 5.5% of the students cited discussion as the source of interest in class, and only 9.6% see it as a good and efficient way of conducting a science class. The most common model arising from students' explanations is reading in the textbook combined with teacher's explanations (reported by 37.8%), and discussion of scientific topics conducted by the teacher (39.3%). Interest in the study topics is a key part of students' motivation to learn science, as shown by statement 3 (55.8% disagreement). This is also supported by such explanations as "this year we learned many interesting things."

2. Locus of control

Locus of control is considered a significant factor in creating a meaningful learning process. It was addressed in items 6 through 9:

6* If I don't understand a science concept, I'll turn to the teacher for an explanation

7* I feel that I have a good command and understanding of the science topics we learn

8* I take an active part in science classes and answer the teacher's questions orally

9* I take part in class discussions and express my opinion

52.7% of the students agreed with item 7; 40.8% agreed with item 8; 52.6% agreed with item 9. Explanations suggest that the main motive defining students' mastery of the subject is self-efficacy: "I know and I understand, I've got excellent perception!", "I feel that I know it well". Explanations for item 9 showed self-efficacy as a crucial factor in students' decision to take part in class discussions: "I know I've got a lot to contribute to the discussion and that's why I always answer and speak out", "I'm not a big shot in science..." Another factor addressed in explanations is their method of studying: "I listen in class and learn," "yes, because I study at home."

Aside from self-efficacy, the teacher is portrayed as a significant figure in the learning process (79.8% agreement with item 6). Explanations show that students perceive the teacher as a source of knowledge and authority: "yes, because he knows how to help with difficulties!" "yes, because she understands it best and can help me," "because when the teacher explains, I understand the material."

3. Relevance

This cluster was addressed by questionnaire items 10 through 12:

10* Science topics that I learn in school are important because they help me understand different phenomena in the world around me.

11* During science classes we deal with topics from everyday life.

12* Science topics we learn in class are not related to real life.

Studies have shown that primary school children find the materials learned in science more relevant than older students do. Our population found them highly relevant (77.4% agreement with item 10; 46.7% with item 11). Explanations show the importance of science as a central component in the students' interest: "it's fun to learn important things." Another recurring factor in their explanations was curiosity, "science lessons help me understand phenomena that I've wanted to understand for a long time."

The results emphasize the teachers' role in encouraging and accepting student autonomy and create a comfortable atmosphere for student expression, within a community of learners engaged in activity, dialogue, and joint thinking of topics relevant to them.

PAPER PRESENTATION

Subjective Theories of Students becoming Teachers about their Professional Identity.

Cindy Grzanna, TU Dresden, Germany

Against the background of partially dramatic and of continuous transformation of teaching in the last two decades and against the background of facing ongoing developments in society it seems to be essential to know more about the states of teachers' identities and its causes and effects to improve professional development of students becoming teachers.

Researching teachers' professional identity is problematic concerning definition of the construct of identity, and time frame, problems and influences of professional identity development. In the course of working life professional identity can change repeatedly and sometimes dramatically. The development of professional identity already starts with studies at university, and not at first with the occupation as a teacher. To solve the problems of research a detailed analysis is needed guided by following questions:

1. Which detailed state of professional identity exists after studies at university?
2. Which factors mainly influence the development of students' professional identity?
3. Which intentions of professional acting exist due to the developed professional identity?

Research partners were 14 VET-teacher students at the stage of the very end of their university study that also had passed an internship at school. Students' identity characteristics were identified according to the multi-layered model of identity regulation by Hauper (1995). Multi-relational semantic networks of students' professional identity were reconstructed by a so-called structure laying technique. The individual networks were analyzed with regard to the characteristics of the identity, and its causes and effects by a categorical and a structural content analysis. Based on

the identified intentions of professional acting existing due to the developed professional identity longitudinal studies with students becoming teachers on different stages can help to improve professional development.

Background and Research Questions:

Researching teachers' professional identity is problematic concerning definition of construct of identity, and time frame, problems and influences of professional identity development. In the course of working life professional identity can change repeatedly and sometimes dramatically. The development of professional identity already starts with studies at university, and not at first with the occupation as a teacher. To solve the problems of research a detailed analysis is needed guided by following questions:

1. Which detailed state of professional identity exists after studies at university?
2. Which factors mainly influence the development of students' professional identity?
3. Which intentions of professional acting exist due to the developed professional identity?

Theoretical Background

According to Haupers' (1995) model of identity regulation, identity is a multi-layered construct. In the narrower sense, identity is composed of three components: self, self-esteem and locus of control. The characteristics of these components result from the processing of several singular experiences which need to be individually meaningful, and affecting. These experiences are integrated, and thus form a professional identity which is valid across several situations, and thus is called over-situational identity. Both, singular experiences and over-situational identity function as motivational source for professional behaviour, professional acting and professional experience. Consequently, identity leads to professional behaviour and/or acting and/or experiencing. This, in turn, is a prerequisite and starting point for the prospective perceptions of individually meaningful and affecting experiences.

Design and Methodology

Research partners were 14 VET-teacher students at the stage of the very end of their university study that also had passed an internship at school. Students' identity characteristics were identified according to the multi-layered model of identity regulation by Hauper (1995).

Data were gathered by interviewing the research partners. The main ideas of each interview were reconstructed as a multi-relational semantic network, composed of concepts and named relations between the concepts. For that purpose, a so-called structure laying technique was used. The resulting networks were validated in the course of a dialogue between interviewer and research partner aiming at coming to a common understanding and to a consensus about the adequacy of the semantic network. The initial network reconstruction was modified partly in this process of validation.

Data analysis followed an idiographic approach. On the ideographic level the individual networks were analyzed with regard to the characteristics of the identity and its causes and effects. Therefore, both a categorical and a structural content analysis were conducted in order to make the individual networks comparable among each other with regard to their content and structure.

Results

As result of the content analyses the identity characteristics of the 14 students were identified. Due to the developed professional identity the intentions of professional acting were differentiated. This mountain of data is not part of this paper.

Beside the three components of over-situational identities (self, self-esteem and locus of control) the situational identities by self-perceptions, self-evaluations and facets of personal control of the practical experiences were analysed. Thus, it is proved that internships in schools are most meaningful and affecting for students' professional identity. Thus, the practical experiences in internships in schools are the factor that mainly influences the development of students' professional identity.

In particular the facets of personal control experienced in internships in school are surprising. Personal control is divided into attribution, anticipation, and influence of situational experiences in a retrospective view (Hauper, 1995). In this study situational experiences in internships in school were divided into sitting in on classes/observations, preparing lectures, and teaching. Concerning preparation of lectures, and teaching, the students see themselves mainly able to attribute, anticipate, and influence their situational experiences. Also attribution and influence of sitting in on classes/observations is mainly seen as possible by the students. So students seem to be well prepared to a great extend for their internship by university studies or other practical experiences.

Only the anticipation of sitting in on classes/observations is dispersing among the interviewed students. The anticipation of sitting in on classes/observations is dispersing from no anticipation over a partially anticipation to a fully anticipation. On the one hand students for instance are barely able to anticipate teachers' methods, and differences between pupils because of lacking experiences at their stage of becoming teachers. And on the other hand they i.e. see themselves able to anticipate differences between teachers observed in sitting in on classes/observations because these meet their expectations. So anticipation of sitting in on classes/observations depends on students' expectations.

Consequently in order to prepare future students to their internship in school they need to be informed about conditions that are likely to be expected. A handbook of diagnosed likely conditions supports students besides helping hands in terms of teacher mentors and school principals.

Conclusion and Relevance

Researching teachers' professional identity development at the stage of the university studies allow to draw first conclusions of causes and effects of teachers' professional development. Identified intentions of professional acting existing due to the developed professional identity of teacher students are an important starting point for longitudinal studies in this research field. Thus, identity characteristics, its causes and effects can be analyzed for trainee teachers in a lectureship at VET-schools and VET-teachers with different years of practical experiences to improve professional development.

The results allowing to draw conclusions how students becoming teachers at the stage of finished university studies are aware of and ready to cope with continuously changing working life. Based on the longitudinal study, it is possible to trace changes or routines in identity over time and find out whether changes in identity occur and thus whether professional flexibility is likely. Consequently, it will be possible to very precisely determine links for teacher training at universities and during continuous education and by that sustainable improve professional development.

PAPER PRESENTATION

Investigating Knowledge Convergence in Computer-Supported Collaborative Learning with Video Cases

Jan Zottmann, University of Munich, Germany; Karsten Stegmann, University of Landau, Germany; Christof Wecker, University of Munich, Germany; Frank Fischer, Universität München, Germany; Freydis Vogel, Munich, Germany

Collaborative case-based learning is ascribed high potential with respect to the education of pre-service teachers as well as the further education of more experienced in-service teachers. Knowledge convergence is considered an important outcome of collaboration when homogeneous benefits are desired for all learners.

An empirical field study with 29 pre-service teachers and 25 in-service teachers was conducted to examine the following research questions:

(RQ1) To what extent does teaching experience affect learning processes regarding knowledge convergence in computer-supported collaborative case-based learning?

(RQ2) To what extent does teaching experience affect learning outcomes regarding the acquisition and application of conceptual knowledge as well as knowledge convergence in computer-supported collaborative learning?

(RQ3) To what extent are knowledge convergence and knowledge acquisition related? This study was implemented in the context of a 4-day teacher training that included individual and collaborative phases of case-based learning.

A new approach to measuring knowledge convergence was introduced using the positions of annotations (i.e., little flags placed on the time bar of the video) made by learners during their case analyses of the cases. Results show that teaching experience had indeed a strong influence on processes and outcomes of case-based learning: particularly the pre-service teachers benefitted from the training. In-service teachers should eventually be supported with instructions that help them to apply conceptual knowledge to cases.

PAPER PRESENTATION

Fostering the analytical competency of pre-service teachers in a computer-supported case-based learning environment - a matter of perspective?

Alison Kearney, Massey University, New Zealand

Many countries around the world are pursuing inclusive education systems at all levels, including the early childhood, school and tertiary sectors. This paper focuses on the school sector, and explores the proposition that a major barrier to inclusive education is a lack of teacher knowledge and understanding. It draws on data from recent studies to show that lack of attention to teacher learning in the area of inclusive education contributes to the exclusion of students from minority groups' experience – exclusion both from and within schools. Recommendations for teacher learning, both pre-service and in-service are explored.

Many countries around the world are pursuing inclusive education systems at all levels, including the early childhood, school and tertiary sectors. This paper focuses on the school sector, and explores the proposition that a major barrier to inclusive education is a lack of teacher knowledge and understanding. It draws on data from recent studies to show that lack of attention to teacher learning in the area of inclusive education contributes to the exclusion of students from minority groups' experience – exclusion both from and within schools. Recommendations for teacher learning, both pre-service and in-service are explored.

Teacher learning, and teacher knowledge are important considerations in the exclusion or inclusion of students from minority groups. This is for two main reasons. First, teachers often report a lack of knowledge and skills as a factor impeding their ability to successfully include these students in their classes (Kearney, 2009; Marshall, Ralph, & Palmer, 2002). Second, research consistently shows the importance of appropriate teacher attitudes and values for successful inclusive education and that teacher learning and knowledge can play an important part in developing these necessary beliefs and attitudes. For example Avramidis, Bayliss, and Burden (2000) and McDonald and MacArthur (2005) report that professional development and learning in the area of inclusive education can have a positive effect on developing teacher attitudes conducive to the facilitation of inclusive education. Similarly, Praisner (2003) found a correlation between school principals' involvement in professional development and learning about inclusive education, and their positive attitude to disabled students. Those with positive attitudes were more likely to provide a more inclusive education whereas those with negative attitudes were more likely to provide restricted education.

However, recent research in New Zealand reveals that while there is general agreement and understanding of the importance of teacher learning and teacher knowledge as a facilitator of inclusive education, there is also confusion and ambivalence regarding how this 'plays out in reality' with few school leaders pursuing programmes of teacher learning and professional development in this area, and a lack of consistency and valuing of inclusive education in initial teacher education programmes. For example, in a New Zealand study that sought to uncover barriers to inclusive education (Kearney, 2009), the majority of school principals responding to a questionnaire believed that successful inclusive education required knowledgeable and skilful teachers, with 65% believing it to be vital. However, when asked to provide a level of agreement with the statement 'to facilitate inclusion, we focus on increasing the capacity and capability of teachers', over 45% of the same respondents indicated that they did not do this. This discrepancy indicates some confusion or ambivalence regarding the important role played by competent teachers with regards to inclusive education.

Similarly, results from studies investigating the place of inclusive education in initial teacher education (ITE) programmes found that the majority of ITE providers did not have clearly articulated policy around inclusion within their qualifications, and that there was limited evidence of the degree to which ITE programmes responded to the literature on inclusive education. (Kane, 2005). Similar results were uncovered in another New Zealand study where McDonald and MacArthur (2005) reported that most teachers in New Zealand have come through initial teacher education programmes where the papers focussing on inclusive education were optional.

What then should be the nature of teacher learning and professional development in this area? This paper argues that it is not necessarily the widely held belief that this knowledge should take the form of special skills strategies around special interventions – research shows that there is little or no evidence that these are required to teach in inclusive education settings (Mittler, 2000; Thomas, Walker, & Webb, 1998). Rather research points to the effectiveness of teacher learning focussed on teacher attitudes, values and beliefs, and the link between these and teachers' practices in the classroom (MacArthur et al., 2005; Mittler, 2000). Rather, effective teacher learning for inclusive education provides opportunities to reflect on beliefs, values and attitudes and the relationship between these to teachers' day-to-day practice (MacArthur et al., 2005; Mittler, 2000). Teacher knowledge to facilitate inclusive education also involves an awareness of the power and hierarchy arrangements in schools that include and exclude some groups of students (Ewing, 2001). Issues of social justice, human rights and citizenship have also been shown to be important aspects of teacher knowledge in relation to inclusive education (McDonald & MacArthur, 2005).

PAPER PRESENTATION

The Role of Teacher Educator Inquiry in the Professional Education of Teachers

Frances Rust, University of Pennsylvania, United States; Joan Whipp, Marquette University, United States

This paper provides a robust review of pre- and in-service teacher educators' research on their practice aggregating it around questions and research that teacher educators are conducting around specific practices and content areas. The major research tool is manuscript review supplemented with interviews. The intent is to highlight the questions that teacher educators are asking about their practice, to determine the ways in which teacher educators are studying their practice, and to gather together lessons learned from these investigations—all for the purpose of developing what Hiebert, Gallimore, and Stigler (2002) describe as "a practical knowledge base" for teacher education.

Throughout the world, teacher educators and traditional university-based teacher education programs are under attack by those who feel they have a better handle on how to prepare teachers whether they be school districts, governments, for-profit organizations engaged in teacher preparation, or non-profit organizations engaged in residency programs designed to situate new teachers learning in schools and classrooms (Au, 2008; Berry, 2009; Wrigley, 2009). Individuals and their programs have been criticized for doing a "mediocre job of preparing teachers for the realities of the 21st-century classroom" (Duncan, 2009) which requires that they know how to manage classrooms for high-needs students and use data to improve instruction and boost student learning." Grossman (2008), Levine (2008), Zeichner (2010) and others have suggested that teacher education is in crisis and that traditional teacher preparation programs may be fast losing their grip on the field. It is critical, writes Grossman, that teacher educators demonstrate that their programs make a difference on student learning and that they improve the quality of research in teacher education so that it can credibly inform practitioners and policy makers.

The recent AERA Panel on Teacher Education Research was also critical of teacher education research suggesting that it was fragmented, limited largely to isolated case studies, and methodologically weak. In the face of this critique, however, a powerful counter narrative regarding teacher education and the role of research focused on teacher education is emerging. Drawing from research on evidence-based practice in a variety of professions including medicine, and law, this counter narrative focuses on two evidentiary frames: whether and to what extent various aspects of teacher education influence the ways in which new teachers practice. To answer these questions, increasing attention is being paid to evidence of carryover of the curriculum of individual teacher education programs and the instructional practice of teacher educators into the practice of their graduates during their first few years of teaching. Thus, the focus of research on teacher education is shifting from efforts to draw from program-comparative studies that have failed to provide clear evidence that certain approaches in teacher education may be more effective than others, and moving to more qualitatively-oriented studies aimed at identifying what works in individual programs and, from there, toward an aggregation of findings that could lead to a bridging of theory and practice (Hiebert, Gallimore, and Stigler, 2002; Korthagen, Loughran, & Russell, 2007; Author, 2010). As Zeichner and Conklin (2005) write, "...it is program substance not structure that is key in influencing prospective teachers. We need [qualitative, descriptive, context-sensitive, longitudinal] research that focuses more on the substance of programs and that goes beyond surface-level assertions about good program features (e.g., the importance of coherence, partnerships, mentoring, and modeling) to elaborate what these characteristics mean in practice and the particular configurations of these features (e.g., what good mentoring practice means) that enable the realization of desired outcomes. (p. 701) Such research begins to help teacher educators address those questions posed more than 20 years ago by Clark (1988) with answers that by making research about practice, "public, storable and sharable, and open for verification and improvement" (Hiebert, Gallimore, and Stigler, 2002, pp. 6-8) could make possible a fundamental reshaping of the field of teacher education. This paper provides a robust review of pre- and in-service teacher educators' research on their practice aggregating it around questions and research that teacher educators are conducting around specific practices and content areas. The major research tool is manuscript review supplemented with interviews. The intent is to highlight the questions that teacher educators are asking about their practice, to determine the ways in which teacher educators are studying their practice, and to gather together lessons learned from these investigations—all for the purpose of developing what Hiebert, Gallimore, and Stigler (2002) describe as "a practical knowledge base" for teacher education.

Our effort is to bring attention to the breadth and variety of research by teacher educators worldwide on teacher education that has evolved over the past 20 years. To date, from the close to 200 studies that we have identified, we have selected for this review those that offer models for research on practice. They are: a) grounded in clear conceptual frameworks, b) provide a robust research design with systematic analysis of data, and c) offer insight about what teacher educators are learning about effective teacher education as they study their own practice. Ball (2010), Cochran-Smith (2003, 2005), Hiebert, Gallimore, and Stigler (2002), Korthagen, Loughran, and Lunenberg (2005), and Murray (2008) hold that such inquiry is critical to reshaping teacher education practices and influencing

the work of teachers at both the preservice and inservice levels. As Ball (2010) notes, The current array of teacher preparation programs offers an unprecedented opportunity to move past trial and error and opinionated debate and to identify the key features of readiness for responsible practice and how it can be learned and assessed. (p. 12)

Following is a sample of the topics and questions that have emerged in this review:

Teacher induction. How can teacher educators support pre-service teachers in the first years of teaching?
Supporting teaching for social justice . How can teacher educators accomplish evidence-based decision making about teaching for social justice?

Teacher educator beliefs. How can teacher educators get beyond their own deficit models of and beliefs about preservice and inservice teachers who have had limited exposure to cultural diversity?

Teacher educator self-study processes and methods. What qualitative and quantitative methods are teacher educators using to develop evidence of program effectiveness?

Problems and Pedagogies of Practice . What core sets of practices embody the knowledge, skill and professional identity needed by entry level teachers?

Uses of New Technologies in Teaching and Teacher Education. How might teacher educators use new technologies to go public with teaching and teacher education?

Supporting Preservice and Inservice Inquiry into Practice. How can teacher educators build research capacity among preservice and inservice teachers?

PAPER PRESENTATION

Junior High School Students' Mechanisms and Explanations of their Perceived Constructivist Learning

Orit Ben Zvi -Assaraf, Ben Gurion University of the Negev, Israel, Israel; Haim Eshach, Ben Gurion University of the Negev, Israel; Moustafa Asley , , Department of Science and Technology Education, Ben-Gurion University of the Negev, Beer Sheva, Israel., Israel

The purpose of the present study is to examine the manner in which constructivist learning environment features, as well as the mechanisms at their base, are expressed in middle school students' conceptions. Thus the present study integrates the quantitative and qualitative approaches in order to arrive at a wider ranging and deeper understanding. 840 students from the 8th and 9th grade from over 15 schools participated in the study. Of the 840 students who completed the questionnaire, the explanations of 200 well-written questionnaires were further analyzed qualitatively. The findings of the study are presented in terms of the 4 scales employed in the CLES, namely: the Autonomy Scale, the Prior Knowledge Scale, the Negotiation scale, and the Student-Centredness Scale. The quantitative results arrived at in the present study concur with parallel studies conducted around the world. The findings indicate that a considerable portion of the students perceive their learning environment as being constructivist one and report positive attitudes towards the way they are being taught. In terms of the qualitative results, however, it appears that in some cases the students' explanations reveal that in fact, and contrary to the bare quantitative results, some students do not perceive their learning environment as being constructivist. This raises the question whether indeed the factors associated with constructivist teaching which are recognized by the students, indeed indicates that they exist in practice. This finding emphasizes the importance of combining qualitative and quantitative methods for arriving at a balanced view of classroom occurrences.

Constructivism and social constructivism which one can relate to as a theory of learning determines the way one learns, no matter what teaching strategies he or she will be exposed to. However, from the literature on science learning and teaching it appears that learning environment which might be considered as effective from constructivist point of view is one which the community of learners engages in activity, dialogue, and joint thinking of topics relevant to them. The teachers' role in such environments is to encourage and accept student autonomy and create a comfortable atmosphere for student expression. Much attention is given to the learner: to his/her previous knowledge, to his/her experience, to his/her thinking strategies, and to his/her motivation. The teacher is also to create a learning environment which invites the development of cognitive skills such as critical thinking, logical thinking, question asking, efficient knowledge use by way of data analysis, and arriving at conclusions. Such learning environments also enable learners to develop the skills to evaluate the learning process and product, as well as the ability to self-reflect. In parallel, skills belonging to the social domain also develop including those of engaging in conversation and dialogue, persuasion and decision-making abilities, team work, and task distribution. Finally, in the personal domain, the learner develops the skills such as persistence, internal drive, initiative taking, personal curiosity, responsibility taking and independence.

Diagnosing the different dimensions of the learning environment as perceived by the learners and analyzing the factors affecting it might explain the social processes being acted out in the class. As well, comprehending how the learners understand the environment's dimensions might assist teachers and educators in planning pedagogical interventions for the purpose of improving the teaching and learning process. Very few studies have examined the educational environment from the student's point of view. The tool most commonly employed in the literature to assess student attitudes towards their environment being a constructivist one is that of Taylor, Fraser's and Fisher (1997) Constructivist Learning Environment Survey (CLES), a Likert type questionnaire. The present study builds on the former but adds a qualitative dimension as well. Students are requested to supply an explanation to the scoring of the statements. Qualitative and quantitative approaches differ in their goals, study array, type of data gathered, how it is collected, its analysis, and the drawing of conclusions from it. The present study integrates the two approaches in order to arrive at a wider ranging and deeper understanding of students' mechanisms and explanations of their perceived constructivist learning environment.

Thus, the purpose of the present study is to examine the manner in which constructivist learning environment features, as well as the mechanisms at their base, are expressed in middle school students' conceptions. 840 students from the 8th and 9th grade from over 15 schools participated in the study. The sample was randomly chosen and represents students studying sciences in public schools in the southern part of Israel. Of the 840 students who completed the questionnaire, the explanations of 200 well-written questionnaires were further analyzed qualitatively. The findings of the study are presented in terms of the 4 scales employed in the CLES, namely: the Autonomy Scale, the Prior Knowledge Scale, the Negotiation scale, and the Student-Centredness Scale. The quantitative results arrived at in the present study concur with parallel studies conducted around the world. The findings indicate that a considerable portion of the students perceive their learning environment as being constructivist one and report positive attitudes towards the way they are being taught. From among the questionnaire's components, the "Negotiations scale" received the highest positive score while the "Previous knowledge scale" received the lowest score (Figure 1). In terms of the qualitative results, however, it appears that in some cases the students' explanations reveal that in fact, and contrary to the bare quantitative results, some students do not perceive their learning environment as being constructivist. For instance even when they agree with the statement in the questionnaire: "In science I talk with other students about the most sensible way of solving a problem" They explained in the qualitative part that the participation stems from their wish to gain higher scores in the course (external motivation) and they did not at all associate discussions with understanding:

a) Students don't speak out because they are afraid of the teacher (10.99%); b) You don't talk during class, only work (25.88%); c) No because I rely on myself and am not interested in others. What I think is the most logical (16.48%); d) Yes, to check if I'm right, to be sure (18.68%); e) Working with friends helps me understand (7.69%) and f) Yes, we argue about the answer, maybe they will suggest ways that will help me reach the right answer and good score (20.27%). This might indicate that although they participate in the discussions in class, the discussions might not contribute to their conceptual development. In other words, one cannot conclude that participating in class discussions indicates constructivist teaching. It is then argued that the fact that students do not perceive their learning environment as constructivist does not necessarily mean that in reality it is not a constructivist one, and vice versa. The findings of this study reveal a gap between the quantitative questionnaire results and the qualitative data. This raises the question whether indeed the factors associated with constructivist teaching which are recognized by the students, indeed indicates that they exist in practice. This finding emphasizes the importance of combining qualitative and quantitative methods for arriving at a balanced view of classroom occurrences. One approach which might address this gap is the explicit instruction strategies, where the relevant constructivist learning environment features are explicitly presented to the students so that they may become active participants in transforming and maintaining their learning environment as a constructivist one.

PAPER PRESENTATION

Entertainment media as learning material – The problem of mental effort

Anja Hawlitschek, Fraunhofer Institute for Digital Media Technology, Germany; Helmut M. Niegemann, University of Erfurt, Germany

In this paper we examine the effects of pupils' perception of entertainment media on learning outcome. According to Salomon (Salomon 1984), the learner usually perceive entertaining learning material as "easy" and "undemanding"

which leads to a decreasing amount of invested mental effort and therefore a lower learning performance. Salomon suggests that the integration of an explicit instruction to learn is necessary for the usage of entertainment media in school. Results from other studies so far not support these findings. Nevertheless the "Salomon-Effect" influences the discussion about learning with entertainment media. Therefore, we see the importance for another research study to answer this question. We conduct a two-group experiment with pupils in a German secondary school. The results of our study indicate that there is no correlation between mental effort and learning outcomes. Increasing mental effort in the experimental group is not accompanied by increasing learning outcomes. These results are a challenge for the premature declaration of entertainment media as "for learning".

Introduction

This paper addresses an instructional problem concerning the usage of entertainment media in school, known as "Salomon-Effect". Salomon's studies (Salomon, Leigh 1984; Salomon 1984) result in a media pedagogical assumption, which consistently influences the discussion about learning with entertaining media: The usage in school should be accompanied by an explicit instruction to learn, to encourage the investment of mental effort. Otherwise, the pupils, who usually perceive entertainment media as "undemanding", would pay little mental effort and therefore achieve poor learning results (Petko 2008). Learning is here defined as knowledge acquisition which can be measured in terms of factual recognition and inference making. In an experiment Salomon tried to change the preconceptions of children towards the mental effort that is necessary to deal with learning material. He concludes: "children's (...) AIME (amount of invested mental effort) and their inference making – are penetrable through the manipulation of the demand characteristics of TV" (Salomon, Leigh 1984: 133). Other studies come to different results: Beentjes (Beentjes 1987) could not show a relation between the media type and AIME. Heers (Heers 2005) could not identify an impact from the learning instruction on mental effort on the one hand and a relation between invested mental effort and learning outcome on the other. Moreover Salomon himself could not identify in every measure an effect on learning outcome (Salomon, Leigh 1984: 125).

We therefore see the importance to conduct another research study concerning this question. If the explicit demand to recognize the entertaining material as learning content is a prerequisite for learning, the usage of entertainment media in school have to be reconsider.

Research Design

Our study took place in a grammar school in Berlin, Germany. 31 pupils from a tenth class were randomly assigned into two groups. The experimental group had a written learning instruction: "Read the following text very careful. Think about the meaning of the story. After reading, we will ask you questions concerning the content of the text." The control group had the written instruction: "You can now read a comic. Have fun!" This instruction was supposed to encourage the typical attitude of reception towards entertainment media – enjoyment.

As learning material we chose a comic strip, which was clearly identifiable as entertainment media. After reading the comic each pupil got the questionnaire and the test for learning outcome. The scale for measuring mental effort contains the following items (cf. Salomon 1984):

- I worked hard to understand the story.
- I invested much mental effort to comprehend the story
- I tried very hard to understand the story.

The participants rated on a seven-point Likert-scale ranging from "strongly disagree" (= 1) to "strongly agree" (= 7). Factual recall was measured through multiple-choice, inference making was measured through open questions. Two researchers rated the inference making test on the basis of a "solution model". Satisfying inter-coder reliability was achieved.

Hypotheses based on Salomon's theory (Salomon 1984) are:

Hypothesis 1: The learning instruction has a positive influence on mental effort.

Hypothesis 2: The learning instruction has a positive influence on performance.

Hypothesis 3: Mental effort has a positive influence on performance.

Results

To examine the first hypothesis an analyses of variance (ANOVA) was conducted with the learning instruction as independent and mental effort (Cronbach's α : .880) as dependent variable. The result did yield a main effect on mental effort (see table 1).

To examine the second hypothesis an ANOVA was conducted with the learning instruction as independent and the learner's performance as dependent variable. The results did not yield a significant main effect on factual recall ($p = .137$, $d = 0.421$) and inference making ($p = .595$, $d = 0.129$).

To examine the third hypothesis the correlation between mental effort and the learner's performance was measured. The result neither yields a correlation between mental effort and factual recall ($r = .129$; $p = .498$) nor between mental effort and inference making ($r = .087$; $p = .648$).

Discussion

Our results indicate that the communication of the entertainment media as learning material do not lead to the expected results. There is no significant main effect from the learning instruction on the learner's performance. Although mental effort could be manipulated through the learning instruction it had no influence on learner's performance. The learning instruction seems to produce only a feeling of effort. The estimation of the media can be altered but without influences on the learning behavior. These results correspond with results from research projects in the field of Cognitive Load Theory, which used similar items. For example DeLeeuw/Mayer (DeLeeuw, Mayer 2008) also do not find a correlation between mental effort and the learner's performance. There are so far no indicators which support Salomon's assumption, that the perception of entertainment media as "for learning" yields better learning performance. Further research has to be done to investigate the correlation between entertainment media and cognitive processing more deeply.

PAPER PRESENTATION

A design-based methodology for practice-oriented research

Cees Terlouw, Saxion University of Applied Sciences, Netherlands

Learning and instructional researchers function in academic and in practical settings. Doing research in an academic setting usually also intends the application of the results in an educational practice. Doing research in a practical setting implies even more explicit pursuing a double goal: developing 'practice' and 'theory'. Practitioners ask for a concrete 'situated' solution, but also for a more general practice-oriented theory for application in other situations. Therefore, both settings are confronted with a theory - practice gap. What methodology, especially which practice-oriented research model, can be used to bridge the gap working as a researcher in a practical setting? We consider the practice situation as a community that is involved in a multi-level, complex learning situation. Besides students, also the other stakeholders such as teachers and managers must learn to apply the intervention. A researcher should also be a stakeholder in such a collaborative learning situation. A dialogue between the different stakeholders is central in such a community. Therefore, an interactive research model is necessary in which managers, researchers and user-groups interact throughout the entire research process. Based on a knowledge theory an ideal typical model for a practice-oriented research project is formulated that consists of such components as practice problem, knowledge base, reasoning mechanisms for extracting and integrating knowledge from the knowledge base, and a knowledge application and acquisition system. An empirical study on transition to higher education will be used to demonstrate the model as a logic-in-use and as a means to improve the model.

Problem

Learning and instructional researchers function in academic and in practical settings. The relation between research and practice is relevant in both settings. Doing research in an academic setting usually intends – on the short- or long-term – the application of the results in an educational practice. This way of working is confronted with a theory – practice gap (De Corte, 2007). Doing research in a practical setting implies more explicit pursuing a double goal: developing 'practice' and 'theory'. Practitioners ask for a concrete 'situated' solution, but also for a more general practice-oriented theory for application in other situation. Therefore, this way of working is also confronted with a theory - practice gap. What methodology can be used to bridge the gap working as a researcher in a practical setting?

Theoretical framework

Several positions are taken for bridging the gap between 'practice' and 'theory' (e.g. Journal of Learning Sciences, 2004 about Design Based Research; Phillips, 2006, De Corte, 2007). The possibilities and limits for 'theory' and 'practice' of the use of objective instruments, double-blind randomized design (the "Golden Standard"), and different levels of empirical evidence characterize the discussion. However, from the perspective of a researcher working in a practice setting the discussion lacks a solution, because the character of the practice situation is not taken into account. For such a researcher I characterize the situation as a multi-level, complex learning situation, because besides students, also the other stakeholders such as teachers and managers must learn to apply the intervention. A researcher is also part of such a collaborative learning situation. A new object / concept is designed and constructed for their collective activity (the planned intervention), implemented in practice, improved in order to solve a problem in practice, and to develop theoretical knowledge and concepts. Engeström & Sannino (2010) call such a complex, collaborative learning process in a community 'expansive learning'. A dialogue between the different stakeholders is central in such a community. Therefore, an interactive research model is necessary in which managers, researchers and user-groups interact throughout the entire research process. This model includes the definition of the problem, the development, selection, implementation, and improvement of the intervention, the theoretical reflection, and the application of the research insights in these components. (Ellström, 2008). Conceptualization and interpretation of the research takes place in a knowledge circulation process between 'researchers' and 'practioners' in order to solve the practical problem and to develop practice-oriented theory. The more specific research question is: Which are the components of a practice-oriented research model that involves a knowledge circulation process between 'researchers' and 'practioners' in order to solve the practical problem and to develop practice-oriented theory?

A model for practice-oriented research

Our grounding for the model is a knowledge theory for practice-oriented research of Strike (1979) in which the concept 'research program' is central. This knowledge theory have three components: (a) the theoretical-normative hard core that is fixed during a research project, (b) action plans to realize the former that can be changed based on the implementation results in practice, and (c) the evaluation of the results of implementation in practice. Based on this knowledge theory an ideal typical model for a practice-oriented research project consists of the following related components (see figure 1): Practice problem. A state of affairs that according to some practioners in an educational community is a problem. The stakeholders must agree on the definition of the problem; Knowledge base. The practice problem activates the present practical and theoretical knowledge for knowledge circulation. The stakeholders must agree which knowledge should be used in the collective knowledge base; Reasoning mechanism. Cognitive and social functions used to get the knowledge available for knowledge circulation and application; Knowledge Application and acquisition system. This system consists of the following parts: Instruction-learning theoretical framework. This is the theoretical-normative 'hard core', the grounding theoretical framework used in the project as a starting point for action. Several action plans must realize this framework, First action Plan. A more specific intervention theory is specified or chosen for the specification of the intervention that should solve the practice problem. The intervention is an IF-THEN proposition, Second Action Plan. This plan concerns a systematic procedure for Instructional Design for developing the intervention chosen Third Action Plan. The resulting instructional design, the intervention, is detailed and constructed in an instructional plan and connected with an evaluative research plan, Execution. The instructional and research plan are executed in the practice for solving the practice problem, Evaluation. Based on the research plan the results of the intervention are evaluated, and Feedback. The evaluative conclusions are feed back to the action plans and the execution for improvement. Several cycles can take place; Reasoning mechanism. Cognitive and social functions used for integrating the evaluative results in the collective knowledge base. Explicit argumentation in terms of claims, evidence, warrant, rebuttal, and backing are important for the growth of practical and theoretical knowledge.

Reconstructed logic and logic-in-use

The former model is reconstructed logic. We will demonstrate the logic-in-use by reporting research on designs of study counseling meetings in order to help high school students learning to transit smoothly to higher education. This research is used to improve the model.

PAPER PRESENTATION

Technology-supported assessment of text-based learner's outcome

Nadine Schlomske, University of Jena, Germany; Michaela Glaeser-Zikuda, University of Jena, Germany; Pablo Pirnay-Dummer, Friedrich-Schiller-University of Jena, Germany

Text-based learners' performance is, in particular, difficult to assess. The study in this presentation focuses on technology-supported possibilities in text-oriented assessment university and school. For comparison (external criterion), the study uses expert model solutions, which allows a comparison of students' individual performance and the expert solution with the tools at hand. Secondly, we tested to what degree the instrument may be supportive and feasible for teachers in assessing students' performance at schools, and how diagnostic competencies may be enhanced. Design, methods, and first results of the study are presented. Finally, implications of the study for assessment at school and university will be discussed.

Assessing learners' performance is an important issue in all educational fields. The instruments currently used at schools and universities are rarely objective, reliable, and valid in their procedures and analyses. Text-based learners' achievements are, in particular, difficult to evaluate (see Ingenkamp & Lissmann, 2008; Klauer, 1982; Linn, Klein & Hart, 1970). The study focuses on technology-supported possibilities in assessing text-based learner's outcome with T-MITOCAR (Text-Model Inspection Trace of Concepts and Relations).

The technology-supported assessment with T-MITOCAR is theoretically based on mental models (c.f. Seel, 1991, Johnson-Laird, 1983). Learners construct mental models in order to explain the world on the basis of their knowledge. The statements presented in a person's knowledge must be plausible according to his or her knowledge of the world, regardless of whether they are true in reality or not (Seel, 1991). Mental models are only constructed if a person cannot explain a particular situation on the basis of his or her present knowledge of the world. Experts differ from novices not only in the amount of knowledge available to them, but also in their knowledge structures (Pirnay-Dummer, 2006).

Observing learner's performance requires diagnostic competencies (Hoge & Coladarci, 1989). Helmke (2009) defines the construct of diagnostic competencies as the knowledge one has of the empirical standards (objectivity, reliability and validity) and of the sources of errors which can occur during the process of evaluating learner's performance, as well as the ability to search for a test, and finally, use and evaluate the same test. In addition, three components are distinguished: the correctness of observation, the variation of observation, as well as the ability to rank students' achievement.

In accordance with the empirical findings in text-based performance assessment, the following research question is of interest: Can T-MITOCAR be used to evaluate written learners' outcomes? Furthermore, may this instrument support teachers in assessing students' text-based performance?

T-MITOCAR is a computer-based software (Pirnay-Dummer & Ifenthaler, 2010; Pirnay-Dummer, Ifenthaler & Spector, 2010) that is automated in its procedure and analysis and has been proven in delivering homogeneous, reliable, and valid results in multiple studies. It measures a specific set of properties of language re-representations and generates associative graphs from texts using heuristics from computer linguistics and graph theory. Based on the instrument learners' progress has already been tracked with a high prediction validity (Schlomske & Pirnay-Dummer, 2009).

The presentation focuses on two studies. The first study that was conducted on the university level includes a sample of (N=37) students in the domain of school education. In the second study a sample of (N=180) students in the domain of educational psychology was selected. Students write an exam at the end of the semester which consists among other things of two tasks where students produce written texts. Based on specific criteria two lecturers independently evaluate students' text-based performances. For comparison (external criterion), the study uses written expert model solutions, which are examined by experts in the domain beforehand, in order to guarantee its validity. This allows a comparison of each individual performance and the expert solution within T-MITOCAR. Finally, the core measures identified by the instrument are compared with the grades the lecturers assigned to the written exams. This allows the examination on whether it is possible to assess teacher's identification of grades for the individual performances with T-MITOCAR.

In a second step, this assessment tool will be tested in school context to what degree the instrument may be used in supporting assessment at school. A group of teachers will be trained in their diagnostic expertise in order to assure their assessment of tests with sufficient accuracy. Moreover, the teachers' knowledge and diagnostic competencies will be assessed before and after being trained. Possible effects of T-MITOCAR on teachers' competencies will be also tested. Finally, results and implications of the study for assessment at school and university will be discussed. If the procedure with T-MITOCAR turns out to be reliable and valid in comparison to established assessment and testing, it may lead to the introduction of automated assessment tools regarding text-based performances to complement the process or help teachers with the time consuming effort of classical grading. However, there are limits in grading with technology-based tools as well as there are aspects of grading, like for instance, writing style that can only be assessed by teachers so far.

PAPER PRESENTATION

How do different task types affect the multimedia effect and what role does WM play in it?

Erlijn van Genuchten, Knowledge Media Research Center, Germany; Katharina Scheiter, Knowledge Media Research Center, Germany; Anne Schueler, Knowledge Media Research Center, Germany

As part of a series of studies about the involvement of working memory in learning with text and pictures, we investigated whether the size of the multimedia effect (i.e., students learn more from text and pictures than from text only) and the involvement of WM components differ between task types. We distinguished between conceptual, causal, and procedural tasks. Ninety-seven students were assigned to a text-only, text-picture or picture-text group (the horizontal layout of the text and picture was manipulated) and studied tasks from these three task types. The results showed that the multimedia effect was smallest in conceptual tasks and largest in procedural tasks when considering free recall of information. A similar pattern was found for recall verification items. The opposite pattern was found for transfer verification items; here, the multimedia effect was largest in conceptual tasks and did not exist in procedural tasks. These results suggest that the value of adding pictures to text depends on the type of information and the type of learning that is required. Finally, the question of whether the importance of working memory components differs between task types could not be answered; measuring working memory involvement appeared problematic due to insensitivity of the working memory capacity measures. Therefore, we proposed to use a dual-task paradigm in future experiments to measure working memory involvement.

The Cognitive Theory of Multimedia Learning (CTML; Mayer, 2009) holds that working memory (WM) is involved in constructing knowledge representations when learning from text and pictures. CTML is based on Baddeley's WM model (1986) — consisting of the central executive (CE), phonological loop (PL), and visuospatial sketchpad (VSSP). The CE is a control system with the capability to focus, divide, and switch attention, and to link WM with long-term memory. The PL and VSSP are responsible for holding and rehearsing verbal and visuospatial information, respectively. However, CTML does not acknowledge fully that WM is composed of these components, that these components process different types of information (i.e., verbal, visuospatial), that the importance of these types of information, and hence WM contribution, may vary depending on task type, and that therefore the size of the multimedia effect (i.e., students learn more from text and pictures than from text only) may vary between task types. We investigated whether the relative importance of text and pictures, and therefore the size of the multimedia effect, as well as the involvement of WM components differ between task types. We distinguished between conceptual tasks, focusing on concepts and their relationships (e.g., members in a family tree; Hiebert & Carpenter, 1992), causal tasks, focusing on cause-and-effect chains (e.g., functioning of the heart; Mayer, 2009), and procedural tasks, focusing on the temporal order and spatial relationships between actions (e.g., assembling a cupboard; Brunyé, Taylor, Rapp, & Spiro, 2006). We also distinguished between recall (remembering) and transfer (reasoning) of information (Mayer, 2009). Specifically, we investigated whether the multimedia effect is larger and whether the VSSP is more involved during learning when pictorial information is more important, and conversely, whether the multimedia effect is smaller and whether the PL is more involved during learning when verbal information is more important. We also investigated whether the CE is particularly involved in the integration of text and pictures when verbal and pictorial information are equally important.

Method

Ninety-seven students were assigned to the text-only, text-picture or picture-text condition (the horizontal layout of text and pictures was manipulated). They studied tasks from three task types (i.e., conceptual, causal, procedural). Students performed two blocks consisting of three learning tasks (one of each task type), post-test questions, and two WM capacity tests. Nine learning tasks were developed — three conceptual, three causal, and three procedural — about a fictitious country. Accuracy on three categories of post-tests was assessed: (a) verbal (written) and pictorial (drawn) free recall, (b) verbal and pictorial recall verification items (yes/no), and (c) transfer verification items (yes/no)

including text-picture integration items. All considered information given in just the picture or in both text and pictures. WM capacities were gauged using digitalised versions of the Digit Span task (PL), Corsi Block task (VSSP), Listening Span task (CEPL) and Spatial Span task (CEVSSP).

Results

In our regression analyses, we predicted accuracy of free recall, recall verification items and transfer verification items from PL and VSSP capacity, condition, task type, and learning time simultaneously. CE capacity was not included, because many students scored zero on the CEPL and CEVSSP task. Investigating PL and VSSP involvement was less problematic, although the range of scores was small. Contrary to our assumptions and contrary to CTML, no relationships between WM measures and learning outcomes were found. We found a multimedia effect for all task types and dependent variables except for transfer verification items in procedural tasks. For free recall, the multimedia effect was smallest in conceptual tasks, larger in causal tasks, and largest in procedural tasks. For recall verification items, the multimedia effect was largest in procedural tasks with no differences in effect size between conceptual and causal tasks. For transfer verification items, the multimedia effect was largest in conceptual tasks. All reported results were significant at the alpha .05 level.

Discussion

The results show that the multimedia effect was confirmed, that is, students learned more from text and pictures than text only in all but one case. The multimedia effect was smallest in conceptual tasks, larger in causal tasks and largest in procedural tasks when considering free recall accuracy. A similar pattern was found for recall verification items. These results imply that memory for the given information is fostered by pictures especially in procedural tasks and less in causal and conceptual tasks. The opposite pattern was found for transfer verification items — the multimedia effect was largest in conceptual tasks, smaller in causal tasks, and did not exist in procedural tasks. These results imply that the ability to draw inferences based on the given information is fostered by pictures in conceptual and causal tasks but not in procedural tasks. Together, these results suggest that the value of adding pictures to text depends on the type of information and the type of learning that is required. However, future studies are required to confirm this pattern of findings. The results about WM involvement show that measuring WM involvement using WM capacity was problematic in this study. The significant proportion of students scoring zero implies that the task instructions were unclear or that the tasks were too challenging. As a result, these capacity measures did not differentiate between students with different WM capacities. Therefore, more sensitive measures, such as a dual-task paradigm, should be used in future studies to measure WM involvement during learning from text and pictures.

PAPER PRESENTATION

Do spatial text contents interfere with picture processing?

Anne Schueler, Knowledge Media Research Center, Germany; Katharina Scheiter, Knowledge Media Research Center, Germany; Peter Gerjets, University of Tuebingen, Germany

According to the multimedia principle texts presented together with pictures lead to better learning than the presentation of text alone. The aim of the reported study was to examine whether this superiority of text-picture presentation is influenced by the text contents that have to be processed: A multimedia effect was expected only when text containing non-spatial information had to be processed, but not when text containing spatial information had to be processed. This hypothesis is based on the assumption that the processing of spatial text contents might interfere with the processing of spatial picture information and the execution of eye movement in spatial working memory. Eighty-four students participated in an experiment based on a 2x2 design with picture presentation (with vs. without) and text contents (visual vs. spatial) as independent variables. In the learning phase, participants received information about different fishes. Afterwards, they had to recall this information. The results of the experiment confirmed the hypothesis that a multimedia effect appears only with non-spatial text contents: Whereas learners who received visual text contents benefited from picture presentation, learners who received spatial text contents did not. These findings are in accordance with the hypothesis that there is a specific interference in spatial working memory when processing spatial text information together with pictures. Therefore, the presentation of pictures together with

spatial text contents should be avoided. Instead, it might be better to convey spatial information only through pictures and to reduce the amount of spatial information conveyed through the texts.

In the research on multimedia learning, there have been several recommendations on how to present text and pictures to learners to support a deeper understanding of the presented topic. According to one of these recommendations, the so called multimedia principle, texts presented together with pictures lead to better learning outcomes than the presentation of text alone (Mayer, 2009). However, contrary to this general recommendation, we expect that pictures are beneficial only for learning when presented together with non-spatial text contents but not when presented together with spatial text contents. This assumption is based on finding concerning the structure of working memory (WM), and especially of the Visuo-Spatial Sketchpad (VSSP) as one of WM's substructures. The VSSP consists of a component which mostly deals with processing visual characteristics of objects (e.g., shape or colour), and a component which is responsible for handling relational or spatial information (Logie, 1995). Under very specific conditions not only pictures but also text will be processed in the VSSP, namely, if the text contains information about visual (e.g., colours or shapes; e.g., Deyzack, Logie, & Denis, 2006) or spatial aspects (e.g., locations of objects or spatial relations; e.g., De Beni, Pazzaglia, Gyselinck, & Meneghetti, 2005). Finally, the spatial VSSP is not only responsible for the processing of spatial information but also for the control of movements, especially eye movements (Postle, Idzikowski, della Sala, Logie, & Baddeley, 2006). Based on these findings, we assume that spatial text contents interfere with the processing of pictures in the spatial VSSP, because the processing of spatial pictorial contents, spatial text contents, and the control of eye movements take place there. Accordingly, the presentation of spatial text contents together with pictures should not enhance learning outcomes compared to the presentation of spatial text contents without pictures.

When presenting pictures together with text that does not contain any spatial information, one would expect less interference because the load is distributed more equally across the different VSSP components. Accordingly, when presenting text not containing any spatial information, pictures should be beneficial for learning (see also Schmidt-Weigand & Scheiter, in press). To test this hypothesis 84 participants were randomly assigned to four groups, resulting from a 2x2 design with picture presentation (with vs. without) and text contents (visual vs. spatial) as independent variables. We expected that only learners who received visual text contents would profit from the presentation of pictures, resulting in better learning outcomes compared to the other three groups, which should not differ from each other. A computerized learning environment, which consisted of information about fictitious fishes, was presented to learners. The texts differed with regard to contents: Learners with visual text contents received information about the visual characteristics of the depicted fishes, that is, the colour or form of a specific component (e.g., "The pectoral fin has the same light brown color as the dorsal fins"). Learners with spatial text contents received information about the spatial characteristics of the fishes, that is, the place of a component or its spatial relation to other components (e.g., "The pectoral fin lies between the two dorsal fins"). In the picture groups, pictures were presented on the screen showing the fish described in the texts, whereas in the non-picture groups the corresponding part of the screen remained blank.

After the learning phase, learners had to write down everything they recalled about two of the presented fish. To test our assumptions we used orthogonal contrast analysis following a procedure proposed by Niedenthal, Brauer, Robin, and Innes-Ker (2002). We created a contrast that described the hypothesized rank ordering of the means and two additional contrasts that were orthogonal to the first contrast and to each other. Then all three contrasts were entered simultaneously as independent variables in a multiple regression analysis, in which participants recall performance was regressed on all three contrasts.

As expected, the regression analysis revealed that learners with visual text contents and pictures ($M = 30.00\%$) differed significantly from learners with visual text contents without pictures ($M = 17.96\%$), learners with spatial text contents and pictures ($M = 19.16\%$), and learners with spatial text contents without pictures ($M = 11.29\%$), $F(1, 84) = 14.25$, p R^2 change = .14. The other three conditions did not significantly differ from each other, $F(1, 84) = 1.79$, $p = .17$, R^2 change = .04. To summarize, pictures supported learning only when presented together with non-spatial text contents, but not when presented together with spatial text contents. Furthermore, the recall of visual and spatial text contents did not differ when no pictures were presented, which indicates that the missing multimedia effect with spatial text contents can not be traced back to higher difficulty of these texts. Therefore, these findings support the hypothesis that there is a specific interference in spatial VSSP when processing spatial text information together with pictures. To conclude, the presentation of spatial text contents together with pictures should be avoided. Instead, it might be better to convey spatial information only through pictures, because they are assumed to be more efficient than texts to convey information about visuo-spatial properties.

PAPER PRESENTATION

Disentangling the influence of argument type and comprehensibility on information persuasiveness

Lisa Scharrer, University of Muenster, Germany; Marc Stadtler, University of Muenster, Germany; MaryAnne Britt, Northern Illinois University, United States; Rainer Bromme, Universität Muenster, Germany

The presented experiment investigates whether inconsistencies in previous findings on the persuasiveness of different argument types (causal vs. noncausal) might be explained by argument comprehensibility acting as a confound. To assess whether argument types differ in their persuasiveness independently from their comprehensibility, both factors were manipulated orthogonally. The differential persuasive effects of argument type and comprehensibility were assessed with 88 undergraduates in a 2 (argument type: causal vs. noncausal argument) * 2 (comprehensibility: comprehensible vs. incomprehensible) within-subjects design. Participants read four arguments about medical issues and evaluated their credibility and strength. Furthermore, claim acceptance and confidence in the acceptance decision were measured. Results show that although laypeople deem causal arguments as stronger and more credible, argument type has no effect on acceptance of a claim as true and confidence in the acceptance decision. In contrast, comprehensibility not only has an effect on argument evaluation but also on claim acceptance and decision confidence. Our results suggest that inconsistencies in previous findings on the persuasiveness of argument types might be at least partly accounted for by confounding effects of argument comprehensibility.

Background and rationale

In the context of science communication, a factor which has previously received attention as a potential influence on laypeople's acceptance of scientific claims is the type of argument in which information is presented: In "causal arguments", scientific claims are supported by explanations of the underlying mechanism (e.g. "Cholesterol increases the risk of cardiovascular disease because it blocks the blood vessels"), whereas in "noncausal arguments", claims are supported by references to statistical data (e.g. "Cholesterol increases the risk of cardiovascular disease because 84% of people suffering from heart attack have above-average cholesterol levels"). It is assumed that causal arguments induce stronger claim acceptance, since their coherence and plausibility account for the human desire to understand and predict the world (Tobin & Raymundo, 2009). However, whereas some studies have indeed confirmed a persuasive advantage of causal arguments (e.g., Slusher & Anderson, 1996), other findings showed recipients to consider noncausal arguments as more convincing (Brem & Rips, 2000; Sandoval & Cam, accepted). One possible explanation for these mixed results is that argument comprehensibility might have acted as a confound; according to Trout (2002), understanding an argument causes feelings of success and consequentially positive affect towards the claim, which then leads recipients to accept the claim as correct. Moreover, a persuasive advantage of causal over noncausal arguments might only be brought out if arguments are well understandable; only when comprehensibility is high should recipients be able to appreciate the coherence and plausibility of explanations as favourable qualities. As comprehensibility has previously not been controlled, it is therefore possible that detected differences in persuasiveness between argument types might at least have partly resulted from variations in their respective comprehensibility. Our current experiment disentangled the influence of argument type and comprehensibility on laypeople's argument evaluation and claim acceptance. For this purpose, argument type and comprehensibility were manipulated orthogonally. Furthermore, we examined laypeople's confidence in their claim acceptance by assessing their desire to revert to the 'division of cognitive labour' (Bromme et al., 2010; Keil et al., 2008), i.e. their need to consult an expert for decision support rather than relying on their own judgment. We hypothesized that across argument types, laypeople will agree more strongly and confidently to claims supported by comprehensible than incomprehensible arguments. Furthermore, we expected an interaction effect of argument type and comprehensibility; laypeople should agree more strongly and confidently to claims supported by causal arguments than to claims supported by noncausal arguments when argument comprehensibility is high. However, no difference in persuasiveness should occur when comprehensibility is low.

Methods Participants and Design Eighty-eight

undergraduates were each allocated to four experimental conditions in a 2x2-repeated measurement design with the within-subject factors argument type (causal vs. non-causal) and comprehensibility (comprehensible vs. incomprehensible).

Materials and Procedure

Expository texts about four fictitious medical issues were generated, each consisting of an argument supporting an issue-related causal claim. For every text, four variations were created, analogous to the experimental conditions. In the causal argument conditions, the claim was supported by an explanation of the underlying mechanism and in the noncausal argument conditions by statistical data. Comprehensibility of both argument types was manipulated by use of technical terms and inclusion/omission of unnecessary, distracting detail. Participants completed a booklet containing one version of every expository text, each preceded by a scenario description which required participants to decide about the claim accuracy. The booklet also comprised Likert-scale measures to capture perceived argument comprehensibility, perceived argument strength and credibility, claim agreement and confidence in the agreement decision (indicated by confidence in one's claim judgment and desire to consult an expert for decision support). Claim agreement and decision confidence were assessed before and after participants read an argument.

Results

A manipulation-check revealed that comprehensibility varied between text versions as intended and independently from argument type. Regarding our hypothesis about the persuasive effect of argument comprehensibility, results showed that, as expected, comprehensible arguments were perceived as stronger ($F(1,87)=11.41$, $p<.001$). The hypothesized interaction effect of comprehensibility and argument type was not confirmed: No interaction of comprehensibility and argument type on either argument credibility or strength was observed, and neither did an interaction of both factors on claim agreement, confidence in laypeople's own judgment or desire to consult an expert reach significance. Our data also revealed unhypothesized main effects of argument type on claim evaluation. Participants rated causal arguments as stronger ($F(1,87)=13.067$, $p=.001$, $\eta^2=.131$) and slightly more credible ($F(1,87)=6.607$, $p=.012$, $\eta^2=.071$) than non-causal arguments. No main effect of argument type on claim agreement or decision confidence in the agreement decision was found.

Theoretical and educational significance

In summary, our results show that although laypeople evaluate causal and noncausal arguments differently regarding argument strength and credibility with causal arguments being slightly preferred, this does not transmit to their actual acceptance of a claim as true and confidence in their acceptance decision. In contrast, comprehensibility proved to be of great importance not only for argument evaluation but also for laypeople's claim acceptance and decision confidence. Comprehensibility might therefore at least partly account for previous findings of a varying persuasive impact of different argument types. The present results have implications for the communication of scientific information to laypersons: Depictions of science issues tailored towards lay audiences often increase comprehensibility not only by omission of technical terms or unnecessary detail but by concealing complexities which are in fact relevant for an informed judgment of the proposed claims (Goldman & Bisanz, 2002). This may lead lay readers to overestimate their ability to evaluate the information, cause them to accept claims as true and refrain from gathering further expert information. Thus, on a practical level, our results can inform instructors about the risks of presenting oversimplified information in terms of uncritical claim acceptance by readers.

PAPER PRESENTATION

Effects of Learner generated Representations as a Strategy for learning from Text and Pictures

Felix Wagner, University of Ulm, Germany; Tina Seufert, Ulm University, Germany

Learner generated pictorial representations such as drawings as a strategy to support text comprehension has been analyzed in several studies with inconsistent results. Beneficial effects that were found in text based learning material could not yet be verified in material comprising text-picture combinations. In a pre-study we investigated the effects of learner generated drawings when learning from text and pictures. As results have shown, generating one's own representation increases extraneous cognitive load, consequently hinders learning and is also dependent on the learners' spatial abilities. Learners do not invest effort in generating more comprehensive pictures but rather externalize visual perceptions of the already given pictures. Based on these findings we are conducting a 2x2 factorial design to investigate whether learner generated representations are more helpful for learning with text only or for learning with text and pictures.

Introduction and Theoretical Background

To understand scientific topics represented with text and pictures, learners need to select, organize and integrate relevant information of each representation into a coherent mental model (Mayer, 2005). Recent studies investigated

beneficial effects of learner generated representations when learning with verbal material. Findings revealed positive as well as negative effects on learning: Instructed to generate an external pictorial representation, learners are fostered to mentally represent the topic's global structure (Seufert, Zander, & Brunken, 2007; Van Meter, Aleksic, Schwartz, & Garner, 2006; Van Meter & Garner, 2005). Results of these studies also indicate interaction effects for learners with high and low spatial abilities using the strategy of generating representations (Seufert, et al., 2007). Despite these positive effects, generating representations also increases cognitive load and hence, hinder learning (Leutner, Leopold, & Sumfleth, 2009).

In the present pre-study we investigated effects of learner generated pictorial representations when learning from text and pictures. We expect that being instructed to generate coherent pictorial representations of a to-be-learned subject learners are activated to build a coherent mental model as well. We also assume interaction effects between learners with high respective low spatial abilities.

Method

33 psychology-students were randomly assigned to the experimental or the control group and were given material about a biological process including text and pictures. The experimental group was instructed to take graphical notes while learning, the control group was instructed to take notes in any form. In addition to learners' prior knowledge specific characteristics have been assessed as control variables. For analyzing the ATI-effects two groups with low respective high spatial abilities have been built by a median split, hence all analyses have been conducted as a 2x2 factor ATI-design.

Learning outcomes (including recall, comprehension and transfer), the amount and quality of the constructed representations have been assessed after the phase of learning and constructing. Moreover cognitive load had to be rated subjectively after learning on a 5-point likert scale from 1= very low mental effort to 5 = very high mental effort (based on Paas, 1992).

Results

Concerning the assessed control variables, the groups did only differ with respect to their current motivation, hence it has been included as covariate in all ANOVAS. For learning outcomes we found - contrary to our expectation - no treatment effect and no main effect for spatial abilities or ATI-effects on the learning outcomes for neither of the subscales.

For the amount and quality of pictures a main effect for the instruction was found: the amount of pictures that have been constructed ($F(1,28)=8.73$ $p<.01$, $\eta^2=.24$) as well as their quality ($F(1,28)=8.11$, $p<.01$, $\eta^2=.23$) were higher in the experimental group. No main effect for spatial abilities or ATI-effect could be revealed. However, contrasts showed that especially learners with low spatial abilities have responded to the instruction.

For cognitive load during the learning process no treatment effect or main effect for spatial abilities was found. By trend we found an ATI effect ($F(1,28)=3.88$, $p=.059$, $\eta^2=.22$) (see Figure 1): Contrasts revealed that learners with high spatial abilities reported a higher cognitive load in the experimental group ($MD=-1.01$, $SE = 0.37$, $p=.011$) whereas learners with low spatial abilities did not differ significantly between the groups.

Summary and Discussion

We analyzed the effects of learner generated pictorial representations while learning from text and pictures. Results showed that the instruction led to a higher amount of pictures produced as well as a higher quality. But drawing pictures as a learning strategy for learning with text and pictures had no impact on either of the learning outcome subscales.

Learners with high spatial abilities seem to invest more effort in drawing but without any positive effects on the assessed learning outcome. Hence, the highly reported load could be extraneous load that constrains the active learning process. These results are consistent with studies reporting an increase of cognitive load and the learners' need of support and guidelines during construction (Leutner, et al., 2009; Van Meter, et al., 2006). Based on the model of text and picture comprehension by Schnotz and Bannert (2002), learners externalize only visual perceptions of the already given pictures and are not engaged in building or interacting with the mental model.

In a follow up study we are investigating the inconsistent findings of learning generated representations when learning from text only compared to learning from material comprising text and pictures. Substantial interest is whether learner generated representations will show different effects depending on the learning material (text+pictures vs. text only). We expect that generating graphical representations will be most effective when learning

from verbal material whereas learning outcomes will decrease in the condition of text-picture learning material. Concerning cognitive load we expect that generating graphical representations will increase cognitive load during the learning phase. We also assume that the amount and quality of learner generated representations will be moderated by spatial abilities.

PAPER PRESENTATION

Supporting scientific discovery learning by feedback that is adapted to strategy use

Jessica Marschner, University of Bochum, Germany; Hubertina Thillmann, Ruhr-University Bochum, Germany; Joachim Wirth, Ruhr-University Bochum, Germany; Detlev Leutner, Duisburg-Essen University, Germany

Several studies showed that learners often fail in using appropriate strategies in scientific discovery learning (SDL) (Azevedo, Cromley & Seibert, 2004). Therefore learners need some instructional support referring to strategy-use. Support should be given during learning and should be adapted to learners' individual strategy use (Azevedo et al., 2004). According to models of self-regulated learning, feedback is relevant to regulate the strategy use adequately (Butler & Winne, 1995). Feedback can also produce positive effects on motivation (Kluger & DeNisi, 1996). Our research questions were: Is adaptive support more beneficial for SDL than non-adaptive support? Can feedback adapted to learners' strategy use increase the effects of adaptive support on SDL? 93 students learned with a computer-based learning environment. They were assigned to four conditions: receiving either adaptive feedback, or adaptive prompts, or non-adaptive prompts or no support (control group). We used logfile data to assess strategy use and a questionnaire to assess current motivation. Results reveal that learners in the feedback condition could be more motivated than learners with other support. Additionally, the feedback group showed significant more good strategy use than the control group and the non-adaptive prompt group. According to theoretical assumptions we showed that feedback adapted to individual strategy use is an appropriate support to enhance SDL.

Aims of the study

Studies show that learners often make mistakes and rarely use appropriate strategies during scientific discovery learning (SDL) (Azevedo, Cromley & Seibert, 2004; Klahr & Dunbar, 1988). Appropriate cognitive strategies for SDL are described within the Scientific Discovery as Dual Search (SDDS) model by Klahr and Dunbar (1988). It describes strategic experimenting as an interaction between two spaces. In the hypothesis space, generating hypotheses takes place. In the experiment space, these hypotheses should be tested by conducting systematic experiments, i.e. experiments using the control-of-variables strategy (CVS). Conclusions from those experiments should then be drawn in the hypothesis space again, which may result in new or modified hypotheses. To help learners using these strategies, some instructional support is needed. Studies show further that learners have strategy knowledge available but don't use it (Veenman, van Hout-Wolters & Afflerbach, 2006). A prominent method to overcome such a production deficiency is prompting (Bannert, 2003). However, results of prompting studies show that the effectiveness could be enhanced further. One approach to do this is to adapt support to learners' individual needs (Azevedo et al., 2004). According to Schwonke, Hauser, Nýckles and Renkl (2006) adaptive support should be perceived as more beneficial than non-adaptive support. Another approach is to provide additional strategy-use-related feedback which should increase learners' motivation to use the support (Kluger & DeNisi, 1996). Furthermore, feedback during the learning process should improve learners' monitoring which in turn should enable learners to regulate their strategy use adequately and to eliminate mistakes (Butler & Winne, 1995). So far adaptive support in general and especially feedback adapted to strategy use is practically not used in SDL. Thus, our questions were: Is

adaptive support more beneficial for motivation and strategy use in SDL than non-adaptive support? Can positive effects of adaptive support be increased by providing additional feedback which is adapted to individual strategy use?

Methodology and research design

A sample of 93 German high school students took part in this study (mean age: 14.62 years ($SD = 0.62$); 35.5 % male, 63.4% female). All learned self-regulated within a computer-based scientific discovery learning environment on 'buoyancy in fluids'. This learning environment consisted of a hypothesis space, in which hypotheses could be charted, and an experiment space, in which simulated experiments could be conducted. Students had to find out as much as possible about 'buoyancy in fluids'. During the 20-minute-phase of self-regulated learning learners' mouse-clicks were registered into logfiles. Different support measures, all regarding experimenting strategies, were implemented into the computer-based learning environment and were given during learning. Students were randomly assigned to one of four different learning conditions. Group one received adaptive feedback which means that information about their previous experimenting strategy performance was added to an adaptive prompt. These adaptive prompts were adapted to learners' individual strategy use and prompted that strategy which was used insufficiently so far. Group two received adaptive prompts without feedback. Group three received non-adaptive prompts (general hints to good strategy use) without feedback. Group four was the control group and received no support at all. Before and after learning, all students had to fill in a "current motivation" questionnaire. Based on behavioral logfile data, a measure for good strategy use was calculated. It measures conduct of experiments with CVS according to stated hypotheses and drawn conclusions, as it is described in the SDDS model.

Results

First, we tested whether the support conditions differ in students' current motivation. To account for baseline differences, we used the gain in the current motivation score from before learning to after learning. As expected, the ANOVA shows a significant difference between the various support conditions ($F(3,86) = 2.18$, $p \eta^2 = .071$) (see Figure 1). Contrasts show a higher gain in motivation for the feedback condition compared to the adaptive prompt condition ($t(86) = -1.89$, $p t(86) = 2.28$, p

Second, we examined whether the experimental groups show a difference in good strategy use. Figure 2 shows that the group with adaptive feedback has the highest score in good strategy use. Results of an ANOVA indicate a significant difference between groups ($F(3,86) = 2.20$, $p \eta^2 = .072$). Contrasts show significant differences between feedback condition and control group ($t(86) = -1.90$, $p t(86) = -2.51$, p

Theoretical and educational significance

From a theoretical perspective, our study supports the assumption that feedback information fosters monitoring (Butler & Winne, 1995) because we could improve strategy use by strategy-related feedback but not by prompts.

From a practical perspective, our results provide helpful information for designing appropriate methods to support self-regulation competencies. Providing learners adaptive feedback during SDL with information about their shown strategy use and adaptive hints to further strategy use is beneficial for learning. It can keep up motivation and can enhance strategy use.

PAPER PRESENTATION

Experiences of linking schools' learning environments to students' personal online environments

Teemu Valtonen, University of Eastern Finland, Finland; Tiia Koponen, University of Eastern Finland, Finland; Mikko Vesisenaho, University of Eastern Finland, Finland; Stina Hacklin, University of Eastern Finland, Finland

Supporting students' collaborative learning has long been a target of using different ICT tools in education. Today, social software emphasising users' communication and active role as producers of content provides interesting possibilities for building learning environments that enable and foster collaborative learning activities. Use of social software for learning is also interesting because of its popularity among today's students. However, students' reactions to mixing the tools and environments used for learning and leisure can bring challenges.

In this paper, we describe a pilot study of using Facebook as part of a learning environment. The aim of using Facebook was to link online learning environments and students' personal online environments. This paper reports students' reactions to using Facebook in the learning process and how students' learning was affected by bringing the learning process into their personal online spaces. The study was conducted in a university context and the target group consisted of 46 teacher students.

Background

Supporting students' collaborative learning has long been a target of using different ICT tools in education. According to Dillenbrough (1999), collaborative learning is a "situation in which particular forms of interaction among people are expected to occur, which would trigger learning mechanisms". From this perspective, social software is well suited for collaborative learning. Social software emphasises users' communication and active role as producers of content. Social software is interesting for teaching because of its popularity among today's students who are characterised as net generation. The assumption is that net generation students have readiness to use the Internet and ICT. This readiness should be taken into consideration in schools, i.e., to bring learning activities to environments where students already are. However, students' reactions to mixing the tools and environments used for learning and leisure can bring challenges. Earlier results about students' reactions are contradictory (Jones et al. 2010; Roblyer et al. 2010). We argue that social software provides tools for concretising and making visible the mechanisms of collaborative learning. The question is can we take advantage of students' motive for using Facebook, i.e., motive for reading the RSS feeds by their friends for learning. In this study, we used Facebook as part of the learning environment. The aim is to link online learning environments to students' personal Facebook profiles.

Research

This pilot study was conducted as part of student teachers' ICT and pedagogy course (N=150 in 7 groups). Students built their own blogs as their learning environment and linked them to other students' blogs using RSS. The teacher created a Facebook profile for the course and linked students' blogs to the profile. Participation in the Facebook pilot was voluntary and altogether 50 students from different groups participated. At the end of the pilot, students responded to a questionnaire (N=46) focusing on students' experiences of the pilot. The research questions were: How do students react to connecting school activities and their Facebook profile? Does the use of Facebook affect students' learning?

Results

Here we provide preliminary results from the pilot. Questionnaire contained statements using a 5 point scale, 1 indicating strong disagreement and 5 strong agreement. The first three statements were merged into a subscale for measuring students' attitudes toward the experiment (alpha value .84).

These statements were:

- Course contents on my Facebook page did not bother me
- I could use Facebook as part of my studies also in the future
- Facebook is well suited for higher education learning

Respondents were divided into three groups align with quartiles (Q1, Q3) of distributions of subscale above:

Groups:

Average of the subscale

N

Neutral attitude

2.8

22

Negative attitude

1.4

11

Positive attitude

4.1

13

These results indicate that students' experiences varied. Most of the students had a rather neutral opinion. Results of the Negative attitude group indicate that they do not want to use Facebook in their studies while students in the Positive attitude group find Facebook suitable for their studies.

The second part of the questionnaire dealt with the effect that using Facebook had on interaction and motive during the course.

The following statements were used for building the second subscale:

- Use of Facebook increased awareness of the work done by my peers
- Facebook helped me familiarise myself with other students' work
- Being reminded of other students' work on my Facebook page increased my motive for the studies

When compared to the three groups described above, we can see differences.

Groups:

Average of subscale

Neutral attitude

2.9

Negative attitude

1.1

Positive attitude

3.4

General attitude toward the experiment aligns with students' experience of the effect of using Facebook. Students with negative attitude indicated clearly that using Facebook did not increase their awareness of each others' work or motive for learning. On the contrary, students with positive attitude indicated that using Facebook increased their motive and awareness of each others' work.

Results from qualitative data brought up more information, aligning with the results described above. Students with negative attitude experienced that a large amount of feeds on their personal page was disturbing and caused lack of interest. Also, they felt lack of interest in the topic of the course as well as lack of time. On the contrary, students with positive attitude found it useful that they could see each others' work and progress in Facebook. These students indicated that seeing the work of their peers on their Facebook page reminded them about the course and doing their assignments. Also, students indicated that active presence of contents by their peers supported their own learning. An important result was also that students indicated willingness for reading especially the feeds by the students in their own small group. Altogether, students found the experiment a refreshing change from the normal teaching and learning practices. Yet, most of the respondents indicated that using Facebook did not change their ways of studying. Based on these preliminary findings we can state that students' experiences of connecting school activities to their personal Facebook page varied, which demands more research. However, the results are encouraging for further developing the idea of linking environments for leisure with environments for learning. Especially important was the indicated interest in reading the RSS feeds by their friends and classmates. This brings further ideas for developing software such as Facebook as tools of collaborative learning. In the presentation, we bring up more detailed results from the experiment, especially regarding the qualitative data.

PAPER PRESENTATION

Technopedagogical design versus reality in an inter-institutional online remedial course

Manuel Juarez, CENIDET, Mexico; Jose Luis Ramirez, CENIDET, Mexico; Ana Remesal-Ortiz, Universidad de Barcelona, Spain

The authors present a case study on the design and implementation of a remedial online course, implemented in collaboration among three different institutions nationwide. The course was addressed to computer engineering master students. After several years of detecting certain lack of basic skills in logical language, the course was designed to offer the students the chance to overcome these deficiencies. The design of the course foresaw the participation of instructors from three institutions and the collaboration of students from the same institutions working in pairs both synchronously and asynchronously via a learning management system (Moodle) in a blended modus. Altogether, three instructors and fourteen students took voluntarily part in the experience. The course design is grounded in the second generation of activity theory. The eventual, actual development of the course was thoroughly followed by an external auditor and questionnaires were gathered at the end from students and instructors, in order to collect information about their satisfaction with the course. Results of this external evaluation point to problems in the design and implementation of the blended course and challenges set by the distribution of participants in time and space, which usually are defended as the very advantages of e-learning. The discussion of results will particularly address these challenges.

NOTE: All references have been avoided for the sake of blind review.

Background and research questions

The authors present a case study on the design and actual development of an inter-institutional blended online computer supported course. The course is offered as a remedial online course for Computer Engineering Master (CEM) students. During the past decade a growing lack of skills in logical language was identified in one national institution among students entering the CEM program. After several attempts of addressing the need for assistance, an online course was designed. The course was carried out twice entirely online before extending it to an inter-institutional blended proposal. These two first implementations were quite successful. However, the extension to an inter-institutional and blended context was less satisfactory, due to additional unforeseen challenges. In this paper, these challenges will be addressed.

The basic techno-pedagogical design of the course is grounded in the second generation of activity theory. The interaction of students among themselves and of students with the instructor of the course was regulated by the team accelerated instruction (TAI) model. Basis for the orientation of actions were designed in order to scaffold students construction of translation skills from natural and logical mathematical language. The participants were offered both synchronous (video-conferences and chat) and asynchronous tools (general whole class forum and small team private forum) along the course.

After a thorough audition of the course, the following questions rose, and eventually guided this study:

- (a) 1) Was the participants' interaction in accordance with the course design? Did it develop as expected?
- (b) 2) In case of unexpected phenomena, what happened? What could be a likely reason for the actual development of the course?
- (c) 3) What conclusions can be drawn for future design of similar courses which combine face-to-face and online modus, and promote inter-institutional collaboration, both among students and among instructors?

Participants and design

Three national institutions participated in this course. The course was in pilot phase, hence, the participation was voluntary and eventually three instructors and fourteen students took part in the course. It was offered through the learning management system Moodle and lasted 4 weeks (October 2008). The techno-pedagogical design of the course regulated the interaction of participants in the following way:

- (1) 1) The course contents were designed by all instructors in collaboration.
- (2) 2) A principal instructor (who was more experienced in e-teaching, for having developed the previous two editions of the course in a single institution) was in charge of the main whole class activities in the online platform.
- (3) 3) The other two instructors were in charge of additional educational online support and individual tutoring upon request by the students. In addition, they carried out the face-to-face part of the course in their respective institutions.
- (4) 4) Students from different institutions would collaborate in pairs, gathering always two students who were very unlikely to meet face-to-face, due to geographical distance.

(5) 5) After working in pairs, whole class discussions were organized for the clarification of contents, by means of video-conference.

Data collection

All throughout the course, an external auditor was following the process, from the design phase until the final assessment of students. Different sorts of data were collected: system log files, forum and chat interaction of students and instructors, and a final satisfaction questionnaire to all participants involved in the course. All the data were put together for a qualitative, comprehensive analysis of the course.

Results

Unexpectedly, this third edition of the online remedial course was less successful than the previous two editions. The authors (designers, instructor and auditor of the course) had to face this situation and identified eventually the challenges of the specific context. Despite the high satisfaction rate of the participants, clear deficiencies could be placed at:

- (1) 1) The lack of experience of the instructors in e-learning/e-teaching
- (2) 2) The lack of experience of the students in e-learning
- (3) 3) The extreme demand of co-regulation through the geographical distribution, which ended up in a limited online interaction among students, who preferred the direct face-to-face interaction with their peers at their home institution.

Particularly the last point is challenging in the context of distance computer supported education since, traditionally, one of the advantages of this kind of instructional proposals was placed in the time and space distribution, which should enhance the chances for complex knowledge construction. However, in this case, even the implementation of synchronous audio and video tools did not offer such kind of advantages to overcome the geographical distribution. The key for such a disappointing result was eventually placed in the blended mode of the course. It seems evident, hence, that the design of blended courses requires the consideration of very particular factors and elements that do differ from purely online proposals. These particular factors and elements will be presented for discussion.

PAPER PRESENTATION

Students' aims for building Personal Learning Environments

Teemu Valtonen, University of Eastern Finland, Finland; Stina Hacklin, University of Eastern Finland, Finland

ICT provides numerous ways to meet the needs of today's society and student generation. An interesting newcomer in the field of ICT and education is the concept of personal learning environments (PLE). PLE refers to teaching and learning emphasising student central role in two ways: first, students are the designers of their own learning environments and second, teaching and learning emphasises students' role as self-directed learners. These features indicate a strong change in the roles and responsibilities of students and teachers. Typically, teachers and schools have been responsible for building and administrating the learning environments used. Also, teacher's role as the leader of the learning process has traditionally been stronger and more visible.

This paper outlines some features and challenges related to the use of PLEs. The paper also provides insight into students' experiences and aims related to their PLEs after the first implementation year. The context of the study reported here is an EU funded "PeLE" project for developing the use of PLEs for everyday teaching and learning. This is a qualitative method study and the research data consists of 27 student-made descriptions of their PLEs.

Today's world, described as knowledge society, and today's students as net generation, ready and willing to use ICT for learning, pose challenges for schools and teachers. ICT provides numerous ways to meet the needs of today's society and student generation. An interesting newcomer in the field of ICT and education is the concept of personal learning environments (PLE). PLE has been suggested as one solution for the challenges described above. This paper outlines some features and challenges related to PLE and provide insight into students' experiences after the first year of using PLEs.

This paragraph outlines central features of PLE employing mainly the ideas by Attwell (2007) and Downes (2005). PLE refers to teaching and learning that emphasises students' central role in two ways. First, students are expected to build their own learning environments with the ICT tools and software they find appropriate. Second, the idea of using PLEs emphasises students' self-directed learning, i.e. students' more active role in the learning process. These features indicate a strong change in the roles and responsibilities of students and teachers. Typically, teachers and schools have been responsible for building and administrating the learning environments used. Also, teacher's role as the

leader of the learning process has traditionally been stronger and more visible. These changes pose challenges both for students and teachers. In this paper, we concentrate on students' perspective.

PLE allows students to use the tools they find appropriate for their learning. They can also personalise their learning environment and link it to their life outside schools. At best, this approach will also bring new ideas for teachers and schools about how to take advantage of different software and ICT, such as mobile technologies, for learning. However, there are also challenges. Even though today's students have been described as net generation, they do not necessarily have skills to use their knowledge and ICT skills for learning (Valtonen et al. in press). Another challenge relates to learning skills. Skills for learning relate to students' meta-cognitive skills, i.e. skills for planning, controlling and evaluating learning. According to Hakkarainen et al. (2007, p 72-73), the problem is that development of these skills is typically of teachers responsibility and that students do not necessarily develop these skills without guidance.

Research settings

This paper concentrates on personal learning environments created by students of a university of applied sciences and a vocational institute. The context of the study is an EU funded "PeLE" project. The aim of the project is to develop the use of PLEs for everyday teaching and learning. This is a qualitative method study and the research data consists of 27 student-made descriptions of their PLEs. The object was that students outline the aims that they had for their PLE and describe the overall experiences of using a PLE. These are the results after the first year into the project. The research question was to see how students see PLEs and what is the aim of their PLEs?

At the beginning of the project, students were instructed about the ideas of PLE. For students who had no idea about possible software that they could use, teachers suggested the Ning-environment. In addition to using PLEs to support students' learning, the project also had an aim to direct the PLEs to special focus areas according to student's discipline. For example, students of business were suggested to build their PLEs focusing on seeking of jobs and business cooperation. Despite these suggestions, students were free to design their environments in the way they wanted.

Results

Results indicate that most of the students chose the Ning environment as their PLE environment. Exception was the computer science students who built their PLEs from the scratch or chose to use different software, e.g. Wordpress or Blogger. Results from students' descriptions of their PLEs provided the following aims for designing PLEs.

PLEs as learning environments: The aim of the first approach is to build environments to work as traditional "learning environments" with strong similarities to learning management systems (LMS), such as Moodle. Students uploaded their learning assignments into their PLEs so that their teachers were able to comment them and give feedback. The PLEs contained a clear, curriculum bound structure.

PLEs as reflection environments: The aim was that PLEs would be platforms for students' reflective thinking, aimed for summarising and deepening learning of the course content. Students wrote down their experiences of these courses and practice periods. These environments usually contained blogs or other similar tools for students' writings and for teacher's and other students' comments.

PLEs as tools for bringing up students' skills: These PLEs were designed for bringing up students' skills and knowhow. These PLEs typically consisted of a CV, a large portfolio of students' assignments and projects and other material for introducing the person. This approach was typically used as a tool for showcasing students' skills for their teachers and when applying job.

In addition, students mentioned the importance of collaborative activities in their PLEs. Another feature that divided students' experiences was the openness of their PLE, whether everyone should be able to access their PLEs or only the people they chose. These results can be seen as the first step toward taking advantage of PLEs. It seems that the traditional way of using LMS still shows in students' work. Also, results indicate that building PLEs is a task that needs support, even if the students belong to the net generation. Altogether, students were mainly positive about the possibility to build their own learning environments.

PAPER PRESENTATION

The digital school and teacher education in Norway

Rune Krumsvik, University of Bergen, Norway

This paper focuses on how the new national curriculum for school and the new general plan for teacher education in Norway change the underlying premises for teaching and learning in today's schools. This has become particularly pressing as a result of the new educational reform 'Knowledge Promotion' whereby digital competence is now the fifth basic competence in all subjects at all levels as well as in the new teacher education in Norway. The aim of the paper is to consider ICT in the light of these policy documents, relevant research studies, teacher education and the general digitisation of schools in the Norwegian context. The question considered by the paper is how the new curricula in school and the general plan for teacher education in Norway influence the underlying premises for teaching and learning in today's schools and teacher education Norway.

The main focus of this paper is why the new national curriculum in Norway (MOK, 2006), a new general plan for teacher education (MOK, 2010), the digitisation of schools and the use of ICT make it necessary to highlight the possibilities, dilemmas and challenges schools and teacher education are facing today. This has become particularly pressing as a result of the new educational reform 'Knowledge Promotion' (MOK, 2006) whereby digital competence is now the fifth basic competence in all subjects at all levels (stages 1 to 13, 6-19-year-olds), as well as in the new teacher education (MOK, 2010). Consequently, Norwegian schools are infiltrated with new technology, and obligatory ICT in all subjects is in many ways making us question both our general perception of 'technology' as an educational term and teachers' use of technology in school. The introduction of this national curriculum has created a situation where the pedagogical and didactical conditions in Norwegian classrooms have changed considerably. This situation calls for a more in-depth consideration of how ICT influences 'how teachers teach and learners learn' in the digital era as well as how it is reflected in the new teacher education. Neither Norway nor other countries have highlighted the ICT challenges to which teacher education has been exposed as a result of the digitisation of society and schools. Kirschner, Wubbels and Brekelmans (2008) observe that the majority of teacher educators (TE) have paid the ICT area little attention and researchers have largely ignored ICT in teacher education. Against this background the aim of the article is to consider ICT in the light of policy documents, research studies, teacher education and the general digitisation of schools in the Norwegian context and formulate advice that may be useful for other countries. The question considered by the paper is how the new curricula in school and the general plan for teacher education in Norway influence the underlying premises for teaching and learning in today's schools and teacher education in Norway. In recent years, Norway has become one of the leading countries with regard to accessibility of technology in society and schools, and consequently there is a need for more knowledge and awareness about how this situation influences socio-cultural participation, socio-economic patterns and digital divides. This digitisation of society and schools in Norway leaves little doubt that the digital revolution has made its mark on both society and school systems to an even greater extent than in other countries. In recent years, Norway has been one of the highest ranking nations in relation to technology penetration in society (Castells, 2001; Vaage, 2005, 2008, 2009; Utdanningsdirektoratet, 2008; OECD, 2010). According to the Norwegian Media Monitor (Vaage, 2009), in 2009 92% of Norwegian households owned a PC (average 2.1 PC per household) and 91% were connected to the Internet (82% with broadband access). Among young people, 97% of 16-19-year-olds had broadband access at home in 2009. 98% of the Norwegian population owned a mobile phone in 2009 and 65% of households used their PC for an hour and 46 mins every day in 2009. In elementary schools there were 3.7 pupils per PC in 2009 (Hægeland, Kirkebøen & Raaum, 2009). In upper secondary schools, there was one pupil per PC in 2009, and for the first time in Norwegian history, every pupil who started their upper secondary education in 2008-09 received their own laptop free of charge from the government (Utdanningsdirektoratet, 2008) and 55% of 9-15-year-olds and 70% of 16-24-year-olds used social media (Facebook, Twitter, etc.) every day (Vaage, 2009). Of these, 41% of 16-19-year-olds spent five hours or more every day in front of a screen in their leisure time outside school (Vaage, 2008). For elementary pupils (age group 9-16) the tendency is the same and digital learning resources are increasingly replacing textbooks for homework (SAFT, 2006). In some counties, paper textbooks have been replaced by digital textbooks for several subjects in upper secondary schools. Consequently, Norway is a particularly good starting-point when it comes to technology access and the opportunities, challenges and dilemmas it faces in the running of schools. One can therefore ask to what extent does this have any impact on pupils' knowledge and learning?

As regards the pedagogical use of ICT in teacher education and schools in Norway, there are three important frame factors that must be considered: the enormous digitisation of society and school in the last ten years, the new

national curriculum (MOK, 2006) for schools and the new general plan for teacher education (MOK, 2010). These frame factors have altered so many of the underlying conditions for teaching, learning and knowledge that although many of the former conceptions of pedagogy and didactic are still valid, Krumsvik and Almås (2009) found it necessary to revitalise general didactic to take into account the new pedagogical and didactical streams we are facing today. To describe this situation in conceptual terms, we found it appropriate to present a new concept, digital didactic, which takes into account the didactical terrain teachers, pupils, teacher students and TEs' are treading in digitised schools and teacher education. One definition of this concept is: 'Digital didactic is an instructional theory of technology which puts a special focus towards the art of teaching in technology dense learning environments' (Krumsvik & Almås, 2009:14). When revitalising pedagogy and didactic for the digitised school and teacher education, however, it is quite clear that one has to give particular consideration to the structures which have strongest impact on teachers' and TEs' professional development today.

The aim of the paper is to consider ICT in the light of these policy documents, relevant research studies, teacher education and the general digitisation of schools in the Norwegian context. The question considered by the article is how the new curricula in school and the general plan for teacher education in Norway influence the underlying premises for teaching and learning in today's schools and teacher education Norway. The methods used in the study was quasi statistics (Maxwell 2005) and document analysis (Merriam 2009).

PAPER PRESENTATION

Using social media to activate unemployed youth and early school leavers

Paulo Moekotte, Utrecht University, Netherlands; Henk Ritzen, Applied University Edith Stein, Netherlands; P. Robert Jan Simons, Netherlands School of Educational Management, Netherlands

The paper presents the results from the first phase of an education design research, identifying and describing design criteria that can be used for designing learning arrangements that are (1) designed for school leavers and unemployed youth with little or no access to learning opportunities; (2) more context driven than curriculum driven; (3) situated in an out-of-school context and (4) providing malleable technology that can be appropriated by the intended users.

Learning is seen as of the greatest importance in trajectories and tracks aiming at promoting participation on the labour market. But most job counselling or work-placement programmes do not entail training or education because of the dominant 'work-first approach' or because of the difficulties that social services or job counsellors encounter when trying to match supply and demand.

Data has been gathered from contextual analysis, combining desk research and interviews of focus groups of managers, and needs analysis, i.e. several interviews of focus groups consisting of social professionals and school leavers. The contextual and needs analysis have been combined with findings from the literature study..

The findings that will be presented, illustrate the constraints and perceived needs of professionals and youth with regard to attention in guidance and counselling tracks for social competencies and social capital as contributing factors to self-sufficiency and opportunities, and the use of social media in the process of negotiating goals, establishing agreements and carrying out individual 'learning contracts'.

Introduction

In the Netherlands like in many other countries, many early schoolleavers become disengaged with learning (Appleton, Christenson & Furlong, 2008) and finally are 'pushed' or 'pulled' out of the vocational educational system (Meng et al., 2009). A relatively large number of the local unemployed youth above 18 (n=11390) in the region of Twente in the Netherlands is low-skilled (78% are qualified under ISCED 3C short level) and can be considered 'inactive' and hard to reach (60% not registered/on welfare). The reluctance to register one self can be seen as part of the problem of social services to reach unemployed youth.

Rationale

Persistent problems like social exclusion (Eimers & Verhoef, 2004; Roest, 2010), unemployment (Ewalds, 2009) and school drop-outs, have proven that economic improvement in its own, does not warrant or create the opportunities for early school leavers to participate in a lasting way. Learning is still seen as of the greatest importance in trajectories and tracks aiming at promoting participation on the labour market, but most job counselling or work-placement programmes do not entail training or education because of the dominant 'work-first approach' or because of the difficulties that social services or job counsellors encounter when trying to match supply and demand (Inspectie Werk en Inkomen, 2008). Seeing employment as an important factor for lasting self-sufficiency and taking into account the labour market demand for flexibility, more lasting effects of counselling programmes could be expected if the transition to work would also encompass more attention for the development of participatory

competencies (Wildemeersch et al., 2001). Furthermore educational institutions should spend more attention to social competencies and social capital as factors that influence economical and social participation and opportunities to grow in a lasting way (Bronneman-Helmers & Herweijer, 2004; Berghouwer & Van Wieringen, 2006; De Graaf-Zijl et al., 2006; Hovels, Visser & Schuit, 2006).

Research questions

The questions that should be answered with regard to the arrangement that should be developed, are the following:

- which social competencies contribute to active participation?
- how can social capital be developed and sustained?
- which educational, technological and social affordances are required to design the according learning arrangements?

This research aims at developing criteria that can be used for designing learning arrangements that are (1) designed for school leavers and unemployed youth with little or no access to learning opportunities; (2) more context driven than curriculum driven; (3) situated in an out-of-school context and (4) providing malleable technology that can be appropriated by the intended users.

The focus of these arrangements is on developing young people's social competencies, communicative skills and social capital (resources and meaningful connections) to enhance their self-sufficiency and ability to react to and cope with labour market demands. Depending strongly on the willingness and ability of several local institutions to cooperate, the research is designed with requirements like interaction and collaboration in mind.

Theoretical framework

Important theoretical insights and concepts with respect to this research are drawn from several theories, i.e.

- adaptive structuration theory (Desanctis & Poole, 1994)
- affordance theory (Gibson, 1977)
- theory of situated learning (Wenger & Lave, 1991)
- the appropriation theory (Bakhtin, 1979/2000)
- the concept of the technology appropriation cycle (Carroll, 2004)
- the concept of the sociability of CSCL environments (Kreijns, Kirschner & Jochems, 2002)
- the construct of psychological ownership (Barki1, Pare & Sicotte, 2008; Gaskin and Lyytinen, 2010)

Research design

This research is designed as an educational design research (Van den Akker et al., 2006) comprising of several phases or stages of research activity. The paper will cover the first, preliminary phase of research that leads to the identification and description of design criteria to be used for the development of an educational intervention. This preliminary phase consists of three major research activities:

- a contextual analysis of the local policies and practices combined with the data analysis of the local results (desk research) and focusgroups with managerial representatives from local stakeholders
- a needs analysis in the form of focusgroups of social professionals and school leavers
- a literature study or review

The combination of the needs analysis and literature study aids in the identification of the design criteria for an educational intervention whereas the contextual analysis frames the requirements, intricacies and demands that are inherent to the local context. A final element that is part of the preliminary phase is the study of 'inspiring examples' which resemble the case at hand. These inspiring examples may be subjected to 'reverse engineering' in order to detect additional criteria that can be used.

The research is conducted in the region of Twente in the Netherlands. A design study requires interaction and collaboration between researchers, teachers, and other stakeholders. Among these stakeholders are representatives from municipalities, social services and local youth work. Such interaction opens up possibilities for richer, more relevant research, but also brings along methodological challenges as methodological quality and rigor have to be paired with contextual relevance and usability. The research therefore requires a qualitative research approach on a local scale. In this sense the contextual analysis can be considered to be treated as a case study on a regional level (Hamel, Dufour & Fortin, 1993).

The first phase of this research will be concluded in February of 2011. The needs analysis and part of the contextual analysis is being conducted in the form of semi-structured interviews with focus groups consisting of local social professionals and managerial representatives (from educational institutions, municipalities, social services and youth

work) and focus groups consisting of local youth who have dropped out of school or are considered 'at risk' of quitting school. These school leavers are selected by means of 'key informant recruitment' (Peek & Fothergill, 2007) by the social professionals or teachers/counsellors who work with them. The interviews are guided by a lead questionnaire. Three different questionnaires have been created to conduct the semi-structured interviews. The interviews are recorded, transcribed and labelled with the aid of a software tools for qualitative analysis (Atlas TI) en further statistical analysis (SPSS).

Findings

Results from the first phase of this research will be presented during the EARLI 2011 conference "Education for a Global Networked Society" in Exeter, UK.

PAPER PRESENTATION

Towards a New Motivational-Based Model of Innovation Adoption

Ellen Usher, University of Kentucky, United States; Francesca Fanni, Università della Svizzera Italiana, Switzerland;
Jayson Richardson, University of Kentucky, United States

In this presentation, we seek to offer a conceptual model that draws on insights from two complementary theories of behavioral change—diffusion of innovation theory and social cognitive theory—to explain why individuals and groups adopt any given innovation. Both theories have been used extensively to explain human action (or inaction) in a variety of domains and settings. We situate this new conceptual model within the field of education, where the potential for technological innovation has created new possibilities and challenges for administrators, teachers, and students. We then offer implications for practices that enhance the adoption of educational technology innovation in diverse global societies.

Relevance of EARLI: Learning and Instruction

Psychologists and education researchers alike have long attempted to identify those behaviors that produce better learning outcomes for students. These behaviors have historically included curriculum development, classroom management, pedagogical mastery, and classroom practices. At the close of the first decade of the twenty-first century, optimized instruction seems to rest increasingly on the successful integration of digital technologies for individualized learning. This calls for educators who are both competent and confident in their ability to adopt new instructional technologies.

Among the aims of the EARLI 2011 conference is to examine how technology is creating new possibilities and challenges for teachers. In this conceptual paper we seek to identify the willingness or reluctance of teachers and school leaders to adopt and implement new learning technologies in their practice. The goal of the proposed theoretical paper is to present complementary insights from two theoretical viewpoints regarding behavior change.

Complementary Theoretical Perspectives

Perspective 1: Diffusion of Innovations Theory

Rogers' (2003) model of the diffusion of innovations theory refers to the "process by which 1) innovation 2) is communicated through certain channels 3) over time 4) among the members of a social system [author's emphasis]" (p. 11). According to Rogers, adoption of novel ideas, practices, or objects requires "a decision to make full use of an innovation as the best course of action available" (p. 473). He designed a model to explain the processes through which ideas, practices, or objects are communicated and thereby adopted by members of a particular society, that is, the process by which innovations lead to systemic change.

Rogers (2003) identified five attributes that influence a person's choice to adopt an innovation: relative advantage, compatibility, complexity, trialability, and observability. He called these five attributes, perceived attributes of innovations. Other authors have expanded these attributes and called them perceived characteristics of innovations (PCIs) (Moore & Benbasat, 1991). These innovation attributes are realities perceived by the end user and thus are specifically determined by the individual. Rogers (2003) notes there are five stages in the innovation adoption process:

1. Knowledge – First exposure to innovation.
2. Persuasion – Actively seeks out information about the innovation.
3. Decision – Weighing advantages / disadvantages of innovation; decision to adopt or reject.
4. Implementation – Use of innovation to a varying degree.
5. Confirmation – Final adoption of innovation.

Perspective 2: Social Cognitive Theory

In social cognitive theory, human functioning is viewed as the product of a dynamic interplay of personal, behavioral, and environmental influences. How people interpret the results of their own behavior informs and alters their environments and the personal factors they possess which, in turn, inform and alter subsequent behavior. This is the foundation of Bandura's (1986) conception of reciprocal determinism, the view that (a) personal factors in the form of cognition, affect, and biological events, (b) behavior, and (c) environmental influences create interactions that result in a triadic reciprocity (see Figure 1).

Social cognitive theory provides an agentic view of human behavior in which individuals, through their own self-referent thoughts and feelings, can in part determine the course of actions they take. Of these self-referent thoughts, none is more important than the beliefs individuals hold in their own capabilities, or self-efficacy beliefs (Bandura, 1997). For this reason, "what we know, the skills we possess, or what we have previously accomplished are not always good predictors of subsequent attainments because the beliefs we hold about our capabilities powerfully influence the ways we behave" (Madewell & Shaughnessy, 2003, p. 381). This refers to "the knowing-doing problem—the challenge of turning knowledge about how to enhance organizational performance into actions consistent with that knowledge" (Pfeffer & Sutton, 2000, p. 4).

Towards an Integrated Theoretical Model of Technology Adoption

We propose that social cognitive theory helps bridge the knowing-doing gap that likely takes place at the persuasion stage in Rogers' (2003) model. That is, a focus on this stage could help researchers to discern key differences between adopters and non-adopters. A better understanding of the personal factors that operate at this stage (e.g., self-efficacy) could lead to targeted and specific interventions that directly address the challenges experienced by school practitioners who work in technologically-supported educational systems. Social cognitive theory can be used to not only explain why this gap exists and why an implementation lag may exist, but also can provide us with an understanding of how better to support end users so that effective innovation adoption is increased.

Significance

The proposed conceptual model is needed in the field of education for two reasons. First, given the limited funding that is dedicated to technology-focused professional development, using allocated funds in targeted, specific ways can increase spread, sustainability, and scalability of a technology innovation. Second, schools are struggling to understand how best to train teachers and thus prepare students for a technology-suffused world. By understanding where to allocate resources and funding (i.e., which teachers need more support and when), school leaders are better poised to make more appropriate allocations of their limited resources. This debate is imperative given the need for seismic shifts in the innovative uses of technology in diverse learning settings.

PAPER PRESENTATION

Modeling the characteristics of innovative, progressive schools

Liisa Ilomäki, University of Helsinki, Finland; Minna Lakkala, University of Helsinki, Finland

The paper describes elements, structures and practices for an innovative, progressive school. It aims at creating a model for understanding innovation based on empirical results but which is also a practical tool for schools to reflect on and improve their pedagogy. The preliminary results indicate that successful schools have a whole-school strategy and collaborative aims, visions and practices.

Modeling the characteristics of innovative, progressive schools

Liisa Ilomäki and Minna Lakkala, Technology in Education Research Group TEdu University of Helsinki

Aims

The aim of our study is to investigate schools for creating a model about necessary elements, structures and practices for an innovative, progressive school. The society has expectations for school to educate children for the knowledge society with relevant digital and academic competence, but the international findings from schools show that digital technology is only seldom used for improving pedagogies or for ensuring that all students acquire relevant digital competences (OECD 2010; Pedersen et al., 2006).

The background for our work is multifaceted: the extensive research about school improvement, the studies about innovations, and the research about pedagogical practices, especially the approaches emphasizing knowledge creation. Our specific interest is to include digital technology in the research focuses: we are interested in studying how the new digital technology has influenced schools and how new technologies can be used to improve pedagogical and knowledge practices in schools. The main functions of school are often conservative and apparently even contrary to innovation orientation. However, the trends for knowledge-creation pedagogy are well in-line with many elements of innovation policy. In this sense we focus also on the promotion of innovations in schools, connecting it to the improvement of pedagogical and knowledge practices.

The first version of the school model was developed using empirical data from nine schools in the research project assessing The Developing School Project of Espoo City during 2000–2004. In the present study, we have collected data from five schools in Finland to update the model. The elements of the innovative, progressive school are modeled as follows:

1. The vision level of the school: The content of the vision, The vision of using digital technologies, The coherence of the vision, Intentions for progressing
2. Leadership: Distributed leadership, Principal's networking, The role of the principal
3. The culture of knowledge work: Shared knowledge practices, Networking on school level, Collaborative ICT-projects
4. Digital technology in use: Accessibility and sufficiency of resources, ICT tools in use, Students' and teachers' digital competence and use of technology, Support for digital technology and pedagogy
5. Working practices of teacher community: Pedagogical collaboration and sharing of expertise, Culture of expertise, Teachers' networking
6. Pedagogical practices: Conceptions about the pedagogical use of digital technologies, Learning activities that utilize digital technology, Support for improving knowledge practices, Digital technologies supporting motivation

Our aim is to build the model for explaining connections between the school level practices and the classroom level, and for integrating the investigation of new technology and concrete everyday practices at school (see Ilomäki, 2008). The phenomena are actualized on "lower" levels but the "upper" level has a strong impact on the realization of phenomena. We suggest that there is a strong and essential interaction between different levels; this is one of the main starting points of our study. Investigating the culture of knowledge work on the school level and on knowledge practices on the classroom level is a new research perspective.

The aim of the current research project is, further, to develop a practical, theory-based model for schools to improve their own practices. There is a need for practice-oriented methods that help schools and teachers themselves to reflect and even investigate their own practices and thus improve those (Angelides, Leigh & Gibbs, 2004). The aim is to narrow the gap between empirical research and practical school work (Wikeley, Stoll & Murillo, 2005).

Methodology

In order to capture the multilevel and multifaceted phenomena in a school, the methodological background is in the mixed methods research (Teddle & Tashakkouri, 2003), which intentionally engages a multiple set of approaches and leads to a better understanding of the objects of investigation. In our study, the data collection concentrates on the main actors – students, teachers and the principals – and the data is both qualitative and quantitative.

The study is a multiple case study; and the data from five schools consist of:

- videotaped classroom observations (five lessons from each school in which ICT is used);
- interviews of five teachers and the principal;
- questionnaires concerning the competence and use of digital technologies (all teachers and 6th and/or 9th grade students);
- other material and observations about technology usage in the school.

Preliminary analyses from three schools are ready, and the analyses from two other schools will continue during the autumn 2010.

Findings and educational implications

Results from the first three schools indicate that there are major differences between primary and secondary level school in their working culture. Innovations and improvements seem to be easier to conduct on primary level. In best schools there is a well-functioning teacher community which has shared vision, aims and practices for improving the school. The use of digital technology is very diverse; at best it is inspiring and wide spread, at worst limited and old-fashioned. Students' possibilities to use and learn digital media embedded in the learning and knowledge creation activities are not equal because of the differences between schools and between teachers within one school.

Schools need explicit support for whole-school development work. The model appears to be a useful tool for schools to reflect their practices. Resources for technology or training are not enough; supporting the community is central. Collaborative development projects appear to be a good way to train; more resources should be put on them but emphasizing projects that concern the whole school or aim at disseminating the practices wider from the most active teachers. Data from all five schools will be used to further specify the innovative, progressive school model and the recommendations.

Significance of the study

New methods and tools are needed to disseminate and implement digital technologies in education, for teachers and schools. The model appears to be a practical and collaborative tool for schools to reflect their own practices. The model has raised interest and suggestions for collaboration in research fields and in training organizations.

PAPER PRESENTATION

Procrastination In An Online Learning Context: Effect of collaborative task

Virginie Demeure, Universitat Autònoma de Barcelona, France; Margarida Romero, Esade, Spain

The well known phenomenon of procrastination is studied here within the context of online distance learning. This context is particularly of interest in regards to the advancement of the characterisation of procrastination behaviour. Although many studies have gathered several characteristics which enable procrastination, such the level of responsibility of the students on the time-on-task regulation, very few studies focused on online distance learning. Within this specific context, this paper explores the impact of collaborative learning tasks compared to individual tasks, in regards to individual procrastination behaviours by analyzing anticipated temporal patterns and the actual temporal learning patterns of online distance students engaged successively in individual and collaborative learning tasks. The results of this study conducted in an authentic context of online distance learning showed a global positive effect of collaborative activities in regards to individual procrastination behaviours. Indeed, compared with individual context, online students tend to increase their time-on-task earlier regarding the deadline in collaborative context. They also start to work on the task at non-conventional moments, (i.e. week end and early/late hours of the day), since the mid-term of the activity, thus signalling feelings of time constraint. Finally, the comparison between anticipated and actual temporal patterns of learning activities, show that students deviate more from their anticipated pattern in a collaborative context, this tendency increasing with the approach of the deadline. Implications of these results for online distance education are discussed at the end.

Academic procrastination is a well known phenomenon consisting in behavioural postponement leading to time pressure and often linked in the literature with a lack of self efficacy in self regulation.

In a context of high time flexibility, such as in distance education, in which students have the possibility to regulate their time-on-task allocation, procrastination, can have serious implications. Indeed, in a distance education context, external regulations by peers or teachers fall dramatically and if students are not able to self regulate, they have more chances to fail at the task.

Distance education has, however, the particularity to be mostly chosen by adults with work and family constraints, which allows for other explanations in relation to behavioural postponement. To avoid this kind of confusion, e-learners were asked to declare their available time for academic task on a specific tool. This information was also visible by the other members of their group to facilitate collaboration and students had the possibility to change their initial declaration all along the task.

As explained previously, distance education contexts, due to their high time flexibility, can facilitate procrastination. However, the specificities of collaborative environments should act as a barrier against procrastination behaviours.

Two group phenomenons lead us to think that procrastination should be less important in a collective task than in an individual task.

Firstly, working in a group can increase the temporal pressure because of group interdependence. Indeed, teammates often divide the work to do among themselves, and regularly pool their work to advance on the task. This type of organization is close to adding intermediate milestones along the task. In this situation, learners' tend to organize their time-on-task considering their group organization and the internal milestones and responsibilities defined by the group. As a result of this interdependency, time flexibility in collective activities is reduced, increasing at the same time, the time structure and pressure through out the task. We could suppose that the reduction of time flexibility and the highest level of interdependency will incite the students to work more regularly, and reduce the interdependency level.

Secondly, as predicted by the Social Facilitation Theory of Zajonc (1965), working in a group can lead to an improvement in performances because of the simple fact that the student is being observed.

The objective of this study is to explore, in an authentic CSCL context, the impact of collaboration on academic procrastination. The data of students ($n = 66$) having to realize successively individual and collaborative tasks are analyzed at this aim. The general tendency of work on the task during the time allowed is considered regarding three periods: the beginning of the task, the mid-term of the task, and the end of the task. As well, in order to have time pressure indicators, we consider the use of weekends and late hours of the night by students to work on the task across these three periods.

Data was recollected both from the Knol environments used by students to produce the task (writing first individually, then collaboratively a paper on the theme of CSCL), and from the collaborative awareness tool enabling students to declare prospectively their availability for the academic activity. The Knols logs describe the type of contribution made by each group member, with its date and hour of publication. For our analysis, we considered the date of the contribution in relation to the beginning of the task, (day after the start of the activity), the day of the week when the contribution was made and at what hour. The tools logs describe the same information but prospectively declared by students.

Results were analysed using within subject ANOVA and show a main effect of individual/collective dimension [$F(2,51) = 28.93$, $p = .02$], a main effect of phases (beginning of the task, mid-term and end of the task) [$F(2,102) = 24.66$, $p = .02$], and an interactional effect between these two variables [$F(2,102) = 7.70$, $p = .001$, $\eta^2 = .07$].

The first effect is due to the fact that students tend to increase their academic work at the approach of the deadline (mean participation of 2.35 ($SD = .46$) at the beginning of the activity, to 6.97 ($SD = 1.08$) at the mid-term, and to 11.98 ($SD = 1.84$) at the end of the task). The second one comes from the fact that students in collaborative context made more contributions (mean = 11.73 $SD = 1.81$) than in individual context (mean = 2.47 $SD = .38$). Finally, the interaction effect shows that, whereas in collaborative context students tend to constantly increase their work from the beginning to the end of the task, in individual context a rise is observed at the end of the activity, leading us to think that there is a higher rate of procrastination behaviours.

Complementary results exploring time pressure show that students in the individual context tend to work longer in the day (between 6 a.m. and 9 p.m.), at the end of the task than at the beginning and mid-term (between 10am and 1pm), whereas in a collaborative context, they work at the same time periods (between 10 a.m. and 9 p.m.), from the beginning to the end [$F(10,510) = 1.23$, $p = .27$].

Finally, analysis comparing prospective declarations and actual participation in regards to the academic tasks, show that students in individual contexts tend to work more during non projected moments than in collaborative contexts [$F(1,27) = 32.09$, $p = .02$]. This tendency increases with the approach of the deadline [$F(5,135) = 4.65$, $p = .001$, $\eta^2 = .13$], in both contexts.

These results suggests higher procrastination behaviours and time pressure in an individual context than in collaborative one, evoking a positive effect from group work on procrastination. This study having been conducted in authentic and thus quasi-experimental context, means that these results need to be verified deeply, however, the development of a collaborative task in distance education has to be considered as a possible preventive measure for procrastination and failure.

PAPER PRESENTATION

Learning Through Collaborative Creation of Knowledge Objects in Teacher Education

This contribution presents an empirical study of object-oriented collaboration, in which groups of teacher students work on shared knowledge objects that will be used at their internship places. The study addresses the problem of how higher education students attend to open-ended problems, which requires them to materialize their theoretical and practical knowledge into knowledge objects (e.g., didactic material, evaluation instruments, research reports), and collaborate with peers. The knowledge creation approach to learning, which places collaborative creation of knowledge objects at its core, served as a guide for a pedagogical design that attempts to support students' learning in situations as the one described above. The mechanisms of collaborative creation of knowledge objects are central to this investigation, with a focus on productive interactions and mechanisms of knowledge object elaboration. We collected different types of data, during a one-year long design study. The analyses followed three lines of investigation: analysis of group interactions, of concepts and ideas uptake, and of object co-construction and development. Findings unveiled distinctive mechanisms of collaborative creation of knowledge objects and showed various degrees of idea sharing and of co-elaboration of object iterations. These findings assist us in formulating recommendations for future research and pedagogical design, especially regarding pedagogical settings and technological support for object co-construction and co-elaboration.

Introduction and theoretical considerations

In this contribution we investigate how teacher students learn in collaboration through creating and developing knowledge objects that will be employed at their internship places. We focus especially on mechanisms of object-oriented collaboration within student groups and we provide a detailed insight into how knowledge objects are developed and elaborated by a number of groups. Higher education institutions are nowadays consistently challenged to expose students to knowledge practices they will perform as professionals. At the same time, students are confronted with increasingly demanding learning situations, which feature problems with an open-ended character and challenge them to make their own knowledge explicit. This involves theoretical and practical knowledge being materialized in knowledge objects (e.g., in educational material, evaluation instruments, research reports), where this knowledge becomes transparent for all participants. Becoming actively involved in such complex processes and creating sophisticated knowledge objects is a challenging task for students. The knowledge creation approach to learning (Paavola & Hakkarainen, 2005) can serve as a guide to develop new practices of learning and instruction, which places collaborative creation of knowledge objects at its core. Knowledge creation processes not only shape the knowledge objects constructed but are also transformed by the actions that are performed on these objects (Stahl, 2006). Nevertheless, little is known about the mechanisms of learning in collaboration when creating these knowledge objects. Collaborative learning has been extensively studied from the perspective of dialogic interaction, but less attention was given to how students interact productively when they work together on objects that materialize their knowledge. Furthermore, the way these knowledge objects are constituted and iterated is also an aspect that deserves in-depth investigation.

Empirical setting, methods and data

We collected a rich set of data, consisting of: a) interaction data; b) knowledge objects, both produced in KPE or during fieldwork and c) reflection data. The analyses consisted of three discrete processes. First, we selected and coded action-relevant episodes from the group's interactions, in order to understand the nature of their interactive activities, employing a coding scheme developed based on a similar data set. Second, we mapped the relevant concepts and ideas discussed during the analyzed interactions, and examined whether they were taken-up and materialized into the knowledge objects and their iterations. Finally, we operationalized object progression and elaboration, and analyzed how relevant concepts and generated ideas were gradually materialized and elaborated into object iterations. We identified how concepts and ideas were taken-up from one interaction to another. We employed an instrument derived from the integrative complexity system by Cummings, Schlosser and Arrow (1996) to determine the type and degree of elaborations from one iteration to another.

Results

The findings indicate that most student groups became engaged in co-constructing shared knowledge objects, but also that individual elaboration and division of labor, without much feedback on object iterations, occurred. Results indicate that groups employed different strategies to organize their work. The analyzed interactions proved also to be of heterogeneous nature. The productive interactions that explicitly contributed to the conceptual enrichment and development of the shared knowledge objects were those labelled as 'creating shared understanding' and 'collaborative generative'. The analyses of the interactions and object versions also yielded sets of relevant concepts, considered by the group as relevant for the knowledge object to be developed. The concept-maps showed that the majority concepts and ideas put forward in the 'productive' type of interactions was taken-up, expanded and elaborated. Elaborations led to the materialization of the groups' shared views and stances. Co-construction moments

occurred in some groups' work, such as discussing ideas and concepts and then following up and materializing these ideas into iterations of the objects. Elaboration of object sections was, however, often done individually, and the outcomes were placed in the group's shared space, where the other group members could read it and provide it with feedback. Finally, individual contributions were closely combined with joint activities. Individual elaboration led to numerous feedback moments by the other group members. The findings indicate that the sections of the object that were discussed and provided with feedback more than once showed a higher degree of elaboration. Some groups had difficulties to concretize the knowledge on the matter into the object iterations. Most recurrent situation was that ideas were discussed but not taken-up and not materialized. In these groups mutual feedback and revisions on iterations of the objects were less common. Theoretical and practical significance This paper focused on understanding the mechanisms of collaborative creation of knowledge objects, by analyzing interactions of students engaged in an authentic project and by tracing the development process of the knowledge objects students worked on. The findings call for attention to students' understanding of this pedagogical setting and of the type of co-construction task must engage in; also, to how these types of designs can provide more clear scaffolds for students when engaging in the object (co-)elaboration process.

PAPER PRESENTATION

Effects of Distributed Tutorship in a Blended University Course

Nadia Sansone, University of Bari, Italy; Maria Beatrice Ligorio, University of Bari, Italy

In this paper the distributed tutorship is considered as a mean to sustain active and constructive participation in a blended university course. Role Taking principles are used to assign to students specific functions and responsibilities. Covering a specific role means for students taking up a new position, being able to participate from a different point of view and, consequently, to appropriate new learning strategies. This study refers to a blended university course about e-learning, offered at a specialized level of Work Psychology, where students in turn perform the role of e-tutor. Quantitative and qualitative analysis were conducted to observe how students participation was affected by the Role Taking. Results show that students covering the role of e-tutor steadily increased their participation, even when the role was dismissed. Furthermore, they modified their participation style by becoming more supportive of the group and more collaborative. Therefore they acquired new positions during the course, especially in their participation to the group work. Practical implications can be seen in terms of indications of how to organize and structure virtual online group and collaborative learning.

Introduction

Universities and Higher Education institutions are increasingly offering online and/or blended courses (Alvarez, 2005; Bonk & Graham, 2006). These courses provide many advantages, but they often suffer of a limited students' participation and of a difficulty in setting effective constructive collaborative learning. In order to overcome these limits, online Role Taking (RT) proves to be an effective educational strategy through which specific functions and responsibilities are assigned to students (Hare, 1994; Mudrack & Farrell, 1995; Topping, 2005). Through RT students feel entitled to assume new positions and to structure their participation at the service of the group (Harre & Van Langenhove, 1992). In fact, RT is mainly intended for: (a) modeling individual behavior and regulating intra-group interaction, (b) facilitating learning, (c) stimulating group cohesiveness and a sense of responsibility towards the group, (d) supporting coordination (Johnson et al., 1992). Furthermore, RT fosters knowledge-building because it promotes students' focussing on the learning goals (Schellens et al, 2005; Strijbos et al., 2004).

The context

This research refers to a course on E-learning delivered in a blended mode at a specialized level of Work Psychology, activated at the University of Bari (Italy) during the 2006-2007 academic year. It lasted 14 weeks and it was structured into seven didactic units. Seventeen students attended the course (12 F, 5 M), divided into two groups. The starting point of each unit was the professor's offline lecture. Right after, the professor assigned the educational material to be read. As suggested by the Progressive Inquiry Model (Muukkonen, Lakkala & Hakkarainen, 2003), a research question guides the reading, the preparation of written reviews on that material and the consequent online discussions. Each group had one student playing the e-tutor and this role was re-assigned at each unit. In this way at the end of the course twelve students could cover this role. During the first unit, an expert tutor modeled the role. For

the rest of the course she supervised the e-tutors by giving them advises when requested. In fact, the supervision of the expert tutor gradually faded away and at the end of the course she intervened only occasionally. Furthermore, students covering this role could use a specific web-forum, within the virtual space of the course, to talk and compare about their experience of being e-tutors.

E-tutors were in charge of the group management by: (a) making sure all group members read the educational material (b), checking everyone posted online their reviews (c), inviting the group to read all the reviews, (d) supporting the participation to the web-forum discussion in order to answer to the research question.

Aims

This paper aims to observe how university students' participation is affected by taking the role of the e-tutor during a blended course. In particular, we want to understand whether covering a role can foster the acquisition of new positions as members of a group.

Methodology

To pursue our aims we chose to observe the two students covering the role of e-tutor during the third unit, which occurred halfway the course. This choice satisfied the need to contrast students participation before covering the role (during the first two units), whilst playing it, and once it was dismissed, during the subsequent four units.

A quantitative analyses was run on the total number of notes posted online by all the students. Frequency and mean were pondered considering the total number of notes produced by the group for which the e-tutor was playing the role. These values were calculated for each unit. Through this analysis we could monitor how much the e-tutors intervened through all the seven units.

The notes posted by the two e-tutors were also qualitatively analyzed through a content analysis. Five categories were outlined and they could be conceptualized as positions taken during the group activities, but with different focus: (a) educational: on the content (b) collaborative: on the group interaction, (c) supportive: on individuals, (d) organizational: on time and on the virtual space, (e) emotional. Two independent judges categorized the notes by discussing the contrasting categorization until reaching 100% of agreement. The percentage of each category was calculated for every unit.

Findings

Through the quantitative analysis we found that all the students reached the pick of their participation when playing the e-tutor. This applies also to our two target students (see Table 1).

Unit E-tutor 1 E-tutor 2

1	20%	7%
2	39%	8%
3	51%	10%
4	27%	9%
5	17%	8%
6	26%	3%
7	25%	1%

Table 1. Percentage of notes posted by the two target e-tutors for each unit.

Their participation changed also qualitatively. In particular, when playing the role, these students adopted a supportive position (i.e. "Good job! I think you explained the central topic very well; probably you could tell us where you found the additional information you gave us. However, you've been great!") (see Table 2).

Category E-tutor 1 E-tutor 2

Educational	21%	12 %
Collaborative	27,1%	25,5%
Supportive	36,1%	30%
Organizational	5,2%	16,5%
Emotional	10,6%	16%

Table 2. Distribution of categories whilst playing the role of e-tutor (Unit 3)

Moreover, during the four units after taking the role, the two e-tutors display different patterns:

- a) e-tutor 1 adopted a more collaborative position, aimed to offer help, negotiate decisions and propose solutions (Unit 4: 28 %, Unit 5: 40 %, Unit 6: 33 %, Unit 7: 32 %);
- b) e-tutor 2 wrote notes more referring to the educational material, displaying an educational position (Unit 4: 28 %, Unit 5: 26 %, Unit 6: 29 %, Unit 7: 33%).

By looking at the first two units, before playing the e-tutor, we found that these students never used these position. These positions appeared whilst playing the role and, to a certain extent, were maintained even when the role was dismissed.

Theoretical and educational significance

Increasing the quality of the participation is one of the most important goals of online and blended education. This research shows that RT promotes students' appropriation of collaborative and educational positions that were maintained even when students no longer acted as e-tutor for their group. From this result it can be gathered indications on how to structure students participation online. It can be also deduced that more roles could be designed so to maintain students participation high and effective.

PAPER PRESENTATION

Teacher learning within multiple collaborative settings in primary schools

Jannet Doppenberg, Eindhoven University of Technology, Netherlands; Anouke Bakx, Fontys PABO Eindhoven, lectoraat L&I., Netherlands; Perry den Brok, Eindhoven University of Technology, Netherlands

During the last two decades there has been a growing awareness of the potentially strong role of teacher collaboration in relation to teacher learning. When teachers collaborate with their colleagues, learning can take place in different formal and informal settings. Because most studies focus on teacher learning in one collaborative setting, often related to a specific innovation in a school, little is known about how teachers learn within regular multiple collaborative settings in schools. Moreover, while theoretical 'ideals' of teacher learning are abundant in the literature, relatively little is known about what teacher learning actually looks like in everyday work. The aim of this exploratory study was to obtain more detailed understanding of teacher learning in collaboration with colleagues at primary schools during everyday work. In this study teacher learning was investigated within multiple existing collaborative settings, taking into account both the undertaken activities by teachers and learning outcomes. Data was collected through semi-structured interviews with two teachers and one school leaders within seven primary schools. Analysis of the qualitative data showed that teacher learning does take place within different collaborative settings in schools however, with different degrees of intensity and outcomes across these various settings. Thus, depending of the collaborative setting more or less different activities and learning outcomes were reported by teachers and school leaders.

Rationale and theoretical framework

During the last two decades there has been a growing awareness of the potentially strong role of teacher collaboration in relation to teacher learning (Levine & Marcus, 2010; Westheimer, 2008). Collaboration with colleagues is seen as a powerful learning environment, which stimulates the professional development of teachers, the innovative development of schools as well as student learning and also characterises professional learning communities (McLaughlin & Talbert, 2006; Vescio, Ross, & Adams, 2008; Westheimer, 2008). When teachers collaborate with their colleagues, learning can take place in different settings which may vary from formal settings like team meetings to informal settings like hallway encounters (Little, 1990, 2003). Because most studies focus on teacher learning in one collaborative setting, often related to a specific innovation in a school, little is known about how teachers learn within regular multiple collaborative settings in schools (Orland-Barak & Tillema, 2006). Moreover, while theoretical 'ideals' of teacher learning are abundant in the literature, relatively little is known about what teacher learning actually looks like in everyday work (Borko, 2004; Little, 2003). In this study teacher learning is defined as a process of conscious and unconscious undertaken activities by teachers in collaboration with colleagues, which lead to change in cognition and/or behaviour at the individual and/or group level (Meirink, 2007). However, what teachers actually do in collaborative settings and what undertaken activities lead to learning is quite unclear, especially in the context of primary education. Thus, to better understand teacher learning in this project, it is studied within regular multiple collaborative settings, taking into account both the undertaken activities by teachers and learning outcomes.

The aim of this (exploratory) study was to obtain more detailed understanding of teacher learning in collaboration with colleagues at primary schools during everyday work. Accordingly, the following three research questions were formulated:

- 1) In what settings at the workplace do primary teachers and school leaders report that teachers learn in collaboration with each other?
- 2) What learning activities are reported to be undertaken by primary teachers in these settings?
- 3) What are the reported individual and group learning outcomes as a result of collaboration in these settings?

Method To obtain insight into teachers' and school leaders' perceptions of teacher learning in collaboration with colleagues in schools, data was collected through semi-structured interviews with two teachers and one school leader within seven primary education schools (21 interviews in total). The data analysis was conducted in different steps. First, the transcribed interviews were analysed based on meaningful fragments. Second, the meaningful fragments were placed in a within case matrix to understand the relation between collaborative settings and the undertaken activities and learning outcomes. Third, data of these matrices was analysed in more detail with key-concepts from the literature and categories emerging from the data. Fourth, a frequency analysis was conducted for each case. Frequencies for each collaborative setting were determined with respect to activities and learning outcomes as reported by the respondents. Finally, a cross-case analysis was carried out across cases (schools). In the cross-case analysis the result of the cases were combined and summarised in overview matrices (Miles & Huberman, 1994).

Results and conclusions

The reported collaborative settings could be categorised based on the persons involved, the aim and frequency of the setting, in: group of schools, school team, part of a team, working group, class, informal and collegial support. The categories identified in our study for activities could be categorised in terms of categories distinguished by Little (1990). For the categories; story telling and scanning, aid and assistance, and sharing singular activities were identified and for the category joint work compound series of activities were identified. Individual as well group learning outcomes could be categorised. However, the subcategories of the learning outcomes at the individual and group level were not equivalent. In literature activities and learning outcomes are assumed to be strongly related with each other. However, the respondents in our study usually connected learning outcomes to collaborative settings rather than activities. Depending of the collaborative setting more or less different activities and learning outcomes were reported. It seems that there is a correlation between the sum and amount of different reported activities and the reported learning outcomes however, from this study this cannot be directly inferred. Besides, the results seem to confirm that the dependency between teachers correlates with learning outcomes (Little, 1990). In the presentation the categories and conclusions will be discussed in more detail.

PAPER PRESENTATION

Indicators and instruments in the context of IBSE – A meta-analysis of research from 2005-2009

Inquiry learning, Organization of educational research, Science Education

Jana Heinz, Technische Universität München, Germany; Alexander Groeschner, Technische Universität München, Germany; Katrin Lipowski, Technische Universität München, Germany; Tina Seidel, Technische Universität München, Germany

This study conveys research on inquiry based science education (IBSE) with a focus on indicators and instruments. We conducted a literature review about IBSE in the fields of policy, teacher education/teacher professional development and instruction from 2005-2009. As a result of searching in the database "Web of Science" 600 articles were found and

coded with regard to their focus on motivational-affective, cognitive or metacognitive contents. We furthermore differentiated between empirical and non-empirical articles. The results of our review emphasize that the majority of research on IBSE is rather fragmented and specific to individual research questions as well as to single aspects of IBSE. By this study we want to contribute to supplying a systematic overview about instruments and indicators in the field of IBSE.

Theoretical framework

Scientific research in politics and society points to the need of enhanced scientific literacy. (OECD, 2010) Scientific knowledge and competences are regarded as prerequisites for an active participation of people in everyday and public life.

In this process, schools are regarded as key players. They should provide applicable scientific knowledge and competences as well as keep and develop the interest of students in scientific subjects. To adopt learning outcomes to these demands, teaching and learning approaches are on the test bench. One of the learning and teaching approaches regarded to be especially suited to meet these demands, is inquiry based science education (IBSE). (European Commission, 2007)

Research in educational science conveys numerous studies investigating IBSE. Mostly however, they analyze single features of IBSE and single implementation levels in the educational system. Some recent reviews systematically consider indicators and instruments in the context of IBSE – however without an explicit analysis of them (Minner, et al. 2010; IAP, 2007).

This study aims at providing a systematic collection of indicators and measures in the field of IBSE. To receive a comprehensive picture about the implementation of IBSE, we extended the scope of this review beyond a focus on instruction (1). We additionally considered research about IBSE in the implementation areas of politics/stakeholders (2) as well as teacher education and teacher professional development (tpd) (3).

Research method and design

Our review on indicators and instruments in the field of IBSE was guided by the following research questions:

1. How many studies about IBSE can be found from 2005-2009?
2. How are these studies distributed in the implementation areas of instruction (teachers, students) (1), politics/stakeholders (2) and teacher education and tpd (3)?
3. How are the instruments underlying these studies distributed with regard to cognitive, metacognitive or motivational-affective dimensions?

We searched the internet-database: "Web of Science" with ten key words, for instance: "inquiry based science teaching", "science teaching and learning", or "science literacy and scientific literacy". Each of these keywords was crossed with the three implementation level keywords: "policy, stakeholders", "teacher educators, teacher education", "teachers" and „students, pupils".

The research led to a total of 600 studies. After excluding studies due to a missing focus on IBSE, 538 studies remained. We then differentiated the studies according to their empirical or non-empirical approach.

In a second step we summarized studies, indicators and measures according to their implementation level (policy and stakeholders; teacher education and tpd; instruction).

The indicators and instruments on these three levels were further clustered around the dimensions of IBSE that were investigated (indicator area). Here we differentiated between cognitive, metacognitive and motivational-affective measures. Cognitive measures and indicators refer to student achievement or teacher professional knowledge of IBSE. Metacognitive instruments include learning and teaching strategies as well as strategies used by politicians and stakeholders to implement IBSE. Motivational-affective dimensions cover beliefs, attitudes or self-efficacy.

Three independent coders categorized the publications with regard to the categories "implementation level" and "indicator areas". Inter-rater agreement reached a mean of 80 % of codes.

Results

The majority of studies could be found on the instruction level with 160 of them investigating teachers and 222 students. In the area of policy/stakeholders 63 studies were counted and 93 studies in the field of teacher education and tpd.

We found 360 empirical and 178 non-empirical studies. A closer look at this distribution reveals that the amount of empirical studies was more than twice as high as the amount of non-empirical studies in the area of teacher education and tpd as well as in the area of instruction with a focus on teachers. In contrast to these results, in the area of policy and stakeholders more non-empirical than empirical studies were counted.

In a next step, we examined the instruments the studies were based on. As a result, tendencies in the measuring foci on the different implementation levels become visible. Thus the distribution of the instruments on each implementation level differs notably, especially with regard to the measured dimensions of IBSE.

The majority of instruments in the context of IBSE are focused on motivational-affective aspects. Most of these instruments can be found in the area of teacher education and tpd (43). A similar amount of instruments can be found in the area of instruction, namely 57, of which 29 focus on teachers and 28 on students. 18 motivational-affective instruments can be located in the field of policy/stakeholders.

Cognitive measures are predominately used in the area of instruction with a focus on students (57), followed by instruments investigating teachers in the area of instruction (13). Only three cognitive instruments could be found that are used in the areas of policy/stakeholders and teacher education as well as tpd.

Looking at the distribution of metacognitive measures, the lack of measures in the area of policy/stakeholders is notable. The majority of metacognitive measures are located in the area of instruction/students (57).

Discussion

As a result of this review the importance of further empirical studies on the policy level can be stated. Looking at the instruments, our review shows the focus of cognitive instruments is on students and student learning. In contrast, motivational-affective instruments can mainly be found in research on teacher education, tpd and teachers. Thus, research about teachers concentrates on attitudes, beliefs and opinions about IBSE. This finding points to the demand of the development of adequate instruments to measure IBSE related knowledge of teachers, university instructors and administrative stakeholders who are especially responsible for implementing IBSE into the classroom teaching practice.

PAPER PRESENTATION

Preprofessional competences: an evaluated experience working with problem based learning model

Rosario Del Rey, Seville University, Spain; Eva M Romera, Cordoba University, Spain; Rosario Ortega-Ruiz, Universidad de Cordoba, Spain

Assessment is presented as one of the greatest challenges of High Education focused on competences. But it has been one of the subjects least raised (AGAE, 2009) in Spain, after three academic courses analysing pre-professional projects adequacy as a learning tool in an experimental European Credit Transfer System –ECTS– implementation. The aim of this work is to design and develop Problem Based Learning (PBL) profits evaluation instruments in relation with the subject Psychology of Instruction of Psychopedagogy degree students' competences. For that, two instruments were used, the first one, focused on students' perception about the development of general competencies, and the second one based on student's perception about the methodology used in pre-professional projects, focused on following dimensions: motivation, practical implementation, impact on learning and knowledge transfer. Main results

showed that students had a positive perception about the methodology by pre-professional projects in relation with four dimensions of study. Moreover, there were found positive results regarding to general, cognitive, professional and transversal competence development.

Introduction

In line with what is proposed in Declarations of Bergen (2005) and London (2007), nowadays the society hopes of graduates that they have not only specific knowledge, but also know how to apply them to solve complex problems effectively. This implies the need to combine data acquisition of information with the development of useful skills to the professional field (Dochy, Segers, Van Den Bossche, and Gijbels, 2003). In this sense, Problem Based Learning (PBL, hereafter) is presented as a tool that produces benefits on competence development, compared to traditional methodologies based on the transmission of knowledge. PBL was used for the training of doctoral students but actually is a didactic tool which has shown positive results related the development of the high level competences in university students in general. The PBL model starts from the premise that we learn from meaningful and motivating problems to the students. A methodology used to develop the PBL is the model we have called Education Based Pre-Professional Projects (EBP, hereinafter) (Ortega, Rodriguez, Romera and Garcia, 2009).

This work parts from a review of international studies related to this field of study (Fernandez et al., 2006), which establishes five categories that include different aspects that have been taken into account in assessing the implementation of the PBL model: emotional component, performance practice, learning effects, generability (to other subjects, utility of learning, etc.) and skill development. Specifically, this work focuses on the evaluation of innovative processes in relation to the PBL model.

The main objective is directed to the design and implementation of tools to assess the benefits of PBL focusing the general cognitive knowledge, the transversal and the professional skills of Psychopedagogy students at the University of Córdoba. Psychopedagogy is a master studies to training the School Counsellor in Spain.

Procedure

The program has been developed in double-shifts, morning and evening, of Psychology of Instruction, a four-month subject of the first year of Degree of Psychopedagogy. Pre-professional projects were developed in practice sessions. The sample consisted of 146 students, who also participated in the project completed the questionnaire "Evaluation of academic success Based Learning" (Romera, Del Rey and Ortega, 2009), composed of 33 Likert-scale items (1-5) on: Motivation- achievement, practical implementation, knowledge transfer, effects on learning and coping with professional problems.

Results

Positive perception of perceived achievement and motivation by students in relation to the carrying out pre-professional projects, obtaining an average of 3.85 (SD = .66). Practical realization: an average of 3.91 (SD = 0.68). Transfer of knowledge greatly values the influence of working by projects to achieve these objectives, with a mean of 3.98 (SD = 0.72). Effects on learning an average of 3.97 (SD = .71) by grouping the four variables that make up this dimension.

No statistically significant differences were found based on gender or shift schedule. Furthermore, linear regressions were made to deepen variables related to skill development. Results highlight that in relation to procedure skills is found that there is an increased competence development ($F_{1,129} = 24.971$; $p = .00$) when there is greater motivation, better able to learning to learn, greater assessment of their scores on evaluation and higher use of learning. Perceived motivation is what else might be influencing the variability of our dependent variable ($R^2 = .30$).

Conclusions and Discussion

It is concluded that there is an overall positive perception by students on the benefits of pre-professional projects, highlighting the opportunity of learning to cope with problems in their professional reality, creating in them the feeling and the satisfaction of having learned useful strategies that allow them to continue learning throughout life, it is, learn to learn. With regard to skill development, students seem to express a positive view on it, which can lead us to believe that this type of methodologies not only promote competence at a generic, cognitive, procedural and transversal level, but also is linked to development metacognitive skills that allow students be aware and reflect on their own learning (Boakaerts, 1999).

A weaknesses was the demand for more tools to help them. In this sense, for the next year we try to promote the use of virtual tools such as real sources of support, following the approach of the new proposed based on e-learning which is proving to have a good impact on university students' motivation (Schneckenberg, 2005).

PAPER PRESENTATION

Managing transitions and continuity of scripted inquiry learning

Yang YANG, University of Exeter, United Kingdom; Stamatina Anastopoulou, University of Athens, Greece; Mike Sharples, University of Nottingham, United Kingdom; Charles Crook, LSRI, United Kingdom; Shaaron Ainsworth, University of Nottingham, United Kingdom; Claire O'Malley, University of Nottingham, United Kingdom; Mike Paxton, University of Nottingham, United Kingdom

A web-based toolkit, named nQuire, has been designed for networked portable devices to support inquiry learning. It has been tested with a class of Year 8 students and their science teacher through a sequence of activities including problem formation, question setting, investigation, discussion and presentation across different contexts. This study aims to understand how the nQuire toolkit enabled transition and continuity of learning across contexts. Taking a multi-method research approach, knowledge transfer across time, inquiry phases and locations were investigated. We make recommendations for ways to manage transitions across these three dimensions. For the 'time' dimension, the toolkit should offer more flexibility in sequencing the activities. For the 'inquiry phase' dimension, the toolkit should empower the teacher and students to socially and continuously construct meaning across different phases. For the 'location' dimension, the connectedness afforded by the toolkit should provide students with more contextual information, in order to overcome negative situatedness in contexts.

Introduction:

This study aims to understand continuity of inquiry learning and transfer of knowledge across time, inquiry phases and locations. A class of 13-year-old students and their science teacher were recruited to use an inquiry learning toolkit on netbooks and mobile data-probes. The toolkit supports students through a sequence of activities including investigation, debate, inquiry and presentation across formal and informal settings (Anastopoulou et al, 2010). They iterated three scientific inquiries across different contexts, i.e. their classroom, a nature reserve, their school grounds and a private garden which they did not visit.

Our research questions were:

- 1) How does the teacher manage transition and facilitate knowledge transfer across time, inquiry phases and locations?
- 2) From the teacher's perspective, how does the toolkit function to support knowledge transfer across time, inquiry phases and locations?

Theory and Challenge:

Learning is continuous. Our experiences continue across spatial, temporal and social contexts; and learning happens whenever there is a break in the flow of routine daily experiences and we reflect on the current situation, resolve to address a problem, to share an idea, or to gain an understanding (Sharples et al., 2002). Mobility afforded by technology provides learners with greater diversity of experience, unbounded by time and location (Looi et al, 2010). Hence, within exploiting mobility, continuity of learning needs to be maintained and sustained across contexts (Chan et al, 2006). Situated learning (Brown et al, 1989) offers a perspective in contextual learning. These authors argue that 'knowledge is situated, being in part a product of the activity, context and the culture in which it is developed and used.' On the other hand, Bereiter (1997) criticises the weakness of situatedness in relation to problems of transfer,

saying: "as learning proceeds it tends to become less and less generalisable to other situations...advanced stages of situated learning may, in fact, begin to yield negative transfer." Hence, both the richness of contextual learning and the seamlessness of transitions by overcoming situatedness need to be acknowledged. In this study, the contexts are defined as configurations of three dimensional elements: time, inquiry phases and locations.

1) Time is linear and not reversible. Across time, learning is structured in activities and lessons (stages) by the nQuire toolkit.

2) Inquiry phases are sequential but can be revisited and reiterated.

3) Locations are discrete and parallel to each other. Thus, the challenge to the teacher was how to manage the complexity of structured movement between stages, inquiry phases, and locations.

Methods:

In order to unpack the complexity, we adopted a multi-method research approach to reveal the inquiry learning process and capture the teacher's perspective. During ten science lessons and a day fieldtrip to a nature reserve, an intervention took place with 28 Year 8 students and their science teacher. The students conducted three different inquiries (observation, correlation and experiment) on an overarching topic of birds and noise pollution. The inquiry learning process was firstly documented in the teacher's lesson plans, the researchers' observation notes and the students' log files in the toolkit. Secondly, the teacher's interpretation of the process was captured by 10 after-lesson interviews with the teacher. The interviews were semi-structured and designed to be 20-30 minutes long.

Results and Discussion: Transitions between Inquiry Phases (See Figure 1) Figure 1: Transitions between inquiry phases The numbers in Figure 1 represent the number of directed transitions between the phases. When carrying out three different inquiries, the students had the chance to enact the different inquiry phases more than once. But not every inquiry phase was interconnected. It reveals that the transition between 'reflection' and 'plan' occurred more frequently than other phases. This strong interconnection was intended to improve continuity between what students did in the past and what students will do next.

Knowledge Transfer between Inquiry Phases

We identified that students had difficulties in linking between the activities of different lessons. This issue was particularly a matter of concern for the teacher in lesson 7, when the students needed to enact data collection twice. They had collected baseline data in lesson 5. And they were asked to plan to collect comparison data in lesson 7. Figure 2 shows how activities in lesson 7 were sequenced across time, locations, inquiry phases and inquiries. Figure 2: The Sequence of activities in lesson 7 We have addressed 'context' as a configuration of three dimensional elements. Sequencing activities within a lesson or across lessons is one type of configuration. Changing the sequence of activities will also change the learning context of each individual activity. This example not only indicates the complexity of the context, but also highlights that the toolkit should be flexible in sequencing and reconfiguring activities.

Knowledge Transfer between Inquiries

We also identified that specific strategies arise when students move from one inquiry to the next. Mobility of data requires students to make sense of the data collected from another context and envision what happened in another context. The teacher was challenged to facilitate students to make sense of what happened, based on a certain amount of relevant information. The toolkit as a networked boundary object should be able to provide more contextual information, in order to overcome the negative situatedness. With richer contextual information the teacher will be able to guide the students to continually elaborate and de-contextualise their skills and understanding.

Conclusion:

In order to optimize the students' experiences, we make recommendations for ways to manage transitions across these three dimensions. For the 'time' dimension, the toolkit should offer more flexibility in sequencing the activities. For the 'inquiry phase' dimension, the toolkit should empower the teacher and students to socially and continuously construct meaning across different phases. For the 'location' dimension, the connectedness afforded by the toolkit should provide students with more contextual information, in order to overcome negative situatedness in contexts.

PAPER PRESENTATION

Results of federally-funded RCT using PBL in high school economics

Jason Ravitz, Buck Institute for Education, United States; John Mergendoller, Buck Institute for Education, United States; Neal Finkel, WestED, United States

Over the years, supporters of project- or problem-based learning (PBL) in K-12 have generally had to rely on limited research, weak research methods, and sometimes mixed results. Results from a federally funded, randomized

controlled experiment in high school economics provide evidence for the efficacy of PBL and should fuel growing interest in this approach to instruction. The study examined the impact of a one-week summer professional development institute and use of five PBL curriculum modules on the economic knowledge of approximately 7,000 12th grade students, taught by 76 teachers in 66 schools. Student outcomes that were studied included scores on the standardized Test of Economic Literacy (TEL), and scores on performance assessments of student conceptual understanding. Teacher outcomes included confidence in teaching economics and satisfaction with teaching materials. The findings, prepared by the Regional Educational Laboratory West (REL West) at WestEd, indicates there were significant positive impact for students of teachers who received the curriculum compared to their peers and teachers scored higher in satisfaction with teaching materials and methods than those in the control group.

Why study economics?

In the US, forty-eight states now include content standards in economics, with 40 requiring their implementation, and 17 requiring a course in the subject for graduation. (National Council on Economic Education 2007). Economics is a required course for high school graduation in California and Arizona, the two states where the study takes place, and is usually taught to seniors for one semester. While there is growing agreement on the need for some economics content in K–12 education, there is less consensus about how to teach it effectively (Walstad, 2001, Watts, 2006).

Why study PBL?

PBL is an approach to instructional design that can help organize the curriculum and deliver instruction. It provides a mechanism to gain student attention, to motivate and anchor learning. There have been relatively few well-designed K-12 experiments, however a few studies do suggest PBL can be effective in diverse K-12 settings (Barron & Darling-Hammond, 2008; Boaler; 1992; Edutopia, 2001; Marx, et al., 2004). Research involving higher education settings has generally shown promising results, particularly for longer-term learning outcomes (Strobel & van Barneveld, 2008; Walker & Leary, 2008).

There has been an evolution of thinking about what PBL is. PBL can no longer be equated with “minimally-guided or “discovery learning” (Hmelo-Silver, Duncan & Chinn, 2007; Mayer, 2004; Kirschner, Sweller & Clark, 2006). Gradual consensus appears to be building that not all PBL is created equal. Considerable effort has to go into problem or project design, scaffolding and management of learning activities, and the requisite professional development for teachers in order for PBL to be effective.

A PBL approach to economics

The approach to PBL in this study represents a modification of the problem-based approach originally developed for use in medical schools (Mergendoller, Maxwell, and Bellisimo 2000). The step-by-step teaching guide that is provided is the cornerstone of each module, as provided by Social Studies School Service (2010). It lays out for teachers the problem statement, introduction, placement in curriculum, concepts taught, objectives, content standards, time required, lesson description, resource materials, sequence of the unit, procedures, and do’s and don’ts.

Research Questions

The research questions for the study reflect the expected changes in teacher knowledge and practice, attitudes toward teaching economics and student outcomes, they include:

1. Does PBE change students’ content knowledge in economics?
2. Does PBE change students’ problem-solving skills in economics?
3. Does PBE change teachers’ content knowledge of economics?
4. Does use of PBE change economics teachers’ instructional practices?
5. Does the use of PBE change teachers’ satisfaction with teaching materials and methods use?

Note. A full report of methods and results for all five research questions are available from Finkelstein, et al. (2010) . This paper draws extensively from their report.

The study population and sample

This study targeted high schools in urban, suburban and rural areas and engaged teachers who committed to teach economics for two semesters during the 2007/08 academic year. After random assignment, and accounting for attrition and missing data, the intervention group for Spring 2008 included 35 teachers and their 2,502 students, while the control group included 29 teachers and their 1,848 students.

Measures

The primary outcome measure for this study is content knowledge gains for students in economics measured by the Council for Economic Education's Test of Economic Literacy (TEL), a 40-item closed-response exam (Walstad and Rebeck, 2001). This is a widely accepted, standards-aligned test used across the United States to measure economic literacy among high school students.

Student problem-solving skills are measured with open-response performance assessments of applied economics concepts (performance task assessments) developed by the Center for Research on Evaluation, Standards, and Student Testing at the University of California, Los Angeles (UCLA CRESST). These written tasks gave students the ability to demonstrate problem-solving skills as they answered open-ended essay questions, as outlined by Baker, Aschbacher, Niemi & Sato (1992) and Niemi (1996).

All outcome variables were treated as continuous variables in the impact analyses (estimated using multilevel or single-level linear regression models). To increase the precision of the estimates, a set of baseline characteristics of students and teachers was included in the models as covariates.

Key Findings

Results indicate that students whose teachers had received professional development and support for use of the PBL economics curriculum outscored their control group peers on the Test of Economic Literacy by 2.60 items (effect size = 0.32).

Student academic performance was also assessed using open-ended performance tasks that tested problem-solving abilities in short essays. On a composite score of these tasks, students in the intervention group outperformed those in the control group (effect size = 0.27, $p < .05$).

Finally, the economics teachers who used the PBL approach were significantly more satisfied with the materials and methods than their peers who did not use the curriculum. The effect size was quite substantial (effect size = 1.09, $p < .01$).

Conclusion

The positive outcomes from this study are ground breaking in many ways. We are not aware of any other federally funded studies of this kind that examined PBL in a K-12 setting. However, in other respects this study only scratches the surface.

A study like this only looks at "bottom line" differences attributable to the intervention. It does not address variations in the outcomes due to the quality of implementation or differences within teachers (e.g., who was more successful teaching economics than others using the curriculum and with which students, or how their practices in general and implementation of the curriculum differed).

Observations of classrooms indicate that implementation of the PBL units varied enormously depending on the individual teacher. There were a lot of teachers in both treatment and control groups who were extremely engaging and had a certain "spark" for economics that was conveyed to students, while in both groups there were teachers who lacked this spark. (Personal communication with Neal Finkelstein, September 24, 2010)

There is an inherent inability for this study, as it was designed, to untangle curriculum and pedagogy. The treatment group received not just a PBL approach to curriculum but a series of information sessions and materials designed to support their content knowledge and teaching during the curriculum. This makes drawing conclusions about the effectiveness of the PBL approach problematic without further investigation.

PAPER PRESENTATION

Paying for Quality? Associations between private school fees, performance and use of resources

Peter Davies, University of Birmingham, United Kingdom; Neil Davies, University of Bristol, United Kingdom

Using a sample of schools responsible for teaching 70% of 18 year-olds in private schools in England this study investigates effects of resource variation on students' attainment in private schools. The restriction of focus to private schools alleviates some of the problems with studies of resource use in the state sector. That is, (i) there is substantial

variation between private schools in the per student level and deployment of resources; (ii) there is very limited between school compensatory finance; and (iii) since these schools operate in a competitive market they are expected (e.g. Hanushek 1997) to face incentives to use additional resources in ways that increase students' attainment. If market incentives encourage improvements in student attainment we should expect find (i) that parents pay higher fees in schools which achieve higher value added; and (ii) that schools with higher per student income devote that additional income largely to uses of resources for which there is greater evidence of positive impact on attainment. Contextualised Value added was found to be significantly (peach of a lower pupil-teacher ratio, higher average staff earnings, larger school size and a lower proportion of teachers in the staff. Higher fees (at age 11 and 18) were found to be significantly positively associated with value added, the size of the school (students enrolled) and average staff earnings and negatively associated with the pupil-teacher ratio and the proportion of teachers in the staff.

Aims

1. To investigate effects of resource variation on students' attainment in private schools. The restriction of focus to private schools alleviates some of the problems with studies of resource use in the state sector: (i) there is substantial variation between private schools in the per student level and deployment of resources; (ii) there is very limited between school compensatory finance; and (iii) since these schools operate in a competitive market they are expected (e.g. Hanushek 1997) to face incentives to use additional resources in ways that increase students' attainment.
2. To provide indicative evidence of effects of market forces on schooling quality. If market incentives encourage improvements in student attainment we should expect find (i) that parents pay higher fees in schools which achieve higher value added; and (ii) that schools with higher per student income devote that additional income largely to uses of resources for which there is greater evidence of positive impact on attainment.

Methodology

Two OLS regression models (dependent variables of contextualised value added in one and termly fees in the other) with robust standard errors are tested. The independent variables included in the models are: (school resources) staff salary levels, pupil-teacher ratio, teachers as a percentage of all staff, (peer effects) average examination grade per student at age 18, dummy variable for faith school status, (household income) average weekly wage by region, (school assets) school reserves per pupil. These data are compiled in a unique data set from school web sites, school official accounts lodged with the UK charities commission and school performance tables published by the Department for Schools, Children and Families. The sample comprises all private schools in England included in the national Times Independent School league tables for which individual school level data are available through accounts published by the Charity Commission. This sample of 348 schools accounts for 70% of all 18 year olds educated in private schools in England.

Findings

1. Contextualised Value added was found to be significantly (peach of a lower pupil-teacher ratio, higher average staff earnings, larger school size and a lower proportion of teachers in the staff.
2. Higher termly School fees (at age 11 and 18) were found to be significantly positively associated with value added, the size of the school (students enrolled) and average staff earnings and negatively associated with the pupil-teacher ratio and the proportion of teachers in the staff.

Theoretical and educational significance

Relationships between resources, value added and fees in private school have not previously been investigated despite strong claims (e.g. Hanushek 1997) that these would be likely to show significant resource effects demonstrating the efficacy of market incentives in schooling. This neglect perhaps reflects the difficulty in compiling data sets which include the appropriate variables for schools outside the state sector. One previous study (Graddy and Stevens 2005) using data on private schools in the UK found that value added was higher in private schools with lower pupil teacher ratios. This study uses a more secure basis than Graddy and Stevens in measuring value added and includes additional measures of resource use: salary levels and the proportion of teachers in the staff complement. In addition, the associations found between fees, value added and resource use are consistent with the hypothesis that market forces provide incentives to schools and parents which encourage more efficient use of resources. Whilst these findings do demonstrate causation they provide useful starting points for further study. References Graddy, K. And Stevens, M. (2005). PAPER PRESENTATIONS

Last year in Secondary School. Any problem?

Merce Clariana, UAB Universitat Autònoma de Barcelona, Spain; Concepcion Gotzens, Universitat de les Illes Balears, Spain; Candido Genovard, Universitat Autònoma de Barcelona, Spain; Teresa Dezcallar, Universitat Autònoma de Barcelona, Spain

The purpose of this study was to investigate both the academic and psychological changes observed in 196 female secondary and university students aged 16 to 22. To find out about these developmental and learning transformations we analyzed 3 so-called "good for learning" variables: previous cultural knowledge, average mark, and conscientiousness. To such helpful characteristics, we added 3 "bad for learning" characteristics: academic procrastination, academic cheating, and extraversion.

While we were expecting a steady increase in good for learning variables (Knowledge, Mark, and Conscientiousness) and a continual decrease in bad for learning features (Procrastination, Cheating, and Extraversion) over the years, none of the kind has been found. First of all, the progress made by our variables was neither steady nor did it followed the hypothesized direction. On the other hand, the students aged 18, who are finishing secondary school and get ready to go to university, were found to exhibit the worst characteristics with regard to learning and studying. According to our data, the 18 years-old are significantly different from all other students in all the variables analysed. They are less conscientious, have less previous knowledge, get lower grades at school, are more extravert, and tend to procrastinate and cheat more in academic settings. So the initial question is still open: Is there any problem at the end of secondary school?

The study analyses relevant academic and personality characteristics of female students attending secondary schools and universities in Barcelona (Spain).

The research was carried out during last year. Depending on their current age and course, the girls were assigned to one of the following groups:

- Age 16, fourth year compulsory secondary school students, n=47.
- Age 18, last year post-compulsory secondary school students, n=35.
- Age 20, second year Psychology undergraduates, n= 62.
- Age 22, final year Psychology undergraduates, n=52.

As we were looking for homogeneous samples, males and students from other ages were not included.

The aim of the study was to test the evolutionary pattern of the following variables:

- "Good for learning":
 - o K = Previous cultural knowledge.
 - o M = Last term academic grade average.
 - o C = Conscientiousness.
- "Bad for learning":
 - o P = Academic procrastination.
 - o F = Academic faking and cheating.
 - o E = Extraversion.

According to previous results (Dietz et al., 2007; Furnham et al., 2009; Komarraju et al., 2009; Rätty et al., 2010; Shokri et al., 2007; Spinath et al., 2010)), "good" variables were supposed to show an increasing tendency from ages 16 to 22. When the students reach their final year at the university they have survived a long selective process, and they are meant to have gained skills to cope with the academic demands. So, we expected the 22 year-olds to be expert learners, to know a large amount of content (K), to have developed a high conscientiousness (C), and to have got high marks in their previous modules (M).

Also, undergraduates aged 22 were supposed to show low levels of the "bad" variables. Close to graduation, the girls were thought to know to overcome procrastination (P), to replace cheating for studying to pass the courses (F), and to withdraw from deficient study tendencies commonly associated with extraversion (E), such as the lack of perseverance and the incapacity to reject social activities when they struggle with the scheduled time for studying. In summary, we expected a consistent growth of "good" variables (Knowledge, Marks, and Conscientiousness) from ages 16 to 22, and a continuous decrease of "bad" variables (Procrastination, Cheating, and Extraversion) at the same age interval.

To test our hypotheses we asked the participants to answer the following questionnaires:

- K. Knowledge of curricular content from secondary school; 12 items; Alpha=.78.

- M. Last academic term average mark.
- C. Conscientiousness (MacCann et al., 2009); 10 items; Alpha=.90.
- P. Procrastination (Clariana & Martin, 2008); 15 items; Alpha=.92.
- F. Cheating (Clariana & Martin, 2008); 10 items; Alpha=.82.
- E. Extraversion (Rammstedt & John, 2007); 2 items; Alpha=.73.

The raw data from the questionnaires were then transformed to T-notes (mean=50 and SD=10), to have them represented appropriately on a graph. In addition, some ANOVAs series were performed to find out whether the differences for the same variables between ages were significant. Figures 1 and 2 show the results.

---Figure 1---

There are significant differences in the "good" variables (previous knowledge, marks, and conscientiousness) for the different ages, but they do not progress as we had hypothesized through the age and course of the students. The characteristics change but neither in the direction nor at the pace we thought. Firstly, none of the "good" variables alterations show a progress in a straight steady line. Secondly, these beneficial characteristics reach their highest level both at 16 and at 20 years of age, when the students are just starting post-compulsory secondary school or have begun at university. As a conclusion, this result may suggest that the beginning of an educational cycle is a positive time, because it helps the students develop advantageous attitudes to learning.

---Figure 2---

Besides, the traits which are said to disturb academic learning, procrastination, cheating, and some aspects of extraversion, are attaining peak values when the students are 18, when they are ready to finish post-compulsory secondary school and start university. Moreover, the age 18 group is the one that got the worst results in the "good" variables, so all in all, it is possible to conclude that at 18 the students have the worst profile for school learning.

Thus, experts should be asking what happens when the students are 18 and reach the end of secondary education. Is it the age or some other developmental or social factors? Or is it the education system, the high level of difficult contents, the almost all declarative type of curricular knowledge they are taught, the kind of instructional methodology, pressure to get a place university, the difficulty university entrance exams we oblige them to take...?

More research will have to be carried in the future in order to answer these questions.

PAPER PRESENTATION

Feminization of the teaching profession and the system level context

Svenja Vieluf, German Institute for Internat. Educational Research, Germany: Eckhard Klieme, Deutsches Institut für Intern. Pädagogische Forschung, Germany

Policy makers and researchers have frequently drawn public attention to the process of feminization of the teaching profession. Triggered by economic and sociocultural changes this tendency may have some potential downsides; it may contribute to teacher shortages and a lack of male role models for boys. But while a similar pattern can be observed across a large number of education systems, there are also noticeable cross-national differences in the actual proportions of female teachers and principals. Some potential reasons and consequences of these differences

are discussed in the literature. The present contribution combines information from different public databases to examine this question empirically and to shed light on the system level context for differences in the degree of feminization. Analyses with data from 23 countries show that the proportion of females in the teaching profession is negatively related with average wages for teachers, but not with other economic variables or the global gender gap index. At the individual teacher level there is some evidence for differences in professional practices between men and women. Finally, the proportion of women in the teaching profession does not appear to be related with student achievement in math and reading, but significant relations are found with the size of the gender gap in reading. These findings suggest that the level of feminization may in fact be relevant for the aim of equity in education. It further suggests for policy makers to be aware of the relationship between the gendering in school organization and teachers' wages.

Background and Aim of the Study

During the 20th century women have entered a number of male dominated professions. For teachers this process of feminization has advanced far already. However, the predominance of women in classroom teaching contrasts sharply with the relative absence of women in school management positions. A similar pattern has been documented in a large number of education systems, but there are also noticeable differences between countries in the rate to which feminization has occurred (OECD, 2009). This suggests some scope for policy influence. To explain the process of feminization of the teaching profession the literature suggests a prominent role of sociocultural and economic factors (e.g. Acker 1996; Benavot, 1989). Based on the queuing model (Thurow, 1975) it can be argued that differences between countries in the gender ratio may be related with differences in wages and career opportunities for teachers. On the other hand also gender ideologies may have an influence, especially those that consider requirements of the teaching profession – e.g. social competencies – to be female qualities (e.g. Drudy, 2008). The rate of female teachers may be higher in societies where such traditional norms prevail. But whatever the reasons are, does it actually matter that most teachers are women? Two arguments are frequently raised: With a number of countries facing teacher shortages, it is argued that the supply of teachers could be improved by attracting more men to the profession (OECD, 2009). Moreover the gender gap in teaching is blamed for boys' underachievement, arguing that they lack role models for academic success (e.g. Arnot et al., 1999; Mills et al., 2004). Finally there is evidence that instructional practices may also vary as a function of the teacher's gender (Martin, Yin, & Baldwin, 1998; Klieme & Vieluf, 2009), which could potentially affect the general achievement level of students. In summary the process of feminization of the teaching profession is a culture general phenomenon, but it has occurred at different rates. Research suggests that the degree may be related to several context variables, educational processes and outcomes, but many questions are still left open. The present paper aims at answering some of these questions by taking a closer look at the country level context of the phenomenon. More specifically two research questions will be examined, (1) what characterizes education systems with lower versus higher gender inequalities in the teaching profession, and (2) are gender inequalities in the teaching profession related to educational processes and outcomes?

Method

The paper draws on data from different large scale surveys and public databases. Information on teachers' gender, beliefs about the nature of teaching and learning, teacher self efficacy classroom teaching practices and teacher cooperation is based on the OECD Teaching and Learning International Survey (OECD, 2009). The Programme for International Student Assessment (OECD, 2007) is used as a source for data on educational outcomes. Indicators on the expenditure on education and annual statutory teachers' salaries in public institutions were taken from Education at a Glance (OECD, 2010). Moreover country level data on GDP per capita (World Bank, 2009), the global gender gap index (World Economic Forum, 2010), and women's share of labor force (United Nations, 2010) are used. Most analyses are conducted at the level of education systems. At this level the sample consists of 23 countries that have participated in TALIS. Due to this small sample size mainly descriptive analyses are carried out. However, to examine gender differences at the level of individual teachers, multilevel multiple regression analysis is used with a representative sample of 73,100 teachers.

Results

Across the countries participating in TALIS on average 69% of the teachers are female. Percentages above 80% are found in Eastern European countries, while in Australia, Denmark, Mexico, Spain, and Turkey the gender ratio is more equal (52-69%). Analyses relating this degree of feminization of the teacher profession to other characteristics of education systems show that neither GDP per capita nor the expenditure on education is a relevant correlate. No significant relations are further found for the global gender gap index, or women's share of labor force. However, a strong correlation is found for teachers' salaries; the higher the starting and maximum salary of teachers in a country, the lower the proportion of women in the profession ($r = .78^{**}$ and $r = .45^{**}$). Regarding relationships with educational processes and outcomes, findings are also mixed. At the individual teacher level significant differences between men and women exist with regards to their self reported professional practices. In a majority of countries

women agree less with a direct transmission view on teaching, they report to use more structuring and student oriented classroom teaching practices than men, and their participation in cooperative activities with other teachers is also higher (see table 1). But at the level of education systems the degree of feminization of the teaching profession is neither related with general student achievement in reading and mathematics nor with the achievement gap in mathematics. A significant relationship is only found with gender equity in reading; the higher the percentage of female teachers in an education system the stronger the tendency of girls to outperform boys in this domain ($r = .53^{**}$).

Discussion

Policy makers and researchers have frequently expressed concern about the feminization of the teaching profession occurring in a number of countries. The present study suggests that the proportion of female teachers may in fact be relevant for student learning. While the degree of feminization does not have an effect on the general level of achievement, a significant association is found with the size of the gender gap in reading. This can be interpreted as confirmation of the hypothesis of a lack of role models for boys, but it may also have other causes. By all means, the findings suggest that counteracting gender imbalances is a potential direction for policy-makers, considering the importance of gender equity for society. Teacher's wages seem to be one potential instrument of governance. However, more experimental and longitudinal research is needed to clarify the causal chain behind these relationships.

PAPER PRESENTATION

Factors influencing teachers acceptance of national educational standards in Finland and Germany

Annette Fruehwacht, University of Wurzburg, Germany; Walter Mueller, University of Wurzburg, Germany;

Uwe Maier, University Erlangen-Nuernberg, Germany

According to the OECD (Arbeitsgruppe Internationale Vergleichsstudien 2007) national educational standards are said to be a characteristic of successful school systems. Finland as one of the most successful PISA participant has national educational standards since the 1970s. As a consequence of sobering PISA results, German federal states implemented educational standards in the past decade. However, the countries Finland and Germany both realized national performance standards in a different way. While Finland controls educational standards on the regional level, Germany has established educational standards and mandatory testing on the school system level. Based on school governance theory (Kussau & Brýsemeister 2007), a qualitative transnational field study with teachers from Finland ($N=10$) and Germany ($N=20$) examines in which way such educational policies are handled by primary teachers. In both countries the results reveal influencing factors to teachers' attitude and logic of their actions. First and foremost teachers' way of handling the national educational standards is dependent on their pedagogical beliefs. We only found some country-addicted factors influencing teachers' patterns of action.

Introduction and aim of the study

Education policies in all countries define national educational standards in order to guarantee equality and to raise the quality of the national school performance level. Implementation and effects of educational standards on teaching, instruction and student achievement are evaluated in different ways. In Germany the national assembly of the state secretaries of education ("Kultusministerkonferenz") has implemented a national accountability test-system for 3rd graders whereas in Finland communal authorities control educational standards in the field of primary education with a system of trust and discussions with teachers and principals. Both evaluation methods are intended to influence teachers' routines of action. This transnational comparative study focuses on how primary teachers understand and use national educational standards.

Theoretical framework and research question

Governments in all countries try to influence school and classroom level by top-down regulations such as national educational standards. Research on the actual effects of such regulations deals on the one hand with effects on institutional level (e.g. Verhaeghe et al. 2010) and on the other hand with effects on teachers' professional work. In school governance theory, Kussau and Brýsemeister (2007) define the teacher as an individual actor within a complex school system. Individual teachers act as professionals and mostly do not react on top-down reform inputs in a predictable way. School governance theory stresses that practitioners develop their own individual patterns of action how to make sense of educational reforms. However, theory of school governance also strengthens the fact that the constellation of actors on different system levels impacts on the individual action (Kussau & Brýsemeister 2007). School system features influencing the constellation of actors can be found on different system levels: (A) judicial

institutionalisation: implementing of curricula, national educational standards, (B) organisational framework: implementing of control mechanisms like mandatory testing systems and (C) school climate: in-school arrangements. This model allows analyzing the relation of reform efforts such as educational standards and teachers' professional work. We used a cross-country comparative approach for a quasi-experimental variation of school system features and educational policies (Finland, Federal German state Bavaria) to find out what factors of the institutional framework influence teacher usage and acceptance of educational standards. (A) Finland has national education standards for several years. The explication of those standards is made by local authorities. That procedure is intended to guarantee an adaption to individual local conditions. (B) The control system in primary education is very low and local authorities are in charge of it. (C) In Finland every school has the obligation of developing school curricula which shape their school profile. (A) In Germany the federal states implemented national education standards for primary education in 2004. (B) National educational standards are evaluated by a large mandatory assessment. (C) Current policies intend to enhance school-autonomy which is assumed to change in-school constellations.

According to school governance theory we want to find out if and to what extent the different factors (A - C) in countries with different approaches to educational standard reform impact on how teachers make sense of and use educational standards.

Methodology

We conducted expert interviews in Bavaria with teachers from the 3rd grade (N=20) and in Finland with teachers from the 4th grade (N=10). Data were analyzed with Qualitative Content Analyses (Mayring 2010). Interview data were divided into sections according to the subject sections of the interview guideline. After that the statements were classified in deductive and inductive categories. Thus each country had its own system of categories. Afterwards both systems were compared and conclusions could be drawn.

The validation of the data was made by a conceptual validation. The classifications of the data into the category system were made by several persons who are well-acquainted with the project. In addition the data were validated by construct validation. Teachers' statements were justified with statements from school authorities and by interviewing all teachers of the 3rd grade at one school. Furthermore non-reactive data like tests were drawn into consideration.

Results and discussion

The analyses reveal that acceptance and usage of national education standards and mandatory testing systems is low. The transnational methodology allows the assumption that institutional impact on teachers' pattern of action is low and first and foremost influenced by individual school conditions and personal characteristics. The reasons can be linked to school governance theory (Kussau & Brýsemeister 2007). The results reveal that judicial implemented parameters (A) seem to have a highly limited influence on teachers. Mandatory testing systems which are able to affect the pattern of action of some teachers, are more influential (B). We also found cases which allow the conclusion that institutional regulations (A) are only brought into usage through an implicit way, such as mandatory testing systems (B). Furthermore the results show that school climate (C) is supposed to have an impact on the individual teacher action. An atmosphere of collaboration and regular conferences are likely to influence teachers' action in a positive way. In regard to acceptance and usage of educational standards and mandatory testing systems a basic discontent at school and a bad relationship between teachers (C) are negative influencing parameters.

We draw the overall conclusion that the impact of different national reform policies on the implementation of educational standards is lower than school features and teachers professional beliefs about school and teaching.

PAPER PRESENTATION

Women who choose a science-oriented major – factors determining career decision-making

The current longitudinal study examines the career and vocational decision-making of 481 female high school leavers during transition from high school to higher education. The aim of the study was to understand whether female students who intended to study Science, Technology, Engineering or Mathematics (STEM) finally did or did not choose a science-oriented major two years later. Quantitative and qualitative analyses were combined. Results from quantitative analysis indicated that the majority of the students who intended to choose a STEM field finally put their intentions into practice. These students demonstrated better competencies in mathematics, placed more importance on pursuing academic activities and on choosing a major that matched their area of interest and their practical orientation in comparison with students who entered social sciences or humanities. However, their endorsement of the stereotype of women's inferiority in mathematics was comparatively higher. Qualitative analysis revealed that learning experiences and role models were decisive for their decision-making, whereas counselling was hardly ever mentioned in their narratives, nor was gender. It was concluded that the blend of high aspirations, interest, practical orientation and a strong desire to conform could lead to conflicts in a male-dominated STEM context, which might challenge the female students' sense of identity. This paper discusses possible implications for higher education.

Introduction

The globalisation of markets causes a great worldwide demand for qualified employees in the state-of-the-art technology. This can be contrasted with the stagnating number of students entering Science, Technology, Engineering and Mathematics (STEM) in various European countries. As a result, an increasing pressure on the educational system can be observed in order to raise the number of students in these disciplines. The European Higher Education System is, therefore, challenged to create new recruitment strategies and counselling programmes to attract and retain students. During the past decade, many University programmes have particularly been established to support women to choose science-oriented majors.

Aim of the study

There is a wealth of knowledge from international research on career and vocational decision-making about the importance of factors, such as interest, ability, choice of mathematics, participation in high-level courses in mathematics, competence beliefs, self-efficacy in mathematics, perceived difficulty and expectations of success in mathematics, attitudes toward science-related domains, gender stereotypes, as well as background characteristics, including socioeconomic status, gender and ethnicity (Holland, 1997; Eccles (Parsons) et al., 1983; Pekrun, 1993; Bandura, 1997; Eccles, 2005; Wigfield & Eccles, 2002; Lent et al. 2005; Bonnot & Croizet, 2007). Nevertheless, there is little research on the extent to which female high school leavers, intending to choose a STEM field, actually carry their intentions to completion within a two-year span. The current study aims at gaining insight into the factors and circumstances influencing former high school students in their decision to choose or not to choose a science-oriented university major.

Methodology

This research project started in 2006 and is based on a longitudinal study, which combines quantitative and qualitative data and aims to evaluate the correlations between the intention of choosing a science-oriented major and the actual realisation of that intention. The study includes 481 former Swiss female high school students, who were questioned about their career options six months before finishing high school and then followed up with another questionnaire two years later. For the purpose of this paper a sample of 144 women studying engineering, information technology, natural sciences, social sciences or humanities was selected in order to examine the impact of several predictors on the choice of 'STEM studies versus social sciences or humanities'. A logistic regression was carried out to compare these two groups, and grounded theory (Glaser & Strauss, 1967, 1998; Strauss & Corbin, 1996) was used to analyse qualitative data. Out of the 144 sample, 12 students were selected for follow-up interviews one year later in order to qualitatively assess the consistency of their decisions. Quantitative and qualitative data of the different parts of the study were then combined in a 'Triangulation process' (Denzin & Lincoln, 2005; Kelle, 2006; Flick, 2008).

Findings

Overall, the results indicate that the majority of young women, who intended to choose STEM studies during high school, accomplished their goals two years later. These students had attended more advanced courses of mathematics than students with a major in social sciences or humanities. Women with a STEM major were found to have had better grades in mathematics during high school and placed more importance on choosing a major that matched their area of interest and their practical orientation, in comparison with those in the social sciences or humanities. In addition, they attached more importance to the opportunity of pursuing academic activities. However,

their endorsement of the stereotype of women's inferiority in mathematics was higher than that of women studying social sciences and humanities. Findings from the qualitative analysis showed that learning experiences had led to a particular interest in sciences and role models within the family or a wider network played a significant role during the decision-making process, whereas counselling was hardly ever mentioned. What seemed to be decisive for their choice, was a wide range of career options, as well as an interest in practical application. Female students presented themselves as career and family oriented but did not specifically mention gender in their narratives. Mathematics did not seem to play such an important role and was seen as a 'necessary evil' to pass the examinations and to achieve the career goal. Moreover, abilities in mathematics were cautiously presented as 'not bad' rather than 'good'.

Theoretical and Educational Significance of the Research

The current study contributes to the literature on career and vocational decision-making. The results are broadly in line with other studies and confirm Holland's (1985) and Engler's (1993) assumptions positing that a 'good fit' between interest and requirements of a specific working environment, or a disciplinary culture is of significant importance for choosing a university major. However, the study sheds light on important factors beyond interest and competence in mathematics, such as gender stereotype endorsement. The involvement in STEM studies does not seem to prevent women from stereotype internalisation (see also Eccles et al., 1994). It is assumed that female students strive to balance the threat of social identity (Tajfel, 1987) by presenting themselves as different from other women in order to restore a positive identity (Codol, 1984; Bonnot & Croizet, 2007). It can be concluded that the blend of high (intellectual) aspirations, interest, practical orientation and a strong desire to conform could lead to conflicts in a male-dominated STEM context, which may challenge their sense of identity. Internalizing their group inferiority in terms of mathematical skills might lead to a vulnerability to stereotype threat during their future career. The findings, thus, confirm the need for interventions in higher education. Yet, interventions should not only focus on individuals but also on other factors, such as parents, teachers, lecturers, peer groups, counsellors and administrative planning. Hence, it can be inferred that science-oriented subjects should be taught in more consideration of social identity and that a more 'gender-neutral' classroom instruction in (higher) education might help to support and retain women in the STEM fields.

PAPER PRESENTATION

Student characteristics associated with academic performance. The Generation Psy study

Bjorn de Koning, Erasmus University Rotterdam, Netherlands; Sofie Loyens, Erasmus University Rotterdam, Netherlands

This study reports on the recent findings obtained in the Generation Psy project, which aims to identify the student factors related to academic performance as well as the temporal stability of these factors throughout all three bachelor years. Data from nine cohorts of psychology students (N = 1793) were used. The variables that were examined are gender, age, ethnicity, secondary school grade point average (GPA), level of prior education, intelligence, personality characteristics, students' professional behavior as well as their prior educational attainments at university. Using multiple regression analyses, a number of these factors were shown to have an influence on academic achievement, as measured by students' annual university GPA and the number of obtained credit points.

Results indicated that students with better secondary school grades and a higher pre-university education obtained higher course grades and more credit points in all bachelor years. In addition, students who are intelligent, conscientious, introvert, and emotionally stable also performed better in the first two bachelor years. Moreover, students' professional behavior and prior attainments at university also had a strong and persistent influence on students' grades and credit points. These results suggest that the students' pre-university knowledge as well as the knowledge and skills they acquire during their studies have a strong influence on academic performance in all bachelor years. Specific aspects of intelligence and personality also play an important role in academic performance, especially in the first bachelor years. These findings might have important implications for selecting and supporting students in higher education.

Currently, increasing student retention and graduation rates are one of the main challenges in higher education. In most European countries the number of students who obtain a bachelor degree is at best 55% (Van Den Berg & Hofman, 2005). In recent years, researchers have identified a wide variety of factors associated with students' academic achievements varying from student-related characteristics, such as personality (e.g., Chamorro-Premuzic & Furnham) and the study environment such as classroom climate (e.g., Bruinsma & Jansen, 2007). Of these factors, student-related characteristics seem to be most relevant in explaining differences in academic performance (Van Den Berg & Hofman, 2005). Accordingly, the current paper reports on findings from a large-scale study set up at the Erasmus University Rotterdam, called the Generation Psy project, which examines students' personal background

variables and individual differences in order to explain and predict student persistence and dropout in university education.

The Generation Psy project uses a database, called Isis, which contains data of almost ten cohorts of students. The present study can therefore provide novel insights into the student factors associated with academic performance. First, this study examines the influence of student characteristics on academic performance throughout all three bachelor years, whereas the majority of prior research only investigates performance in the first bachelor year. This allows us to investigate the extent to which variables influencing academic performance in the first year also influence performance in the subsequent bachelor years. Second, our study examines a large number and a wide variety of student-related factors simultaneously such as gender, age, personality, intelligence, and prior educational attainment. Most previous studies only focus on several of these variables and do not consider a large number of student factors in a single study. Third, the present study is conducted in a curriculum that is based on the principles of problem-based learning rather than in a traditional teacher-centered curriculum (Schmidt, 1983). Consequently, our study provides insight into the relative contribution of a wide variety of student-factors to academic performance, the temporal stability of these factors, and the generalizability of previous findings to another type of curriculum.

Data were collected from the three bachelor years of the psychology curriculum of the Erasmus University Rotterdam, from the academic years 2001/2002 to 2009/2010. The total number of students in the sample was 1753 (male = 452, female = 1298, mean age = 20.04 years). Information on the student background variables and outcome variables was obtained from the Isis database.

Different outcome variables available in Isis were used in this study: 1) the grade point average (GPA) computed over all courses in a bachelor year, 2) the total number of received credit points computed per bachelor year. The student background variables provided by Isis and used in this study are gender, age, ethnicity, GPA in secondary education, type of pre-university education (VWO -which is the highest stream in secondary education-, higher vocational education, or another preparatory training such as foreign diploma), personality (i.e., extraversion, agreeableness, conscientiousness, autonomy, neuroticism), and intelligence (i.e., abstract reasoning, verbal reasoning, numerical reasoning). In addition, students' GPA obtained in the first and second bachelor years were used as predictors for students' performance in the second and third bachelor year respectively. Furthermore, separate GPA's were computed for students' observed learning activities (i.e., preparation for tutorial meetings, participation during the meetings, and fulfillment of chair and scribe during the meetings) in bachelor 1 and bachelor 2 and these were included as predictors for academic performance.

In order to investigate the relationship between student factors and academic performance, multiple regression analyses per bachelor year with the above mentioned student factors as predictors and course GPA and the number of credit points as dependent variables were conducted. These analyses revealed that the higher the students' secondary school GPA, the higher their grades and the more credit points they obtained throughout all bachelor years. Similarly, students' pre-university education has a significant influence on the number of credit points and course GPA in bachelor 2 and 3 (VWO > higher vocational education > other). Gender had a minimal influence on academic performance, indicating that females obtained higher course GPA's than males only in bachelor 1. Ethnicity and age did not significantly influence students' academic performance. These findings suggest that the prior knowledge students bring with them to university has a determinant influence on academic performance. This might have important implications when looking at which aspects to consider for selecting students for educational programs. Furthermore, higher GPA for observed learning activities and course GPA are also associated with higher scores on both outcome measures of academic performance during all bachelor years, but the effects were strongest in the first year. This suggests that making students aware of the fact that their initial study activities and grades influence subsequent academic performance as early as possible could help them to perform well academically later on in their studies and ultimately to obtain a bachelor degree.

With respect to personality and intelligence, conscientious, introvert and emotionally stable students as well as those with higher verbal, numerical, and abstract intelligence obtained higher course GPA's and more credit points in the first two bachelor years. Autonomy and agreeableness did not significantly influence academic performance. These results suggest that intelligence and certain personality traits should be considered when selecting students for university or to identify students in a curriculum who are at risk of academic failure.

PAPER PRESENTATION

Factors Promoting and Hindering Collaborative Learning – Students' Experiences from a Virtual Course

Essi Vuopala, University of Oulu, Finland

The aim of this study is to investigate factors promoting and hindering collaborative learning during a virtual course. Students (N=86) from seven universities participated CSCL course for two months. Students were divided into 8 small groups. The course consisted of three differently structured studying phases in a virtual environment Optima. After the each phase the students filled in an on-line questionnaire in which they reflected factors that affected their small group's collaboration.

In the analysis of on-line questionnaires (N=311) students' descriptions about factors promoting and hindering collaborative learning were analysed and coded into five categories: course arrangements, factors related to group, tutoring, individual factors and factors related to the Optima. Each small group's collaborative learning during each phase was also coded either successful or less successful based on students' experiences. In order to characterize successful and less successful collaborative learning situations small groups' Optima discussions (N=330) were analysed according to their contents.

The findings indicate that the most important factors promoting collaborative learning are related to 1) group (shared understanding, argumentative and reciprocal discussion), 2) course arrangements (pedagogical model) and 3) tutoring. Factors hindering collaborative learning are related to 1) group (problems in communication), 2) course arrangements (too loose schedule) and 3) personal issues (lack of studying skills).

Analysis of discussion notes indicates that in successful collaborative situations the mostly used message type was reciprocal message, whereas in less successful collaboration students' messages were mostly independent.

Recent research in Computer Supported Collaborative Learning has shown successful results in enhancing learners to reflect their thoughts together with other learners and promote deep learning (Scardamalia & Bereiter, 2006.) However, collaborative learning is not easy and it sets new roles and challenges for learners: How to collaborate effectively and benefit from other learners? In order to provide support for learners it is important to identify the critical requirements of collaborative learning (Kirschner, Sweller, & Clark, 2006).

In former studies concerning requirements of collaborative learning the focus of the analysis has been in groups' functionality and interaction between group members (e.g. Arvaja, 2005; Lipponen, Rahikainen, Lallimo & Hakkarainen, 2003). Results have shown that successful collaborative learning requires for example deep level discussions, learners' equal participation to collaborative activities and common ground (e.g. Stahl, 2007). However, less is known about learners' experiences of collaborative learning. In order to design, implement and support students' collaboration it's essential to understand learners' perspective.

The aim of this study is to explore university students' experiences about factors promoting and hindering collaborative learning in a virtual course. Specific research questions are:

1. What factors promote and hinder collaborative learning?
2. How do successful and less-successful collaborative learning situations appear in the contents and structure of on-line discussions?

Methods and analysis

Data has been collected from an international CSCL-course which lasted for two months. The students (N=86) were from five Finnish, one Norwegian and one German universities and they were divided into groups of eight to ten students. The pedagogical structure of the course was aimed at promoting collaborative learning, and consisted of virtual studying in Optima environment.

In Optima, small groups' collaborative learning was supported with three pedagogical models, namely a) loosely structured theme discussion, b) discussion with functional roles and c) problem-based learning. Each studying phase lasted two weeks, and after each two-week phases the students filled in an on-line questionnaire in which they reflected the collaboration in their own small group. Each student had to define whether their collaborative learning

was successful or less successful and what factors promoted and hindered collaborative learning during each studying phase.

In the qualitative content-driven analysis of on-line questionnaires (N=311) each small groups' collaborative learning during each three phases was defined either successful or less successful based on students' descriptions (presuming that at least 80% from small group's members defined their collaborative learning either successful/less successful). In order to characterize successful and less successful collaborative learning situations small groups' discussion notes (N=330) were coded according to their contents. Finally students descriptions about factors promoting and hindering collaborative learning were analysed and coded into five different categories: course arrangements, factors related to group or group's behaviour, tutoring, individual factors and factors related to Optima environment.

Results and conclusions

Questionnaire data results indicate that the most important factors promoting collaborative learning are related to group and its' behaviour. 43% of respondents experienced that positive group processes such as active participation in collaborative actions, reciprocal discussions and shared understanding promoted collaborative learning. Factors related to group was also experienced the most significant factor which hinder collaborative learning (41% of respondents). Negative group processes, like problems in communication, prevented students to gain collaborative aims.

Secondly, students experienced that course arrangements have an important role in successful collaborative learning. 33% of respondents experienced that course arrangements, especially the tightly structured pedagogical model (problem-based learning), promoted collaboration in their small group. 20% of respondents experienced that factors related to course arrangements (e.g. loosely structured pedagogical model, too loose schedule, too heterogeneous study group) can also hinder collaborative learning.

Thirdly, 16 % of respondents experienced personal issues (e.g. motivation, studying skills) as factors which rather hinder than promote collaborative learning. The role of tutoring was experienced as factor which promote collaboration (10 % of respondents) Finally, factors related to Optima environment were experienced less significant requirement for successful collaborative learning.

Analysis of discussion notes supports findings from questionnaire data. In the situations which students defined their collaborative learning successful, the mostly used message type was reciprocal message where earlier discussions and others' opinions were taken into account and others' ideas were developed further. In less successful collaboration students' messages were mostly independent messages without connections to previous discussion. Analysis of discussion notes also indicate that in tightly structured studying phase discussion was more active and reciprocal than in loosely structured phase.

The results indicate that it is challenging to design, implement and support collaborative learning. In order to enhance successful collaborative learning, there is a need to consider appropriate pedagogical model and group formulation (e.g. group size, group members' background). It is also essential to ensure that students have sufficient skills to study collaboratively. In addition, learners need various kind of support during collaborative learning process.

PAPER PRESENTATION

Identification of Effective Mentoring Practices for New Academics

Heather Kanuka, University of Alberta, Canada

To gain a better understanding of how to implement effective mentoring relationships in research intensive universities a national survey was conducted. Three thousand names of invited participants were drawn randomly; a total of 1361 usable surveys were completed. Based on the results of the survey, focus groups were then conducted with new faculty members and department heads. Consistent with prior research, the outcomes of this study indicate that to be effective and sustainable, mentoring programs must include these components: mentor selection; mentor and mentee preparation; department and institutional support; and accountability. Perhaps unsurprisingly, this study also revealed the existence of barriers to implementing and sustaining effective mentoring programs. These barriers include reward systems, time, resources, and structuring of mentoring programs.

Mentoring Practices in Canadian Universities

As an applied research study the purpose of this project was to gain a better understanding of how to implement effective mentoring relationships, resulting in creating a campus-wide community in research-intensive universities, a survey was conducted. Three thousand names of invited participants were drawn randomly; a total of 1361 usable surveys were completed. Based on the results of the survey, focus groups were then conducted with new faculty members and department heads. The purpose of this study was to investigate mentoring practices within Canadian Universities.

The method used to collect the data was a questionnaire, with a follow-up focus group. The objectives of this study were to:

1. Identify current mentoring activities for new faculty members in universities that identify themselves as research-intensive across Canada
 2. Identify past mentoring activities for mid- to late-career faculty members in universities that identify themselves as research-intensive across Canada
 3. Determine if there are: (a) relationships between mentoring practices and academic career development; (b) relationships between mentoring practices and academic career satisfaction
- Participants There were two types of participants: Newly hired university faculty (within the last five years and non-tenured) and mid- to late-career university faculty (employed as an academic for more than ten years and tenured).

Results

The findings have implications for mentoring practices in research intensive universities in Canada. Following is an overview of the results. - The survey results reveal that fewer spontaneous mentoring relationships are currently being formed with new faculty (51.5% of mid- to late faculty had spontaneously formed relationships vs. 28.2% of new faculty) and fewer senior colleagues are offering to mentor new faculty (15.2% of mid- to late-faculty vs. 6.4% new faculty). - While it would seem obvious that new faculty should be provided with this information, the survey results show new faculty are not being provided with the following information:

- information of the formal institutional rules
- constructive feedback about teaching
- constructive feedback about research
- constructive feedback about committee work

As expected, there was strong agreement that an excellent mentor will have the following characteristics:

- accessible
- respected among professional peers within the institutions
- an exemplary researcher

Less clear is how mentors should be rewarded. New faculty believe mentoring support should be recognized on the faculty member's annual report, whereas mid- to late faculty believe recognition of mentoring should be informal. In regard to mentor assignment, there were inconsistencies. The greatest agreement occurred with mid- to late-faculty believing that mentoring relationships should be mutually formed with some combination of input from the new faculty member, mentor, department chair/head and dean. - The duration of the mentoring relationship should be ongoing until the new faculty member has attained tenure, requiring 2-4 hours / month. - There was agreement that preparation for mentoring should be provided by the university's faculty development centre (as compared to other options).

Minority faculty members (visible minority, sexual orientation) experience significantly less help in the following areas:

- lack of information and help in terms of expectations for achieving tenure and promotion
- absence of role models and mentors
- lower levels of perceived career satisfaction
- lower levels of good collegial relationships

Conclusions

Consistent with prior research, the outcomes of this study indicate that to be effective and sustainable, mentoring programs must include these components: mentor selection; mentor and mentee preparation; department and institutional support; and accountability (Kajs, 2002). Perhaps unsurprisingly, this study also revealed the existence of barriers to implementing and sustaining effective mentoring programs. These barriers include reward systems, time, resources, and structuring of mentoring programs. Despite the positive impacts of mentoring documented in three decades of research, not all mentoring relationships are successful (see also Sandler, 1993). Co-operative and group mentoring models, such as the mosaic mentoring model, offer a structure for mentoring programs that might have greater likelihood of overcoming the barriers. Problems that tend to cause mentoring relationships to fail often arise from the unstructured and spontaneous hierarchical dyads that characterize them. Boyle (1996) maintained that successful mentoring begins with institution-wide programs that provide support and resources to achieve a sense of connectiveness for new and early faculty members. Later research by Boyle and Boice (1998) revealed a strong justification for systematic mentoring and institution-wide programs. Research by Kalbfleisch and Davies (1993) supported these findings. Kalbfleisch and Davies concluded that those individuals who need help the most (e.g., visible minorities, non-traditional faculty) are the least likely to find it. Wunsch (1994) advanced this argument further by asserting that when individuals agree to enter into a mentoring relationship related to academic and career goals, the relationship moves from the personal to the institutional realm; this can result in inequity of opportunities, which the institution must address. To be exact, when some individuals have access to certain career advantages (e.g., mentoring relationships) and others do not, inequity of career opportunities (e.g., advancement, promotion) occurs. It is the responsibility of the institution to ensure that all individuals have equity of access to the same career opportunities. Structured mentoring relationships, such as the mosaic mentoring model, appear to be key to ensuring equity of access to mentoring relationships.

PAPER PRESENTATION

Shared regulation and knowledge construction

Angelika Meier, Institute for research in teaching and learning, Switzerland; Franziska Vogt, Pädagogische Hochschule des Kantons St. Gallen, Switzerland

This study investigates the shared regulation and knowledge construction of learning in an activity-oriented setting in the natural sciences. Twenty teams of students from grade 4 to 6 were video-recorded while working on an experimental task relevant for the understanding of climate change. Prior to working on the activity-oriented task, students responded to questionnaires on self-regulation and motivation as well as on prior knowledge of the topic. After working on the task, students were shown excerpts of the video and interviewed about the regulation of their learning process (video-recall). The analysis of the twenty videos and video-recalls provides information about the shared regulation of pairs in relation to their respective preconditions (prior knowledge and self-regulation) as well as task characteristics (problem-oriented task versus step-by-step instruction). Thus the research question for this study is: how do pairs of primary school children share the regulation of the activity-oriented learning process and thereby co-construct knowledge under these two conditions? The insights of this study are relevant for the provision of effective learning environments for primary school students in the natural sciences.

Aims of the study

The general purpose of this study is to establish how children with different ability in self-regulated learning (SRL) as well as with different levels of prior knowledge respond to the experimental tasks within the learning space

(Lernwerkstatt in German). Learning spaces evolve around a core theme. The theme for the present study focuses on climate change. A class with their teacher visits the learning space for the duration of a half-day. Students choose tasks freely and often work in small groups or pairs. Learning spaces seek to encourage students' self-regulated learning (SRL) through activating learning tasks, with the aim of a deeper understanding, an increase in intrinsic motivation and domain-related interest as well as a higher competence of self-regulation. To what extent students need instruction and how self-regulation can be fostered is controversially discussed amongst the teachers involved with learning spaces. Thus the extent of guidance is systematically varied in this research project: The same content is covered in a problem-oriented experimental task versus a step-by-step instruction for conducting the experiment. As collaborative learning settings are increasingly employed in classrooms, understanding students' shared regulation in relation to their self-regulation becomes paramount (Järvelä & Järvenoja, in press). Therefore, this study addresses the following research question: how do pairs of primary school children with different levels of SRL and of prior knowledge share the regulation of the inquiry-based learning process under two conditions (problem-oriented vs. step-by-step instruction)?

Methodology

The research has been conducted in the setting of the learning space. In a quasi-experimental design, two types of tasks were used: a problem-oriented task with only the description of the problem and materials for the experiment provided and a step-by-step instruction with directives of how to conduct the experiment and solve the problem. Eight classes (grade 4 to 6) visited the learning space and took part in the study. Prior to their visit, all students were given questionnaires which included scales of self-regulated learning (Bruder, 2006), goal orientation (Spinath, Stiensmeier-Pelster, Schöne, & Dickhäuser, 2002) interest in the topic, and familiarity with environmental issues (Frey et al., 2009). They also completed a test capturing the prior knowledge of the topic. The total number of participants in the study were 158 primary school students (79 girls) between 9 and 14 years ($M = 11.2$ years, $SD = 0.9$ years). Upon arrival in the learning space, pairs of students were randomly assigned to work on the prepared experiment. A total of 20 pairs were video-recorded while working on this task. Immediately after completion of the task, they were interviewed in a video-recall (Spärrer & Brunstein, 2006). The questions for the video-recall are based on Pintrich's (2004) model of self-regulation.

The videos and video-recalls were transcribed and then examined for evidence of shared regulation and knowledge construction (Bos & Tarnai, 1999). The focus is on how the teams build a shared understanding of the task, set themselves goals, adapt the goals to the current situation and react to difficulties when solving the given task. A qualitative data analysis software was used for micro-coding, using statement units, defined as a codable unit of speech (i.e., a word, a phrase, sentence, or sentences) within a turn, as units of analysis (Hogan, Nastasi, & Pressley, 1999). In addition, macro-coding of episodes including a significant shift in the content of the discussion or action was developed in relation to the inquiry-based learning cycle (Llewellyn, 2007). Within the episodes different types of regulation of learning can be observed, e.g. individual regulation and shared forms of regulation (Vauras, Liskala, Kajamies, Kinnunen, & Lehtinen, 2003).

Outcomes

A first analysis of six teams with differing levels of self-regulation allowed the development of the following macro-codings: Understanding of the problem, hypothesis, elaboration of the problem, interpretation of results and evaluation of solution. Results from preliminary analysis (Meier, 2010) suggest that problem-oriented tasks allow for more high-level dialogues. In contrast, the step-by-step instruction supports students in the evaluation of the evidence. This analysis, however, is now extended over the whole sample of 20 pairs and compared with the interview data from the video-recalls.

Theoretical and educational significance

The results of this research are of high practical relevance for developing effective learning spaces and in informing teacher education. The OECD (2006) report on students' interest in science recommends early, positive, hands-on experiences, and student interaction in the field of natural sciences for the development of interest and competence. In addition, the ability to work in teams is a key skill for today's students. The insights of this study help to provide further understanding of the processes of shared regulation amongst primary school children.

PAPER PRESENTATION

The influence of self-regulation competencies on learning with expository texts

Melanie Schuette, Ruhr-University Bochum, Germany; Joachim Wirth, Ruhr-University Bochum, Germany; Detlev Leutner, Duisburg-Essen University, Germany

The study focuses on competencies required for a successful self-regulated learning with expository texts. Although there has been a lot of research on self-regulated learning, there exists no commonly accepted model which describes all competencies necessary to fulfill the five main metacognitive demands during self-regulated learning, i.e. goal setting, planning, observing, evaluating, and adapting. We present a comprehensive theoretical framework which includes all competencies necessary to fulfill the metacognitive demands during self-regulated learning. Based on this framework, the aim of the study was to analyze if some of these competencies are more important in terms of a high learning outcome than others. We used a multiple regression to analyze the relative effect of the different competencies on learning outcome. Results reveal that the strategic competencies activating strategy knowledge and applying learning strategies as well as the metacognitive competency evaluating task demands are significant predictors of students' learning outcome. Based on these findings, we discuss the effects of prior knowledge as well as the effect of specific task features on the application of self-regulation competencies and, furthermore, with respect to the theoretical and practical use for further research.

Aims of the study

Self-regulated learning with texts has been studied extensively. On the one hand, psychological research proposed process models which describe different phases of self-regulated learning (e.g., Zimmerman, 2000). Within these phases, five metacognitive demands have to be met for a successful learning outcome: 1) goal setting, 2) planning, 3) observing, 4) evaluating and 5) adapting. However, process models do not explicitly specify the competencies needed to meet the metacognitive demands. On the other hand, researchers proposed component models which describe learners' competencies that foster self-regulated learning from texts (e.g., Boekaerts, 1997). Even though component models define competencies important for becoming a successful learner, they do not explicitly specify in which phase of the learning process the different competencies are needed. In sum, there exists no commonly accepted model which can describe all competencies necessary to fulfill the five metacognitive demands during self-regulated learning. Based on this gap in research, we developed a comprehensive theoretical framework which includes both the metacognitive demands as well as the necessary competencies during self-regulated learning (Schütte, Wirth & Leutner, in press). In terms of the five metacognitive demands, the authors identified nine competencies which are necessary to fulfill the metacognitive demands (see figure 1). Using this comprehensive framework, the aim of the study was to analyze the relative effect of the nine competencies on students' learning outcome in a realistic learning setting.

Methodology

The reported results are based on a sample of 559 German ninth grade high-school students. The mean age of the sample was $M = 14.92$ ($SD = .51$) with 52.1% of the students being female.

The design of the study was twofold. Per student we administered two expository texts which covered either topics from chemistry or physics. On day one, we administered the first expository text to the students to initiate self-regulated learning. Within 20 minutes, the students were asked to learn as much as possible while reading the

challenging text. Before and after reading the text, we used content-valid achievement tests to assess the (prior) knowledge of the students. One day two, we assessed the nine competencies relevant for fulfilling the five metacognitive demands using the second expository text. For each of the nine competencies the students filled in one test. The tests assessed whether the students had the competence (1) to evaluate the given task demands, (2) to evaluate their prior knowledge, (3) to set up learning goals, (4) to activate their strategy knowledge, (5) to apply learning strategies, (6) to adjust an action plan, (7) to evaluate their gained knowledge, (8) to evaluate the achievement of learning goals or (9) to evaluate the reasons for non-achieved learning goals. Thus, for each of the nine competencies the students received one score which indicates the degree of the specific competency. All nine competency scores were then used for the analysis of the relative effects of the competencies on learning outcome in a realistic learning setting assessed at day one.

Results

A multiple regression analysis was used to analyze the relative effect of the nine competencies on the learning outcome in a realistic learning setting. The results of the multiple regression analysis (see table 1) revealed that next to prior knowledge ($\beta = .34, p > .01$) three out of nine competencies assessed at day two were predictive for students' learning outcome assessed at day one. Significant predictors of students' learning outcome at day 1 were the competencies evaluating task demands ($\beta = .11, p > .05$), activating strategy knowledge ($\beta = .15, p > .01$) and applying learning strategies (text-highlighting strategy: $\beta = .14, p > .01$; concept mapping: $\beta = .09, p > .05$). However, the other three competencies in the forethought phase as well as all competencies of the self-reflection phase were not significant predictors of students' learning outcome. Possible reasons for this might be the lack of prior knowledge as well as the characteristics of the learning task when learning with expository texts (e.g. self-paced study time or specific task demands).

Theoretical and practical use

In the study a comprehensive theoretical framework was presented which includes metacognitive demands as well as necessary competencies to fulfill the metacognitive demands during learning. The comprehensive framework made it possible to analyze the relative effect of the different competencies on learning outcome in a realistic learning setting. The results showed that in addition to the strategic competencies activating strategy knowledge and applying learning strategies the metacognitive competency evaluating task demands was a significant predictor for learning outcome. In sum, the analysis of the relative effect of the competencies on students' learning outcome provide a deeper insight in the relevance of specific competencies during self-regulated learning which could be used for future study.

In terms of practical relevance, the identification of the most relevant competencies during self-regulated learning could be the first step for the development of more efficient training materials. Standardized tests to assess the most relevant competencies could be used to selectively promote only those competencies which are low instead of time consuming general trainings.

PAPER PRESENTATION

Investigating the quality of learning strategy use in self-regulated learning: a video study

Peter Ludwig, University of Koblenz-Landau, Germany; Claudia Finkbeiner, University of Kassel, Germany; Markus Knierim, University of Kassel, Germany

Up to now, learning strategy research has typically focused on how frequently certain types of learning strategies are used. It can be assumed, however, that it is not mainly the frequency of strategy use which influences the learning process and outcome but the adequacy of each single strategy used. Hence, the present video lab study ADEQUA adopts a micro-analytic approach to assessing the quality of strategy use. Learners of English as a foreign language (EFL) were videotaped while working in dyads on reading comprehension tasks in a self-regulated, cooperative learning environment. Multiple regression analyses show that the measurement of the adequacy of strategy use succeeded with high validity. Adequacy of strategy use turned out to have a significant effect on learning outcome when controlled for other predictors (EFL proficiency, cognitive ability, interest in EFL reading, previous school year's

EFL grade). ANCOVAs and regression analyses were used to identify the characteristics of students using strategies non-adequately.

Learning strategies are deemed significant to successful learning, especially in self-regulated learning environments. However, empirical evidence to corroborate this assumption was scarce initially, despite its well-established plausibility. In particular, this applies to correlational studies, most of which yielded no or only weak correlations between habitual strategy use (i.e., a learner's trait-dependent strategy style) and generalized measures of achievement (e.g., a student's grade). More recently, learning strategy research has attempted to capture learners' strategies through data collection procedures which are more proximal to specific learning situations. In studies using these procedures, strategy use has been found to correlate more strongly with (situation-specific) achievement. The video study ADEQUA (ADEQUAcY of Learning Strategy Use and Teacher Support Actions) picks up this trend in learning strategy research and develops it further. The study wants to gain empirical evidence as to how autonomous learning in the English as a Foreign Language (EFL) classroom can effectively be supported during cooperative classroom activities by means of teacher support actions.

Up to now, strategy research has typically focused on how frequently certain types of learning strategies are used. ADEQUA explores a new approach: Instead of taking the frequency as an indicator of the quality of the learning process and predictor of the learning outcome, the present study assesses the adequacy of each single strategy used during a given task. Adequate strategy use is conceived of as being situationally appropriate. Hence, ADEQUA adopts a micro-analytic approach.

The project consists of an extensive piloting phase as well as two main studies, i.e., a lab study and a follow-up field study. In both main studies, 9th grade EFL learners in Germany worked in dyads on reading comprehension tasks in a self-regulated, cooperative learning environment. For the lab study, student dyads were drawn from their regular classrooms in order to observe their independent use of learning strategies without their teacher's intervention. In the subsequent field study, the same tasks were implemented with whole EFL classes to observe how teachers supported their students. This presentation will focus on the lab study. The main emphasis of the lab study is on reconstructing the students' use of strategies and assessing the strategies' adequacy. Thus, we aim to gain a more thorough understanding of the impact of specific strategies at the micro level of students' actions. These insights are intended to guide the optimization of high-quality strategy use in student-centered learning environments.

In a student pre-survey, data on a range of student characteristics were collected, including students' questionnaire-based self-reports on self-regulated learning, and several standardized proficiency tests. Representing the core element of the lab study, the task performances of student dyads were videotaped. The recording took place separately for each pair of students in a dedicated room at the students' school. Special care was taken to make even cognitive strategies observable by designing the tasks in such a way that would require the students to communicate continuously with each other about the content of the text, any comprehension problems they were facing, and how to proceed working on the task. Immediately after the task performance, the students participated in a written post-survey which addressed retrospectively the students' task experience and perceived self-efficacy. Moreover, a task-specific reading comprehension test was administered. In an additional follow-up interview the students were asked to recall – based on the video recording of their task performance – the specific strategies they had used while working on the task. This stimulated recall procedure was intended to shed some more light on learning activities and processes which would otherwise be difficult to reconstruct. Subsequently, the video recordings of the students' task performance and the stimulated recall interview were used to identify the strategies employed. For each occurrence of each strategy, a group of raters assessed its adequacy (see above), based on theoretically founded criteria. These highly inferential assessments were aggregated in an index of strategy use quality for each student. A total of 15 whole classes with 352 ninth-grade students from eleven German schools participated in the pre-survey; all tracks of the German secondary education system were represented. For the videotaping of the task performance, 164 students were selected.

Key findings:

Firstly, multiple regression analyses show that the assessment of the adequacy of learning strategy use succeeded with high validity ($R=0.66$; p

Theoretical significance of the research:

In comparison to the prevailing approach to learning strategy research (which focuses on the frequencies of strategies used), the new approach taken here (which emphasizes on the adequacy of strategies used) can stand its ground. This becomes evident from our finding that (a) the habitual use of strategies in EFL reading as well as (b) the frequencies of the strategies actually used during the given task correlate less strongly with learning outcome than adequacy of strategy use does. Secondly, the determinants of adequate strategy use have been identified by means of ANCOVAs

and regression analyses. Students who tend to employ inadequate strategies and who may, therefore, be in greater need of teacher support share the following characteristics: (1) lower EFL proficiency and poorer EFL grades; (2) lower verbal cognitive ability; (3) immigrant family background; (4) they attend less prestigious tracks of the German secondary school system; (5) lower perceived interest in and engagement with the task; (6) they perceive the task to be difficult; and (7) they are doubtful of successfully completing the task.

Educational significance of the lab study:

The study contributes to our knowledge about which learning strategies students tend to use adequately vs. non-adequately in the given learning environment. The latter, therefore, may require the teacher's support. Moreover, we were able to identify typical characteristics of students who may be in need of additional support from their teacher in order to employ strategies more adequately and, hence, improve their learning processes and outcomes.

PAPER PRESENTATION

SRL and metacognition in young children: What can interview and observational data tell us about it?

Uta Wagener, University of Osnabrueck, Germany

Metacognition and self-regulated learning play an important role in learning and are an important predictor of learning outcomes. The presented study examines children in the first and second year of school (aged 6 to 8) in their daily classroom contexts. Methods of video observation and interviews are used to learn more about young children's self-regulated learning and to enlighten different facets of their competencies in this area.

Results of this qualitative study show that children were metacognitively active in their learning process. They knew and used different criteria for the evaluation of their work and they reflected about task properties and their own skills. Anyhow, in general they showed more of these competencies in the observations than in the interviews. The presentation addresses the question what this difference means and what kind of knowledge different data sources represent.

Another aspect that has to be considered is that children's self-regulation did not always occur in a way that was likely to promote learning effectiveness. Sometimes children focused their monitoring and regulation on aspects that are not central to the task, or they used it in the pursuit of non-learning goals. Nonetheless, these young children showed metacognitive knowledge and use of metacognitive procedures that are a basis for their further development as self-regulated learners.

Introduction

Metacognition and self-regulation play an important role in learning and have proven to be an important predictor of learning outcomes (e.g. Veenman, Van Hout-Wouters & Afflerbach, 2006; Paris & Winograd, 1990).

However, some experimental studies have stated deficits in children's monitoring and regulation (e.g. Kuhn, 2000). On the other hand, recent studies in naturalistic settings showed that already young children are metacognitively active, able to monitor and regulate their behavior (e.g. Whitebread et al., 2007). In the presented study, different methods of data collection have been applied in a naturalistic school setting and are used to enlighten different aspects of these complex phenomena.

Aims

The aim of the study was to develop a fine-grained analysis of young children's self-regulated learning in a naturalistic school setting. Children were observed in their daily classroom situation and indicators for self-regulation and metacognition were analyzed. Their perspective on their own learning was explored with interviews and thereby knowledge was compared with actions and behavior. Interview and observation have been used to enlighten different facets of young children's competencies in this area.

Methods and Methodology

For the investigation of metacognition and self-regulated learning the methods of observation, video-observation, and interview were combined. Data collection was conducted in three steps. In a first step learning processes were observed in three classes with 23 to 26 children, aged from 6 to 8, in different German primary schools. In a second step video observation was done in one of the classes and finally, interviews were conducted in the same class. This qualitative, microanalytic approach was chosen because there is evidence that methods such as self-reports or experiments are likely to underestimate the metacognitive competencies of young children (Whitebread et al., 2007). Observation in a naturalistic setting can be a way to learn more about children's metacognitive abilities (Winne & Perry, 2000). Interviews are a way of learning more about their thoughts and reflections.

In the analysis, inductive and deductive methods were used. Concepts that are central to self-regulated learning and metacognition were used to build codes such as "Use of criteria for evaluation" or "Evaluation of personal skills".

Inductive coding procedures (e.g. Strauss, 1987) were used to complement the analysis and to extend the theoretical view on self-regulated learning.

Interviews and observational data were analyzed independently at first and in a second step they were compared and matched systematically. The analysis of different sources of data was integrated in AtlasTi. Coding procedures and categories were regularly discussed in a team of researchers.

Findings

Results of this qualitative study show that children are metacognitively active. Children regularly spoke about metacognitive aspects during independent work phases without being prompted. They talked to themselves or to other children and these reflections were used as one indicator for metacognitive activities.

Children monitored their learning, they knew and used different ways for checking results, and they applied various criteria for the evaluation of their work during observation. They were also observed to link task properties to their own skills spontaneously.

In the interviews children were able to speak about strategies they used and thoughts they have about their learning. Anyway, they mentioned much less strategies in the interviews than they used during their learning activities. However, the amount of strategies and procedures that were mentioned increased when the questions focused on a specific task that the children had been working on recently.

We have to address the question what this difference means and what kind of knowledge these different data sources represent. If, during observation, children talk for example about a strategy for monitoring their results spontaneously while they are using it, but do not mention this in the interview, what kind of awareness is this? Can this be called metacognition (cf. Veenman et al., 2006)? An important point is how we can use these different forms of knowledge to foster further reflection and understanding.

Another aspect that has to be considered is that metacognitive activities did not always occur in a way that is likely to promote learning effectiveness. Sometimes children focused their monitoring on aspects that were not central to the task, or they used metacognitive monitoring in the pursuit of non-learning goals. Nonetheless, these children showed knowledge and use of metacognitive procedures.

Significance

Children in this study performed metacognitive activities and reflections that are a basis for their development as expert self-regulated learners. The micro-analysis of processes, contexts, and conditions of metacognitive monitoring is crucial to gain knowledge about what children think and do in learning situations. There has been a lot of discussion about methodological aspects and how to collect data about self-regulated learning and metacognition in young children; this study helps to enlighten the benefits of different data sources if we aim at learning more about children's competencies as well as difficulties in this area.

PAPER PRESENTATION

Effects of early bilingualism on deductive reasoning in elementary school age

Sebastian Kempert, Goethe-University Frankfurt, Germany; Ilonca Hardy, Goethe-Universität Frankfurt, Germany

In the present study we examined bilinguals' advantages in executive functioning when reasoning with conditionals of the form if p then q. Deductive reasoning is an area of cognition highly relevant for academic settings as mathematics and science learning. Specifically, we assumed that bilinguals would outperform monolinguals on conditionals with counterfactual and abstract content as these problems call for the application of attentional control and inhibition processes. In contrast, we did not expect differences between the groups on conditionals with concrete content as

well as on conditionals designed to put demands on working memory by providing additional information since general advantages in working memory of bilinguals have not been reported in the literature. In a study with a total of $N = 54$ German monolingual and German-English bilingual third-graders we confirmed the postulated differences in performance with bilinguals showing an advantage on conditionals with counterfactual and abstract content, while, as expected, we did not find any differences between the groups in performance on conditionals with concrete content and with additional information. The results are discussed in terms of the development of deductive reasoning and their possible relevance for school-related learning.

A growing number of studies report cognitive advantages of bilinguals (Adescope et al., 2010). Especially advantages in executive functioning (EF) have been repeatedly shown to be affected by bilingualism (Carlson & Meltzoff, 2008; Martin-Rhee & Bialystok, 2008). This means that bilinguals in comparison to monolinguals are better able to focus their attention on relevant stimuli in ambivalent situations as well as to inhibit prevalent responses. It has been assumed that the necessity to separate two linguistic systems from early age on will result in a training and automatization of aspects of EF, namely attentional control and inhibition processes (Martin-Rhee & Bialystok, 2008). Bilinguals' advantages with regard to EF have been replicated with verbal as well as nonverbal tasks (Adescope et al., 2010). However, most of the tasks used in this research are highly artificial; practical implications with regard to school settings are rarely postulated. This is surprising since EF is considered an important factor for (school-related) learning processes (St Clair-Thompson & Gathercole, 2006).

In the context of bilingual advantages in academic domains, the investigation of deductive reasoning seems to be especially promising. Successful reasoning with conditionals of the form if p then q has been connected to working memory (WM) capacities and to processes of attentional control and inhibition: While for reasoning with conditionals of concrete content, WM is considered to be the most important factor, reasoning with conditionals of counterfactual or abstract content has been related to attentional control and inhibition processes (Handley et al., 2004). Here, reasoning has to be carried out solely on the basis of the formal structure of the conditional; additionally, prevalent (but invalid) answers may have to be inhibited in order to give a correct answer. Bilinguals, due to their enhanced EF, may therefore show an advantage on these types of reasoning tasks which are generally particularly difficult to answer. Advantages would be extremely interesting as the ability to reason deductively is an important prerequisite of participation in various academic domains such as scientific thinking (Zimmermann, 2007).

Background of the study

To investigate potential advantages of bilinguals in EF we conducted a study with 54 German monolingual and German-English bilingual third-graders. We assumed that bilinguals would outperform monolinguals on conditionals with counterfactual and abstract content as these problems call for the application of attentional control and inhibition processes. In contrast, we did not expect differences between the groups on conditionals with concrete content as well as on conditionals designed to put demands on WM by providing additional information as general advantages in WM of bilinguals have not been reported in the literature. Finally, since differences between monolinguals and bilinguals should be specifically traced back to attentional control and inhibition we did not expect differences in logical thinking abilities per se. Accordingly, group comparisons on indeterminate (typically more difficult) and determinate (typically less difficult) conditionals should reveal no group differences.

Method

54 third-graders (27 German monolinguals and 27 German-English bilinguals) participated in the study. As control variables, we administered a test of oral proficiency in German (and English for bilinguals) and a nonverbal test of cognitive ability. As an indicator for SES we used a books-at-home index. We developed five sets of conditionals of the form if p then q with the following variations in content: concrete, counterfactual, abstract, concrete with additional facilitative information, and concrete with additional distracting information. Each set included the four possible combinations of inference modi (modus ponens, modus tollens, affirmation of the consequent, denial of the antecedent) resulting in 20 conditionals.

Results

In a repeated ANCOVA including cognitive ability, verbal ability, and SES as covariates we found a significant difference between the two language groups on conditionals with counterfactual and abstract content, $F(1, 49)=7.40$, $pp=0.13$, while the effects of type of content and the interaction group \times type of content were insignificant. Univariate follow-ups confirmed a bilingual advantage on conditionals with counterfactual and abstract contents, $F(1, 49)=4.77$, $pp=0.08$; $F(1, 49)=2.96$, $pp=0.05$, respectively. In a further ANCOVA on conditionals with concrete content, facilitative, and distracting information, no significant differences between the groups were observed (group \times type of content: $F(2, 48)=0.14$, $p=.86$, $\eta^2p=0.00$, group: $F(1, 49)=0.09$, $p=.75$, $\eta^2p=0.00$) although the manipulation of the conditionals was successfully indicated by a significant effect of the factor of type of content, $F(2, 48)=3.34$, $pp=0.12$.

The direction of the manipulation was confirmed by pairwise comparisons. Finally, a repeated ANCOVA on the type of conditional reasoning (determinate, indeterminate) revealed a significant effect, $F(1, 49)=9.35$, $p=0.016$, while no group effects or interaction effects were observed.

Discussion

Drawing from results of previous research, we expected advantages of bilingual children on tasks that require attentional control and inhibition but not on tasks that call for additional resources in WM. Accordingly, we found statistically significant differences in the performance of the group of monolinguals and bilinguals on conditionals with counterfactual and abstract content, while no differences were observed with regard to conditionals with concrete content or with additional facilitating or distracting information. At the same time, this variation showed the expected effects for both bilingual and monolingual students. Finally, the data reveal that the two groups did not differ in their ability to solve determinate and indeterminate conditionals indicating that there are no differences in logical thinking abilities in general. Our results are promising as conditional reasoning is considered to play an important role in academic learning such as mathematics and the natural sciences. For example the formulation of hypotheses from theory and the design and interpretation of experiments are areas in which deductive reasoning is necessary. It is also in these domains where the confrontation with counterfactual or abstract contents is very likely. Future studies will need to replicate our findings in more applied settings such as science learning in order to specify bilinguals' application of EF in these domains.

PAPER PRESENTATION

Content and Language Integrated Learning (CLIL): Predictor variables of dropout

Nadira Saab, Leiden University, Netherlands

Content and Language Integrated Learning (CLIL) is a form of education where students are educated in another language than their mother tongue. The goal of CLIL is improving the English proficiency next to providing the regular education. In 2008, 99 schools in the Netherlands used CLIL. This study investigates possible predictor variables of dropout in Dutch schools that use CLIL. Variables that are investigated include social economic status, parent support, affective factors (motivation, self-esteem), and cognitive factors (English proficiency, performance in primary school (CITO scores)). This study involves 512 seventh/eight-grade students who are participating in a CLIL program. The students are followed during the first two years of pre-university education (seventh and eight grade) In the first year, 7 % of the students dropped out. Based on preliminary results, it can be concluded that students who dropped out had a lower SES than students who continued with CLIL. Furthermore, students who dropped out had lower results on the English skills test. More results will be presented at the conference.

Theoretical and educational significance

Content and Language Integrated Learning (CLIL) is a form of education where students are educated in another language than their mother tongue. Most of the schools in The Netherlands that implemented CLIL use English as the second language. The goal of CLIL is improving the English proficiency next to providing the regular education. In 2008, 99 schools in the Netherlands used CLIL (European Platform, 2008). However, little research has been conducted into CLIL in the Netherlands. Huibregtse (2001) investigated the effects of CLIL on the academic performance of students. The study showed that students attending schools that integrated CLIL had higher grades for English than students who attended regular schools. No differences were found for grades of other subjects. Weenink (2006) compared the social economic background of parents of children attending the CLIL and parents of children attending gymnasium (small scaled regular pre-university education specialised in classical language such as Latin and Greek) with the social economic background of parents of children from regular pre-university education. It was found that most parents of

the first group were from higher social economic background than the second group. Furthermore, the first group stressed the importance of internationally oriented education more than the second group. In 2008-2009 41.785 students in the Netherlands dropped out of school (Secretary of OCW, 2010). 10.183 of these students were high school students. These students actually left school. In this study we see dropout as quitting the form of education the students is following, in this case CLIL. It is possible that students quit CLIL and go to regular education. Research into the factors that influence dropout show that social economic background, motivation, academic performance, gender, and self-esteem are possible predictors of dropout (Lee & Burkham, 2003; Luyten et al., 2003). Aim This study investigates possible predictor variables of dropout in Dutch schools that use CLIL. Variables that are investigated include social economic status, parent support, affective factors (motivation, self-esteem), and cognitive factors (English proficiency, performance in primary school (CITO scores)). Furthermore, difference in dropout rate between girls and boys is investigated.

Methodology

This study involves 512 seventh/eight-grade students from seven schools in The Netherlands who are participating in a CLIL program (297 boys and 215 girls). These schools teach half of the courses in English. The schools use a total immersion method (Wytzes, 2002; Van der Mee, 2003), which implies that students have to speak English rather than Dutch during those courses. A questionnaire measuring the variables described above was administered at two times: in the seventh and eight grade, both at the beginning of the school year. So the same students, except for the dropouts, are followed during the first two years of pre-university education (seventh and eight grade). At this moment, only the data of the first measurement is analysed. The results of the analyses with the data of the second measurement will be presented at the conference. In the first analyses, analyses of variance were used to find possible predictor variables..

Findings

In the first year, 7 % of the students dropped out. Based on preliminary results, it can be concluded that students who dropped out had a lower SES than students who continued with CLIL. This finding corroborates with findings from Lee & Burkham (2003) and Luyten, et al. (2003). Furthermore, students who dropped out had lower results on the English skills test (part of the questionnaire). A surprising result is that dropout students received relatively more support from their parents. This is in contrast with results from earlier research (e.g. Cutrona et al., 1994; Ryan, 2001; Wentzel, 1998) where more social support most often leads to better academic performance. However, in both groups the parents were more than willing to help the students with their homework. No differences were found between boys and girls.

PAPER PRESENTATION

An investigation of foreign language learning attitudes among Turkish EFL learners

Ozgul Ozbak, University of Essex, United Kingdom

This paper reports on a pilot study that was conducted before the longer proposed study. The aim of the study was to look at the issue of foreign language learning attitude in depth via addressing two central research questions: What factors affect or determine Turkish EFL learners' attitudes towards language learning situation at tertiary level? What

are Turkish EFL learners' attitudes towards the EFL classes at tertiary level? Contrary to the traditional quantitative attitude surveys, this study adopted exploratory and qualitative methodology by employing diary entries and interviews as data collection instruments. Six Turkish EFL learners doing English classes at two different universities were asked to keep a weekly diary for three weeks. After the analysis of the diary data, three individual interviews and one group interview were conducted to go into detail of the diary findings. The results showed that participants found English classes necessary. They also reported that they liked English language. One important finding is that despite their favourable attitudes towards English language, they reported unfavourable attitudes towards the classes. Various factors related to the language classes, language teacher and language programme were found to affect the participants' overall language learning attitudes. Since this study is based on both theoretical and practical considerations, findings suggest considerable theoretical and pedagogical implications for foreign language learning. This paper presents the empirical results in detail and discusses the implications for both theory and practice.

Attitude has long been a matter of scholarly attention in second language acquisition field since it has been well defined by scholars that each individual learner has different disposition towards second language learning. Technically first initiated by Gardner (1985) with socio-educational model, attitude has been of interest to a number of scholars, (e.g. Burstall, 1975; Brown, 1983; Chambers, 1999; Clark and Trafford, 1996; Dörnyei, 2003; Ushioda, 2005). There is a plethora of research on the topic in SLA field, however, as Mitchell & Myles (1998:26) also mention, most language learning attitude research appeared within broader motivation research although attitude itself is an "umbrella term" covering a wide range of issues. (Baker, 1992:29). In Gardner's socio-educational model the term appeared in line with the target language community, language learning in general and language learning situation. However, since Gardner's focus was on integrativeness, attitudes toward the learning situation was not given considerable attention. With the educational shift in 1990s putting the classroom concept in the agenda, a number of critical treatments and theoretical expansions have emerged. (Dörnyei, 1994; Gardner & Tremblay, 1994; Oxford & Shearin, 1994).

In recent frameworks, classroom gained more importance than before but as already mentioned not in pure attitude research but within broader motivation research. Bearing in mind that although attitude and motivation are two closely related concepts since it's been well evidenced that attitude affect motivation and motivation affect overall L2 development (e.g. Gardner, 1985), there should be a clear-cut between the terms in order to better understand both issues in depth. (e.g. Crookes and Schmidt), and that as Chambers state "to treat them as one and same thing, however, is unhelpful." (Chambers 1999:26), this study aims to look at the issue of foreign language learning attitude in depth via addressing following research questions: What factors affect or determine Turkish EFL learners' attitudes towards language learning situation at tertiary level? What are Turkish EFL learners' attitudes towards the EFL classes at tertiary level?? As also addressed by some scholars, (e.g. Crookes and Schmidt, 1991) most of the attitude surveys initiated by Gardner and his AMTB and factor analysis have traditionally adopted quantitative methodology by collecting data via standardised likert-scale questionnaires and by employing statistical analysis with an aim to produce quantifiable generalizations of variables limited to the pre-set ones thus leaving the door closed to other attitudinal factors probable to arise in an explorative research. Because attitude is a complex and broad term stemming from individuals' emotional world and because it changes from person to person and open to interpretation, an exploratory approach was decided to be more consistent with this attitude survey.

This paper reports the results of a pilot study that was conducted before the longer proposed study to see how qualitative research instruments would work. Six Turkish EFL learners doing English classes at two different universities were asked to keep a weekly diary for 3 weeks. Before they start writing their diaries they were given a training session on diary writing. After the collection and analysis of the diary data, 3 individual and one group interviews were conducted to go into detail of the diary findings. T

he results showed that participants found English classes necessary. They also reported that they liked English language. One surprising finding is that despite their favourable attitudes towards English language, they had unfavourable attitudes towards the classes. Based on both diary and interview data, various factors were found to affect the participants' language learning attitudes. Among the most commonly reported ones are course materials, learning tasks, lesson topics and contents, lack of practice in classes, language skills classes with focus on grammar classes, teacher motivation, teacher personality, teacher feedback, teaching style, teacher modelling, non-native speaker of English teachers, teacher-student relationship, teacher authority, English classes as obligatory class, overall assessment, exam, homework and assignments. These reported factors were put under three categories: attitudes towards lesson related variables, attitudes towards teacher related variables and attitudes towards obligatory English preparatory programme as an external force.

This exploratory and qualitative study is based on both theoretical and practical considerations and findings indicated that attitudes towards the language is not necessarily in parallel line with attitudes towards the language classroom which indicates that in foreign language learning situation where exposure to the target language is mainly and in many cases only the classroom, language learning situation that is classroom has a great impact on overall language learning attitude. The findings of the present study also suggest considerable pedagogical implications for foreign language classrooms.

PAPER PRESENTATION

Comparing English and Japanese 5 year-olds development of language, a transversal skill.

Stasia Cwenar, Liverpool Hope University, United Kingdom

Japanese pupils consistently outperform English pupils in international league tables of academic performance, yet there is little data on their relative starting points prior to starting school. A comparative study has compared early performance in each country on a range of abilities significant in subsequent school success.

A total of 110 pre-school children with an average age approaching 5 years were individually assessed in a study matching gender, age, sample size and social background. Parent and educator interviews on early education provided further, qualitative data to augment and clarify quantitative results. Quantitative test results showed significant differences between performances of the Japanese and English children (Mean Rank for Japanese children was $M = 74.69$, with the Mean Rank for the English $M = 36.31$ (p

Qualitative data from interviews on the relative philosophies and practices of the two countries regarding child rearing, early education and communication competence are discussed, including those regarding the preparation of children for the shift from home to school styles of learning. The results overall are considered as to whether there is any relationship between the philosophy and practice of teaching in the pre-school years and latter educational performance.

Introduction:

Global competition has led to an interest in international comparisons of performance in education and the workplace, and more recently on the relationship between outcomes, curriculum and pedagogy. Tables of academic performance in Mathematics and Science (TIMSS) show that in general pupils from Pacific Rim and Scandinavia achieve the highest results (Mullis, Martin and Foy, 2005). For example, Japanese pupils consistently outperform English pupils by the age of 9 yet they do not begin formal schooling until age 6-7. Most school assessment deploys the 'secondary' language modes of reading and writing yet as Sage (2000a) suggests, around 75 percent of children experience some difficulty shifting from informal, home talk to formal, school discourse, dependent upon their ability to assimilate and assemble information. This may be attributed to current child-rearing circumstances and practices and less opportunities for extended, formal types of talk between the child and other adults.

Methodology:

This study forms part of a project designed to compare children's understanding as they approach statutory education and their 'primary' oral ability to make meaning from experience. The data will also consider any relationship between levels of cognitive-linguistic competence and later academic success. As English children start Primary education at around age 5 years and Japanese children at age 6+ years, tests were administered to participants whose average age was 5 years.

Participants: There were 55 Japanese and 55 English pupils aged 40-59 months, 56 males and 54 females (Japanese, $M = 49.09$; English, $M = 50.15$, p

Materials:

Activities which require participants to apply their existing knowledge in new situations reveal the nature and extent of underlying concepts and meta-cognitive abilities, while expression of ideas in natural language allows a valid examination of children's conceptual knowledge. On this basis two language tests were developed to examine the capacity of children to assemble and reproduce information.

Tasks involved a General Knowledge test and Retelling of a Story, the latter suggested by Beilin (1975) to be the best indicator of learning potential, with children reproducing information according to their cognitive and linguistic levels. They were designed to be 'culturally fair', age appropriate and valid for assessing cognitive development in young children. Cultural features that provide 'meaning' in the tasks (Anastasi, 1988; p.298) were protected as meaning-making was a key component of the cognitive assessment criteria. Reliability and validity were tested at the developmental stage for linguistic accuracy of target questions and tests by native speakers.

Also addressed were the ethical safeguards necessary when testing very young nursery/kindergarten participants, aged around five years and when conducting adult interviews. Consent was obtained through universities and schools which met the standards of each country, prior to project clearance and commencement.

Methods of Analysis:

Answers to the General Knowledge questions related to personal understandings essential for comprehending received language: animate/inanimate function, space, time and comparatives. Responses were coded as right or wrong. Responses to the Story Retelling task were examined for oral usage of propositions and coded for: correct ideas, sequence and degree of detail.

Results

Language tasks: Findings for the General Knowledge show that only 19 percent of the English 3-4 year-olds did not know their age, confirming that, in general, children's understanding of 'self' develops before that related to the wider world. There was no difference between the Mean Ranks of boys and girls; boys: $M = 20.75$, $SD = 6.97$; girls: $M = 20.04$, $SD = 7.09$. There was a strong correlation (Mann-Whitney U Test) between the results of the general knowledge and story re-telling tasks at $r = .311$ with a significance level of p

The Japanese children recalled the story more completely and coherently, demonstrating a significantly greater sense of narrative than the English children who paid greater attention to individual items than the story as a whole. Differences between performances of the Japanese and English children was statistically significant. The Mean Rank for Japanese children was $M = 74.69$, with the Mean Rank for the English $M = 36.31$ (p

Conclusion: Further qualitative data obtained in discussions and classroom observations in the Japanese kindergarten and elementary schools revealed a pattern of adult awareness of the major shift required of young children when moving from informal home talk to the more formal styles of school talk. For example formal speaking (in class) is coached as part of daily practice in Japan, and the strategy of providing opportunities for all children in the class to communicate their ideas, combine to provide a strong base structure for learning about written words and numbers. These are rarely seen in British educational practice and may relate to their relative underlying educational and child-rearing philosophies.

In a global society involving international cooperation and collaboration, comparative studies bring greater insights and understanding of both individual and group functions, and differing degrees of balance between the two. Intercultural comparisons must respect cultural differences involving unmatched variables, and importing educational practices without such consideration is inappropriate. Nevertheless the above results and other early years pedagogy may warrant wider examination in relation to international levels of performance in core or 'transversal' skills.

PAPER PRESENTATION

Explicit/implicit knowledge and working memory in L2 reading comprehension

Cem Alptekin, Turkey; Gulcan Ercetin, Bogazici University, Turkey

The distinction between explicit and implicit knowledge has been investigated in terms of the contribution of each type of knowledge to L2 development. However, little attention has been paid to the role of explicit and implicit knowledge in the development of language skills. That is, how explicit and implicit knowledge resources and the corresponding explicit and implicit processes of learning contribute to the development of a skill. Similarly, the limited research investigating the role of working memory (WM) in L2 skill development has largely ignored the delineation of interactions between WM and the declarative and procedural memory systems underlying long-term memory (LTM). Considering that late L2 learning predominantly occurs in a consciously controlled manner, with an enhanced declarative memory system and a corresponding attenuated procedural system, it can be assumed that explicit linguistic knowledge plays an important role in L2 reading compared to implicit knowledge and that interactions between LTM and WM represent the controlled processes of explicit knowledge. The current study aimed to shed light on issues relevant to a better understanding of how knowledge types (explicit and implicit) and memory systems (LTM and WM) interact for L2 reading comprehension. The participants were university students who were advanced

EFL learners. Correlations among the variables were obtained and examined through a factor analysis. The results indicate that explicit linguistic knowledge, WM capacity, and L2 reading constitute a factor altogether. Implicit linguistic knowledge constitutes a factor on its own, yet WM capacity is related to implicit knowledge to a certain extent.

The distinction between explicit and implicit knowledge has been extensively investigated in applied linguistics in terms of the contribution of each type of knowledge to L2 development. However, little attention has been paid to the role of explicit and implicit knowledge in the development of specific language skills. That is, how explicit and implicit knowledge resources and the corresponding explicit and implicit processes of learning contribute to the acquisition of a L2 skill. Similarly, the limited research investigating the role of working memory (WM) in L2 skill development has largely ignored the delineation of interactions between WM and the declarative and procedural memory systems underlying long-term memory (LTM). WM, for instance, consciously processes tasks that are fundamentally explicit. Accordingly, it predominantly subserves declarative memory (DM), which is in charge of storing and retrieving explicit knowledge. This is in sharp contrast to the operation of the procedural memory (PM), which is responsible for storing and retrieving implicit knowledge and skills. Considering that late L2 learning predominantly occurs in a consciously controlled manner, with an enhanced DM and a corresponding attenuated PM (Ullman, 2001), it is reasonable to assume that WM operations will have a significant relationship with the conscious processing of explicit knowledge.

The current study aimed to shed light on a number of issues relevant to a better understanding of how knowledge types (explicit and implicit) and memory systems (LTM and WM) interact for L2 reading comprehension, taken up as the language skill to be examined. To this end, the following research questions were investigated:

Are there significant relationships between explicit/implicit knowledge types and WM capacity?

Are there significant relationships between L2 reading and explicit/implicit knowledge types on one hand, and WM capacity on the other? Do these variables form coherent subsets that are relatively independent of one another?

It was hypothesized that there should be a significant relationship between explicit knowledge and WM capacity, as cognitive processes underlying both LTM-based explicit knowledge operations and WM functions are characterized by consciousness and attentional control. In contrast, a non-significant relationship was expected to be the case in what concerns the connections between implicit knowledge and WM functions since all WM operations, as indicated by Baars (1997), rely on conscious elements even in cases when these may recruit the mediation of unconscious resources to perform the given tasks (Hypothesis 1). Next, it was assumed that explicit knowledge rather than implicit knowledge would be closely related to L2 reading comprehension, considering that late L2 readers rely mostly on explicit knowledge as a result of their formal educational experience with L2 learning, not to mention the fact that PM, known to be responsible for implicit knowledge, attenuates with age, its linguistic functions being taken over by DM (Ullman, 2001). As for the relationship between L2 reading and WM capacity, a significant correlation was expected because of the significant associations observed between WM capacity and L2 reading comprehension in research findings (Alptekin & Erçetin 2009, 2010; Harrington & Sawyer 1992; Miyake & Friedman 1998; Leiser 2007; Walter 2004) (Hypothesis 2). Based on these hypothesized relationships, it was assumed that explicit knowledge, WM capacity, and L2 reading comprehension would form a coherent subset in a factor analysis as these variables are characterized by controlled explicit processes whereas measures of implicit knowledge would form a separate subset (Hypothesis 3).

The participants were 51 Turkish university students who were advanced EFL learners. They were given standard tests measuring their implicit L2 knowledge, explicit L2 knowledge, and L2 WM capacity. L2 reading comprehension was measured through a standardized reading test (Nelson-Denny). Correlations among the measures were obtained to explore the relationships. The data were also exposed to an exploratory factor analysis using principal components extraction and varimax rotation. The findings indicate that explicit linguistic knowledge, WM capacity, and L2 reading comprehension constitute a factor altogether. The relationship between the use of explicit knowledge and WM operations in the L2 is to be expected given that conscious and intentional processes of selective attention that are involved 'in the control, regulation and active maintenance of task-relevant information' in WM (Miyake & Shah 1999: 450) are also indicative of bottom-up processes of explicit knowledge that direct learners to focus on the relevant features of the L2 input. Therefore, explicit knowledge-based performance correlates with L2 reading comprehension since L2 readers' performance in reading is predominantly guided by the DM's explicit knowledge. The outcome is word-bound reading, characterized by lexical processing at the expense of syntactic processing—which is subserved by PM. This places a heavy load on WM capacity and hampers efficient L2 reading by preventing the interaction of bottom-up and top-down processes. The relationship between WM capacity and L2 reading comprehension corroborates previous evidence obtained between the two constructs (e.g. Alptekin & Erçetin 2010; Harrington &

Sawyer 1992; Leiser 2007; Walter 2004). WM, in fact, significantly contributes to reading comprehension due to both constructs sharing similar cognitive properties.

The results further indicate that implicit linguistic knowledge constitutes a factor on its own, yet WM capacity is related to implicit knowledge to a certain extent. This finding renders support to those critics (Halford et al. 2007; Hassin et al. 2009; Reber & Kotovsky 1997) of the prevalent position of viewing WM as operating intentionally and consciously on tasks that are strictly explicit. Evidently, although WM is primarily responsible for bottom-up processing of explicit data, it also attends to the input that is to be processed in a top-down way in the event input is of an implicit nature. In a way, the conscious components of WM help mobilize and guide unconscious routines that carry out automatic processing of implicit tasks (Baars & Franklin 2003) while they sustain controlled attentional processing for complex explicit tasks. Thus, technically speaking, WM is a central executive for all types of cognitive processing, with controlled processes of explicit learning taxing its limited capacity much more heavily than automatic processes of implicit learning. The implications of the findings for L2 reading instruction will be discussed.

PAPER PRESENTATION

Recreational and Academic Reading Motivation in Primary School

Jessie De Naeghel, Ghent University, Belgium; Hilde Van Keer, Ghent University, Belgium; Maarten Vansteenkiste, Ghent University, Belgium

Given the importance of reading motivation for reading frequency and academic reading performance, an in-depth understanding of reading motivation is essential to keep children motivated and encourage them to read. The first aim of this study was to develop and validate a questionnaire measuring recreational and academic reading motivation (SRQ-Reading Motivation), based on self-determination theory, and to explore fifth graders' reasons for reading. Second, the relationship between reading motivation, reading engagement, reading frequency, and reading comprehension was studied to deepen our understanding of reading motivation. 1260 fifth graders completed the SRQ-Reading Motivation, 8 subscales of the Motivation for Reading Questionnaire (MRQ), a standardized reading comprehension test, a scale concerning reading frequency, and reading self-concept. Teachers also rated their students' reading engagement. Exploratory and confirmatory factor analyses indicate that both recreational and academic reading motivation comprise two factors: autonomous and controlled reading motivation. Comparisons with the MRQ and the teacher rating of students' reading engagement confirm the construct validity of the instrument. Participants mainly report autonomous reading motivation in both contexts (recreational and academic). Not surprisingly, controlled reading motivation is fairly higher in the academic setting. Both structural equation models, designed to clarify the relationship between reading motivation and several reading outcomes, have a good fit and support the predictive utility of the SRQ-Reading Motivation questionnaire. As expected, autonomous reading motivation, relative to controlled reading motivation, is associated with more positive outcomes (i.e. more reading engagement, higher leisure-time reading frequency, more reading comprehension).

Relevance and Objective

Reading motivation declines as children grow older, starting already in primary school (Guthrie & Wigfield, 2000). This tendency challenges us, since reading motivation is a critical predictor of reading frequency (Guthrie, Wigfield, Metsala, & Cox, 1999) and reading performance (Taboada et al., 2009). In order to keep children motivated to read and to encourage reading motivation, an in-depth understanding of this concept is essential.

Theoretical Background

According to Guthrie and Wigfield (2000), reading motivation refers to "the individual's personal goals, values, and beliefs with regard to the topics, processes, and outcomes of reading" (p. 405), indicating different reasons for reading. However, a further examination of the dimensions of reading motivation is recommended (Watkins & Coffey, 2004) and should consider contextual differences (McKenna & Kear, 1990). In this perspective, Self-Determination Theory (SDT) (Ryan & Deci, 2000) presents a promising theoretical framework to conceptualise autonomous and controlled types of reading motivation. According to reading research (Guthrie et al., 1999; Taboada et al., 2009) and SDT (Connell & Wellborn, 1991; Ryan & Deci, 2000), autonomous reading motivation has been associated with more reading engagement, higher reading frequency, and better reading comprehension. However, an indirect relationship between reading motivation and comprehension via reading frequency (Guthrie et al., 1999) or through engagement (Connell & Wellborn, 1991) is also suggested.

Research Goals

The main goal of this study is to develop and validate a reading motivation questionnaire based on SDT, and to explore fifth graders' reading motivation in recreational and academic contexts. Further, the relationship between reading motivation, reading engagement, reading frequency, and reading comprehension is studied.

Research Method

Participants

1260 fifth graders from 45 Flemish (Belgium) primary schools participated.

Instruments

Based on SDT (Ryan & Deci, 2000), the SRQ-Reading Motivation was developed to capture autonomous and controlled reading motivation, in recreational and academic contexts (McKenna & Kear, 1990).

To validate this instrument, students completed 8 subscales of the Motivation for Reading Questionnaire (MRQ) (Baker & Wigfield, 1999) and teachers rated students' reading engagement (Reeve, Jang, Carrel, Jeon, & Barch, 2004). A standardized reading comprehension test (www.steunpuntloopbanen.be) and two scales concerning leisure-time reading frequency and reading self-concept (<http://pirls.bc.edu/pirls2006/>) were also administered.

Results and Discussion

Regarding the first aim, the results reveal that the SRQ-Reading Motivation can be seen as a reliable and valid questionnaire measuring reading motivation in recreational and academic contexts. Regarding the structural validity, exploratory and confirmatory factor analyses [recreational: $SB\chi^2=502.828$ ($df=116$, $p\chi^2=541.965$ ($df=116$, p indicate that reading motivation comprises two factors: autonomous ($arecreational=.94$, $aacademic=.94$) and controlled motivation ($arecreational=.84$, $aacademic=.85$), which corresponds to the theoretical motivation types within SDT (Ryan & Deci, 2000). The correlation pattern between autonomous and controlled reading motivation, the MRQ-subscale, and the teacher ratings confirm the construct validity of the instrument.

Descriptive results of the SRQ-Reading Motivation reveal that fifth graders' mainly report autonomous motivation in recreational ($M=3.55$, $SD=.96$) and academic contexts ($M=3.54$, $SD=1.00$). As expected, controlled motivation is slightly higher in the more demanding academic setting (recreational: $M=2.21$, $SD=.67$; academic: $M=2.60$, $SD=.77$).

Concerning the second goal, both SEM models depicting the relationship between reading motivation and reading-related outcomes, have a good fit [recreational: $SB\chi^2=.0755$ ($df=1$, $p>.05$), $RMSEA=.000$, $SRMR=.012$, $CFI=1.000$, $TLI=1.003$; academic: $SB\chi^2=1.148$ ($df=1$, $p>.05$), $RMSEA=.011$, $SRMR=.015$, $CFI=1.000$, $TLI=.998$] and support the predictive utility of the SRQ-Reading Motivation (Figure 1 and 2). Consistent with reading research (Guthrie et al., 1999; Taboada et al., 2009) and SDT (Ryan & Deci, 2000), recreational autonomous reading motivation relates positively to more leisure-time reading and comprehension. Recreational controlled reading motivation is negatively related to comprehension. Regarding academic reading motivation, only the equivalent pathways concerning reading frequency are significant. Both models confirm that engagement functions as a behavioral pathway between autonomous reading motivation and comprehension (Connell & Wellborn, 1991). The indirect relationship between reading motivation and comprehension through reading frequency (Guthrie et al., 1999) cannot be corroborated.

The development of the SRQ-Reading Motivation is of theoretical and empirical significance, since SDT is not applied in the context of reading research before and appears to be relevant for this area. Further, it allows teachers to get a grip on individual differences and students' development in reading motivation, and to evaluate reading promotion interventions. Additionally, the SEM models highlight especially the importance of autonomous reading motivation as antecedent of important reading outcomes, which is relevant for teacher behaviour in educational practice.

PAPER PRESENTATION

Testing a path model of text comprehension among 5th grade students

Vanessa Seuring, Justus-Liebig-Universität Giessen, Germany; Joachim Brunstein, Justus-Liebig-University, Germany

This study was designed to explore the effects of reading time, reading fluency, vocabulary and reading strategies on the text comprehension of fifth grade students.

Our aim was to test if reading strategies are an indispensable component of a path model of text comprehension. Additionally we wanted to explore if reading strategies are interconnected and sequentially affect text comprehension or if a model without those interconnections but with reading strategies showing parallel effects on comprehension, reveals a better fit for the data. The sample consisted of 217 fifth-grade students. The model fit was evaluated by the comparative fit index (CFI) and the standardized root-mean-square residual (SRMR).

The fit was not acceptable for a reduced model (CFI = .742; SRMR = .148), but it was for the resulting sequential model (CFI = 1.000; SRMR = .037) as well as for a parallel model (CFI = .950; SRMR = .059). Comparing the reduced model with the sequential model revealed a significant better fit for the latter (Delta Chi² = 79.46, p = .000).

The results of this study indicate that reading time, reading fluency and vocabulary have significant effects on text comprehension. Therefore combined intervention programmes, fostering all of these components, should be implemented. Additionally the reported results concerning the sequential interconnections of reading strategies provide information about the most effective order of strategy application.

This study was designed to explore the effects of reading time, reading fluency, vocabulary, and reading strategies on the text comprehension of fifth grade students. Data was analyzed using path analysis. Results reveal that a path model integrating sequentially interconnected reading strategies shows the best fit for the data.

Evidence for the effects of reading fluency on text comprehension comes from German studies analyzing data collected in the course of the PISA-studies (Artelt, Schiefele, Schneider & Stanat, 2002; Schaffner, Schiefele & Schneider, 2004). But the connection of reading fluency and text comprehension is not unquestioned. The effects of training studies for fostering reading fluency for example do not in all cases transfer to text comprehension (Kuhn & Stahl, 2003).

The effects of vocabulary instruction on children's comprehension of text were proved through a meta-analysis by Stahl and Fairbanks (1986), who reported an effect size of .30 of vocabulary instructions on comprehension measures. Furthermore in the direct and inferential mediation model of reading comprehension (DIME model) by Cromley and Azevedo (2007) the direct effect of vocabulary made the largest contribution to comprehension. They also found a significant indirect effect of vocabulary on reading comprehension mediated by inference. Lately Cromley, Snyder-Hogan and Luciw-Dubas (2010) tested the fit of the DIME model for a sample of biology students and found a better fit for a modified model including a path from vocabulary to reading strategies and therefore an additional indirect effect of vocabulary on reading comprehension.

The importance of reading strategies for text comprehension was proved by studies comparing reading experts with novice readers (Bereiter & Bird, 1985; Pressley & Afflerbach, 1995) as well as by studies analyzing models of text comprehension (Artelt et al., 2002; Schaffner et al., 2004; Cromley & Azevedo, 2007). Additionally a lot of research was done in the area of fostering reading strategies through interventions (e.g. Palincsar & Brown, 1984; Fuchs, Fuchs, Mathes & Simmons, 1997; Souvignier & Mokhesgerami, 2006).

Aims

The major purpose of this study was to analyze how the variables reading time, reading fluency, vocabulary and reading strategies contribute to text comprehension. Furthermore our aim was to test if the integration of reading strategies (clarifying, questioning, summarizing and predicting) in a model of text comprehension account for unique variance beyond reading time, reading fluency and vocabulary (sequential model vs. reduced model). Additionally we

wanted to explore if reading strategies are interconnected and sequentially affect text comprehension (sequential model) or if a model without those interconnections but with reading strategies showing parallel effects on comprehension, reveals a better fit for the data (parallel model).

Method

The sample consisted of 217 fifth-grade students of 10 classes. Text comprehension, vocabulary and reading fluency were assessed using standardized German tests (Souvignier, Trenk-Hinterberger, Adam-Schwebe & Gold, 2008; Weiß, 1998; Auer, Gruber, Mayringer & Wimmer, 2005). Reading strategies were assessed using an experimenter developed test (Seuring & Spßrer, 2010). Students had to read a text passage and apply the four strategies to the passage. For the analysis the polarity for the variable clarifying was changed to simplify interpretation of results. Therefore the respective variable in the model is named "clarity". Reading time was assessed by one item asking the students for the daily time they usually spent voluntarily on reading in their spare time (scaled from 0 = "no time" to 5 = "more than two hours daily"). Data collection was cross-sectional. During the testing students were not allowed to use additional material, as dictionaries.

Results

Data was analyzed using Amos 18. According to recommendations by Hu and Bentler (1999) for sample sizes N The fit was not acceptable for the reduced model ($CFI = .742$; $SRMR = .148$), but it was for the resulting sequential model ($CFI = 1.000$; $SRMR = .037$) as well as for the parallel model ($CFI = .950$; $SRMR = .059$). Comparing the reduced model with the sequential model revealed a significant better fit for the latter ($\Delta\chi^2 = 79.46$, $p = .000$). Figure 1 shows the resulting sequential model with standardized path coefficients. The only path hypothesized which failed significance was the one from predicting to reading comprehension.

Figure 1: Sequential model with standardized path coefficients. *p p p

Educational significance of the research

Even though directional connections were analyzed in this study, because of the cross-sectional design, there cannot be drawn conclusions regarding causality. So the evidence for causal relations we get from this study should be verified with longitudinal data.

Still the results of our study indicate that reading time, reading fluency and vocabulary have significant effects on text comprehension. The comparison of the reduced and the sequential model reveals that reading strategies are an indispensable component of a path model of text comprehension. With regard to intervention studies the reported results concerning the sequential interconnections of reading strategies are of essential importance. They provide information about the most effective order of strategy application. Additionally, not only strategies, but also reading time, reading fluency and vocabulary have significant positive effects on text comprehension. Therefore combined intervention programmes, fostering all of these components, should be implemented

PAPER PRESENTATION

Effects of guided oral reading interventions for poor readers in grades 2 through 4

Ron Oostdam, University of Amsterdam, Netherlands; Henk Blok, Kohnstamm Institute, University of Amsterdam, Netherlands

On nearly every primary school one might find students lagging behind in reading fluency. These students keep reading slowly or with many errors. We wanted to know if guided oral reading would be an effective remedy for low achieving readers in the lower grades. Guided oral reading implies that a student reads a text aloud, while an experienced reader supervises the reading process and provides feedback or help when necessary. A total of 126 reading retarded students from grades 2 to 4 participated in the study. They were randomly divided between two treatment groups and a non-treated control group. In the treatment groups the intervention was delivered in a one-to-one setting by a para-professional in one of two versions, either in a repeated reading or in a continuous reading format, depending on how often students had to practice with the same text. Each student went through 48 reading sessions of 20 minutes, with a maximum of four sessions each week. Measurements included tests for fluency, reading comprehension, vocabulary, and reading attitude. The results demonstrate that guided oral reading is effective for improving fluency and reading attitude. Within and between grades the two versions (continuous or repeated reading) proved to be equally effective. Effects with regard to reading comprehension and vocabulary could not be established.

On nearly every primary school one might find students lagging behind in reading fluency. These students keep reading slowly or with many errors. Reading fluency is important because students who recognize words effortlessly should be able to devote more attention to reading comprehension. In theories regarding information processing and verbal efficiency, improving the level of reading fluency (speed and accuracy of reading text) frees students to devote

more of their attention to understanding the meaning of text. In other words, improving reading fluency is a prerequisite for improving reading comprehension, which in turn is an important basic skill for the educational career of students.

We wanted to know if guided oral reading would be an effective remedy for low achieving readers in the lower grades. Basic assumption is that a lack of reading fluency can best be remediated as early as possible in order to prevent serious arrears.

Guided oral reading implies that a student reads a text aloud, while an experienced reader supervises the reading process and provides feedback or help when necessary. In this paper the results are discussed of a study into the effectiveness of two methods of guided oral reading: repeated reading and continuous reading. Because students with low reading fluency have problems with recognizing words quickly as well as recognizing them accurately, repeated reading is often recommended for improving the reading rate. Repeated reading is a method according to which students reread a passage until mastery or near mastery level is achieved. By doing so students will increase their feeling of being a competent reader which will motivate and stimulate their reading development. Alternatively, the method of continuous reading is suggested. Continuous reading implies that the student reads new texts as much as possible. Rather than the repetition of reading a limited number of texts, reading different texts across a range of text types should generate reading improvement. Continuous reading is more in line with how students read in daily life and should therefore be more motivating and stimulating. Students practice more by reading different texts and are exposed to a broader number of words within different contexts. This should not only improve reading fluency but also their vocabulary knowledge and in turn overall reading comprehension.

Each of the two methods of guided oral reading could generate different outcomes for students in the different grades, i.e. the different stages of reading development. For students in grade 2 repeated reading might have greater impact on improvement in rate and word recognition due to the fact that they experience feelings of becoming more competent. For older students in grade 3 and 4, continuous reading could be more effective because repeated reading might become rather boring and demotivating.

In our study the effectiveness of the two methods of guided oral reading was tested. The overall question was: how does repeated reading compare with continuous reading for improving the reading rate and overall reading outcomes of struggling readers in grades 2 to 4?

A total of 126 reading retarded students from grades 2 to 4 of eight primary schools in the Netherlands participated in the study. Within each class students were randomly divided between two treatment groups and a non-treated control group. In the treatment groups the intervention was delivered in a one-to-one setting by a para-professional in one of two versions, either in a repeated reading or in a continuous reading format, depending on how often students had to practice with the same text. Each student went through 48 reading sessions of 20 minutes, with a maximum of four sessions each week. Measurements included standardised tests for fluency, reading comprehension, vocabulary, and reading attitude. Monitoring of treatment fidelity was done by means of questionnaires and observations.

Based on multi-level analyses the results demonstrate that guided oral reading is an effective method for improving fluency as well as reading attitude. Within and between grades the two versions (continuous or repeated reading) proved to be equally effective. Effects with regard to growth in reading comprehension and vocabulary could not be established. In relation to these results implications for the educational practice are discussed.

PAPER PRESENTATION

Teaching and Learning about social and moral values for active citizenship in the early years

Susan Walker, Queensland University of Technology, Australia; Jo Brownlee, QUT, Australia; Charlotte Cobb-Moore, Queensland University of Technology, Australia; Eva Johansson, University of Gothenburg, Sweden; Jo Ailwood, University of Newcastle, Australia; Gillian Boulton-Lewis, QUT, Australia

Research suggests that there is a correlation between teachers' beliefs about knowing and their approaches to teaching (Edwards et al, 2008). However, there has been little investigation into the relationship between these beliefs and teaching moral values and we know little about how children learn moral values (Halstead & Pike, 2006). This study investigated: what teachers think and do in the classroom to promote social and moral learning; and what children think about social and moral values. Eleven teachers were interviewed about beliefs about the learning and teaching (epistemic beliefs) of social and moral values and 100 children were interviewed concerning their ideas about social and moral values around concepts of fairness and "doing the right thing". There were a range of views about how children learnt moral values. Teachers stated that children learnt from observation, structured and incidental

teaching, from discussions, reflections, from active engagement and their everyday experiences. Children explained that doing the right thing was related to showing concern for others, following the rules and obeying the teachers. The children related fairness to being nice and caring for others. The findings contribute to our knowledge about effective teaching for social and moral learning in the early years.

Schools have long been seen as institutions for preparing children academically, and for life as moral agents in society. This recognition has resulted in values education becoming a part of the curriculum in many schools. Moral values, are both positive and negative qualities (good or bad), that we express and experience in our own and others' behaviour, acts and attitudes. Research suggests that there is a correlation between teachers' beliefs about knowing and their approaches to teaching (Edwards et al, 2008). A substantial body of research spanning the last 30 years shows that we hold core beliefs about knowing and learning (epistemic beliefs) which may influence our learning and teaching practices. These are core beliefs because they are considered to filter all other knowledge and beliefs including the knowledge we enact about teaching and learning. The range of epistemic beliefs has been described by Kuhn and Weinstock (2002) as a developmental trajectory from absolutism (reality is replicated, knowledge is absolute and transferable), to subjectivism (knowledge is based on personal opinions) and then finally to evaluativism (judgments involving evidenced-based critique of multiple perspectives).

Typically, this progression from absolutism to evaluativism is described as a shift from naïve to sophisticated beliefs. However, there has been little investigation into the relationship between these beliefs and teaching moral values and we know little about how children learn moral values (Halstead & Pike, 2006). This study investigated: what teachers think and do in the classroom to promote social and moral learning; and what children think about social and moral values. The focus is on teachers' epistemic beliefs, how teachers describe their teaching practices for children's moral learning, how they conceptualize children's moral learning and on young children's perspectives of values and participation in school in relation to active citizenship learning. Teaching for moral values, or moral pedagogy, refers to a variety of teaching practices that aim to develop moral awareness, reasoning, understanding, and behaviours in children. Basourakos (1999) has described moral pedagogies that fall into two dominant paradigms. He describes the first as conventional moral pedagogy in which abstract moral reasoning is taught directly to children. The epistemology of this approach reflects moral knowledge as absolute and transferable. Teaching approaches that emerge from this tradition would include strategies like direct instruction in moral values or modelling appropriate values in interactions with children.

An alternate pedagogy, according to Basourakos (1999) is described as contextual moral pedagogy which takes a different epistemological perspective to the conventional pedagogies. From this perspective, moral knowledge is constructed within and related to certain contexts. In contextual moral pedagogies, children are encouraged to reflect on multiple "truths". This means that there is no one truth in moral values and moral education helps children to reflect with sensitivity on competing perspectives. Eleven teachers were interviewed about beliefs about the learning and teaching (epistemic beliefs) of social and moral values. Results from the teacher interviews indicated that teachers in our study demonstrated three main ways of thinking about moral education. These understandings were reflected in teaching practice for learning moral values, their beliefs about children's learning of moral values and their epistemic beliefs. The teachers understood moral pedagogy as: "following others"; "reflecting on points of view"; and "informed reflection for action". Teachers who understood moral pedagogy as "following others" believed that moral values are best learnt through modelling, extrinsic rewards and discussion, reflecting a conventional moral pedagogy. These teachers also held subjectivist epistemic beliefs. In the second way of thinking, described as "reflecting on points of view", teachers describe a focus on evaluating different perspectives as a way of knowing. Their moral pedagogy was about building meaning through problem solving, taking responsibility, and children making decisions. All of the teachers who described "reflection on points of view" also talked about practical ways of knowing. That is, they referred to evaluating knowledge based on what works in practice. In the third and final way of thinking about moral education, teachers viewed knowledge about moral values and pedagogies as an informed construction using both research and practice, reflecting a contextual moral pedagogy. These teachers' epistemic beliefs went beyond a focus on the practical - what works - to include an evaluation of research perspectives (evaluativism).

100 children were interviewed concerning their ideas about social and moral values around concepts of fairness and "doing the right thing". Children were asked a series of open-ended questions, relating to their rights and responsibilities, including their ideas about: right and wrong in school choices and decisions in school. Children's responses reflected both moral issues (e.g., concern for others' feelings) and social conventional issues (e.g., the value of authority and rules in the school). Children explained that doing the right thing was related to showing concern for others, following the rules and obeying the teachers. The children related fairness to being nice and caring for others. Doing the right thing refers, according to the children, to moral values, but also to disciplinary values to ensure or maintain the order in school. The value of others wellbeing and the value of the good disciplined student stand out

as common threads working together in the children's descriptions. Implied in this is a value of authority, taken for granted by the children. Decisions in school seem from the children's understandings to be strongly connected with the teachers' authority.

Teaching moral values for active citizenship is strongly emphasized in early education and teachers need various competences to be able to help children acquire such values. This study indicates an intertwined relationship between moral values and epistemic beliefs. One cannot exist without the other. Complex epistemic beliefs seem to be productive in teachers' (and children's) constructions and understandings of moral values central for active citizenship. These values concern being an active part in a community, knowing and sharing rights and responsibilities for others' wellbeing and for the common good. The findings contribute to our knowledge about effective teaching for social and moral learning in the early years.

PAPER PRESENTATION

Good teachers for special education in Italy

Maja Antonietti, University of Modena and Reggio Emilia - Department of Education and Human Sciences , Italy;

Roberta Cardarello, University of Modena and Reggio Emilia, Department of Education and Human Sciences, Italy;

Maria Cristiana Martini, University of Modena and Reggio Emilia, Department of Communication and Economics, Italy

Since 1971 in Italy all children with special needs should be included in regular school: that implied the closure of almost all special schools and the introduction of particular forms of support that were clearly identified - some years later - with support teachers (Gelati, 1996). Support teachers' profession should be relevant for school integration and individualised teaching, but they are still not completely recognized (Gelati, 1996; Ianes, 2004). This research starts from previous studies on teachers opinion about their profession (e.g. Cardarello et al., 2009), by deepening the analysis of the support teacher's profile. The aim of this research is twofold: to identify which areas of profession preschool and primary school teachers ascribe to support teachers profession and to verify if professional identity influences those opinions. Through an ad hoc questionnaire teachers' opinions on support teachers' competences were collected. Factor analysis highlighted 10 main areas of support teacher competences and we identified differences in teachers opinions about the main areas of support teacher competences according to professional experience.

In Italy Act 118 (1971) and 517 (1977) defined that all children with special needs should be included in regular school, that implied the closure of almost all special schools and the introduction of particular forms of support that were clearly identified - some years later - with teacher specialized for supporting children with special needs, also called support teachers (Gelati, 1996). The professional identity of support teachers was not well defined: in the last 30 years teachers training was initially based on a medical training model, while after 1984 more attention was given to pedagogical and psychological aspects (Albanese, 2006). In the praxis, support teachers often work only with children with special needs, even if they have the co-responsibility of the classes where they work (Act 104/1992).

According to regulations and the Italian pedagogical literature (Albanese, 2006; Ianes, 2004) support teachers are expected to:

- know the development and the way of learning related to the different disabilities;
 - be able to plan activities and lessons according to special educational needs by using the ICF approach;-
 - be able to use observation and documentation methods;
 - promote inclusion;
 - connect the school with local social and health services;
 - possess good communication and relationship capability for mediation, particularly with parents.
- Support teachers are assumed to be relevant for special education, particularly for school integration and individualised teaching, but in the past they were often considered less important teachers (Ianes, 2004) and the reason is probably the ambivalent definition of their professional role.

In Italy empirical researches about inclusion practices are rare (Begeny & Martens, 2007), but those about support teachers are fewer. The legitimation of his/her role into the school is yet an open question, although support teachers represent about 10% of teachers as a whole (Fondazione Agnelli, 2008). This research moves from previous studies (e.g. Cardarello et al., 2009) investigating teachers' opinion about their profession, and attempts to describe the school world through the eyes of the teachers themselves. The intention is to obtain a description of crucial points of the profession practice, and to verify how much some aspects which literature highlighted as central were actually deemed to be important.

The aim of this research is twofold: to identify which professional areas preschool and primary school teachers ascribe to support teachers and to verify if the teaching experience influences this opinion; a survey was conducted to collect data on the teachers' personal characteristics, professional experiences and opinions. The sample includes 714 Italian teachers of primary and pre-school from Emilia-Romagna, interviewed through a self-administered questionnaire at the beginning of a University specialization course they attended (2004/2005; 2006/2007); 95% of teachers attending the courses participated in the survey. The questionnaire was designed to survey several aspects of the class teachers and support teachers profile; the questionnaire's sections mainly used in this study was devoted to ask teachers' opinion on the importance of a series of 36 competences for the support teacher's professional profile. The 36 items were drawn from the pedagogical literature and refer to a wide range of professional competences (see, e.g., Coggi et al., 2004; Perrenoud, 1999), and were asked on a 4-point quantitative scale. Although the measurement scale is numerical, some doubts arise about the metric properties of such a short scale, hence the collected data are considered ordinal variables and preliminarily re-scaled through an optimal scaling procedure (Gifi, 1990).

After assessing the adequacy of a factorial approach (on the whole set of items, Cronbach's Alpha is equal to 0.839), re-scaled scores are analysed using factor analysis with Varimax orthogonal rotation (Kaiser, 1958), in order to highlight the main independent competence areas. 10 factors were extracted, accounting for 52.3% of the total variance: they refer to lesson and teaching tools, emotional and social awareness, ethical purpose of learning-by-doing, knowledge of special needs and appropriate technologies, individualized teaching, disciplinary contents, school management, collaboration with colleagues, networking, children competences assessment. Unrelated factor scores have been computed through the Anderson-Rubin method, and then analysed to compare the values assumed in different sub-groups of the teachers population.

The analysis of variance conducted on factor scores helps to identify differences in the ideal profile of support teachers, as seen by subgroups of teachers with different individual and professional experiences. Among the preliminary results, we can mention that individualised teaching, disciplinary contents, school management and networking are considered equally important by different subgroups of teachers (support and class teachers, primary and pre-school), while in general support teachers credit their professional role with a wider range of needed competences than class teachers do; in some sense this implies a richer and more complex picture of the professional profile. On the other hand, class teachers attribute to the support activity a higher degree of emotional and social awareness, maybe because, seen from a distance, the emotional challenge is the most striking aspect.

PAPER PRESENTATION

The role of accountability in school placement decisions: An experimental study

Florian Klapproth, University of Luxembourg, Luxembourg; Matthias Bohmer, University of Luxembourg, Luxembourg; Sabine Glock, University of Luxembourg, Luxembourg; Sabine Krolak-Schwerdt, University of Luxembourg, Luxembourg

Within an experiment Luxembourgish teachers were presented with 16 case descriptions of fictitious students, and the teachers were required to make a school placement decision for each student. Two experimental conditions were realized which differed according to the accountability of the teachers. It was found that teachers of the low-accountability condition considered less cues that were performance-related, but more cues that were not related to performance for their school placement decisions than teachers did who were in the high-accountability condition. Implications might be drawn with respect to real school placement decisions.

Introduction

One structural characteristic of educational systems which has been repeatedly discussed is school placement, which corresponds to an ability-based grouping of students in different school tracks at a specified moment of their school career. It has often been hypothesized that school placement may lead to phenomena of social and ethnic segregation (e. g., Ehmke, Siegel, & Hohensee, 2005).

School placement decisions may even get worse if they are made within a group. In group decisions, the accountability for the decision is distributed over the group members (Latané, Williams, & Harkins, 1979) which may result in reduced accountability for each group member. According to dual process models of social cognition (Fiske & Neuberg, 1990; Tetlock & Lerner, 1999), low accountability should lead to heuristic information processing which is characterized by its cognitive economy and the predominance of stereotypes that guide the information processing,

resulting in less information being considered for the decision. In contrast, high accountability corresponds with an information integrating mode in which each single piece of information is regarded.

One example of school placement decisions made within groups is the Luxembourgish school system. The groups involved consist of primary and secondary school teachers and schools inspectors, and the decision is taken at the end of six years of primary school. The students are then oriented towards three clearly hierarchical tracks, which are the Enseignement Secondaire (ES), the Enseignement Secondaire Technique (EST) and the Enseignement Prééparatoire (PREP). Students are generally oriented towards the ES when they have a flawless achievement profile. An achievement profile showing difficulties in one or more subjects generally leads to an orientation towards the EST track, while students with major learning difficulties are oriented towards the PREP track.

Aims of the Study

With the study at hand we investigated the cognitive processes of teachers that determine the choice of the future school type. More precisely, we examined which cues influenced the transition decision of teachers beyond pure school performance data that teachers have at hand regarding a specific student under different degrees of accountability.

Hypotheses

In terms of regression analysis, both processing modes should differ in the number of significant regression weights that are pertinent to school performance, with more significant regression weights being expected for high accountability than for low accountability. However, when put under low accountability, teachers should base their decisions on more cues that are not related to school performance (like migration background or gender) than when high accountability is induced.

Method

Within an experiment Luxembourgish teachers were presented with 16 case descriptions of fictitious students, and the teachers were required to make a school placement decision for each student. Two experimental conditions were realized which differed according to the accountability of the teachers. In the lowaccountability condition, the teachers were encouraged to make a noncommittal suggestion of the track which they considered most suitable for each student, leaving the final decision to a group. In the high-accountability condition, the teachers were told to make a school placement decision of which they were solely responsible.

Participants

21 Luxembourgish primary school teachers (six men and 15 women) took part at the experiment and were randomly assigned to two experimental conditions ($n_{\text{high}} = 10$, $n_{\text{low}} = 11$). The mean age of the participants was 35.1 years ($SD = 10.3$).

Stimuli and Materials

Each case description entailed seven attributes which were (1) school marks in the main subjects, (2) scores of standardized school performance tests, (3) working and learning habits, (4) social behaviours, (5) nationality, (6) socio-economic status, and (7) gender. The attributes were coded as dichotomous variables. To create a case description, combination of the values of the variables (0; 1) was done under the constraint that the intercorrelations between the variables should be minimal. In fact, the variables "school marks", "test scores", "nationality" and "socioeconomic status" were completely independent from one another, and with the remaining variables maximum intercorrelations were found not be larger than $r = .25$.

Procedure

The case descriptions, printed on sheets of paper, were presented successively and in random order. After each case had been presented, the participants were asked to make a school placement decision for this case, choosing between three options which were ES, EST, and PREP.

Results and Discussion

Since PREP was chosen less than 5 % of the choices, the dependent variable was transformed to a dichotomous criterion, containing the values "ES" and "Non-ES". After that, logistic regression analysis was performed separately for both experimental conditions.

For the high-accountability condition, the regression weights for "school marks", "test scores", and "working and learning habits" were high and significant. For the low-accountability condition, regression weights were high and significant for "school marks" and "test scores", and high but almost significant for "gender".

As was hypothesized, teachers of the low-accountability condition considered less cues that were performance-related, but more cues that were not related to performance for their school placement decisions than teachers did who were in the high-accountability condition.

Implications might be drawn with respect to real school placement decisions taking place in groups like in the Luxemburgish school system. However, caution is indicated when directly relating experimental data to educational practices. Further investigations of our research group are dedicated to this problem.

PAPER PRESENTATION

Dealing with teaching dilemmas in higher education

Elisabeth Wegner, University of Freiburg , Germany; Matthias Nuckles, University of Freiburg, Germany

Teaching is a complex task that comprises many contradictory demands. Therefore, teachers continuously need to decide between competing goals that cannot be fulfilled at the same time. For example, students should be offered opportunities for self-determination to be motivated and to learn effectively. On the other hand, in order to establish a learning community, teachers also need to set up rules, thereby undermining students' possibilities for self-determined learning. Dealing with such dilemmas requires the ability to make reflective judgments. That is, teachers should be aware of the existence of dilemmas, and they should be able to make informed didactic decisions by carefully weighing and evaluating the pros and cons inherent to a contradictory or dilemmatic situation. Forty university lecturers in differing levels of teaching experience and training in teaching participated in a structured interview that challenged them with dilemmatic decisions. A content analysis of the interviews showed that teachers experienced the dilemmas in three conceptually different ways: as non-ambiguous, as dilemmatic or as problems to be addressed individually depending on context. Also, the perceived content focus of the problems differed: mainly as being of didactic nature (i.e., contradiction of different learning goals or different methods) or as rooted mainly in values (such as fairness of assessment, freedom of choice). Teachers who focused on values tended to see decisions as non-ambiguous. Teachers with training were more likely to describe the problems in didactic terms, which indicates that training influences the general epistemological conception of teaching.

Theoretical Background Teaching is a complex and ill-structured task which often confronts those that undertake it with contradictory demands. Several authors have described fundamental dilemmas of teaching as follows:

- Students need to learn in a self-determined fashion, but prescribing or enforcing self-determined learning poses a contradiction to the general idea of self-determined learning.
- Assessment needs to be reliable and at the same time valid. However, increasing reliability (e.g. by using multiple choice tests) often reduces validity and vice versa.
- Teachers should make no discriminations between students, but each student has different needs and abilities which have to be taken into account. It is the very nature of these dilemmas that they cannot be resolved, because two (or more) goals are equally important.

In trying to reach one of the goals, the other is automatically affected, resulting in a conflict between the goals. These teaching dilemmas can be described in terms of ill-structured problems, that is, "problems where there is not a single unequivocal solution which can be effectively determined [...] by employing a particular decision-making procedure." (Kitchener, 1983, p.224). All problem-solving activities are fundamentally influenced by processes that monitor the epistemological nature of the problem, such as its solvability, the limits thereto or the certainty of knowing (Kitchener, 1983). Consequently, in order to balance different goals and to make adequate, informed didactic decisions, teachers need to develop appropriate conceptions with regard to the contradictory nature of the abovementioned dilemmas. The epistemological conception of teaching is therefore an important aspect of teaching competence. However, little

empirical research has been conducted on teachers' ability to deal appropriately and reflectively with these teaching dilemmas. Previous studies are largely theoretical and case-based or restricted to certain phenomena such as conflicting goals in cooperative learning. The present study seeks to fill this gap by exploring how teachers deal with dilemmatic decisions and which factors influence this ability. More precisely, we investigated university teachers' argumentative reasoning and decision-making when reflecting on teaching dilemmas.

Participants and Methods

A total of 40 university lecturers with an average of 8.6 years of teaching experience ($SD = 9.0$) were interviewed. Twenty-three of the teachers had participated in staff development programs or had received other forms of training in teaching. We developed a structured interview procedure containing a number of teaching dilemmas and guiding questions. The interview was inspired by Kohlberg's "Moral Judgment Interview" (Colby & Kohlberg, 1987) and King and Kitchener's "Reflective Judgement Interview" (King & Kitchener, 1994). Our interview contained the following dilemmas:

- Compulsory vs. voluntary writing of learning journals with journal writing introduced as a self-guided learning method (see Nýckles, Hýbner & Renkl, 2009)

- Abstract vs. concrete opening in an introductory lecture- Individual oral vs. standardized written assessment Teachers were asked to explain how they would handle each dilemmatic situation.

They were further asked to explain their decision and to identify criteria which would influence their decision. Finally, we asked them to assess how ambiguous they felt with their decision. A two-dimensional coding system was developed. The first dimension, the general epistemological understanding of the nature of the problem, contained three categories:

1. non-ambiguous (one option is generally better than the other),
2. dilemmatic (both options have pros & cons, no decision or decision on basis of pragmatic aspects or personal preferences) and
3. context-based decision (different aspects collide, certain criteria have to be taken into account).

The second dimension, the perceived content focus of the problem, differentiated between the main focus of the problem (as related to didactic concepts, such as learning goals, or related to values, such as freedom or fairness). Answers were rated by two independent raters. Inter-rater reliability was good (Cohens Kappa between .77 and .94, depending on the dilemma).

Results and Discussion

The tendency to judge a given dilemma as non-ambiguous increased with the tendency to conceive of the dilemma as a matter of values rather than as a didactic problem, $r = .39$, $p(t(25.58)) = 2.72$, $p r = .234$, ns., nor the content focus, $r = .09$, ns. The results indicate that the university teachers in our sample indeed understood the presented dilemmas differently and that the epistemological understanding of the dilemma was related to the content focus of their reasoning. Participation in training seemed to enhance the tendency to think in didactic categories, thus indicating that training had an effect on the perspective university teachers adopted to reason about complex didactic situations. In summary, our study suggests that the theoretical approach of conceptualizing didactic decision making as a form of reflective judgment (see Kitchener & King, 1994) proved to be fruitful. Further research should aim at clarifying the implications for current models of teaching competence (see Borko & Putnam, 1996) and investigate, how the ability to make informed didactic decisions relates to other aspects of teaching competence, such as teacher beliefs, or the ability to react flexibly to student behavior in an ongoing and dynamic classroom discourse.

Learning in movement: conceptualizing in-between and across site learning

Chairperson: Eva Hjerne, University of Gothenburg, Sweden

Organiser: Tania Zittoun, Institute of psychology and education, Switzerland

Sanne Akkerman, Utrecht University, Netherlands

Discussant: Sten Ludvigsen, University of Oslo, Norway

Learning demands the use of knowledge, from one situation to another, or from one site to another one. Learners themselves have to move in and out of different social settings during the same day or the same week. How can people learn and develop despite the fact that they have to engage in activities in extremely diverse situations? Drawing on pragmatism, dialogical theories and a generally speaking sociocultural understanding of learning, recent studies emphasise three mutually dependent processes: the identity processes learning entails, the necessary processes of meaning making it demands, as well as the need to appropriate specific symbolic systems and develop specific skills.

This invited symposium groups three papers that examine learning in young adolescents – a life period during which moving in and through various social situations becomes central. In the first paper, Akkerman and Van Eijck explore how participations in different social worlds of biology students impinge on school experiences. A dialogical approach is proposed to explain students' identity across situations. In the second paper, Petersson, Lantz-Andersson, and their colleagues follow students asked to solve a task related to climate change. With an approach inspired by John Dewey, they show how students progressively learn to use the language required by a scientific enquiry. In the third paper, Zittoun explores learning in literature and philosophy classes. With an emphasis on semiotic processes, she highlights processes by which students confer personal sense to learning situations thanks to their experiences in non-academic sites.

Learner's identity through and across sites

Sanne Akkerman, Utrecht University, Netherlands; Michiel van Eijck, Technical university Eindhoven, Netherlands

Both cognitive and socio-cultural traditions have traditionally theorized learning in terms of processes of progression within single communities. Since 1995, educational scholars have started to focus on learning as a horizontal process of boundary crossing between multiple communities. Problematic in this approach is that boundaries are often analytically laid out on system level, without explaining whether and how boundaries relate to discontinuities at the level of a learning process of an individual student. What is needed is theoretical elaboration on how an individual learner can be simultaneously part of one and another practice. By drawing on a dialogical approach to Self we intend to theorize learners as participants of practices and transcendent selves. Doing so, we point out that boundaries are dynamically evolving discontinuities that mediate or obstruct potential hybridizations of school and everyday life experiences in learning.

Objective

For long educational theories have discussed how learning progresses within a single domain or community, be it in terms of acquiring certain domain expertise or in terms of becoming a central participant in a particular community. We argue that a student should not be approached as an abstract object of study and educational theory, but as a whole person participating in school as well as many other practices. The focus of this paper is to understand how this complexity relates to his or her learning process. We first elaborate on the notion of 'social individual' according to educational theory. Also we point out a shift from focusing on learning vertically within single social systems towards learning horizontally across multiple social systems. This interest in multiple systems is encouraged by renewed discussion about how transfer should be perceived (e.g., Konkola, Tuomi-Gröhn, Lambert, & Ludvigsen, 2007) as well as by the so-called third generation of activity theory that takes two activity systems as its minimal unit of analysis (Roth & Lee, 2007). It has been proposed to study learning in horizontal movement as a process of crossing boundaries between systems. This literature tends to conceptualize boundaries on system level, and, as we contend, currently lacks to explain the complexity of learning in horizontal movement on the individual level of a student. Understanding this complexity requires a psychological reconsideration of both the individual as well as the social nature of a human's Self, that is, a Self that is simultaneously belonging to and is separate of a social unit (Valsiner & Van der Veer, 2000).

Theoretical framework

To answer our main question we draw from recent psychological and philosophical insights on identity, specifically on Dialogical Self (e.g., Hermans & Dimaggio, 2007; Marková, 2006; Wertsch, 2007) and as strongly rooted in the philosophical and literary work of Mikhail Bakhtin in the 1920s and 1930s (Bakhtin, 1981, 1986). In contrast with a poststructuralist approach towards self as completely decentered, a dialogical approach defines the self as a continuous attempt to make the self a whole, despite the existence of socially informed sub-identities that try to maintain their relative autonomy. We elaborate on how these insights provide initial answers to the question posed, and hence, are valuable to advance educational theory with respect to both vertical as well as horizontal processes of learning.

Modes of inquiry

To address the question in a concrete real-lived context of education, we look at the reflections of a student on his learning process and describe how multiple social systems are negotiated and collide within his learning practice. This data was collected during a design research project in secondary biology education. Two specifically designed teaching units were observed and ten students were interviewed afterwards. The interviews were semi-structured and were designed with the aim to understand whether the unit was feasible and comprehensible to the students and what they had learned about the cardiovascular system and the monitored phenomena by conducting measurements. In the paper we focus on data from the interview with one student to exemplify four observations. The four observations are interpreted by drawing on a dialogical approach to identity.

Results

Our theoretical exploration is connected to four observations: The everyday life of the students impinge on the life within school. On a system level we can speak of school and everyday life as distinct practices in which learners engage. The interview shows how classroom experiences are not isolated from experiences a student has in out of school contexts. The everyday life of students is not singular but consists of a multiplicity of social worlds. The interview shows how the student refers to different practices in which he engages, each informing him differently in his stance within a specific learning situation. This illustrates Bakhtin's concept of multivoicedness. The multiplicity can create fragmentation which can only be resolved by self dialogue. The interview suggests that the multiplicity creates a fragmentation in terms of a diversity of positions and perspectives of the student that do not necessarily coincide. The Dialogical Self theory proposes that the self coheres as far as these different positions are confronted, negotiated and dialogically interrelated. Historically informed boundaries in learning processes can prevent potential 'hybridization' in learning. The interview reveals that the student, though learning in other positions than merely being a student in a biology class (e.g., being a son of a medical doctor, being a swimmer), does not connect this learning to what he perceives as learning within school. This illustrates that an educational practice that addresses students only as peripheral participants of a school community (in this case a biology class) has monological consequences in the sense that students themselves connect learning to 'acquisition of knowledge' and to traditional school artifacts like books. We elaborate on how this prevents hybridization by addressing the other subject positions of the student that are relevant for the particular learning situation.

Sense-making through and across spheres of experiences

Tania Zittoun, Institute of psychology and education, Switzerland

Learning can be said to occur when one is able to use knowledge – and a person is likely to use knowledge if she understand a situation as calling for certain type of activities. As past studies have shown, one critical moment for questioning people's uses of knowledge is located as people move through various spheres of experience – from school, to sport's club, to daily shopping and back. In order to understand why people might actually use knowledge developed in one sphere of experience in another one, a series of studies brought us to emphasize the necessary mutually dependence of three types of processes – learning, identity processes as well as sense-making processes. In this paper, based on a recent research on secondary school students, I will specifically examine processes of sense-making in and across spheres of experiences. I will show what they entail, what they enable, but also, what might facilitate to constrain their emergence. Theoretical and educational consequences will be highlighted.

The aim of the paper is to show the relevance of a close examination of sense-making processes in current analysis of the so-called "boundary crossing" phenomena. Indeed, current dominant formulations emphasize identity aspects of belonging to certain community of practices and associated to specific learning activities. Complementing these approaches, a sociocultural understanding of learning and development emphasizes semiotic processes at the heart of human action, best understood under the notion of "sense making" (Bruner, 1990; Valsiner & Rosa, 2007). Past studies on transitions in the lifecourse have indeed emphasized the mutual dependency of identity processes, learning and sense-making (Perret-Clermont & Zittoun, 2002; Zittoun, 2006, in press).

Our current reflection is based on a study exploring young adults' uses of literary and philosophical texts in and out of school. This study took place in 15 group classes, in three high schools (2 pre-academic, one vocational) and in 3 disciplines (French literature, philosophy and "general education"). Data consisted of interviews with teachers (n=16), a general questionnaire with students (n= 205) as well as face-to-face interviews (n= 20) and focus groups (6 groups) with students, and video- and audio-recorded classroom interactions. Each set of data was analyzed independently, and data was then analyzed transversally along case studies (Grossen, Zittoun & Ros, in press)

In this paper, I will present a case study to explore what sense making entails, enables, but also, what might facilitate or constrain its emergence. First, I will show how a person develops different sets of activities, identity definitions and learning strategies in different spheres of activities (at school and in leisure, "extracurricular" activities). Following sense-making processes (including the elaboration of affects, connecting events through time, progressive distanciation from experience, and imagination) I will show how learning or knowledge developed in one sphere of experience can usefully be used in another sphere (Zittoun & Grossen, in press.). Second, drawing on analysis of classroom interactions and teachers' discourse, I will highlight the social and intersubjective conditions likely to facilitate students' sense making processes, appropriation of knowledge, and possibly, knowledge use. More specifically, the importance of dynamic of recognition of the student's work of sense making, in addition to the usual structure of intersubjectivity taking place in the classroom, appears as central.

The implications of these observations are twofold. First, at a theoretical level, they contribute to highlight the interdependency of learning, identity and sense making. They emphasize the affective and symbolic dimensions of sense making, and thus, of learning. They finally remind the social and cultural nature of these supposedly more "subjective" processes. Second, at a theoretical level, these observations seriously question the status given by school to so-called "extracurricular activities". First, our research shows that these have a subjective and practical considerable importance in young people's lives, although these are usually ignored in evaluation and school programs. Second, it suggests that the trigger of students' commitment into learning and knowledge use can, in some cases, precisely lie in these extracurricular activities. The question is therefore how and under which modalities such observations help to transform educational practices. Based on cases of "good practice", the study thus proposes to consider simple dynamic of "recognition" of students' sense making that can take place in the classroom.

Knowing nature through experimentation: Science literacy and the situatedness of knowing

Emma Petersson, Faculty of Education, Sweden; Annika Lantz-Andersson, G  TEBORGS UNIVERSITET, Sweden; Geraldine Fauville, University of Gothenburg, Sweden; Roger Saljo, Goteborg University, Sweden

The background of the present study is an interest in issues of learning and knowing across social settings. In recent years, such problems have come to be understood in terms of literacy, i.e. the ability of people to use textual and multimodal resources to understand real-world issues. The analysis reported here takes its point of departure in John Dewey's argumentation that learning about scientific methods and inquiry can provide such a platform for learning generalized skills. Students (aged 16-17), studying the environment and climate issues, had access to a virtual lab, referred to as the acid ocean virtual lab, to conduct inquiries and experiments that concern climate change. The analysis builds on a sample of 80 students who took part in written problem-solving test as outcome measure. The students were required to design an experiment addressing a specific environmental issue. The problem was given as an individual written task before as well as after teaching/lab sessions. The results show that students increase their use of scientifically relevant terminology ('sample', 'measure' etc.) and they improve their ability to outline an experiment during the course. However, science literacy also implies realizing what a relevant interpretation of a problem is in order to be able to answer it through a scientific experiment.

Almost a hundred years ago, the pragmatist philosopher, psychologist and educationist John Dewey articulated the problems of how organize teaching and learning so as to accommodate to the increasing production and specialization of scientific knowledge (Dewey, 1966, 1997). It is no longer possible, so his argument was, for schools to keep up with the dramatic expansion of scientific knowledge in all the different disciplines. One of his ideas of how to deal with this problem was to focus on generative skills and insights that carry across contexts and situations. One such set of generative skills is offered by scientific inquiry itself. This implies that one should learn some of the procedures and a language for how to observe and codify the world in scientifically relevant manners (Wickman, 2004). In modern parlance, this could be understood as an issue of how one becomes literate in science matters. At another level, these reflections by Dewey also concern the fundamental problems of situatedness and transfer in learning; issues that continue to create intense debates (Ludvigsen, 2003; Resnick, S  lj  , Pontecorvo, & Burge, 1997). The more complex society becomes in terms of its knowledge base, the more schooling has to focus on generative skills that transfer across settings.

The present study reports an empirical investigation in a naturalistic setting of how students (aged 16-17) learn to do research and how research is conducted in terms of experiments and data collection. This implies identifying how experiments are carried out and what characterizes experiments as a mode of generating knowledge. Knowing about experimentation as a method exemplifies what Dewey conceived as a general insight that has implications across settings. The students, studying marine science within the context of upper-secondary school, were given a problem about how to generate an answer to a problem about water quality in the case of building a fishery that, potentially, could pose a danger to the marine environment. The question was formulated as:

You are an environmental scientist who is hired to complete an environmental impact report for a proposed project. Tropical Fisheries of Hawaii plans to open a fish hatchery on the Luau River, and the river opens to a bay with a large coral reef. Biologists are concerned that water discharge from the hatchery could impact the pH of the river and the bay. What sort of an experiment could you do to see if a change in pH might have an effect on the growth of the coral?

The study is longitudinal and the problem was given before and after teaching, in both cases as an individual writing task. The students participated in a collaboration between Swedish and Californian schools on issues of climate change, environmental pollution and habitat preservation. The schools engaged in networking activities using various media, and they also had access to digital tools such as virtual labs and carbon dioxide footprint calculators. In the present study, however, the students only had access to a virtual lab, referred to as the acid ocean virtual lab, to conduct their inquiries. The analysis builds on a sample of 80 students who took part in both the pre- and post-test.

The paper reports observations on how students a) the appropriate a scientific language (e.g. learn to use terminology such as 'sample', 'measure', 'control group' etc.), and b) how they reason about how to organize an experiment/a study before and after the course. The latter dimension is evaluated through a hierarchical model of the learning

outcome that goes from not understanding how the issue could be addressed to giving a functional account of how an experiment could answer the question presented. The five-level category system is as follows:

- Category 1. Don't know/no answer
- Category 2. Suggests solution to problem with water (but does not describe a study)
- Category 3. Suggests testing the water (or PH or corals)
- Category 4. Suggests testing the water and corals
- Category 5. Outlines study/experiment

The results show that the prevalence of scientifically relevant concepts in the students' responses increases significantly (from a mean of 1,8 to 2,9, z However, an important observation is that in order to be able to reason scientifically one must also be able to understand the problem posed, and how a research study can be organized in response to a particular problem. Thus, it is not enough to learn about scientific concepts and experimentation, one must also learn how such resources can be made relevant in a particular context and in response to a particular question. Put differently, a major difference between the students concerns whether they suggested a solution to the problem asked by outlining a study/an experiment, or if they engaged in analysing the problem of what would happen to the water quality if the hatchery was built. Interpreting a problem as a research problem is different from responding to it as a practical, political concern. Learning what it implies to see a problem as a research issue is per se an important element of science literacy.

SYMPOSIUM

Invited EARLI

Walking under a Chinese umbrella: The influence from Chinese educational philosophy to ECE development

Chairperson: Asta Birkeland, Bergen University College, Norway

Organiser: Li Li, University of Exeter, China

Discussant: Debra Myhill, Exeter University, United Kingdom

This symposium focusing on the cultural aspect of educational philosophy and its impact on early education curriculum, includes three papers from different perspectives to look at the development of curriculum reform, teacher development and the role of information communication technology. The first paper reviews the development of China's early education curriculum policy and how the social cultural beliefs and power distribution exert a powerful influence on the curriculum reform. The second paper discusses the relevance of traditional educational beliefs advocated by Lao Zi to modern kindergarten teacher education. This paper particularly applies Lao Zi's philosophy in teacher education and how teachers should practice accordingly. The third paper presents a review on the application of information technology in early childhood education in China based on a 10-year IBM KidSmart Young Explorer program in China. These three papers, taking different perspectives, collectively and individually presents early education development in the Chinese socio-cultural context, which hopefully will promote more discussion and interest in Chinese educational philosophy.

Review on the Application of Information Technology in Early Childhood Education in China

Lipin Guo, East China Normal University, China

Based on the development of the IBM KidSmart Young Explorer program in China over the past ten years, and by using the methods of questionnaire survey and the like, this study presents a review and reflections on the application and the development of information technology in early childhood education in China. The study shows that the development in the past ten years lays a solid foundation for the application of information technology in early childhood education. And the study believes that the further effective promotion in the application of information communication technology should be guided by the principle of educational equity and harmonious development of

society advocated by the state. The study also offers suggestions on the further effective application of information technology in early childhood education

Review on the Application of Information Technology in Early Childhood Education in China

Based on the development of the IBM KidSmart Young Explorer program in China over the past ten years (from 2001 to 2010), this study presents a review and reflections on the application of information technology in early childhood education in China. Methods used in the study include a questionnaire survey of more than 600 participating kindergartens in different provinces and cities of China; a longitudinal comparative analysis of the survey results over ten years; field observation and teacher interview in some of the representative kindergartens, and text analysis on the specific programs adopted by some kindergartens for the integration of information technology into the curriculum. This study gives a detailed description of the overall development of information technology equipment for early childhood education in China over a ten-year period. Our results provide insights into: the progress in the competency and training of kindergarten teacher in information technology; progress in the development and application of digital resources in the kindergarten curriculum; , the development of theoretical and practical thinking on the integration of information technology with curriculum; related research progress in the appropriateness of the application of information technology for young children and its effect on young children's health, and the digital and network development in the early childhood education service system. This study shows that in the past decade IBM KidSmart Young Explorer program has gone through three stages in promoting the application of information technology in early childhood education: the stage of experience accumulation based on large cities in eastern China (2001 to 2004), the stage of pilot experimentation in favor of the second and third scale cities in the western China (2005 to 2007), the stage of promoting equity in education (2008 to 2010). The development of information technology in early childhood education coincides with the development tendency of China's education reform. This study shows that the education philosophy for the kindergarten principal to introduce information technology equipment into the kindergarten and the concept for teacher to use information technology equipment are critical in determining whether or not information technology can effectively support the enhancement of education. The longitudinal comparative study of the teachers' questionnaire shows that in the past ten years of program development, information technology in China has developed rapidly and the individual competency of kindergarten teachers in information communication technology has also improved significantly. However, theoretical thinking as well as teacher's capabilities in how to effectively apply information technology in kindergarten education has not improved much. Therefore, during the promotion of this program, much emphasis is placed on enhancing teachers' professional qualifications, helping teachers to change their ideas and thinking, stressing the assisting role of information technology in education and teaching as "learning by use of computer" instead of "learning computer", highlighting the integration of the computer-assisted means with the kindergarten curriculum, and improving teacher's educating and teaching abilities. The application of information technology in early childhood education of China has not only its own characteristics and advantages, but also some barriers. The development in the past ten years lays a solid foundation for the application of information technology in early childhood education. And the further effective promotion in the application of information should be guided by the principle of educational equity and harmonious development of society advocated by the state. In the end, the study offers some suggestions on the further effective application of information technology in early childhood education, particularly on the formulation of the relevant policies in the future.

Historical Reflection on the Development of China's Early Education

Zhaocun Li, East China Normal University, China

With the introduction of western teaching concepts like constructivism during the 1990s, China's preschool curriculum policy has gradually changed and begun to emphasize the democratization of curriculum policy and the integration of curriculum implementation, etc. The study shows that China's preschool curriculum policy is reflected from such aspects as social culture, power distribution in curriculum policy, and intrinsic mechanism of the implementation of curriculum policies. The study suggests that the greatest breakthrough in China's kindergarten curriculum reform has been the recognition of the value of children's play in the development of children and setting up play as the basic activity in kindergartens in the form of legislation. However, some different problems emerge in the play arrangement of kindergarten curricula, which reflect the contradiction between teachers' cognition and practical operation of play.

With the introduction of western teaching concepts like constructivism during the 1990s, China's preschool curriculum policy has gradually changed and begun to emphasize the democratization of curriculum policy and the integration of curriculum implementation, etc. Since the beginning of the 20th Century, early childhood education in China has been developing in the context of ongoing conflict and reconciliation of western and eastern culture, traditional and modern culture. During the 1990s, with the introduction of western teaching concepts like constructivism, China's

preschool curriculum policy has gradually changed and begun to emphasize the democratization of curriculum policy and the integration of curriculum implementation. For example, in recent years, the greatest breakthrough in China's kindergarten curriculum reform has been the recognition of the value of children's play in the development of children and legislating for the introduction of play as the basic activity in kindergartens. In 2001, the promulgation of the guideline of kindergarten education reflected this change at policy level. However, some different problems emerge in the implementation of the guideline of kindergarten curricula, which reflect the contradiction between the ideas of the curriculum policy and social culture. This study shows that China's preschool curriculum policy is reflected from such aspects as social culture, power distribution in curriculum policy, and intrinsic mechanism of the implementation of curriculum policies. The main goal of this study is to examine the cultural adaptability of current early childhood education curriculum policy in China and to explore in which aspects the ideas advocated by current curriculum policy are concur or differ from Chinese traditional culture. The primary methods we used are interview and classroom observation. We chose experts who participated in building the Guideline of Kindergarten Education, teachers, parents and educational officials as interviewees. In order to obtain data which could be compared on several levels, we conducted interviews and classroom observations in Shanghai, the most developed city in China, and at Qufu, a relative developing small city. According to the interview data, we analyzed the interactions between the ideas of the curriculum policy and Chinese traditional culture from the following aspects: children's ideas, teachers' ideas, the ideas of learning and play, the perceptions of power and responsibility. Based on theoretical analysis, we found that in Chinese traditional culture the emphases on teacher's role of guidance, the dialectic relationship between imitation and creativity, the focus on the formality of learning and the discrimination of play, and the conscience of teaching all effect the implementation of the current curriculum policy. For example, in Chinese traditional culture, play was often linked to self-indulgence and to time-wasting. It is regarded as being in opposition to achievement. As the saying goes, achievement is founded on diligence and wasted in play. Influenced by this traditional idea, play in the kindergarten is often not valued by parents. A second example suggests that, in Chinese traditional culture, creativity and imitation are not opposing concepts but harmonious ones. Although creativity is a kind of transcending to existing values, and a process of exploration, it cannot be detached from traditional concepts of teaching and learning. Profound knowledge base and solid basic skills are prerequisites of development of creativity. In Chinese traditional literature and art education, so-called Linmo, which means imitation, creativity begins by imitating super calligraphy works of predecessors. So called "After reading up three hundred Tang poems, you can at least intone poems even you can't write them" emphasize the writing beginning from imitating super literature works of predecessors. According to this traditional idea, we have to reflect on the relationship between the guidance from teacher and children's independent activities. Finally, we put forward some suggestions about curriculum reform of early childhood education in the context of Chinese traditional culture

Chinese Traditional Culture In Kindergarten-based Curriculum Development

Yu Qian, East China Normal University, China

This study looked at two cases of kindergarten-based curriculum in Shanghai which deeply influenced by Chinese traditional culture and art. It also explored the reconstruction of curriculum and teacher's roles in this process. In these cases, kindergarten teachers tried to integrate traditional Chinese culture and art into the current curriculum and to help the children understand them better. China presents one of the most dramatic examples of rapid economic transitions in the world. However, we need to pay more attention to our history, especially the traditional culture. While Chinese traditional culture means something classic and ancient, 'School-based curriculum' is a new term that emerged from China about one decade ago. It emerged as an international trend since 1970s, departing from the traditional curriculum that was derived from a centralized decision-making process to a curriculum that is determined by individual schools and teachers (Eggleston, 1980; Marsh, 1989, 1997; OECD, 1979; Sabar, 1985; Skilbeck, 1984). After that, some Chinese kindergartens have kept trying to develop their own curriculum in different ways. Li (2006) investigated how school-based curriculum development (SBCD) was interpreted and implemented in a Chinese context like Hong Kong. Some studies also emerged in Shanghai (Li and Li, 2004; Zhu, 2003).

SYMPOSIUM

New Perspectives on Cognitive Load Measurement

Chairperson: Babette Park, Saarland University, Germany

Organiser: Babette Park, Saarland University, Germany

Discussant: Bobby Hoffman, University of Central Florida, United States

The increasing amount of recent publications that focus on Cognitive Load Theory mirrors the relevance of the cognitive load construct. However, the current discussion on how to measure the construct of cognitive load while learning points to a research gap. The present symposium aims at closing this research gap and giving an impulse for more research on valid and reliable cognitive load methods. Therefore, different methods for measuring cognitive load are presented (DeLeeuw, Mayer, Giesbrecht, & Scheiter; Park & Brýnken; van Gog, Kirschner, Kester, & Paas). Van Gog et al. focus on the most frequently used subjective mental effort rating scale and show how timing and frequency of mental effort measurements affect the results obtained. DeLeeuw et al. show how to measure cognitive load by a new paradigm adapted from the field of visual attention differentiating between so-called perceptual load and working memory load. This new perspective on cognitive load holds promise for both the measurement and theory of cognitive load during learning. Park and Brýnken present how to measure cognitive load in an objective way by using secondary task performance in the frame of the dual-task paradigm. In contrast to the until now used secondary tasks, the new presented secondary task is characterized by its independence from the presentation mode of the learning instruction (primary task). The whole symposium will be discussed by Bobby Hoffman (University of Central Florida) and Gregory Schraw (University of Nevada, Las Vegas).

When to Measure Cognitive Load with Mental Effort Rating Scales

Tamara Van Gog, Erasmus University Rotterdam, Netherlands; Femke Kirschner, Erasmus University Rotterdam, Netherlands; Liesbeth Kester, Open University of the Netherlands, Netherlands; Fred Paas, Erasmus University Rotterdam & Open University of The Netherlands, Netherlands

Subjective mental effort rating scales are widely used to measure cognitive load in research on learning and instruction. However, timing and frequency of application of those rating scales differs, from repeatedly within or immediately after every task, to once after a sequence of tasks. Three experiments are presented here that investigate how timing and frequency of mental effort measurements affect the results obtained. The findings from Experiment 1 and 2, using task sequences containing both simple and complex tasks, show that a single rating after a sequence of tasks results in a higher mental effort score than the average of ratings provided immediately after every task. Experiment 3 shows that this also goes for sequences of complex tasks only, but not for simple tasks only. Taken together, the experiments suggest that there is something about a sequence of tasks that makes the whole more than the sum of its parts when it comes to rating invested mental effort. As long as it is unclear what that is, repeatedly measuring mental effort seems to be preferable.

Subjective mental effort rating scales are widely used in research on learning and instruction to measure cognitive load (for reviews, see Paas et al., 2003; Van Gog & Paas, 2008). Most used are (adapted versions of) the multi-dimensional NASA-Task Load Index (NASA-TLX; Hart & Staveland, 1988) which incorporates measures of perceived performance, effort, frustration, and mental, physical and temporal task demands (e.g., Gerjets et al., 2006; Kester et al., 2006; Scheiter et al., 2010) and (adapted versions of) Paas's (1992) 9-point mental effort rating scale.

An important question, however, is when to apply subjective rating scales. Researchers tend to apply them at different intervals, sometimes at certain intervals during a task, which is possible without interfering with task performance or learning when a single item scale is used (Ayres, 2006; Van Merriënboer et al., 2002; Yeo & Neal, 2004, 2008), sometimes immediately after every task in a learning or test phase, which requires learners to retrospect only on the task they just finished that is probably still (partly) activated in working memory (single-item scale: Kirschner et al., 2009; Paas, 1992; Paas, & Van Merriënboer, 1994; Van Gog et al., 2006, 2008; Van Merriënboer et al., 2002; Wouters et al., 2009), and sometimes only once at the end of the entire learning or test phase, which requires learners to provide a retrospective judgment of the cognitive load imposed by a whole sequence of tasks (single-item scale: Kalyuga et al., 2001; NASA-TLX: Gerjets et al., 2006; Kester et al., 2006; Scheiter et al., 2010). When a mental effort rating scale is applied multiple times, the average of ratings is usually used as an indicator of cognitive load experienced during the learning phase or test phase.

Given these differences in the timing and frequency with which rating scales are applied, there are likely to be differences in the results obtained, and as a consequence, in the conclusions that are drawn. A theoretical reason for favoring the measurement of mental effort immediately after each task over a single measurement at the end of a sequence of tasks, is that students may be able to retrospect on a single task, but it is unclear what that measurement at the end of the sequence reflects. To address the issue of whether the timing and frequency affect the results obtained, we conducted three experiments.

Participants in Experiment 1 ($N = 87$) were given six problems, three simple ones (low in cognitive load, e.g.: "Suppose today is Tuesday. What day of the week is tomorrow?") and three complex ones (high in cognitive load, e.g., "Suppose 5 days after the day before yesterday is Friday. What day of the week is tomorrow?"; see Sweller, 1993). Depending on their randomly assigned condition they rated their invested mental effort on the 9-point rating scale (Paas, 1992) after every task ($n = 44$) or once at the end of all six tasks. There were 4 different sequences of the tasks to ensure order would not affect the results. Participants were given 1 minute to find the answer to each problem, and they had to do it mentally. The mean mental effort invested in all six problems from the condition that rated it immediately after each task was 3.75 ($SD = 1.06$), whereas that of the condition that rated it after all problems was 5.23 ($SD = 1.40$). This difference is significant, $t(85) = 5.56$, $p = .000$. A closer look at the data from the condition in which invested mental effort was rated immediately after each task, shows that the mean mental effort invested in the simple problems was 2.03 ($SD = .79$) compared to 5.47 ($SD = 1.64$) in the complex problems. Note that the mean effort invested in the complex problems is almost equal to the mental effort investment indicated by the group that rated it after completing all tasks. Because a between-subjects design was used in this study, a possible explanation for these findings might be that participants in the condition that provided a single rating at the end of the series of tasks did not have a good recollection of the tasks or the effort they invested in each task, and mainly remembered the most complex tasks on which they then based their judgment.

Experiment 2 ($N = 39$) therefore used a within-subjects design. The same tasks as in Experiment 1 were used, again in four different sequences, but participants now rated invested mental effort both after each task and after all six tasks. Again, the effort score provided after the sequence of tasks ($M = 4.87$, $SD = 1.43$) was again higher than the average over six tasks ($M = 3.99$, $SD = 0.93$), $F(1,35) = 39.99$, $p = .000$.

So, for task sequences that contain both simple and complex problems, the findings from Experiments 1 and 2 imply that researchers measuring cognitive load either after each task or after a sequence of tasks will come to different conclusions regarding participants' mental effort investment, with the single measure leading to a higher score. But if students indeed give the complex problems more weight when providing a mental effort rating at the end of a sequence of tasks, the effect that this leads to a higher score than the average of ratings immediately after each task should disappear when tasks are all simple or all complex.

Experiment 3 ($N = 45$) investigated this, using a mixed design with between-subjects factor task complexity (six simple tasks, $n = 22$; six complex tasks, $n = 23$) and within-subjects factor effort rating (after each task and after all six tasks). A repeated measures analysis showed a highly significant interaction effect, $F(1,43) = 14.76$, $p = .000$, indicating that the rating at the end was higher than the average of ratings for the complex problems, but not for the simple problems.

Results will be discussed in terms of monitoring mental effort investment under different cognitive load conditions, and in terms of consequences for measuring cognitive load in research on learning and instruction.

Measuring Perceptual Load in Multimedia Learning

Krista DeLeeuw, Knowledge Media Research Center, Germany; Richard E. Mayer, University of California, United States; Barry Giesbrecht, University of California, Santa Barbara, United States; Katharina Scheiter, Knowledge Media Research Center, Germany

To successfully measure cognitive load, we must fully understand its structure and associated processes. Currently, theories and measures of cognitive load during learning have only considered processing that occurs in working memory, but this may not be the complete picture. As some studies using dual-task measures already hint at, perceptual processing may play an important role in the experience of cognitive load. In two studies, we have shown that in multimedia learning, adding visual (rather than auditory) text to pictures (Study 1) and presenting text close to (rather than far from) pictures (Study 2) increases the demand for perceptual processing, as measured by a new paradigm adapted from the field of visual attention. This paradigm is able to differentiate between so-called

perceptual load and working memory load, and holds promise for both the measurement and theory of cognitive load during learning.

To successfully measure cognitive load during learning from text and pictures (multimedia), we need to understand the underlying structure comprising the experience of load. Current theories and measures of cognitive load focus on processing that occurs in working memory, but this may not be the complete picture. The Cognitive Theory of Multimedia Learning (CTML, Mayer, 2009) describes cognitive processes that learners must engage in during learning and the working memory (WM) channels upon which those processes rely. Cognitive Load Theory (CLT, Sweller, van Merriënboer, & Paas, 1998) describes different types of demands learning tasks can impose on limited WM. We argue that basic perceptual processing also plays an important role and that effective measures of perceptual processing are necessary to advance the field.

Based on CTML and CLT, several measures of cognitive load have been relatively successful at predicting learning outcomes and supporting these theories. Perhaps the most successful have been dual-task measures. Dual-task measures require a response to a secondary task which is thought to use the same cognitive resources as the primary (learning) task. When the learning task requires more of that resource, performance on the secondary task decreases. For example, Bruenken, Steinbacher, Plass, and Leutner (2002) and DeLeeuw and Mayer (2008) had learners work on a primary task, multimedia lessons that contained pictures with visual text (visual-only) and/or pictures with narration (audiovisual). As a secondary task, learners responded as quickly as possible in a visual monitoring task. Learners responded more slowly in the visual-only condition, which the researchers interpreted to indicate, based on CTML, that the visuospatial channel of WM was overloaded by the visual text and therefore processed the visual secondary task less efficiently. However, this interpretation neglects the possibility that perceptual processes, rather than WM processes might be at play. The visual monitoring task used in these studies might require only basic perceptual processing resources, which would imply that the primary task differed in terms of perceptual processing. Moreover, many multimedia learning effects stem from physical changes in the stimulus—adding visual text to an animation, placing text in a different location, adding arrows in a diagram to direct attention—that can change the way learners process information perceptually. Thus, differences between processing visual-only and audiovisual presentations might be perceptual. By integrating perceptual processing into theories of cognitive load, we will be able to more precisely define the resources demanded by learning tasks. This sort of refinement also requires measures that can differentiate between working memory and perceptual processing.

In a series of studies, we investigated a measure of perceptual load. We used common multimedia materials that tend to result in better learning and lower cognitive load, and compared them to materials that decrease learning and increase load. Importantly, we have used differences between materials that involve a physical change. To measure perceptual load, we have created a new type of dual-task measure by adapting a paradigm from the field of visual attention. This paradigm (e.g. Lavie, 2005) has shown that interference from task-irrelevant distractors during a visual identification task decreases when perceptual load is increased by making the identification task more difficult. This task is similar to dual-task measures, except that it does not require a response – learners should ignore the distractors in order to facilitate performance on the primary task. To adapt the paradigm, we presented visual task-irrelevant distractors next to a multimedia lesson, using eye tracking to measure distraction (i.e. how often learners look at distractors). According to the logic of the paradigm, high perceptual load will cause learners to look at distractors less because they have fewer available perceptual resources.

In Study 1, we examined the modality effect (Mayer, 2009) in a within-subjects design; 36 university students learned from a visual-only lesson and an audiovisual lesson, with counterbalanced lesson topics. We found that, consistent with a perceptual load explanation of the modality effect, participants looked at task-irrelevant distractors less during the visual-only condition than the audiovisual condition, $t(35) = -4.29$, p

In Study 2, we examined spatial contiguity (Mayer, 2009) in a similar within-subjects design; 27 university students learned from a lesson in which visual text was placed very near relevant parts of pictures (integrated) and one in which text was placed far from relevant parts (split). We found that participants looked at distractors less in the integrated condition than in the split condition, $t(26) = -4.11$, p . Importantly, learning outcomes paralleled perceptual processing. This study indicates that in extreme cases, integrated materials may increase perceptual load due to visual cluttering.

These two studies provide initial validation for a measure of the perceptual processing required by a lesson. Promisingly, Lavie's paradigm can also differentiate between perceptual and WM load. In studies of visual attention, higher WM load leads to increased distraction. In future work, we will investigate multimedia manipulations that should lead to WM load and do not involve a change in the visual stimulus, e.g., the coherence of narrated text. If this

measure can differentiate between perceptual and WM load within the setting of multimedia learning, it could prove to be an effective tool in investigating the relative contribution of these two types of load in learning from multimedia. The Rhythm Task - A New Method for Measuring Cognitive Load

Babette Park, Saarland University, Germany; Roland Bruenken, Saarland University, Germany

The present studies join a series of studies about directly measuring cognitive load while learning with multimedia instruction by using the dual-task paradigm. The goal of the present work was to develop a secondary task, which measures cognitive load in a direct and continuous way. In addition and in contrast to the until now used secondary tasks, this new method is characterized by its independence from the presentation mode of the learning instruction (primary task), as the secondary task is realized by internalized cues: A previously practiced easy rhythm is executed continuously by foot-tapping of the learner while learning. The suitability of this method was examined in the frame of three studies ($n = 30$ each). Results show that rhythm precision and errors allow a precise and continuous measurement of cognitive load during the learning process.

Theoretical Framework and Objectives

The present work was initialized due to recent publications in cognitive load research, which discuss the widespread and most frequently used subjective rating scale of Paas (1992) and recommend using objective and direct methods for measuring cognitive load (Plass, Moreno & Brünken, 2010). Direct measurement can be realized for example by brain activity measures and dual-task performance (Brünken, Plass, & Leutner, 2003). A series of studies could already show that secondary-task performance is a reliable and valid method to measure cognitive load (e.g. Brünken, Plass, & Leutner, 2004; DeLeeuw & Mayer, 2008). Within a dual task paradigm, e.g. differences in resource consumption caused by different presentation forms of the learning material (primary task) can be obtained by differences in a simultaneously performed secondary task. The by now used secondary tasks are realized by auditory or visual cues in the learning instruction. For example, participants have to monitor a letter in the upper part of the computer screen and have to press the space bar, when a color change was observable. However, it is unclear, whether auditory or visual secondary tasks do measure total cognitive load, or rather modality-specific aspects. Moreover, these mentioned secondary tasks are reactive with respect to the learning task, as they require a conscious disruption of the learning process to respond to an auditory or visual cue.

The objective of the present work is to solve this reactivity problem by a continuous motor task. Because some authors showed that an additional motor task like frequent tapping seems to stimulate cognitive processing of and the performance in primary tasks in a positive way (Brown & Marsden, 1991; Emerson & Miyake, 2003), the motor task for our purpose should not be characterized by frequent tapping, but require inhibition processes. Inhibition processes are good indicators for executive control processes (Cohen et al., 1997), which can be interpreted as a modality-unspecific total cognitive load indicator. For instance, an easy rhythm with pauses already requires inhibition, when learners have to consciously inhibit to tap. Moreover, the motor task should be independent from the primary task, which can be realized by internalized cues. The new invented secondary task should allow a precise and continuous measurement of cognitive load in the learning process.

Methods and Data Sources

The suitability of a new invented secondary task for continuously measuring cognitive load while learning was examined in the frame of three studies ($n = 30$ each). As primary task, we used computer based learning material with or without seductive details. The seductive details were already confirmed to induce a negative learning effect in the first study, $F(1, 29) = 2.92$, $p_{\text{etap}}^3 = .10$ (Park, Moreno, Seufert & Brünken, in press). The second study should show the hypothesized cognitive load effect and examine the new invented method. 30 high-school students were randomly assigned to one of the two experimental groups (with vs. without seductive details). The learning instruction consisted of a self-paced multimedia environment about the structure and function of a cellular molecule. Learners had to execute the foot-tapping rhythm task simultaneously to learning and continuously all over the learning session under both conditions. The rhythm was written in four-four time that is the easiest meter for playing music and was: tap – tap – pause – pause / tap – tap – pause – pause /.... and so forth. Learners were introduced to this rhythm task

before the learning session started. Working memory capacity, spatial ability, prior knowledge, and time-on-task served as control measures. Learning success was assessed with a learning performance test. Total cognitive load was measured by subjective ratings of mental effort (Paas, 1992) and by the rhythm task, which allowed analyzing the precision (standard deviation from individual rhythm baseline in milliseconds) as well as errors or rate changes (sum of rhythm rate changes in milliseconds). Finally, the third study should replicate the effects of the second study with another instructional design effect, the modality effect.

Results and Conclusions

In line with the first study, learners of the second study took significantly more time to learn in the seductive details-condition than learners who learned without seductive details, $t(27) = 9.96$, p

SYMPOSIUM

Students' critiques of teaching practices and their influence on learning conditions

Chairperson: Dimitris Pnevmatikos, University of Western Macedonia, Greece

Organiser: Dimitris Pnevmatikos, University of Western Macedonia, Greece

Discussant: Wiel Veugelers, University of Amsterdam, Netherlands

Teacher – student interaction is considered an important variable in learning and instruction. Especially, students evaluate their teacher's behaviors inside the classroom and their critiques could constitute a crucial factor for the establishment of a good learning environment. This evaluation is subjective and not necessarily in agreement with what teachers consider as a good behavior. Moreover, we do not know exactly how the general feeling that students have about their teacher's behavior is constructed. This symposium aims to present recent research evidence that shows some of the aspects that arise during the teacher – student interaction inside the classroom and have an effect on the learning conditions. Specifically, the first paper will show that students acknowledge their teachers' content competence, professional preparation, teaching ability, responsibility and sense of duty while highlighting a lack of their teachers' competence in social interaction, understanding and communication. The second paper will show that an increased number of experiences of just and constructive interactions with their teachers will affect the students' positive perceptions of the open classroom climate, which is associated with the effective learning conditions. The third paper, through providing the role of emotions, will show which specific teachers' behaviors influence children's justice perceptions of their teachers, and how they affect children's judgments of their teacher's behavior.

The gap between teachers' understanding of learning environment and communication and students' experience

Mary Koutselini, University of Cyprus, Cyprus; Sophia Agathagelou, University of Cyprus, Cyprus

This paper presents a study aiming at investigating teachers' understanding of teaching and students' experiences in secondary schools of Cyprus concerning both learning environment and teachers' competences for effective communication. The results of the study reveal the gap between students' and teachers' perceptions concerning empathy, collaboration, and communication and indicate differences between the perceived curriculum (teachers' perceptions) and the experienced curriculum (students' experiences). Although students acknowledge their teachers' content competence, professional preparation, teaching ability, responsibility and sense of duty, find a lack of teachers' competences for social interaction, understanding and communication. For the purposes of this study, two questionnaires were developed, one addressed to representative number of students ($N=1282$) and one to teachers. Statistical analysis of the data includes descriptive and factor analysis. Interviews with teachers and students allow further interpretation of the quantitative data. The results are interpreted in light of the Critical pedagogy discourse and its concern about teaching and curricula that de-personalise schooling and communication. The syndrome of undifferentiated teaching of the "content" prevents students from learning and teachers from pedagogy.

Introduction

Are there any differences between teachers' and students' understanding of effective learning environment and communication? What key competences do teachers attribute to themselves? What key competences do students attribute to their teachers? These are the main questions that are being answered in this study comparing aspects of the perceived and experienced curriculum as it has been defined by Goodlad (1983). Empathy and collaboration as key competences of both effective learning environment and teaching are examined and the gap between students' and teachers' perceptions are presented in light of the Critical pedagogy discourse.

Method

Participants in the study were 545 secondary school teachers of a variety of disciplines, as well as 1282 students of the second class of Gymnasium (age 14) and of the first class of Lyceum (age 16) all over Cyprus. A mixed methodology

has been used for data collection, quantitative and qualitative. The quantitative instruments were two questionnaires, one addressed to students and one to teachers. The teachers' questionnaire measures teachers' understanding about the characteristics of their teaching, while the students' questionnaire refers to students' experiences regarding teaching and learning environment. The statements in the students' questionnaire correspond to the statements in the teachers' questionnaire and vice versa so as to allow comparison between students' and teachers' perceptions. The study was completed with semi-structured interviews with teachers and students who gave their explanation about the gap between teachers' and students' perceptions. Factor analysis, discourse and content analysis are the methods of data analysis.

Findings

Students see mainly their teachers' content competence, professional preparation, teaching ability, responsibility and sense of duty and find a lack of teachers' competences for social interaction, understanding and communication. None of the statements in the teachers' questionnaire has a mean score below 3.00 (Likert scale 1-5), showing lack of awareness about their deficiencies, fact that has been confirmed during the interviews. Agreeing with the relevant bibliography, it is confirmed that girls tend to rate their teachers higher on average than boys. Both teachers and students agree that teachers have good subject-matter

Knowledge, respect the responsibilities they undertake and explain the lesson in a clear manner for all students. However, factors that are considered crucial for a constructive communication and learning, such as the relationship and interaction between students and teachers, linking school activities with activities beyond school - extracurricular activities and having students' views listened to and valued (Kerr et al, 2004) are indicated with the lowest mean scores.

Discussion

Differences in teachers' and students' beliefs on "qualitative teaching" are a crucial issue on Learning and Instruction. The gap between teachers' and students' understanding of the learning environment and students' perception that there is a lack of empathy and communication urges for the need to personalise schooling and teaching in a way that moral development of both, teachers and students will include awareness of empathy and collaboration in non prescribed -routine activities and materials (Koutselini, 2005, 2008). Pre-defined routine activities and understanding teaching as delivery of content lead to undifferentiated activities that do not take into account students' real needs, learning and developmental. The discussion of the paper aims at contributing to the construction of a broader context than the positivistic one for understanding Learning and Instruction. Moreover, the investigation of the gap between the perceived and the experienced curriculum should point out preconditions for practicing democracy in a daily basis.

Do teachers' practices inside the classroom differentiate their students' perception of open classroom
Instructional Design, Morality, Teacher thinking

DORIT ALT, Zefat Academic College, Israel

How students experience their everyday school life partly depends on their perception of the climate in classes. Positive class climate perceptions, construct student efficacy and adaptive patterns of engagement. A key component of class climate considered to be the teacher's instructional behavior. This raises the need to explore the affect of teacher's behavior on their students' perception of the class climate. This study examines the hypothesis that increased experiences of just and constructive interactions with their teachers will affect the students' positive perceptions of the open classroom climate. Six teachers and 83 students studying at four 12th grade classes in four Israeli high schools participated the study. A qualitative research included content analysis of guiding principles for open instruction of the "Mass Media for High School" curriculum, and class observations, aimed at documenting and

classifying teachers' instructional behavior. Students' perceptions of the classroom climate were assessed using two questionnaires: "Classrooms" and "School Curriculum" (Torney-Purta et al., 2001). Different instructional behaviors were found between the teachers. In two schools the teachers were classified as "open climate" instructors, whereas the other teachers had failed to implement "open" instructional methods. Accordingly, students of the latter teachers perceived the classroom climate and the curriculum as less open and democratic. This study stresses the central role of the teacher in creating perceptions of favorable social classroom climate among their students.

This study aimed at investigating whether different types of teachers' practice at class influence their high school students' perceptions of the classroom social environment. How students experience their everyday school life partly depends on the climate in their classes (Eder, 1996, 1998; Ichilov, 1984). Class climate is determined by the general pattern of social interactions among classmates and with teachers, as well as by teaching instruction. Teachers' instructional behavior is a key component of class climate. In an adequate open classroom climate, students are allowed for equal dialogue, they have opportunities to explain, justify and test the viability of their own and other students' ideas, thus equally negotiate and construct ideas with others. This environment which enables students to feel justly treated by their teachers (Dalbert, 2001) could explain positive class climate perceptions, which construct student efficacy and adaptive patterns of engagement. This raises the need to explore whether different teaching behaviors within class, differentiate their students' perceptions of the classroom environment. This study examines the hypothesis that increased experiences of just and constructive interactions with their teachers will affect the students' positive perceptions of the open classroom climate.

Method

Participants: Six teachers and 83 students studying at four 12th grade classes (mean age=17.6 years; SD=0.36) in four Israeli high schools participated the study.

Data collection

Teachers practice and behavior at class were examined qualitatively using five pre-dominant categories and 13 sub-categories based on content analysis of the guiding principles for open instruction of "Mass Media for High School" curriculum (The Ministry of Education, 1993).

Class Observations: Observations were conducted during one academic year by two judges, aiming at documenting the teacher - student interactions as well as estimate the frequency and intensity rates of the sub-categories during class lessons. Frequency was estimate in a 5-level scale (1= once, 5= five times or more) per lesson. Intensity was estimate by measuring the duration of each sub-category at a specific lesson in a 5-level scale form 1= up to 5 minutes, 5= 35-45 minutes). The final rate was determined by multiplying the frequency and intensity rates. For example: if the teacher encouraged expression of diverse opinions regarding social issue four times during a lesson (=4 points) and dedicated 40 minutes for the total discussions (=5 points) the total score was 20 points (4X5). Finally, the mean score of every sub-category regarding all observations in each school was calculated, and coded by the judges in a 5-point scale from 1=low to 5=high. Reliability was assessed via Cohen's kappa (school A: $k=0.882$; school B: $k=0.889$; school C: $k=0.877$; school D: $k=0.865$). The judges were later asked to classify the teachers practice on two categories: a. "open climate" instructor; b. "close climate" instructor.

Students' perceptions: Two subscales "Classrooms" and "School Curriculum" from the International Study of Civic Education (Torney-Purta et al., 2001) were used to assess students' perception of the open class climate. "Classrooms" subscale contains seven statements ($\alpha=.78$) describing practices that are related to open classroom climate, in which students have ample opportunities to express their views, discuss issues, and become aware of a multiplicity of vantage points to various issues. Students were asked to evaluate in a Likert type scale (1=never to 4=often) how often do practices described in each statement occur in class. "School Curriculum" subscale includes seven statements ($\alpha=.78$) related to pluralism, cooperation and problem solving. Students were asked to indicate in a Likert type scale (1=strongly disagree to 4=strongly agree) their agreement about having acquired these attitudes and skills in the classroom.

Findings

Observations were classified by two independent judges according to the following categories:

- A. Encourage pupil collaboration (included 2 sub-categories)
- B. Encourage freedom of creation (included 3 sub-categories)

Discussion based on the following principles:

- C. Encourage expression of diverse opinions (included 2 sub-categories)
- D. Enable expression of minority opinions (included 2 sub-categories)
- E. Multi-dimensional presentation of current issues (included 4 sub-categories)

Both judges agreed that teachers in schools A and B are "open climate" instructors who extensively used teaching methods that focused on encouraging pupils' negotiation and creation, conducting open discussion about social and political issues, while underscoring the expression of minority opinions and multi-dimensional presentation of current issues. In contrast to teachers in schools A and B, teachers in schools C and D used practices such as frontal teaching, they did not extensively encourage students to form and express their own views, or to take part in collaborative assignments with other students at school.

In order to examine whether teachers' practices inside the classroom differentiate their students' perception of open classroom climate and the curriculum, t-tests between the schools (A and B, C and D) were conducted. The results showed significant differences between the groups in perception of classroom climate as open to discussion about social and political issues ($t(81)=4.62, p<.001$), and in perception of the curriculum as promoting social values ($t(81)=3.75, p<.001$). Students from schools A and B scored higher means in both indices: perception of classroom climate ($M=3.16$ $SD=0.30$), and of the curriculum ($M=2.64$ $SD=0.47$), than their peers in schools C and D, respectively ($M=2.76$ $SD=0.47$), ($M=2.18$ $SD=0.62$).

Discussion

This research investigated whether students' perceptions of their social environment tend to vary due to different conditions created by their teachers' instruction. According to the findings, students' evaluation of their experiences inside the class could depend on their teachers' instructional behavior. This study suggests teachers' social and instructional behavior as key component of students' perceptions of class climate. Since students' perceptions of their class social environment, based upon their feeling of just, could potentially influence their efficacy and adaptive patterns of learning and engagement, this study stresses the need for favorable social classroom climates. This means practicing "open" teaching methods which shape the class as an open, just and equal sphere of interactions.

Children's cognitions of just and unjust experiences in class:

Dimitris Pnevmatikos, University of Western Macedonia, Greece; Ioannis Trikkaliotis, University of Western Macedonia, Greece

Teachers' social and instructional behavior is considered as a key component of class climate. Specifically, children's justice cognitions regarding their teachers' behavior could partly explain whether the children experience a good class climate. The aim of the present study was to investigate specific teachers' behaviors that influence children's cognitions about their teachers' just or unjust behavior, and to explore the role of the experienced emotions. One hundred eighty children from three age groups 8-, 10-, and 12-years-old participated in the study. Three conditions were prepared: (a) teacher behaved consistently to her/his orders, (b) teacher created uncertainty conditions with a positive end, and (c), teacher created uncertainty with negative end. Three groups, equally divided across the age and gender, experienced each experimental condition. Participants were asked to denote their emotional state after each teacher's behavior, their justice cognitions regarding their teachers' behavior, and to judge their teacher as just or unjust. Hierarchical regression analysis has shown that the generated emotions (in parallel to the children's judgments) could explain partially the children's judgments of their teacher as just or unjust. Children construct their justice cognitions regarding their teachers' behavior (consistent, generating uncertainty) based on judgments revealing from their personal experience and to their emotions accompany these experiences. Implications for teacher's behaviors that affect the learning conditions are discussed.

Teachers' social and instructional behavior is considered as a key component of class climate. Specifically, children's justice cognitions regarding their teachers' behavior could partly explain whether the children experience a good class climate (Eder, 1996, 1998; Hearn & Moos, 1978). How these cognitions do constructed? Peter and Dalbert (2010) have shown that students who evaluate their teachers' behavior toward them personally as just, evaluate the class climate more positively. Thus, we could assume that children's evaluation for their teacher's behavior is progressively constructed through a summation of different experiences from small lasted episodes that children are involved and concern them personally.

Most of the studies, studying the influence of teachers' behavior to the class climate, are based on the children's "general feeling" about their teachers' behavior. This methodology, however, is not informative about the specific teachers' behaviors that influence children's final judgments and how they affect children's judgments about their teacher's behavior.

We assume that teacher's behavior is evaluated by their pupils both emotionally and cognitively, and this evaluation contributes to the construction of children's justice cognitions regarding their teachers' behavior. For instance, we know that situational uncertainty generates situational anxiety (Gray & McNaughton, 2000), and when uncertainty disappears, anxiety should give way to satisfaction or joy (if winning) or some negative emotions ranging from sadness to fear (Knyazev, Savostyanov, & Levin, 2005). We could expect that teachers' behavior that generates uncertainty to her/his pupils could be judged differently depending on the final emotions. At the cognitive level, according to the "Relative deprivation theory", individuals judge the procedures according to the results; when they take less than what they expected to take, individuals judge the procedure as unjust (Skitka, 2002). Furthermore, procedures, consistent with the previous known and clear rules, generate emotional stability and are judged as just. On the contrary, inconsistent procedures are judged as unjust (Van den Bos, Vermunt, & Wilke, 1996).

The aim of the present study was to examine whether the emotional (in parallel to the cognitive) states that are generated by specific teacher's behaviors in the class settings, could explain the produced children's judgments for their teacher's behavior. We hypothesized that children's emotional states (in parallel to the judgments) generated from their teacher's behavior (uncertainty with positive vs. uncertainty with negative end, and consistent behavior) could partly explain their judgments about their teacher's behavior.

Method

Participants: One hundred eighty children (including 90 boys) from three age groups 8-year-olds ($M = 8$ years, $SD = .29$, $n = 60$), 10-year-olds ($M = 9.9$, $SD = .27$, $n = 60$) and 12-year-olds ($M = 11.9$, $SD = .28$, $n = 60$) participated in the study. Participants were from middle-class families.

Data Collection: In testing our prediction, we wanted to mimic children's experiences in school settings. Participants were sitting in groups of 10 in front of the computer and the information given by their teacher appeared on the screen. Three experimental groups experienced three teacher's behaviours (consistent, uncertainty with a positive end vs. uncertainty with negative end). In order to examine the emotions in each condition, the children were asked in the three steps of the procedure to denote their emotional state on a scale (1 = 'very sad' to 5 = 'very happy'). Moreover, participants were asked to express their judgments about their teacher's decisions and to judge the overall teacher's behaviour on a scale (1 = 'unjust' to 5 = 'just').

Findings

Hierarchical regression analysis applied to our data with the children's judgments of the overall teachers' behavior as a dependent variable, and the age, gender (block 1), generated emotions after each teacher's behavior (blocks 2 – 4), judgments for the teacher's decision (block 5) and conditions (consistent, uncertainty with positive end, and uncertainty with negative end) (block 6) as independent variables. Analysis revealed that age (at least for children 8- to 12-years-old participated in this study) and gender did not influence significant percentage of the children's judgments about their teachers' behavior ($F(1,177)=1.424$, $p=.243$). The three emotional states that generated after the teachers' behavior explained the 14.9% of the variance (adjusted $R^2=.022$, $R^2=.149$ and $R^2=.145$ respectively for the three teacher's behaviors). The major change on the R^2 ($R^2=.149$) was produced by the emotions produced after the teacher's behavior that generated uncertainty to the participants ($F(1,175)=27.078$, $p<.001$). However, teacher's final decision to give a positive or negative end did not significantly change children's emotional states ($F(1,174)=.257$, $p=.613$). The cognitive aspect (children's judgments) found to be responsible for the 18.6% of the variance ($F(1,173)=9.656$, $p=.002$). Finally, the experience of the three different teacher's behaviors explained another 11.5% of the variance ($F(1,172)=29.385$, $p<.001$).

Discussion

The experimental design of the present study allowed us to create conditions (consistent, uncertainty with a positive end vs. uncertainty with negative end) that partially explain the pupils' cognitions about their teacher behavior. The results confirmed our assumption that children's evaluation for their teacher's behavior is progressively constructed through a summation of different experiences from small lasted episodes that children are involved and concern them personally. Children's overall judgments for their teachers' behavior are partially explained by their personal experiences during the three short lasted experimental conditions. Moreover, experienced emotions (in parallel to cognitive judgments) explain an important part of children's evaluations (as just or unjust) of their teacher's behaviors. Specifically, the generated emotions after the teacher's behavior that characterized as uncertainty explained a significant portion of their cognitions about their teacher's behavior. Contrary, the end (positive or negative) after of an uncertainty did not explain a significant portion of the variance. That is, whenever teacher with his behavior creates uncertainty to his pupils, independently whether the end is positive or negative, is judged as a negative behavior and should be avoided by the teachers. This avoidance could help teachers to be able to establish a positive class climate and, thus, providing a beneficial developmental, learning, and achievement environment.

SYMPOSIUM

Different Perspectives on Understanding Learning in the Workplace

Chairperson: Hans Gruber, University of Regensburg, Germany

Organiser: David Gijbels, University of Antwerp, Belgium

Margje W.J. van de Wiel, Faculty of Psychology and Neuroscience, Maastricht University, Belgium

Discussant: Christian Harteis, Universität Paderborn, Germany

The interest of researchers and organisations in learning in the workplace has been growing over the past years. Effective learning of professionals during work is key to competence development, and hence, to organisational performance. The aim of this symposium is to widen our understanding of the learning that occurs in the workplace and to get more insight in the factors that contribute (or not) to this learning. The three papers in this symposium all show that learning at work occurs during relevant work activities and benefits from the cooperation with colleagues and/or supervisors. Although the research was done in different contexts and situations and focused on different learning behaviours (team learning in diverse organisations; learning in engineering internships; and learning from information and knowledge sharing among physicians) the common goal was to find conditions that foster learning in daily work and to provide suggestions to enhance this learning. A variety of methods was used to investigate the topic including questionnaires, interviews and the analysis of discussions. After the presentation of the papers the similarities and contradictions in the findings, as well as current research gaps and future research opportunities, will be discussed by the discussant and with the audience.

Learning through information and knowledge sharing in patient review meetings

Margje W.J. van de Wiel, Faculty of Psychology and Neuroscience, Maastricht University, Belgium; Carolin Hanssen, Maastricht University, Netherlands; Ruben Hendriks, Maastricht University, Netherlands; Richard Koopmans, Maastricht University, Netherlands

To maintain their expertise physicians have to keep up to date and learn from their experiences in medical practice. This study examined physicians' workplace learning focusing on information and knowledge sharing in patient review meetings that are weekly held with the complete ward team. These meetings were thought to contribute most to professional development in previous research. Eight meetings of different subspecialties of internal medicine were video-recorded and transcribed to examine the knowledge and information sharing processes in the team and how they might contribute to learning. In particular, we looked whether complex cases were more elaborately and deeply discussed than routine cases, as we expected that they have a higher learning potential through their challenging nature. Coding with Atlas-ti of the 98 patient cases discussed revealed that experienced specialists were most active and complex cases triggered longer discussions. Learning, however, was largely implicit, as most of the information and knowledge shared was clearly directed at patient care. Explicit teaching was only observed at four meetings. A short evaluation questionnaire disclosed that only half of the participants mentioned learning as a meeting goal. The results suggest that the meetings' educational function can be increased by more focused learning efforts.

Introduction

The development of professional competence is to a large extent determined by informal learning in the workplace (Eraut, 2004). People learn by doing from the tasks they are involved in, the situations they encounter and the colleagues they work with. This is also the case in medicine where residents learn their profession while doing the job and experienced physicians need to continue learning to provide the best possible patient care. Several studies have provided qualitative evidence that everyday practices in the clinic play a pivotal role in the professional development of physicians (Teunissen et al., 2007; Slotnick, 1999; Van de Wiel et al., 2010). The patient problems encountered and the discussions about these patients with colleagues were thought to contribute most. The more complex cases that require further thinking can be expected to have the highest learning potential.

The present study, therefore, investigated in detail patient review meetings that are held each week to discuss the current status of patients on the ward with a multidisciplinary team including residents and experienced physicians. The research questions were: 1) Are complex cases more elaborately and deeply discussed than routine cases? 2) Who are involved in knowledge and information sharing and in what way? 3) Can explicit teaching be recognized and what might be implicitly learned? 4) Is education perceived as a goal of the meeting?

Methods

We recorded eight patient review meetings, one of each of eight subspecialties at the department of internal medicine at Maastricht University Medical Centre. Team size varied from 7-12. In total there were 74 participants, including 32 internists (11 with 5-10 and 21 with 11-40 years of experience), 19 residents (9 with 0-3 and 11 with 4-5

years of experience), 13 medical students, 7 nurses and 3 other specialists. Overall 98 cases were discussed varying from 5-19 cases per meeting. Case complexity was rated by one or two attending physicians on a scale from 1-5. Participants evaluated the meetings with regard to its perceived purpose and its effectiveness (response rate of 77%). The recordings were transcribed into verbal protocols and Atlas.ti was used for a detailed bottom-up and iterative content analysis. The coding scheme was determined by a team of four researchers. Two of them coded the protocols after an extensive period of training. At least one code was assigned to each turn taken in the discussions. Codes were grouped in coding families including structuring meeting, information and knowledge sharing (with subfamily problem analysis), teaching, and decision making. The number of words per code was used as a unit of analysis to compare the contribution of participant groups and to describe how much attention was paid to certain topics. Percentages were computed per case. Presentation and discussion time per case were recorded.

Results

Usually the meeting was chaired by the head of the department and patients were presented by the attending resident (60 cases) or advanced medical student (22 cases). Regarding case complexity we found that the time and words spent to the cases increased with their complexity. On average the easiest cases were presented and discussed in 302 seconds and 1037 words, and the most difficult cases in 800 seconds and 2034 words. The more complex the cases the more information and knowledge was spontaneously contributed, requested, and provided as an answer. There was also more problem analysis, in the sense that previous contributions in the discussion or actions in patient management were reconsidered, evaluated, and reflected upon.

Analysis of the participation in the discussions showed that the most experienced specialists contributed most. They were particularly active in spontaneously contributing and requesting information and knowledge, as well as in problem analysis. Among them the chairperson played a prominent role. The junior residents engaged most in providing answers to the requests. The medical students played a very limited role.

Explicit teaching was only present in 4 of the 8 meetings covering 3-7% of the discussions. Implicit learning may have occurred throughout the meetings triggered by the way patients presented themselves, the options considered, the decisions made, and the underlying reasons provided (e.g., "And we gave Haldol, because she was rather upset"). The short evaluation questionnaire revealed that all participants regarded discussing patient care as the meeting's main goal. Only half of both the residents and internists mentioned education as an explicit goal. Some indicated that they valued the open atmosphere of discussion.

Discussion

Patient review meetings provide meaningful learning opportunities in medical practice. Different patient cases are discussed considering the subsequent actions that need to be taken. This first study on the topic showed that the more complex cases indeed entailed a higher learning potential as they were more elaborately and deeply discussed. The dominant role of the chairperson and other experienced medical staff point to their function as role models in the learning of residents and medical students. Although they asked residents for knowledge and information about the patient and their approach, more teaching efforts could be put in checking understanding and providing explanations. Implicit learning might be increased by consistently sharing considerations underlying decisions. As only half of the residents and physicians spontaneously mentioned education as a meeting goal, stressing this perspective may make learning more effective. As time seems an important constraint, efficiently structuring the meeting may allow more learning opportunities. In further analyses we will examine these structural meeting aspects, as well as detail the interventions that contribute to implicit and explicit learning.

Learning in teams: How do group development phases relate to team-level learning behaviour

Stefan Decuyper, Katholieke Universiteit Leuven, Belgium; Sanne Nijs, University of Leuven, Belgium; Eline Degraeve, University of Leuven, Belgium; Filip Dochy, K.U.Leuven, Belgium

When team members engage in collective team learning behaviours, such as giving feedback and sharing information, the probability that the team will live up to the expectations is increased. Moreover, the importance of team learning has been stressed several times through the demonstration of its effect on individual and organisational learning. Although 'team learning' is described as one of the recently discovered keys to team effectiveness, 'group development' was investigated since many decades. Both research strands start from the premise that teams will not be effective unless they collaboratively learn to overcome barriers such as team dictators, free riding, social loafing, etc.

Currently, there is a lack of empirical research that crosses the gap between these two strands. In this study we answer two important questions at the boundary between team learning and group development research: 'How do different development stages relate to team learning behaviour?' and 'To what extent is group development related to conditions for team learning?' We hypothesise that although each stage of group development is characterised by specific learning tasks, some stages are more favourable for team learning processes than others. Results from multiple regression analyses and ANOVA on a sample of 44 professional teams show that teams learn best in the trust and structure phase and in the work phase due to higher levels of team psychological safety and group potency.

Teamwork does not necessarily work (West, 2004). However, when team members engage in collective team learning behaviours such as giving feedback, sharing information, constructive conflict, etc. they radically increase the probability that the team will live up to the expectations (e.g. Van Woerkom & Croon, 2009.). By engaging in team learning behaviours, teams build shared mental models and gradually become more effective (e. g. Edmondson, 1999;). The positive effects of team learning on team effectiveness are attributed to increased capability of team members to work together, generation of new knowledge, and transformation of the team into a unit that is able to deal with the challenges of tomorrow (Sessa & London, 2008). Also, the importance of team learning has been framed repeatedly by its effect on individual and organisational learning (e.g. Hannah & Lester, 2009).

Although 'team learning' is described as one of the keys to team effectiveness, the concept is relatively new. It was only introduced to a wider audience in the beginning of the nineties. However, research on 'group development', which is conceptually related to team learning research, is traced back to the beginning of the previous century (Bennis & Shephard, 1956). Both strands start from the premise that teams or groups will not be effective, unless they collaboratively learn to overcome barriers such as team dictators , free riding , social loafing, ego-trippers, a lack of team psychological safety, etc. However, although the point of departure for both literatures is the same, they seem to have a different focus. A first obvious difference is the fact that 'group development' literature deals with groups and teams, whereas team learning literature only deals with 'teams'. We further elaborate on that difference below. A second difference is that in contrast to group development, team learning is not often regarded as an unintentional process and/or outcome (London & Sessa, 2007). Consequently, the emphasis in team learning research is on examining and predicting under which circumstances specific team learning processes and outcomes come about. In contrast, group development is more often regarded as a naturally occurring maturation process. Consequently, research on that subject is more concerned with describing how and explaining why groups mature over time.. Despite this different focus of team learning and group development literature, we were surprised by the lack of empirical research that crosses the gap between these two distinct fields (Decuyper, Dochy, & Van den Bossche, 2010). After all, in light of the increasingly changing society and the rising importance of team learning, it is important that we start going beyond the link between group development and teamwork, and start to understand how group development is linked to team learning (Ilgen, Hollenbeck, Johnson, & Jundt, 2005). Kasl, Marsick and Dechant (1997) suggested that group development does not guarantee collective learning, stating that "Teams can work their way through the developmental stages of forming, storming, norming and performing (Tuckman, 1965), yet never challenge dysfunctional assumptions or create new knowledge through strategies such as framing or perspective integration." (p. 231). But, this statement has not been subjected to the empirical test.

In this study we answer two important questions on the boundary between team learning and group development research: 'How do different development stages relate to team learning behaviour?' and 'To what extent is group development related to conditions for team learning?' We hypothesise that, although each stage of group development is characterised by specific learning tasks, some stages are more favourable for team learning processes than others.

We examine these questions by combining the group development model of Wheelan (2005) with the team learning development model of Dechant, Marsick and Kasl (1993). In doing so, we examine to what extent basic team learning behaviour (constructive conflict, sharing information, co-construction) is related to different stages of group development (dependency and inclusion, counter-dependency and fight, trust and structure, work and termination). Moreover, we examine to what extent important conditions for team learning such as 'team psychological safety',

which is the shared conviction that the team is safe for interpersonal risk-taking (Edmondson, 1999), and group potency, which is the collective belief of group members that the group can be effective (Shea & Guzzo, 1987), can serve as 'linking concepts'. As such, we examine to what extent group development phases relate to team learning behaviours because they relate to team psychological safety and group potency. Team psychological safety and group potency were selected as potential 'linking concepts' because they are both important predictors of 'team learning behaviour' (Van den Bossche et al., 2006), and conceptually related to the 'trust' concept, which takes a central part in the description of group development (Edmondson, 2003).

Results from multiple regression analysis and ANOVA on a sample of 44 professional teams show that teams learn best in the trust and structure phase, and in the work phase, due to higher levels of team psychological safety and group potency.

Workplace learning during internships: the role of job-characteristics

David Gijbels, University of Antwerp, Belgium; Vincent Donche, University of Antwerp, Belgium; Piet Van den Bossche, University of Antwerp, Belgium; Peter Van Petegem, University of Antwerp, Belgium; Ingrid Ilbroux, Leuven Engineering Collège Groep T, Belgium

It is argued that internships have a distinctive contribution to professional education. It is suggested that the confrontation with the workplace triggers learning. Based on the Demand-Control-Support (DCS) model (Johnson & Hall, 1988; Karasek, 1979; Karasek & Theorell, 1990) the present paper aims to investigate the influence of job-characteristics such as job demands, job control, and social support on the learning in the workplace during internships. We investigated different sources that can guide the learning of interns during work (Oosterheert & Vermunt, 2001). Five such sources are distinguished: (1) external regulation; (2) self-regulation, (3) actively relating theory to practice, (4) collaboration with co-workers; and (5) avoidance behaviour. Moreover, we looked how these relate to the perceived competences reported by both the students and the supervisors. 66 engineering students conducting an internship and their supervisors in the companies participated by completing questionnaires based on existing and validated scales.

Results of regression analyses support Karasek's learning hypotheses indicating that job demands, job control, and social support influence the use of different learning resources in the workplace. In addition, the analyses show that high job demands and support by colleagues contribute to perceived competence. This study provides insight in workplace characteristics that affect learning during internships. Moreover, it disentangles different sources of learning regulation, hereby identifying different ways in which learning is shaped in the workplace. This suggests pathways to promote learning during internships.

Introduction and aims. It is argued that internships have a distinctive contribution to professional education. It is suggested that the confrontation with the workplace triggers learning. Everyday work practice is full of potential learning processes. These learning activities during work can be very effective and necessary for the purposes of becoming more expert in a profession. Despite the theoretical reasoning, research on work-related learning and its antecedents has however remained rather scarce. This paper presents a study that on the one hand questioned antecedents of workplace learning by studying job characteristics, and on the other hand unravelled learning in the workplace during internships.

To investigate the influence of job-characteristics, the present study relied on the Demand-Control-Support (DCS) model (Johnson & Hall, 1988; Karasek, 1979; Karasek & Theorell, 1990). This model stresses the important role of job-characteristics such as job demands, job control, and social support on the learning in the workplace during internships. Job demands refer to stress factors which are present in the work environment. A demanding job thus means that someone has to complete a great deal of work within a limited space of time (De Witte et al., 2005). Job control refers to the opportunities which an employee has to satisfy these job demands. These opportunities are represented by the scope the employee has for taking decisions (De Witte et al., 2005). By social support we mean: the existence of good relations with colleagues, being able to rely on others, obtaining accurate information via others, as well as gaining actual help, understanding and attention when difficulties are encountered (De Jonge et al., 2003).

While earlier studies used self-report of occurrence of work-related learning behaviours as operationalisation of workplace learning (e.g., Gijbels et al. 2010), the present study explores a wider perspective on workplace learning. We investigated different sources that can guide the learning of interns during work (Oosterheert & Vermunt, 2001). Five such sources are distinguished: (1) external regulation; (2) self-regulation, (3) actively relating theory to practice, (4) collaboration with co-workers; and (5) avoidance behaviour. Moreover, we looked how these relate to the perceived competences reported by both the students and the supervisors. 66 engineering students conducting a long term internship and their supervisors in the companies participated by completing questionnaires based on existing and validated scales.

Methodology.

We questioned how individual differences in learning are present among engineering students (N = 66) taking part at a long term internship during engineering education. Hereto, a selection of scales of the ILTP-questionnaire (Oosterheert, Vermunt, & Denessen, 2002) used to map differences in student teacher learning during internships was translated to the specific context of learning during engineering internships. To measure the job-characteristics job demands, job control, and social support we used existing and validated questionnaires that were used in the study by Gijbels, Raemdonck and Vervecken (2010).

Exploratory factor analyses, correlation, and regression analyses were applied to investigate the interrelatedness and predictivity between the constructs under study.

Results.

Results of regression analyses support Karasek's learning hypotheses indicating that job demands, job control, and social support influence the use of different learning resources in the workplace. In addition, the analyses show that high job demands and support by colleagues contribute to (perceived) competence. Results diverged when examining the relation between sources of learning regulation and perceived competence. On the one hand the results indicate that students during internships feel themselves more competent thanks to collaboration with co-workers, while the supervisors label students that integrate theory and practice in the workplace as more competent students.

Theoretical and educational significance. This study provides insight in workplace characteristics that affect learning during internships. Moreover, it disentangles different sources of learning regulation, hereby identifying different ways in which learning is shaped in the workplace. This suggests pathways to promote learning during internships.

SYMPOSIUM

Environmental learning: content, context and challenges

Chairperson: Cecilia Lundholm, Stockholm University, Sweden

Organiser: Cecilia Lundholm, Stockholm University, Sweden

Discussant: Russell Tytler, Deakin University, Australia

Environmental education (EE) is featured in many countries' formal education systems. In recent years there has been an increase in understanding of the kind of learning needed for meeting environmental and societal challenges both in school settings and in more hybrid school-outdoor settings. Books such as *Sustainable Development and Learning* (Scott and Gough 2003), *Social Learning Towards a Sustainable World* (Wals 2007), *Environmental Learning: Insights from the student experience* (Rickinson, Lundholm and Hopwood, 2009), *Resilience in Social-Ecological Systems: The Role of Learning and Education* (Krasny, Lundholm and Plummer, forthcoming) all reflect the emphasis on learning.

This symposium resonates with the conference theme of a globalized world and education for and within such an outlook. It presents and discusses results from empirical studies investigating learning in both formal and informal contexts. They include i) Chinese secondary students learning about climate change from natural scientific, moral and economic perspectives, ii) Swedish upper secondary students' understanding of price and environmental externalities, and iii) a phenomenological study of Dutch primary school children's' learning in a hybrid outdoor-indoor EE program.

The importance of this symposium lies in an exploration of the kinds of learning processes and learning environments that can strengthen students' thinking about nature and environmental issues and their ability to respond to contemporary environmental and societal challenges. The session seeks to initiate lively debate between scholars in the related fields of environmental education, education for sustainability and environmental learning.

Understanding climate change: conceptions from natural scientific, moral and economic perspectives

Li Sternang, Stockholm University, Sweden; Cecilia Lundholm, Stockholm University, Sweden

The concept of climate change is characterized with increasing complexity. It is not only an environmental issue, but also political and economical, as well as a moral. In this study, we examined students' reasoning of climate change from three aspects: First, a fine-grained analysis of how students make meaning of information related to climate change. Second, since climate change calls for local as well as global actions, it triggers students' moral reasoning: who should do what? Therefore, students' moral reasoning of climate change was investigated. Third, since mitigating climate change is tightly connected with economy, students' reasoning of coping with climate change in relation to economic development was examined.

Climate change is now beyond dispute. China, one of the major carbon emission countries, has compelling obligations to reduce CO₂ emissions and to mitigate climate change. Against this backdrop, we studied how Chinese youngsters, the future decision makers, understand climate change from natural scientific, moral, and economic perspectives.

Aims

Three questions were addressed in our study: How do students understand the phenomenon of climate change, or the enhanced greenhouse effect (EGHE)? What is students' moral reasoning in relation to climate change? How do students conceptualise the tensions between economic development and environmental protection in order to mitigate climate change?

Methodology

The participants of the study were students of 14-16 years of age, studying at three different Green Schools in the Beijing area of China. Green Schools is an international concept, focusing explicitly on environmental education.

Data was obtained through semi-structured interviews. Nine group interviews were conducted, aiming to investigate questions regarding the phenomenon of climate change, the causes and solutions to climate change, and its relationship to economic development.

The transcript data was analyzed from an intentional perspective; an analytical method for interview data. By adopting an intentional perspective, the utterances were seen in the interactional as well as wider institutional and cultural situation. Therefore, students' competences were scrutinized according to a careful investigation of both cognitive competences and context simultaneously.

Findings

As stated, we explored three research questions and the following, we describe briefly our findings.

First, how do students understand the phenomenon of climate change, or the enhanced greenhouse effect (EGHE)?

In explaining the phenomenon of climate change, the students have used and incorporated a lot of information. Some information is related to climate change, some is not, like evaporation and the tilt of the earth, and some is only related to environmental problems such as pollution and the depletion of ozone layers. The students reorganized these diversely different pieces of information into coherent entities. For example, a boy student modelled the EGHE in the following way; there are two "tops" of the earth, which are the polar regions; pollutants rise up to the tops and destroyed the ozone layers; the holes of the ozone layers above the polar regions allow more sunlight to come reach the earth; the sunlight cannot escape because the earth is wrapped in the atmosphere which is like a blanket to the earth; and the spinning of the earth spread the heat from sunlight to other parts of the world.

Second, what is students' moral reasoning in relation to climate change?

The students attributed the causes of climate change to emissions from factories and driving cars, and they dedicated themselves to finding solutions to climate change. The solutions that were suggested by the students mainly concern taking actions by the individuals, where the individual is either "myself" or "someone else". Interestingly, as a consequence this brings forth two different ways of moral reasoning, resulting in different relationships and considerations for nature and society.

When the individual is "myself", a student is likely to be more anthropocentric, which means that her/his personal needs and interests are stressed, and the aspect of nature is not discussed and thus excluded in her/his reasoning. Society gives support to "me" to overcome difficulties. When the individual is "someone else", the students are more concerned with the environment and nature. But society and the government played a role of executing power - and punishment - if the individual is "someone else".

Third, what are students' views of the tensions between economic development and environmental protection in order to mitigate climate change?

The students did not address the linkage between producing and driving cars, using coal for energy supply in the factory, and the problem of climate change. Instead, for them, the focal aspect of the task concerned economic development. With regard to environmental problems, they suggested that environmental problems are inevitable, and even a necessary part of economic development, and that environmental problems can be easily solved by scientific and technological means.

Theoretical and educational significance

The investigation of the first research question shows that students create coherent wholes, even if they are incorrect in relation to scientific understanding of the EGHE, which make sense for the students and have powerful explanatory value for them: they help the students to relate disparate pieces of information together and thus solve a lot of problems at the same time. Modelling coherent wholes of the EGHE, or perhaps solving other learning problems, can be necessary stages in the learning process. In this modelling process, some pieces of information are given up, and new pieces of information incorporated, thus approximating the normative models more and more. Therefore, it is desirable that the focus of teaching shifts from changing what is considered 'wrong' to trying to understand how students actually process their acquired knowledge. Therefore, this results are of significance to current research developing learning theory within the constructivistic tradition (e.g. Vosniadou, 2008).

The investigation of students' moral reasoning can be seen as an example of a social dilemma. This is an important topic worthy of being addressed and explored in environmental and science education. Furthermore, environmental/socioscientific issues are multifaceted but students are often expected to reason in a specific context and to understand "what problem goes where". However, research shows that handling socioscientific problems is challenging, as it requires the development of skills where students come to identify different perspectives or different contexts.

The investigation of students' reasoning of climate change in relation to economic development indicate the importance of giving students opportunities to discuss societal and public aspects since actions solving environmental problems are collective (Gardner & Stern, 2002). Also, the results highlight the importance of addressing economic issues, which includes the consideration of not only social benefits, but also environmental benefits and costs (Lundholm, in press).

Students' understanding of pricing goods and services with negative environmental effect

Caroline Ignell, Stockholm University, Sweden; Peter Davies, University of Birmingham, United Kingdom; Cecilia Lundholm, Stockholm University, Sweden

This paper will report results from the first phase of a longitudinal study on students' systems understanding and focuses on conceptions of price linked to negative environmental externalities.

There is a need of research, conducted with respect to students' understanding of environmental problems, within the field of social sciences as modern times demand that students not only develop scientific understanding of environmental problems, but societal and economical understanding as well. Data were collected using a questionnaire with open-ended questions, distributed to students in Swedish upper secondary schools, followed by individual interviews. Preliminary results show that student tend to give explanations of why a particular good, e.g. a hamburger, a pair of jeans or a travel ticket, has a particular price by referring to the demand side or to the supply side but seldom combine them in a system, which interrelate and create price equilibrium. Also, students reasoning on what should be priced when considering environmental consequences of flight travels, reveals an interesting opposite view from pricing external effects in general today.

The results are discussed in relation to previous studies on students' understanding of pricing, which have focussed on early years, up to 14, and undergraduate students, thus leaving students of 16-19 aside.

Aims

This paper will present results from the first phase of a longitudinal study that aims to explore students' systems understanding and in particular in conceptions of price and negative environmental externalities. Earlier research on learning economics mainly focuses on children's progressive understanding of different concepts as money and price (Berti & Bombi 1981; Davies & Lundholm, 2008). It is also shown how economic understanding is qualitatively different, mainly depending on how children understand indirect and direct causal and proportional relations of demand and supply (Siegler & Thompson, 1998; Thompson & Siegler, 2000). This raises the question of how causal and proportional relations, seen as qualitative differences in system understanding, are developed by students in the age of pre-university and this is the overall interest of the study.

Methodology

To increase the possibility of finding slowly developing processes of understanding, a longitudinal study approach is chosen. A second and more specific argument for conducting a longitudinal study relates to research on conceptual development that sees understanding and learning as a gradual shift towards scientific explanations of a concept, rather than replacement of one conception with another (Caravita & Hallden, 1994; Hallden, Scheja & Haglund, 2008.) In general, there are few longitudinal studies concerning students' understanding of social science concepts as the existing research is focused on concepts of science (Hellden, 2005). To reach variation in students understanding of price and systems, a pilot study followed by a main study is set up. The pilot study, reported here, includes interviews

of a sample of 30 students, generated through the use of a questionnaire with open-ended questions, distributed to 90 students. The questions concern pricing everyday goods and services such as travel tickets (flight versus train), hamburgers, bottled water, computers and a pair of socks and jeans. Findings reported here, will allow for designing the main inquiry which will be distributed to students in year 2, and followed-up, in year 3 of upper secondary schools where students attend a three-year educational program of Social Science and Economic.

Findings

Preliminary results show that students' economical reasoning about pricing goods and services, with regard to environmental effect from production or consumption, mostly concern the area of demand or supply. Students seldom combine the two in a system, which interrelate and create price equilibrium, to explain the price of a particular good. The price of a hamburger is for example decided by the restaurant's geographical location or the quality of primary products or wages for employees at the restaurant. Similar reasoning is found regarding the price of a flight ticket from Stockholm to London compared to a train ticket for the same destination where the price determinants lie within the service itself. A train ticket is more expensive because the journey lasts longer and the train passes through several countries.

This can be compared to earlier research that notes how younger children in the age of preschool see the physical characteristics of a good, as determining price. A diamond does not cost much "because it is so tiny", while the price is higher for a book than a wristwatch because "it is bigger" (Burris, 1983). When asked how the flight should be priced, most students considered environmental consequences of flights as needed to be paid for and included in the tickets/price. They revealed an interesting view of pricing external effects, as a lot of environmentally friendly products and services in today's society are more expensive than non-environmentally friendly.

Theoretical and educational significance

The results reported are of theoretical significance as they contribute to the sparse evidence base of upper secondary students' system understanding and pricing related to environmental externalities. It will also, in a broader sense, contribute to the knowledge of how students develop conceptions and system understanding within social science. From an educational point of view the results also add to discussions on content matter and instruction in economical and environmental education at the pre-universal school level. This project distinguishes earlier work in that it is a longitudinal study and the first of its kind, it focuses on an age group that has received very little attention, and, it considers the wider societal context of price in contrast to earlier work (Webley, 2005) as it addresses understanding of price related to environmental issues as climate change.

A phenomenological study of outdoor environmental education for children in the Netherlands

Marlon Van der Waal, Wageningen University, Netherlands; Arjen Wals, Wageningen University, Netherlands

Several studies in the Netherlands and elsewhere indicate that basic knowledge of children about the natural world is declining as a result of many factors including: the decrease in time spent at school for EE, the lack of attention to nature at teacher training colleges, the lack of suitable natural outdoor playgrounds in urban areas, parental fears for the safety of children playing outdoors and the seductive attraction of modern ICTs. Against this backdrop, this paper reports evidence that deep and meaningful engagement in and with nature and the outdoors can have a profound influence on children's future predisposition in adult life towards issues related to nature and environment.

Relevance & significance

Several studies in the Netherlands and elsewhere indicate that basic knowledge of children about the natural world is declining as a result of many factors including: the decrease in time spent at school for EE, the lack of attention to nature at teacher training colleges, the lack of suitable natural outdoor playgrounds in urban areas, parental fears for the safety of children playing outdoors and the seductive attraction of modern ICTs. Against this backdrop there is some evidence, albeit scarce, that deep and meaningful engagement in and with nature and the outdoors can have a profound influence on children's future predisposition in adult life towards issues related to nature and environment.

Aims

In the Netherlands a number of environmental education (EE) programs have been developed in order to (re)connect primary school children with nature and to stimulate their care for nature by taking them outdoors and allowing them to experience, what might be called, nature. These programs usually complement nature-oriented in-class lessons. To add to the evidence-based of the value of such programs and to have a better understanding of the kinds of learning experiences and the conditions allowing for such experiences to unfold in a meaningful and profound way, the Dutch government, the (former) ministry of Agriculture, Nature Food Quality (LNV), commissioned an in-depth study of one program known for its experiential design and its careful linking of outdoor learning and school-based learning: Natuurwijs (NatureWise).

Methodology

A phenomenological study was designed in which children (age 7-12) of eight school classes of six primary schools (with an average of 28 children per class) were followed for two years in order to reach a better understanding of these issues. Using a phenomenological research method, the researchers are not seen as distant observers, but participate fully and personally in the actual 'meeting' of the individual children and create an atmosphere that sets aside taken-for-granted assumptions as it starts from a perspective relatively free from hypotheses or preconceptions. Phenomenological methods can be seen as particularly effective at making explicit the experiences and perceptions of individuals from their personal perspectives and are therefore able to challenge structural or normative assumptions. In the study 'NatuurWijs' is used as case study for each of the urban and countryside schools. The activities of this outdoor program are designed to match the development and the real life experiences of children from the age 7 to 12 and also to match the learning goals of formal education and EE policy. The NatuurWijs program offers schoolclasses the possibility to go outdoors with an official State Forestry ranger for three days. Before these days in which children are allowed to discover relatively undisturbed natural areas by means of their 'head, heart and hands', three preparatory lessons are given and afterwards three reflective lessons. When incorporated in the school curriculum this would mean that children would engage in 9 learning activities on a structural basis. As the NatuurWijs program is longitudinal by character, it is seen as a suitable program for a longitudinal study.

Half of the participating schools are located in urban areas and the other half are located in the countryside, as it is assumed usually that nature experiences will differ considerably as the availability of nature for urban children is reduced. One class in a school participates in the outdoor program while a parallel class from the same school does not follow the outdoor program and is therefore might be regarded as a control group. As not all schools have parallel classes four schools agreed to provide either an 'outdoor group' or a control group.

Data are collected by using 4 research instruments: personal interviews, workbooks, participant observations and 'mind maps' of nature. The interviews are held with teachers and repeatedly with a selected group of 64 children from both the outdoor groups and the control groups throughout the two years. These interviews are about their experience of their daily life: a description of where they live, what they do after school, how the children experience going to school, how they experience EE at school and their relation with animals, plants and natural objects, etc.. In total the selected group of children is interviewed twice before the outdoor groups engage in their outdoor program, twice during the period of the outdoor program and twice after the program.

The use of specially designed workbooks offers a different way of gaining insight in the lives of the children and the importance of nature in their lives. In the first of the three workbooks the children reflect on their memories as very

small children. They write and draw their former favorite places to play, their fears, and their activities at home and outside. The second workbook is dedicated to their experience of their current daily life and the third workbook focuses on their expectations of the future. Again, the workbook assignments give children the opportunity to verbally and graphically reflect on their experiences. Outdoor groups are also observed during their outdoor program in which the researcher fully participates and all groups (outside and control groups) are observed during class and when their teachers engage in EE of science activities. Finally all children make a personal mind map of 'nature' at the start of the research program and at the end of the program.

Results

When having collected all the data the researchers will look for patterns in order to establish categories of experienced meaning of nature in general and the outdoor program in particular that can possibly lead to adaptations to both formal school programs and nature programs. At the moment data of the pretest are being analyzed but the first results will be available in the Spring of 2011 and will be shared at the EARLI conference in August of 2011.

SYMPOSIUM

Professional Development of Experienced and Novice Teachers: Mechanisms for Resistance and Change

Chairperson: Liisa Postareff, University of Helsinki, Finland

Organiser: Liisa Postareff, University of Helsinki, Finland

Discussant: Jan Vermunt, Utrecht University, Netherlands

Research on teacher development has focused on analysing the changes teachers experience in their career, for example through participation in professional development programmes. Resistance to change, although commonplace in professional development efforts, has gained less research attention. The symposium focuses on how individual teachers at different stages in their career confront change or development when faced with new challenges.

Two contributions focus on examining development paths of academics who participate in a professional development course to improve their teaching pedagogies. Both studies identified resistance and withdrawal among experienced teachers, including those who conceived themselves as expert teachers. The third contribution focuses on experienced teachers who take up new roles as teacher-researchers and who exhibit non-learning in response to this professional development endeavor. In all three studies, mechanisms and reasons for resistance and non-learning are identified and discussed. Theories of cognitive dissonance, mental resistance and avoidance, and teacher identity are used to explain the appearance of these responses under investigation.

These studies are particularly relevant in the context of teacher improvement, which is seen by many as the key to any educational innovation. By understanding resistance, withdrawal, and non-learning, teacher educators can more effectively support teachers who are faced with the challenge of learning and development along their own career paths.

Trajectories of Novice and Experienced Teacher Educators in a Professional Development Community

David Brody, Efrata College of Education, Israel; Linor Hadar, University of Haifa , Israel

Stages in career paths have been found to influence the effectiveness of professional development endeavors (Berliner, 2001; Borko, 2004). This study examines professional development trajectories of novice and experienced teacher educators who participated in a Professional Development Community (PDC) focused on infusing thinking into college level teaching. During two yearlong projects for separate groups of teachers, we conducted narrative interviews with ten teacher educators at different points in their careers at the college, seven experienced and three novices. Three times during the year, they were asked to reflect on the PDC's influence on their personal and professional development. Data from these interviews were triangulated with field notes, session recordings and reflective writing of the participants. We identified four stages of professional development in our PDC: anticipation and curiosity, withdrawal, awareness, and change. While all of the teacher educators were found to move predictably from one phase to the next, we found a marked difference in the paths of the novices and experienced teachers who without exception proclaimed their expertise in thinking education, thus they are referred to as experienced experts. The experienced experts entered and often remained in a state of withdrawal, unable to successfully adopt pedagogic changes, while the novices comfortably moved towards awareness and change. Cognitive dissonance theory is used to explain these differences, and implications for designing successful professional development projects are discussed.

Aims

Professional development of teacher educators is a critical element affecting curriculum change which supports higher order thinking (Stes et al, 2010). Our research addresses the effectiveness of the professional development community for teaching improvement, both as a group process (Hadar and Brody, 2010) and individually (Brody and Hadar, 2010). Differences in career paths have been found to influence the teachers' professional development (Berliner, 2001; Borko, 2004; Glaser, 1996). This study explores differences between professional development trajectories of novices and experienced teacher educators who participated in the professional development community (PDC) and to understand the mechanisms by which this development occurs by group. The terms novice and experienced expert are drawn from self definitions of teacher educators relating specifically to thinking education. The correlation between years of teaching and self definition as expert varies considerably and is based on teachers' views of levels of experience and expertise in thinking education.

Methodology and data analysis

Two separate yearlong PDC projects involved twenty faculty members committed to exploring thinking education in their work. A variety of qualitative methods included narrative and group interviews, audio recordings of group sessions, reflective writing, and field notes. Differences between professional development processes and outcomes between novices and experienced experts were identified using the form based mode which explores structure of narrative material (Lieblich et al, 2004). This analysis enabled monitoring of both progression and regression in personal professional development of the participants (Gergen and Gergen, 2000). Grounded theory analysis identified preliminary categories, and narratives were examined again for similarities and differences between individuals. Triangulation was achieved by corroborating these themes with other data sources revealing changes in teacher beliefs and attitudes over time, thereby generating distinct trajectories of development between novices and experts.

Findings

Teacher educators were found to progress through four stages which began with curiosity and anticipation and quickly evolved into a significant withdrawal period. Participants who emerged from withdrawal moved to a stage of awareness of possibilities for implementing new pedagogies, enabling change, which is marked by a positive disposition toward infusing thinking into practice. This examination of novice and experienced expert trajectories revealed distinct patterns. Both groups began with curiosity and anticipation; however, as they moved into withdrawal, the experts regressed to a defensive position of satisfaction with current practice and rejection of new methods. Some remained in stasis at this phase, exhibiting apathy towards change. Others moved onto awareness, and then change. In contrast, novices withdrew into a passive moratorium of observation and delayed implementation, followed by awareness of possibilities for change and actively adopting new methodologies.

Theoretical and Educational Significance

This study points to the decisive role of individual trajectories in the effectiveness of professional development endeavors. Our findings differ from Berliner's (2001) perspective regarding responses of expert and novice teachers in the face of curricular or pedagogical innovations. While he characterized experienced experts as flexible and autonomous, we found that them to experience deep withdrawal, inhibiting implementation of new methods and hindering their professional development. Furthermore, Berliner describes the novice teacher as rigid when dealing with unfamiliar situations, while our data show willingness to applying new methodologies to their practice. Differences between experienced experts and novices are explained by understanding how the PDC affects professional identities of each group.

Changes in identity significantly affect the ability of teacher educators to advance professionally. Borko (2004) claimed that the teaching role is contextual, and teachers often find themselves to be expert in one domain and novice in another. In the context of the PDS, experienced expert teachers see themselves in the novice role, experiencing cognitive dissonance between their identity as expert and their lack of knowledge in the proposed innovative pedagogy. Uncomfortable with this situation, they reframe their current practice, claiming expertise in thinking education, thereby obviating pedagogic change. Withdrawal into this self declared status of expert resolves the dissonance created by the PDC. Novices, on the other hand, find no such dissonance. Accustomed to lack of familiarity with new pedagogies, they are more willing than their experienced colleagues to attempt new practice without a threat to their identity. The absence of cognitive dissonance enables them to move comfortably from withdrawal to awareness and then to change.

This study suggests reconsidering the professional development needs of novice and experienced expert teacher educators. Because the stage of withdrawal is inevitable, professional development initiators might consider developing strategies which support experienced expert teachers to move out of this stage towards change.

Moreover, effective professional development must take into account how personal and professional identity changes in the context of these endeavors and how they affect efforts to improve teaching.

Development paths of university teachers during a pedagogical development course

Liisa Postareff, University of Helsinki, Finland; Anne Nevgi, University of Helsinki, Finland

Research on development of university teachers followed by participation in pedagogical development courses has focused on analysing changes at group level. Individual development paths and a possible resistance to change have gained little attention. The present study analyses reflection diaries of 18 academics who has participated in a 10 credit (European Credit Transfer System) pedagogical development course. The diaries were content analysed, and the teachers were grouped into five different categories depending on what kind of development paths they represented. Most teachers described different types of changes followed by participation in the course, but four teachers' descriptions were characterized by a resistance to change. The results suggest resistance to change is found among teachers who hold a very strong teacher identity or a strong view of an ideal university teacher.

Background and aims

Previous research has shown contradictory results of the effectiveness of pedagogical courses organised for university teachers. Some research has shown positive effects of such courses (e.g. Gibbs & Coffey, 2004; Postareff et al., 2007) while other research has found changes only in some aspects of teachers' approach to teaching (Stes et al. 2007) or no evidence for changes in teachers' behavior or conceptions (e.g. Ho et al., 2001). Most of the previous studies have analysed and reported changes at group level, while analysis focusing on individual teachers and possible resistance to change has gained less attention. One study which has dealt with resistance to change among academics suggests that the resistance may be related to the identity formation as an academic (Winberg, 2008). University teachers' professional is usually strongly based on being a researcher (e.g. Knight, 2002). Participating in pedagogical development course offers teachers both challenges and possibilities to construct their teacher identities besides researcher identity. According to Guskey (2002), resistance might occur if teachers do not have possibilities to experience how changes in teaching practices affect student learning.

The aim of this study is to analyse teachers' development paths during a pedagogical course. The aim is to capture variation in how teachers describe and experience the courses and in how they describe their development as teachers and development of their teacher identity during the course.

Methodology

The study analyses reflection diaries of 18 academics which were written during a five-month, 10 credit pedagogical basic course at the University of Helsinki. The 18 teachers (10 female, 8 male) represented a range of different

disciplines, and their teaching experience varied from 0 to 25 years. The teachers were aged between 29 and 50 years. Teachers' academic positions at the university varied from doctoral student to senior lecturer and professor. The reflection diaries were content analysed by both authors independently. According to the instructions of the diaries the teachers received, the analysis focused on the teachers' descriptions concerning their motivation to participate in the course, their teacher identity and the changes they experienced during the course. It was noticed that there were similarities among certain teachers in how they described their development and changes. Both authors reanalysed the data from this perspective and identified teachers who described the development paths in a similar way. High consistency between the categorizations of similar paths was found and unclear cases were discussed in depth.

Findings

First, the analyses focused on identifying what kind of changes the teachers described. The changes were sorted into three categories: 1) changes in conceptual level, 2) changes in practical level, and 3) changes in teacher identity. However, it was noticed that there was variation in the depth of descriptions concerning change, and that change or development was not described in all diaries. Furthermore, there was variation in how teachers described their motivation to participate in the course and their teacher identity. When analysing teachers' motivation, teacher identity and the changes they described, five different types of development paths were identified from the reflection diaries.

- 1) Motivated teachers with a discrete profession and weak teacher identity who described lots of changes
- 2) Young and unexperienced teachers with a weak teacher identity who learned more than they expected
- 3) Young and unexperienced teachers holding a practical orientation who learned new teaching practices
- 4) Unexperienced teachers with a weak teacher identity who described resistance at some point, but eventually described changes
- 5) Experienced and un-experienced teachers who conceive themselves as expert teachers, who were resistant to change

There was no variation in teaching experience between the teachers who were open to change and those who were resisted. Thus, the results imply that the amount of prior teaching experience does not explain variation in how teachers experience pedagogical courses or in how they develop as teachers. The results suggest, however, that if the teacher conceives him/herself as an expert teacher, or holds a very strong conception of an expert university teacher, the conceptions they hold and practices they apply are likely to be resistant to change.

Theoretical and educational significance

Previous studies have reported on changes teachers experience as a result of participating in pedagogical courses (e.g. Gibbs & Coffey, 2004; Postareff et al., 2007; Stes et al., 2007). Shifting the focus towards individual development paths makes it possible to analyse reactions and descriptions of those teachers who do not exhibit change. From a more practical perspective, it is important to recognize teachers who are resistant to change and analyse factors causing resistance. Furthermore, it is important to consider how these teachers' learning could be supported in pedagogical courses.

When a university teacher participates in a pedagogical development course, his/her identity as an academic and as a researcher becomes challenged and negotiated with the new concepts and theories of teaching and learning (Winberg, 2008). If a teacher has no possibility to experiment new teaching methods in teaching during the pedagogical course, as proposed by Guskey (2002), it may be that the teacher rejects the theories as unnecessary and his/her identity as an academic remains unchallenged. In pedagogical development programmes, the value of new pedagogies should be addressed to minimize the possible resistance to change.

Experienced teachers' non-learning: mechanisms of mental resistance and avoidance

Paulien Meijer, Utrecht University, Netherlands; Helma Oolbekkink-Marchand, Radboud University, Netherlands

This paper focuses on experienced teachers who volunteered to take up a new role as researchers but did not learn in relation to this new role and even seemed to resist such learning. This adds to studies about experienced teacher learning that mainly focus on the teachers who do learn what is expected. Three case studies were performed to examine processes of such non-learning among novice teacher-researchers. The results were interpreted using theories of, among others, Illeris (2007). He described similar processes in terms of mental resistance and avoidance, which he sees as two of the main barriers to learning. Although small-scale, the study provides some interesting insights into the processes that take place when the intended teacher learning does not occur. This has several types of consequences for both research on teacher learning and initiatives regarding teacher professionalization.

Experienced teacher learning is studied by many scholars and from various perspectives. There is general agreement that teachers should continue to learn throughout their career, because of continuous changes in society, in subject matter knowledge, and in knowledge about pupil and student learning. Yet, studies show that experienced teachers find it difficult to keep on learning and to go on developing their knowledge, skills, and attitudes. In addition, many teacher trainers are confronted with teachers who are unwilling to learn or develop themselves, a phenomenon also noted by policy makers who expect teachers to change according to mandatory innovations. Teachers' willingness to learn appears to be an issue of considerable importance (Vermunt & Endedijk, in press), particularly what happens when this willingness is absent.

This paper focuses on teachers who fail to learn or change and who even seem to resist learning. We focus on teachers who are faced with new roles, which they assume voluntarily. In the Netherlands, many experienced teachers take on a new role as a teacher-researcher, which requires of them that they systematically examine their own practice, or more generally practices at their own school. This is consistent with international trends in which teachers are increasingly seen as agents in their schools, and in which schools are increasingly seen as owners and generators of knowledge about education (Cochran-Smith & Demers, 2008). Many studies have been done in which the benefits are described of this type of role-change of teachers, for themselves, for schools, and for education in general (e.g., Zeichner, 2003). In this paper we in no way doubt these benefits. But we do want to shed more light on what happens in the not-so-successful stories, when no benefits are reported by the teachers involved. These stories are hardly described in literature, but they illuminate important aspects of experienced teacher learning and help explain what happens when this learning does not take place. Such insights provide clues about how to proceed with the desired innovations or changes, or how to coach these specific teachers.

Three case studies were performed involving experienced teachers who had indicated that they had learned hardly anything as a result of their new role, even when adopting a broad view on learning that includes acquiring research skills and developing a critical stance towards their own teaching practice or school policies. These teachers were part of a larger study, in which most teachers indicated to have learned or changed as a result of their new role (Meijer et al., 2010). Interviews were conducted to understand the reasons and processes behind the non-learning. Contents of the interviews were first analyzed using a grounded-theory approach, in which categories were formulated that reflected the reasons and underlying processes for the teachers' non-learning. After that, these categories were related to theories about this topic. Results showed that the three teachers had different reasons for non-learning, but in general the processes they described matched Illeris' (2007) ideas about barriers to learning, specifically mental resistance to learning, ambivalence, and avoidance. Examples from the data that illustrate these concepts and how they work are provided in the paper.

In the conclusion section of the paper, the results are related to other studies about teacher learning that also provided some clues about the teachers who did not learn (e.g., Vermunt & Endedijk, in press). Also, links were found in a broad range of literature, for example, literature about student teacher learning and their identity development (e.g., Hong, 2010), and literature about change resistance, in which processes are described that prevent people in general from changing throughout their lives. Indications are provided about how to signal non-learning in an early phase, and how to deal with teachers when such processes occur. Also, with respect to research about teacher learning, a case is made for dealing with non-learning as a process of identity defence rather than unwillingness of a person.

SYMPOSIUM

Identifying key learning activities in strategy instruction in various ill defined do-mains.

Chairperson: Wilfried Admiraal, University of Amsterdam, Netherlands

Organiser: Gert Rijlaarsdam, University of Amsterdam, Netherlands

Discussant: Patricia A. Alexander, University of Maryland, United States

The symposium aims at the identification of effective instructional strategies in various domains of learning, in ill structured tasks. General idea is to bring together and to analyze intervention studies that focus on strategy development. The symposium will address the question 'What works in strategy instruction and why?' with variations in content (the strategy learned), the learning activity and the content domain. Therefore, we selected studies that were set up as componential analysis of instructional components (e.g. Fidalgo et al. in this symposium), studies that analyzed data from complex interventions with multi-components to isolate the contributions of each component to the total effect (for instance Glaser et al. in this symposium), and experiments that aimed at studying the effect of a single learning activity (Groenendijk et al., focusing on observation as learning activity). In three sessions, the symposium will deal with various domains (visual arts: divergent thinking; history: historical thinking and language arts: writing and reading literary texts). The domains have in common that they aim at thinking skills, and are seen as ill-structured

How do self-regulated writing strategies improve students' composition skills?

Joachim Brunstein, Justus-Liebig-University, Germany; Cornelia Glaser, Psychology, Germany

One of the most promising approaches to promote students' writing and self-regulation skills is Graham and Harris's Self-regulated Strategies Development (SRSD) model. Meta-analytic studies have found that SRSD is quite effective in promoting writing skills not only of struggling writers but also of normally achieving students. Yet, only little is known about how self-regulated writing programs help students become better writers and which processes transmit the associated treatment effects on measures of writing performance. In our research, we therefore sought to identify potential causal mechanisms through which procedures of self-regulated learning increase the efficaciousness of teaching young students strategies for writing stories. In general, we found that the addition of self-regulation elements to writing strategies trainings produced incremental effects on students' writing achievements, strategy-related skills, and subjective writing competence. Specifically, path analytic findings indicated that relative to teaching writing strategies alone, teaching strategies in tandem with self-regulation procedures improved students' skills of planning and revising stories and thereby led to superior achievements as reflected in the quality of compositions. Self-regulation procedures also augmented effects of the strategies training on students' knowledge and self-efficacy beliefs, both of which had a positive effect on the use of the learned strategies while planning narratives.

A considerable body of evidence suggests that teaching strategies for planning, writing, and revising text produces strong and lasting effects on the quality of compositions (Graham, 2006; Graham & Perin, 2007). There is also evidence that self-regulated learning methods are particularly effective in helping students acquire a strategic

approach towards writing (Glaser & Brunstein, 2007; Zimmerman & Risemberg, 1997). One of the most promising approaches to promote students' mastery of writing is Harris and Graham's (2009) Self-regulated Strategies Development (SRSD) model. SRSD combines teaching of strategies for planning and revising compositions with self-regulated learning methods, such as monitoring of strategy use, goal setting, and self-recording of learning progress. However, only little is known about the mechanisms that transmit the effects self-regulated writing strategies interventions have on writing performance. Accordingly, the purpose of this paper is twofold. We wanted (1) to demonstrate that teaching writing strategies in tandem with self-regulation procedures is more effective in promoting the quality of compositions than teaching strategies alone, and (2) to identify a chain of putative mediators explaining how self-regulated learning of cognitive strategies produces superior effects on writing achievements. We contrasted fourth graders who were taught strategies for planning and revising narratives in conjunction with self-regulation procedures such as self-assessment of one's writing performance, setting of outcome-related and procedural learning goals, and self-monitoring of strategy use ($n = 58$) with students who were taught the same strategies without instruction in self-regulation procedures ($n = 59$). Students in both conditions were taught by instructional assistants in mixed-ability groups of 4 to 6 students. Both programs were delivered in five sessions (one session per week) each consisting of two consecutive 45-min lessons. In accord with Harris and Graham's (2009) literature review, we hypothesized a set of four writing-related variables to transmit the proposed effects of self-regulated writing strategies on the quality of children's writing: writing knowledge, writing self-efficacy, prewriting planning, and text revisions. We postulated four direct effects from treatment condition (strategies instruction with and without self-regulation) to each of the target variables hypothesized to transmit the effects of writing interventions on students' writing products. We further expected both strategy-related planning and revising to have a direct effect on the quality of students' stories. In addition, we predicted two indirect effects: First, we expected planning to have an indirect effect on students' writing performance, through its influence on the quality of strategy-related text revisions with better plans predicting better revisions. Second, we postulated treatment condition to have an indirect effect on story plans via its influence on students' writing knowledge and self-efficacy beliefs. In our analyses of treatment effects and mediation relationships, we controlled for the clustering of students within instructional groups (intra-class correlations). For this purpose, we analyzed our data with the Mplus software package using the "Type is complex" command to account for the non-independence of data (Muthen & Muthen, 1998-2009). In each analysis we also controlled for individual differences in pretest measures. Results indicated that, both at posttest and at maintenance (6 weeks after intervention), students in the self-regulated writing strategies condition (a) received higher knowledge scores, (b) felt more self-efficacious about their skills of writing narratives, (c) created more complete plans, (d) made a greater number of strategy-related revisions, and (e) wrote qualitatively better stories than students who had been taught strategies alone. To determine the validity of our model, we followed Hu and Bentler's (1999) recommendation and used two fit indexes: the comparative fit index with a cutoff value of .95 and the standardized root mean residual with a cutoff value of .09. Pretest differences were statistically controlled by computing for each variable included in the model residual scores with pretest scores partialled out. We found the predicted model to fit the data quite well both at posttest and at maintenance. As predicted, treatment condition had a direct effect on each of the four writing variables. Further, the direct effects from planning to story quality and from revision to story quality were significant. Furthermore, the mediational chains from (a) treatment condition to self-efficacy, to planning, to story quality and (b) treatment condition to knowledge, to planning, to story quality were significant both at posttest and maintenance. The chain from treatment condition to planning to text revisions to story quality also turned out to be significant at both points of measurement (posttest and maintenance). Taken together, these results suggest (1) that an intervention that combines the instruction of writing strategies with self-regulation skills exerts a strong, coherent, and sustainable influence on procedural (planning and revising), declarative (writing knowledge) and self-related (writing self-efficacy) aspects of writing. (2) that the self-regulated writing program produced its incremental effects (relative to teaching strategies alone) on students' writing performance consistent with theories of self-regulated learning. Writing knowledge, self-efficacy beliefs, planning skills, and revision activities do not act in isolation but work together within a structured pattern of mediational relations to jointly transmit the beneficial influence the self-regulated writing strategies training has on students' task performance. However, strategic planning constitutes the central linkage point in our path-analytic mediation model, a finding consistent with the view that prewriting planning is an essential ingredient in the development of writing competence.

Instruction in revising by means of guided discussion

Olga Arias, University of Leon, Spain; Jesus-Nicasio Garcia-Sanchez, University of Leon, Spain

Writers may have difficulty revising due to limited knowledge or skills at any stage in the process and their overall metacognitive control of the complex revising process may be limited. Children's revisions often have little or no impact on the quality of their writing, so we would redirect the student's attention in the revision process, in order to teach the judgmental skills need both to detect the problem in the text, to recognize opportunities for improving the text and to improve it. The purpose of this study is to test whether guided discussion can be as beneficial in revising as in other domains. The sample of this study comprised 88 students, ranging from 13 to 15 years old and studying in 2nd grade of Spanish Secondary Compulsory Education. They were distributed over three experimental groups and a control group. In the experimental groups, the instruction was carried out by means of guided discussion and individual practice in re-writing the task. The control group received an extra class of ordinary curriculum. The revising procedure emphasized was the following: a) careful reading of the text provided, b) to detect errors and problems in this text, c) to think of and/or suggest improvements, d) re-writing the text, and e) to repeat steps a, b, c and d with your own text. The strategies used during individual practice were self-questions, guides and direct choices.

Writers may have difficulty revising due to limited knowledge or skills at any stage in the process, and their overall metacognitive control of the complex revising process may be limited (MacArthur, Graham & Harris, 2004). Children's revisions have little or no impact on the quality of their text, so we would redirect the student's attention in revision the process, in order to teach the judgmental skills need both to detect the problem in the text, to recognize opportunities for improving the text and to improve it. Revising is a complex process and it has a reflective nature, so that students at primary and secondary school level seem to adopt a least-effort strategy when revising, that is, they generally confine their revisions to local problems changing first what is easiest to change such as small word and phrase substitutions, followed by elaborations (Saddler & Asaro, 2007). Considering that the revision conducted by expert writers includes the overall structure, coherence, and meaning of the text as well as smaller issues of wording and errors (Midgette, Maraia, & MacArthur, 2008), we would like all students to internalize the strategies to realize a differential use of the various components of the revising procedure in all levels of the revision process. There is much evidence that demonstrates the effectiveness of instructional strategies to improve the quality of the texts written by students from various educational levels (Graham & Perin, 2007).

In this study we wanted to check whether guided discussion can be as beneficial in revising as in other domains like mathematics (Horner & Gaither, 2004), health (Williams & Binnie, 2002) and science (Hogan, Nastasi & Pressley, 2000). Guided discussion is a strategy that requires the student to engage actively in the teaching-learning process, because they discover the information they need to build their knowledge through brainstorming and critical thinking, which they secure with individual practice. This strategy stimulates reasoning, critical thinking skills, communication skills, group work and understanding. The sample of this study comprised 88 students, ranging from 13 to 15 years old and studying in 2nd grade of Spanish Secondary Compulsory Education. They were distributed over three experimental groups and a control group. The difference between the three experimental groups was the level of revision: one group worked on surface aspects of revision, the second group emphasized deep aspects and the third group emphasized both aspects of revision. The control group received an extra class of ordinary curriculum. The instruction was carried out by means of guided discussion and individual practice in re-writing the task during eight sessions. All sessions had the same structure. The first part of the session was focused on guided discussion, the teacher presented the topic and the first challenge was to encourage students' participation and reflection. After the guided discussion, a summary was made of the conclusions reached. To keep students' attention throughout the activity, they received a copy of the theoretical aspects that they had worked on, to incorporate into their personal files. The topics were: the revision process, revision categories, and the differences between editing and re-writing text to improve its quality. During the second part of the session, students had to practice the revising procedure. The revising procedure emphasized was the following: a) careful reading of the text proposed, b) to detect errors and problems in the text proposed, c) to think of and/or suggest improvements, d) re-writing the text, and e) to repeat steps a, b, c and d with their own text. In the second part of the session the students had to re-write a text. They

always had to follow the same procedure for each topic of the guided discussion. To facilitate the internalization of the process, students had to practice making use of self-questions, guides and direct choices, according to their needs. By means of IRCE (Instrument of Revision of Written Composition), quality, productivity, and revising measures were taken before and after completion of the instruction (GR: unclear). Results reveal that guided discussion is also effective in the domain of textual revision. Both the text quality as the detection and correction of errors are affected. It also affects the kind of writing activity carried out by the students.

Observational learning in argumentative writing

Martine Anne H. Braaksma, University of Amsterdam, Netherlands; Gert Rijlaarsdam, University of Amsterdam, Netherlands; Huub Van den Bergh, Utrecht University, Netherlands

Observational learning has shown to be an effective instructional strategy in various domains of learning, including writing. Several experimental studies in secondary education provided us insight in the strength of this instructional method in argumentative writing. We address three issues: (1) key processes in the observational process itself, (2) the effect of observational learning on the mediating variable 'writing processes', and (3) the role of learners' characteristics on the effects of observational learning.

Observers are strongly involved in metacognitive activities (observation of the writing of the models, identifying and conceptualizing the models' writing strategies, and evaluating and reflecting on the performance of the models). The performance of these activities suggests that observers have developed, applied, and internalized criteria for effective writing. Observational showed clear effects on the orchestration of the writing processes: writers who learned by observation performed relatively more metacognitive activities at the start and relatively more executional activities in the second part of the writing process than writers who learned by doing. They also showed for some activities a changing execution over time, whereas writers in doing-writing condition performed these activities at a constant rate during the writing process (i.e., a monotonous process). Learners' characteristics were found to play an important role in observational learning: model-observer similarity in competence facilitated learning. Weak learners learned more from focusing their observations on weak models, whereas better learners learned more from focusing on good models.

Learning by observing others who execute tasks has shown to be effective in various school subjects, including writing (e.g., Braaksma et al., 2001, 2002, 2004, 2006; Graham & Perin, 2007; Raedts, et al, 2008; Zimmerman & Kitsantas, 2002). From several experiments (students grade eight – grade eleven), we got insight in the strength of observational learning in argumentative writing. In our presentation we focus on three issues: (1) key processes in the observational process itself, (2) the effect of observational learning on the mediating variable 'writing processes', and (3) the role of learners' characteristics on the effects of observational learning. Key processes in observational learning From analyses of the learning materials and from an observation study, we found that observers are strongly involved in metacognitive activities. They observe the writing of the models, identify and conceptualize the models' writing strategies, evaluate the performance of the models and reflect explicitly on the observed performances. The performance of these activities suggests that observers have developed, applied, and internalized criteria for effective writing. Two of these activities were found to be crucial for the effectiveness of observational learning: evaluation and elaboration. Effects on writing processes

We examined the effects of observational learning on the orchestration of writing processes. We found that observational learning had an effect on the writing processes. Compared with writers who learned by doing/practising, writers who learned by observation 1. performed relatively more metacognitive activities (Goal-orientation and Analysis) at the start and relatively more executional

activities (Writing and Re-reading) in the second part of the writing process than writers who learned by doing; 2. showed more Planning activities over the whole writing process; 3. performed increasingly more Meta-analyzing activities, indicating monitoring and regulating processes, than writers who learned by doing; 4. showed for some activities a changing execution over time, whereas writers in doing-writing condition performed these activities at a constant rate during the writing process (i.e., a monotonous process). Finally, we found that the orchestration of writing processes performed by the students who learned by observation was positively related to the quality of the writing product. Effects of learners' characteristics on the effects of instructions We established that the same instructional method is not the most effective for every learner. Moreover, task familiarity seemed to play an important role. When a task is new, (1) weak students benefited more from observational learning (focusing on weak models) than from performing writing tasks as they are less likely to use metacognitive strategies such as monitoring, evaluating and reflecting. Moreover, they profited from observational learning because their cognitive effort is shifted from executing writing tasks to learning from writing processes of others. They can thus focus on the learning task, providing themselves with a learning opportunity to acquire new understanding about writing. However, weak learners benefited only from observational learning when they reflect on weak models, they did not profit from reflecting on good models. Our explanation of this finding is that it is easier to evaluate the weak model because the performance of the better model provides a frame of reference. Besides, the performance of the observed weak model probably matches the cognitive processes of a weak learner better. (2) better learners benefited not only from observational learning (focusing on good models) but also from performing writing tasks. They are probably able to divide their attention between writing task and learning task, and thus generate enough input for their learning by evaluating and reflecting on their own performance. However, good learners benefited only from observational learning when they reflect on good models, they did not profit from reflecting on weak models. Probably, the performance of a good model is more matched with the cognitive processes of a good learner. Moreover, good learners are able to identify and comment on the qualities of the good model, because they already have their own internal set of evaluation criteria available. When a task is familiar, (1) weak students benefited from performing writing tasks as much as they profited from focusing their observations on weak models' writing. Because the learners had already experienced successes with the tasks, they had a chance to construct knowledge about good writing, and thus were better equipped to learn from doing the writing task themselves. Reflecting on the performance of the better model however, was still not effective for these weak students. (2) good students profited only from observational learning with the focus on good models, not from focusing on weak models or from performing tasks themselves. Maybe, they need the challenge of explaining why the better model performed well. These results contribute to the research about the role that model-observer similarity plays in children's behavioural change (see Schunk, 1987).

SYMPOSIUM

Understanding and use of the inverse relation between addition and subtraction

Chairperson: Greet Peters, K.U.Leuven, Belgium

Organiser: Ineke Imbo, Department Experimental Psychology, Belgium

Joke Torbeyns, K.U.Leuven & GROUP T - Leuven University College, Belgium

Discussant: Michael Schneider, ETH Zurich, Switzerland

This symposium brings together three empirical contributions focusing on children's knowledge and use of the inverse relation between addition and subtraction. Because a good understanding of this principle is of fundamental importance in children's arithmetic knowledge, it is of great interest to those who study cognitive development and mathematics education. Furthermore, an efficient implementation of this principle also facilitates the solution process by eliminating computational effort. Indeed, a child who understands the inverse principle can immediately recognize that the outcome of $57+48-48$ is 57 because adding 48 is canceled by subtracting 48, or that $61-59$ can be solved flexibly by counting or computing how much has to be added to 59 to get at 61 (i.e., by using the indirect addition strategy). Two studies in this symposium show the impact of intervention on children's understanding and flexible use of the inversion principle. Using regression analyses, the third study provides a more detailed view on children's strategy choice process when solving simple subtraction problems. In sum, this symposium does not only increase our understanding of the developmental changes in children's understanding and use of the inversion principle but also offers building blocks to improve mathematics teaching on this topic.

Teaching children how to include inversion principle in their reasoning about quantitative relations

Peter Bryant, Oxford University, United Kingdom; Terezinha Nunes, University of Oxford, United Kingdom;
Deborah Evans, Oxford University, United Kingdom; Rossana Barros, Oxford University, United Kingdom

The basis of this intervention study is a distinction between numerical calculus and relational calculus. The former refers to numerical calculations and the latter to the analysis of the quantitative relations in mathematical problems. The inverse relation between addition and subtraction is relevant to both kinds of calculus, but so far research on improving children's understanding and use of the principle of inversion through interventions has only been applied to the solving of $a+b-b=?$ sums. The aim of the intervention described in this presentation was to study the effects of teaching children about the explicit use of inversion as part of the relational calculus needed to solve missing addend and missing minuend problems (inverse problems) using a calculator. The study showed that children taught about relational calculus improved their ability to indicate how to work out the solution to these problems more than those who were taught numerical procedures. They also showed a significantly better performance in change-unknown problems, which were not included in the training. The effects of the intervention were stronger when children were taught about relational calculus with mixtures of direct and inverse word problems than when these two types of problem were given to them in separate blocks. The success of this intervention study points the way to how children can learn to use formal expressions to represent quantitative relations, which is crucial for modeling and algebra.

Background

The basis of this intervention study is a distinction between numerical calculus and relational calculus. The former refers to numerical calculations and the latter to the analysis of the quantitative relations in mathematical problems. In a result-unknown problem, such as "Peter had 8 marbles; he played a game and won 3; how many does he have now?", the children are told about a quantity that someone had and a change to this quantity, and asked about the resulting quantity. In such problems, children need to implement a numerical calculation ($8+3=?$) but there is no need for a relational calculation. In contrast, in a start-unknown problem, such as "Peter had some marbles; he played a game and lost 3; now he still has 8; how many did he have before the game?", children must implement a numerical calculation ($8+3=?$) but they must also reason about the relations between the quantities: if he lost 3 marbles, he must have had 3 more before the game. Finally, some change-unknown problems, such as "Peter had 8 marbles; he won some in a game and he now has 11; how many marbles did he win in the game?" also require relational calculations. The inverse relation between addition and subtraction is relevant to both kinds of calculus, but so far research on improving children's understanding and use of the principle of inversion through interventions has only been applied to the solving of $a+b-b=?$ sums – i.e. to numerical calculus.

Aims

The aim of the intervention described in this presentation was to study the effects of teaching children about the explicit use of inversion as part of the relational calculus needed to solve start-unknown and change-unknown addition and subtraction problems (inverse problems) using a calculator. The motivation to use a calculator to solve the problems was created by presenting the children with problems in which the computations were beyond the limits of their calculation skills. This helped them realize the advantage of knowing how to work out the solution with a calculator and, therefore, to learn how to represent the solution using formal numerical expressions. Primary school children often solve missing addend problems using an adding-on procedure rather than subtraction. Although adding on is an efficient computation strategy, it must be distinguished from the formal numerical expression that models the solution through subtraction.

Method

The children (N=60) were recruited from two grade levels (2nd, mean age 7.13 years, and 3rd, mean age 8.02 years) in state supported schools in the UK and randomly allocated to one of three groups. They all participated in a pre-test, two training sessions, an immediate post-test, and a delayed post-test, given about 8 weeks later. The pre- and post-tests included three types of addition and subtraction story problem: result-unknown (direct), change-unknown and start-unknown (inverse). The children in the intervention group were only taught about the start-unknown problems; the change-unknown problems were used to assess whether they could apply their relational calculation skills to a different problem type. Two intervention groups were taught how to use the inverse relation between addition and subtraction in relational calculus in order to solve story problems with the help of a calculator. The control group was taught different ways of solving addition and subtraction computations using a number line, including the use of indirect addition to solve subtractions (i.e. counting up) and the use of compensation to solve additions (i.e. instead of adding 9, add 10 and then subtract 1). Thus the control group was taught about the inverse relation in the context of numerical calculus. The two intervention groups differed in one aspect: the block group solved all the direct (result-unknown) problems in the first session and all the inverse (start-unknown) problems in the second session whereas the mixed group solved a mixture of the two types of problem in both sessions. The control group solve the same computations that were required in the problems solved by the intervention groups during the two sessions. The procedure was as similar as possible during the sessions; children in all three groups worked individually with an experimenter; the problems and feedback were presented with the support of a computer.

Results

The groups did not differ at pre-test. At both the immediate and the delayed post-tests, the mixed group performed significantly better than the control group in start-unknown and change-unknown problems; the block group only performed better than the control group in the change-unknown problems. The effect sizes were moderate (Cohen's $d=0.6$) to high (Cohen's $d=0.9$) in these comparisons.

Conclusions and educational implications We conclude that children can be taught about relational calculus and improve their ability to indicate how to work out the solution to inverse problems in the first years in primary school. They performed significantly better than those only taught numerical procedures. This intervention study points the way to how children can learn to use formal expressions to represent quantitative relations, which is crucial for modeling and algebra. It has been suggested in the literature that children's informal methods of computation, such as the use of adding-on to solve subtraction problems, interferes with their learning of how to use numerical expressions that shows how problems can be worked out. It has also been suggested that this is a stumbling block to their learning of algebra. This study shows that it is possible to help children understand the difference between numerical and relational calculus by showing them how the latter are required to solve problems with calculators. Future research should investigate whether children can remain aware of this distinction and continue to use flexible computation strategies when they are not using a calculator but realize the significance of knowing how to work our solutions using formal numerical expressions.

Adaptive strategy use and recognition of tasks characteristics of German 3rd-graders

Aiso Heinze, Leibniz Institute for Science and Mathematics Education, Germany; Franziska Marschick, Leibniz Institute for Science and Mathematics Education, Germany

The indirect addition strategy based on the inversion principle is regarded as an efficient strategy to solve subtraction problems like $304-297$ with a small difference between the minuend and subtrahend. However, empirical results show that only a minority of primary school students use this specific strategy. We assume that the recognition of task characteristics like "small difference between numbers" is important for choosing indirect addition as an efficient strategy for a subtraction task. Analyzing task characteristics can support the interpretation of subtraction by a difference model instead of a take away model and, therefore, promotes the consideration of indirect addition instead of the straightforward application of a direct subtraction strategy. In a three-lesson intervention study with 54 3rd-grade students we addressed the recognition of task characteristics as a criterion for strategy choice, in particular for the indirect addition strategy. In a pre-test with items suggesting indirect addition or simplifying as efficient strategies, the students showed a low adaptive strategy use. In interviews, they referred to task specific criteria for their strategy choice only for 11% of their solutions for tasks suggesting indirect addition. After the intervention, this percentage of strategy choices based on tasks specific criteria increased to 35% and the adaptive strategy use increased significantly. Moreover, the references to task specific criteria were highly correlated with the efficiency of the chosen strategy. Referring to these results, we hypothesize that the analysis of task characteristics is an important element in teaching students the efficient use of the indirect addition strategy.

Aims and theoretical framework

There is a consensus among mathematics educators about the importance of adaptive strategy use in arithmetic, i.e., solving computation tasks efficiently by flexibly choosing a strategy which is advantageous with respect to task characteristics. An important role plays the specific strategy indirect addition based on the inversion principle. It is efficient for solving subtraction tasks like $304 - 297$ where the difference between minuend and subtrahend is small. However, empirical results show that only a minority of primary school students uses the indirect addition strategy for these specific subtraction problems (e.g., Selter, 2001; Torbeyns et al., 2009). A possible reason for these findings might be the fact that students' strategy choice is not based on task specific criteria rather it relies on subject specific criteria (e.g., "I know this strategy best.") or socio-mathematical norms (e.g., "Our teacher said we should do it this way."). We assume that recognizing task characteristics supports the interpretation of subtraction in these specific problems by a difference model instead of a take away model and, therefore, promotes the consideration of the indirect addition strategy instead of the straightforward application of a direct subtraction strategy. Accordingly, the question arises whether students' adaptive use of the indirect addition strategy can be fostered by teaching the analysis of task characteristics. More specifically, in an intervention study with grade 3 students we addressed the following questions: Is there a change in students' criteria for strategy choice? Is there a significant rise in students' adaptive use of the indirect addition strategy? Is the students' ability to solve the computation tasks correctly influenced by the intervention?

Methodology/ Research Design

The sample comprises 54 third graders from three different schools. According to their teachers, all students learned a variety of strategies before and show good mathematics achievement. The intervention took place once a week in groups of 7-10 students, parallel to regular mathematics lessons. It encompassed three sessions (each 45 minutes) which were administered by research assistants. The aims of these sessions were (1) repetition of different strategies, (2) recognizing task characteristics as criterion for strategy efficiency and (3) analyzing and rating the efficiency of different strategies for given tasks. In all sessions, different strategies were addressed but the indirect addition strategy was emphasized. In additional introductory and closing sessions, tests and interviews were administered. Pre- and post-test were identical and consisted of ten three-digit addition and subtraction tasks suggesting indirect addition or simplifying as efficient strategies. Each item was rated dichotomously regarding accuracy and adaptivity. Using the individual test booklet, each student was asked for her/his criteria of strategy choice for four of the test items immediately after completing the test. The answers were classified into five categories: task specific criteria, subject specific criteria, socio-mathematical norms, mixed criteria or no classification (= no or other criteria).

Findings

Figure 1 shows the results concerning the criteria for strategy choices for the two interviews tasks suggesting the indirect addition strategy. From pre- to post-test there is a substantial increase in the reference to task specific criteria for strategy choice. Moreover, the student responses which could not be classified decrease drastically. As expected, in the pre-test, students showed a low adaptivity in their strategy choice ($M = 2.19$, $SD = 3.11$; max. 10 points). Most of the students used the standard algorithms or the stepwise strategy to solve the items. About half of the students did not use any efficient strategy in the test. In the post-test, students showed a significant higher adaptivity in their strategy choice ($M = 3.56$, $SD = 3.60$; max. 10 points; Wilcoxon test: $Z = 2.693$, $p = .007$; effect size: $r = .37$). Nevertheless, about one third of the students still did not solve any item adaptively. For the five test items suggesting indirect addition as efficient strategy, only 5 of all 270 students' solutions (= 1.8%) based on this strategy in the pre-test. In the post-test, this increased to 47 solutions (= 17.4%). Regarding the relation between the frequency of reference to task specific criteria and the frequency of adaptive strategy choice, a significant correlation could be observed within the post-test data for the two items suggesting indirect addition as efficient strategy ($r = .51$, $p < .05$). For the accuracy of students' solutions, a small increase could be observed which was not significant (pre-test: $M = 7.65$, $SD = 2.23$; post-test: $M = 7.96$, $SD = 2.15$; max. 10 points for each test). So, there was no influence of the intervention on students' accuracy.

Discussion

In the pre-test, students showed a low adaptivity in their strategy use which increased significantly during the three lesson intervention. This increase of adaptivity did not change the accuracy which remains on a high level. Overall, the post-test results for adaptivity were still on a moderate level. For the five items suggesting indirect addition, only 17.4% of the solutions based on this strategy, though this strategy was emphasized in the intervention. After the short intervention, the percentage of strategy choices based on task specific criteria strongly increased for the indirect addition tasks and the reference to task specific criteria significantly correlates with the adaptivity of the chosen strategy. Based on these results, we hypothesize that the analysis of task characteristics is an important element in teaching students an adaptive use of the indirect addition strategy. However, this result is limited by the fact that we chose students with good mathematics achievement for our sample, i.e. students knowing various strategies. It is unclear which effects can be expected for students with a restricted strategy repertoire.

Children's use of the indirect addition strategy

Greet Peters, K.U.Leuven, Belgium; Bert De Smedt, University of Leuven, Belgium; Joke Torbeyns, K.U.Leuven & GROUP T - Leuven University College, Belgium; Pol Ghesquiere, Katholieke Universiteit Leuven, Belgium; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

Subtraction problems of the type $a - b = ?$ can be solved by means of various strategies. For the present contribution, we investigated third- to sixth-grade children's use of indirect addition on two-digit subtractions. We first examined regression models in which different problem characteristics predicted reaction times. Second, we compared performance on two-digit subtractions presented in 2 presentation formats, i.e., the standard subtraction format ($81 - 37 = .$) and an addition format ($37 + . = 81$). Both methods lead to the conclusion that children switched between direct subtraction and indirect addition depending on the relative size of the subtrahend: If the subtrahend was smaller than the difference, direct subtraction was used; if the subtrahend was larger than the difference, indirect addition was the dominant strategy. This strategy choice pattern was very clear when the distance between the subtrahend and the difference was large (e.g., $71 - 2$ and $71 - 69$). In contrast, when these two numbers were close to each other (e.g., $75 - 36$ and $75 - 39$), there was only a subtrahend-dependent strategy selection when the subtrahend was smaller than the difference: those problems were mainly solved by means of direct subtraction, whereas both strategies were used when the subtrahend was larger than the difference. This performance pattern was the same in each grade. These findings are of great relevance for mathematics education as they might challenge classroom practices that only focus on the routine mastery of direct subtraction.

Subtraction problems of the type $a - b = ?$ can be flexibly solved by means of various strategies. One way to solve them is by relying on the inverse principle between addition and subtraction (i.e., if $a - b = c$, then $b + c = a$) and asking yourself how much needs to be added to b to get to a . A rational task analysis indicates that this indirect addition strategy is particularly efficient on subtractions with relatively large subtrahends, such as $81 - 79$. This strategy can be clearly distinguished from the more common strategy of direct subtraction, in which the smaller number is directly subtracted from the larger one (e.g., $81 - 79 = .$ via $81 - 70 = 11$ and $11 - 9 = 2$). Previous work on children's and adults' use of indirect addition in the domain of elementary subtraction indicated that children hardly apply this strategy spontaneously, whereas adults solve subtractions efficiently and flexibly by means of indirect addition (see Verschaffel et al., 2010 for an overview). For the present study, we started from some intriguing results of post-hoc analyses of the study by De Smedt et al. (2010), in which third-grade children almost only reported the use of direct subtraction. If this was indeed the case, an increase in reaction times should have been observed from items with relatively small subtrahends ($81 - 7 = .$) over items with medium-sized subtrahends ($81 - 43 = .$) to items with relatively large subtrahends ($81 - 79 = .$), since subtracting a larger subtrahend requires more and/or larger calculation steps (Peters et al., in press). This reaction time pattern was not found: Problems with a relatively large subtrahend were solved significantly faster than problems with a medium-sized subtrahend, which indicates that the actual use of indirect addition might be greater than suggested by the verbal protocols. Therefore, these results justify the application of other (non-verbal) methods of inferring strategy use, which have already been successfully applied in the past, such as the regression-based approach (Groen & Poll, 1973; Woods et al., 1975) and the manipulation of presentation formats (Campbell, 2008; Peters et al., 2010). We presented 99 third- to sixth-grade children with 32 two-digit subtractions in 2 presentation formats, i.e., the standard subtraction format ($81 - 37 = .$) and an addition format ($37 + . = 81$). We first fitted children's reaction times to 3 regression models, which modelled the use of direct subtraction, indirect addition, and the switching between both based on the relative size of the subtrahend (see Groen & Poll, 1973; Peters et al., in press; Woods et al., 1975). For all four grades and for both formats, the model representing the switching between direct subtraction and indirect addition provided the best fit. In order to learn more about the characteristics that influence this strategy choice, we also compared performances between the two formats (see Campbell, 2008; Peters et al., 2010). We expected that the relative size of the subtrahend would only affect strategy choice when the distance between subtrahend and difference was rather large (as in $71 - 2 = .$ and $71 - 69 = .$) and not when these two integers were close to each other (as in $75 - 36 = .$ or $75 - 39 = .$), because in the latter case the computational advantage of one strategy over the other is not clear. However, a repeated measures ANOVA showed that small-distance problems with the subtrahend smaller than the difference (such as $75 - 36$) were solved preferably by means of direct subtraction, whereas both strategies were used to solve problems with the subtrahend larger than the difference (such as $75 - 39$). For the large-distance problems, strategies were chosen based on the relative size of the subtrahend, as expected: problems such as $71 - 2$ were solved by means of direct subtraction, whereas problems such as $71 - 69$ were solved with indirect addition. This performance pattern was the same in each grade. The only significant effect related to grade was a main effect on response times, showing that third-graders needed more time to solve the two-digit subtraction problems than the older children. To conclude, these results

reveal that primary school children from third grade on spontaneously and efficiently apply indirect addition on two-digit subtractions presented in the $a - b = \dots$ format. These results are thus in contrast with previous work on the use of this strategy, where verbal self-reports were used. Our findings can be of great relevance for mathematics education as they might challenge classroom practices that only focus on the routine mastery of direct subtraction.

SYMPOSIUM

Informing CSCL participants about their collaboration to promote collective and individual learning

Chairperson: Rupert Wegerif, University of Exeter, United Kingdom

Organiser: Alfonso Bustos, University of Barcelona, Spain

Manoli Pifarre Turmo, University of Lleida, Spain

Discussant: Paul A. Kirschner, Open Universiteit, Netherlands

Informing CSCL participants about their collaboration to promote collective and individual learning: Awareness tools to support collaboration Using research methods and tools along with a process-oriented approach is now common for achieving deeper understanding of learning processes in electronic environments (Gress, Fior, Hadwin, & Winne, 2010; Stahl, Koschmann, & Suthers, 2006; Suthers, Dwyer, Medina & Vatrappu, 2009). Three relevant aspects here are related to: How to capture the complexity of learning processes in CSCL; How to overcome the restrictions of analyzing the extremely complex CSCL environments by resorting to only one source of information or one single data analysis method (Dennen, 2008; Naidu & Jarvela, 2006), and How to inform CSCL participants about the whole process and their own individual implication to promote achievement of the desired objectives. This symposium will present and discuss several theoretical approaches and empirical results related to the importance of awareness in relation to CSCL. The symposium will contribute on research about the organizational aspects of CSCL activities and the possibilities and constraints of designing awareness tools to support different forms of collaboration among participants to encourage the collective and individual learning. The proposal has an important scientific and educational relevance in that it will help guide the design of more effective, efficient and satisfactory computer support scenarios for collaborative learning and discuss the uses and effects of awareness tools.

Incidence of group awareness information on students' perception about their CSCL processes

Manoli Pifarre Turmo, University of Lleida, Spain; Ruth Cobos, Universidad Autonoma de Madrid, Spain; Esther Argelagos, University of Lleida, Spain

For researchers in the fields of CSCW, it is of interest to establish how group awareness can be designed and implemented in such a way as to foster collaboration within computer-supported teams. User performance, user perception and satisfaction should be used as indicators of usefulness and usability of awareness features for a better group task resolution and in order to foster collaborative learning processes. This paper studies how the awareness services in the Knowledge Management system called KnowCat might enhance students' group processes to solve a collaborative learning task. The study focuses in knowing students' perception about the utility and the impact of the different awareness services used in their group learning processes. A questionnaire was used to assess seventeen university students' opinion and perception about how, when and for what they used the awareness services. Over 80% of students reported high levels of frequency of use of the different awareness information provided by the KnowCat system. Most of students agreed that the awareness information increased their perception of working collaboratively with other classmates. Moreover, the awareness information provided to the students seemed to help them to orientate, monitor and regulate their collaborative processes. In this line of argument, the widgets most used by students were those that gave graphical information about others users' contribution. Students revealed that knowing what, where and how many their classmates were contributing acted as a positive feedback which encouraged their participation and orientated their own cooperation behaviour and their contribution to the collaborative work.

Theoretical and educational significance

It is well known that members of work groups need information about one another, about shared artefacts and about the group processes. This information is often referred to as group awareness (Briggs, 2006). When this information is provided to the different group members and individuals receive feedback about highly cooperative co-workers individuals increase their rate of cooperation. For researchers in the fields of Computer-Supported Collaborative Work, it is of interest to establish how group awareness can be designed and implemented in such a way as to foster collaboration within computer-supported teams.

However, previous research has shown that the type of information presented and the design of presentation formats can influence people's experiences, perceptions and individuals' contribution behaviour (Ware, 2000). Four types of awareness that are relevant in computer-supported collaborative work are highlighted, named as informal awareness, social awareness, group-structural awareness and workspace awareness. Besides, many researchers highlighted the necessity to shift the focus to human-centred perspective on awareness in which features enabling mutual awareness of group members should be empirically tested with respect to their individual utility and group support. User performance, user perception and satisfaction should be used as indicators of usefulness and usability of awareness features for a better group task resolution and in order to foster collaborative learning processes (Gross, Stary & Totter, 2005).

In this vein, this paper studies how the incorporation of awareness services in the Knowledge Management system called KnowCat (Cobos, 2003), which supports collaborative knowledge construction can improve the students' group processes to solve a collaborative learning task. The study is centered in knowing students' perception about the utility and the impact of the different awareness services used in their group learning processes.

The proposed prototype of awareness services appears in a console in the bottom part of KnowCat. The Awareness console is composed by the following six awareness widgets: Registered Users. It provides brief information about the registered users in KnowCat. On-line Users. It provides relevant information of the on-line users in KnowCat: contact data and the current location of a selected user. Radar View. It provides the locations of the on-line users through a replicate knowledge tree of the KnowCat site. Moreover, in each topic of the replicated knowledge tree the number of the on-line users, who are interacting in each topic, is shown. History View. It provides chronically and graphically information about the realised tasks of a selected user. Participation view. It provides in a table information about the rates of users' participation in the different activities and knowledge spaces of the system. Notes View. It provides graphically information about interaction among users in the annotating task. Users can know which document was annotated, who annotated it and what was annotated. With this widget the users can see graphically how the annotation process is going on among the different group members.

Methodology

Participants

Seventeen university students participated in the study (Universitat de Lleida, Spain). They used KnowCat during a one-term period of one regular university course in the Psychopedagogy degree.

Procedure

Students used KnowCat to solve in groups two problems or case-study. Students had to design an educational intervention to attend two children with learning difficulties.

At the end of the semester students were asked to answer a questionnaire in relation to their collaborative work with the system. In the questionnaire there were eight groups of questions related to the students' use of the different elements of the KnowCat system, one of these groups referred to the awareness console.

Findings and Discussion

Over 80% of students reported high levels of frequency of use of the different awareness information provided by the KnowCat system. Most of students agreed that the awareness information increased their perception of working collaboratively with other classmates because the awareness services informed them efficiently about when and who has contributed with what and where.

The awareness widget most used by the students was the "participation view". This result is in line of previous research that confirms individuals orientate their own behaviour toward that of the other members of the group (Kimmerle & Cress, 2009). Students revealed that knowing what and how many their classmates were contributing acted as a positive feedback which encouraged their participation.

The awareness information catalogued by the students as the most useful were the "History view" and "Notes view", both widgets gave graphical information about users' contribution. Especially the "Notes view" gave graphical information about the annotation task. This task was relevant in the instructional use of the KnowCat system, students were strongly encouraged to use the annotation element as a way to scaffold and help a classmate to improve his/her work. As it is argued in previous research (Kimmerle & Cress, 2009) students highlighted that knowing graphically which documents were annotated most, who annotated and what was annotated orientated their own cooperation behaviour and their contribution to the collaborative work.

To sum up, the awareness information provided to the students during their collaborative work using the KnowCat system seemed to help them to orientate, monitor and regulate their collaborative processes. In future work we will intent to confirm this exploratory result with a larger number of students and assessing in more detail students' work using the system and how it is evolving during time as students gain experience in using the awareness information reported by the KnowCat system.

The collaborative learning activity reflect on the Computer Learning Environment and its impact on

Margarida Romero, Esade, Spain

The collaborative learning activity reflect on the Computer Learning Environment and its impact on the students' organizational and knowledge awareness. In distance Computer Supported Collaborative Learning (CSCL) tasks, the learners' activity is not always reflected through the Computer Learning Environment (CLE). The lack of reflection of the learners' activity hinders the development of a correct intersubjective perception of the teammates' activity (group awareness) within the group members. A low level of reflection of the collaborative learning activity could lead the learners' to underestimate their teammates' engagement in the CSCL task and develop a more negative group awareness of their teammates' organization and knowledge. Aiming to promote a better group awareness, we studied the impact of a reflective learning tool providing the students with a collaborative representation of the teammates' status and activity during the duration of the CSCL task. We analyze the impact of the Collaboration Awareness Tool EuroCAT both in terms of organizational awareness (perception of the teammates' organization and contribution) and knowledge awareness (perception of the teammates' knowledge on each of the learning objectives of the task). We analyze then the differences of this tool impact in the evolution of the students' organizational awareness and the evolution of the knowledge awareness within the task duration.

Theoretical and educational significance

Learners enrolled in Virtual Campus (VC) programs may have temporal or location constraints for attending the traditional university. For them, the VC spatiotemporal flexibility is both a necessity and a challenge for the regulation of their learning process on an individual and collective level. In collective learning situations in the VC, students not only face the difficulties of their own constraints, but they should consider their teammates' constraints for organizing the Computer Supported Collaborative Learning (CSCL) task. Nevertheless, in distance learning, the learners' activity is not always reflected through the Computer Learning Environment (CLE). The findings suggest that a lack of reflection of the teammates' activity and status through the CLE could hinder the group awareness development process. In CSCL, group-awareness refers to the understanding of the activities of others, which provides the background of one's own activity (Dourish & Bellotti, 1992). This intersubjective perception consider the knowledge of who is working and what has happened and how (Dix, 1997). For the last years, group awareness has been an emerging topic in research on CSCL, considering the study of group awareness typologies (Gross, Stary & Totter, 2005) and its development and its impact on the knowledge construction and convergence process, the social relations within the group and the performance impact of organizational and knowledge awareness (Bodemer & Dehler, 2010).

Aims and methodology

This study is focused on the impact of the mirroring capabilities of the CLE on the group awareness development difficulties during long term collaborative tasks. The findings suggest that the lack of reflection of the learners' activity hinders the development of a correct intersubjective perception of the teammates' activity (group awareness) within the group members. A low level of reflection of the collaborative learning activity could lead the learners' to underestimate their teammates' engagement in the CSCL task and develop a more negative group awareness of their teammates' organization and knowledge (Romero, Demeure & Lambropoulos, 2010).

Aiming to promote a better group awareness, we studied the impact of a reflective learning tool providing the students with a collaborative representation of the teammates' status and activity during the duration of the CSCL task. We analyze the impact of the Collaboration Awareness Tool EuroCAT both in terms of organizational awareness (perception of the teammates' organization and contribution) and knowledge awareness (perception of the teammates' knowledge on each of the learning objectives of the task). We analyze then the differences of this tool impact in the evolution of the students' organizational awareness and the evolution of the knowledge awareness within the task duration. We analyze the impact of the tool creating a quasi-experimental study including groups using the Collaboration Awareness Tool EuroCAT and control groups.

We considered some individual traits of the students and the group characteristics, such the group size and the degree of previous activity within the group members that we considered as the group history.

Findings and discussion

Results of the study indicate that not only the reflection capabilities of the CLE (use of the Collaboration Awareness Tool EuroCAT) but also the group history are important factors in the development of the organizational group awareness in long term CSCL tasks. Considering the group awareness as a perception of the teammates' status and activity, we could consider that the group will increase this group awareness throughout all their previous interactions before the task (group history) and duration of their collaboration.

Supporting Online Learning with Distributed Teaching Presence indicators

Alfonso Bustos, University of Barcelona, Spain; Cesar Coll, University of Barcelona, Spain; Anna Engel, University of Barcelona, Spain

Recent years have seen the development of a particular interest in the presentation of the output of Interaction Analysis (IA) in real-time (usually in a visualized form) to the participants in online learning environments to support learning and collaboration processes. However, there is a clear lack of proposals that incorporate a set of theoretically grounded IA indicators with a high level of interpretative capacity. This paper focuses on a number of potentially useful IA indicators concerning Distributed Teaching Presence and how the delivery of information related to these structural indicators has an impact on the level of the distribution of teaching presence between participants and on the learning process and the results. Three different conditions of information delivery were probed (no-information, personal and private information, and public personal and group information) with three different groups working in the same task in a Moodle forum. The results show that the groups that received information about DTP indicators (groups 2 & 3) exhibit the highest level of distribution and the highest diversity of profiles associated with the exertion of teaching presence. Finally, we will discuss some issues related with providing users with activity information in relation to the applied pedagogical methodology, the need to present information more efficiently, and the need to study the impact of previous information and training in using cues related to access, participation and connectivity in online learning environments.

Theoretical and educational significance

Interaction Analysis, IA, in computer mediated activities is usually based on the aggregation of interaction data from logfiles in a set of indicators, which are presented to the participants (usually in a visualized form and in real-time) in order to increase the effectiveness of learning and collaboration processes in online learning environments. According

to Dimitracopoulos (2008), one of the main challenges is to define theoretically grounded IA indicators with a high level of interpretative capacity, that is to say, indicators related with the quality of collaboration.

This contribution focuses on a number of potentially useful IA indicators concerning Distributed Teaching Presence, DTP. From our theoretical viewpoint, the concept of Teaching Presence (Anderson, Rourke, Garrison & Archer, 2001) has some similarities with the concepts of support adjustment and educational influence (Coll, Onrubia & Mauri, 2008). Seen from this perspective, progress in students' learning is mainly related to the educational influence of others, that is to say, the support and help provided through the students' and teachers' joint activity. Sometimes the support is mainly provided by the teacher, but other times it is highly distributed between participants. In this latter case, we talk of DTP. Collaborative learning, especially CSCL, requires a high level of DTP.

Our previous research, based on a multi-method approach to the study of the DTP, combining structural analysis of the participants' activity with content analysis of the participants' contributions (Coll, Bustos & Engel; in press; Coll, Engel & Bustos, 2009), has demonstrated the usefulness of a set of indicators of structural activity for the construction of participants' profiles in relation to the exertion of the Teaching Presence. Our model of structural analysis includes eight indicators. Five of them concern participants' presence (access and participation). The other three deal with the connectivity between the participants (reciprocity and responsiveness). The information provided by our model of structural analysis could be useful for students' regulation of group learning processes and the self-regulation of individual learning processes.

Aims and methodology

The objective of the present work is to analyze whether the delivery of information related to these structural indicators to the participants has an impact on the level of the distribution of teaching presence between participants and on the learning process and results.

The analyzed data come from a course included in a postgraduate program in Educational Psychology at the University of Barcelona. The participants consisted of three groups of students (6 members per group) who carried out the same learning task – the elaboration of a synthesis of the core content – through an online forum in the Moodle platform during four weeks. Group 1 was used as control group and its members did not receive any information about their activity. The other two groups were provided with information about their activity (access, participation and connectivity) on three occasions. In case of group 2, the members were personally and privately informed only about their own values of the indicators and their own profile. In case of group 3, the report was carried out collectively and all the members had access to their own values of the indicators and their own profiles as well as to the values of indicators and profiles of the other members in the group.

The values of the indicators were calculated on the basis of the logfiles that were provided by the system and were delivered by an adapted version of the GISMO system. The primary body of data used in the analysis of manifestations of teaching presence consists of all participants' contributions. This analysis applied a system of categories that considers three dimensions: the management of the social participation, the management of the academic task and the management of the meanings (Coll, Bustos & Engel, in press).

Findings and discussion

The results show a clear difference between the three groups with regard to the level of the distribution of the teaching presence between the participants, the dynamics of the collaborative work during the activity, and the learning results. Group 1 shows the lowest level of DTP, while group 3 exhibits the highest level; group 2 is at an intermediate level. Concerning the dynamics of the interaction and the collaboration, the most significant difference between the groups has to do with the occurrence of the noticeably differentiated activity profiles. The number and the diversity of profiles are higher in groups 2 and 3. These profiles reflect different modalities in the exertion of teaching presence and can be interpreted in terms of the assumption of roles within the framework of the online collaborative work. The evaluation that the teacher makes of the synthesis shows better results in groups 2 and 3, in contrast to group 1.

This work leaves some important questions unresolved, such as the issue of providing users with activity information relevant and adjusted to the applied pedagogical methodology, the need to examine alternative methods in order to present information more efficiently, or the need to study the impact of previous information and training in using cues related to access, participation and connectivity in online learning environments.

SYMPOSIUM

Learning from Multiple Documents: Individual Differences and conditions that foster comprehension

Chairperson: Marc Stadtler, University of Muenster, Germany

Organiser: Jean-Francois Rouet, Universite de Poitiers, France

Marc Stadtler, University of Muenster, Germany

Discussant: Rainer Bromme, Universitat Muenster, Germany

With the advent of the Internet in educational settings, research has gained in influence that examines how readers of different age levels comprehend multiple documents, which revolve around a shared topic. Indeed, there is growing evidence that having students read multiple texts can lead to deeper understanding of complex topics, compared to situations where they learn from a single source. There are, however, concerns that not all teenage readers readily possess the cognitive and language skills needed to face the specific requirements of reading and comprehending information across multiple and possibly heterogeneous documents. Therefore, researchers have tried to identify those cognitive processes and underlying belief systems, which differentiate between good and poor comprehenders of Multiple Documents. Within this line of research, variables such as prior knowledge, Epistemological Beliefs, Need for Cognitive Closure and the ability to accurately monitor one's comprehension have emerged as highly influential determinants of Multiple Documents comprehension. At the same time, research is burgeoning, which examines the instructional conditions that may promote effective reading, comprehension, evaluation and integration of multiple documents. The phrase "Instructional conditions" as we use it encompasses techniques such as preinstructions, guidelines, cueing, or more elaborated training curricula. The purpose of the symposium is to shed some light on what works, for what students and why. Presentations will be grounded into recent theories of document comprehension and present original empirical data regarding individual differences and the effectiveness of one or several of the aforementioned techniques with populations ranging from primary school to college students.

Comprehending multiple documents: Do readers benefit from linguistic markers of conflict?

Marc Stadtler, University of Muenster, Germany; Lisa Scharrer, University of Muenster, Germany

Our study examined whether rhetorical connectors (RC) in multiple science documents facilitate lay readers' acquisition of controversial information. This effect should be moderated by the goal readers pursue: Goals emphasizing argumentative differences between documents should amplify the beneficial effect of RC compared to goals requiring readers to focus on facts. We investigated this assumption with 121 undergraduate readers in a 2 (reading goals: "Summary" vs. "Argument Analysis Instruction") * 2 (presence of RC preceding claims) between-subjects design. Participants read nine medical web sites containing conflicting information under time pressure. Logfiles were recorded during reading. After reading, knowledge of intertextual conflicts and its application in a written communication situation were measured. Results revealed a beneficial effect of RC in terms of knowledge about conflicting information. Also, readers receiving texts with RC included more explicit references to the conflicting nature of information when communicating their knowledge to a fictitious friend. Navigational data supported the results by showing that participants receiving RC accessed texts that contained pairs of conflicting claims more often directly after one another. The expected interaction between reading instruction and RC was not supported by our data. Summarizing, lay readers benefitted significantly from the presence of RC when dealing with multiple documents. This result was obtained regardless of reading goal. Currently, we extend the picture by examining reading goals that involve less focus on macro-structure formation. On an educational level our study underlines the importance of metatextual knowledge when accessing large information resources, which require fast and efficient text processing.

Perspective and source effects when high-school students read multiple contradictory documents

Raquel Cerdan, Faculty of Psychology. University of Valencia, Spain; M^o del Carmen Marin Perez, Catholic University of Valencia, Spain; Eduardo Vidal-Abarca, Universidad de Valencia, Spain

This proposal aims to test the effects of perspective when high-school students read conflicting information from multiple documents to perform a specific task, as well as study if the trustworthiness of a source exerts any kind of influence on students' decision to read and use information from a particular document. We complementarily analyze students' ability to judge sources in terms of trustworthiness and how the interaction with the information may significantly modify students' judgments. Results seem to indicate that high-school students are able to correctly identify sources as untrustworthy without accessing the contents. However, for more trustworthy sources an interaction with the contents seems to be necessary. Results also indicate that perspective instructions can help students focus on trustworthy sources and, in general, having a perspective, irrespective of which kind, seems to focus students on the use of perspective-related contents from trustworthy sources, in contrast to a neutral condition.

Aims

McCrudden & Schraw (2007) show how that the way students interact with a text is mediated by the instructions they are presented with, which significantly modifies the reading process. Specifically, perspective instructions prompt readers to use background knowledge to evaluate text from an assigned point of view. Research on perspective in single texts demonstrated that readers confer relevance on text segments that are consistent with the assigned perspective (Pichert & Anderson, 1977). This proposal will test the effects of perspective when high-school students read conflicting information from multiple documents to perform a specific task, as well as study if the trustworthiness of a source exerts any influence on students' decision to read and use information from a particular document.

Method

Participants. They were 59 high-school school students, with a mean age of 16 years old. **Materials.** We selected six texts of approximately 300 words each on the topic of transgenic food (see table 1 in the appendix). They varied as regards trustworthiness, with three more and the other three less trustworthy (ranking task by expert biology teachers). The texts also varied as regards level of agreement towards the topic: 2 in favor of transgenic food, 2 in opposition and 2 neutral. We created three conditions that varied according to the perspective assigned to students. The task consisted on providing an answer to the convenience of using transgenic foods, from the perspective of a green activist (against condition), from the perspective of a businessman who owns a company of transgenic food (in favor condition) and finally to generally justify if it is convenient or not to use transgenic food (neutral condition). We developed a trustworthiness ranking task to be filled in before and after the experiment. Students were presented with a list of the six sources that they would read in the experiment. These sources contained source cues and content cues that indicated their trustworthiness and content type. They were asked to order them according to how trustworthy they considered them. Those ranked in position 1 to 3 were classified as trustworthy, whereas those classified from 4 to 6 were classified as untrustworthy.

Procedure. The experiment lasted three sessions. In session 1 students performed the trustworthiness ranking task. Session 2 was dedicated to the actual experiment. It was conducted using Read&Answer, software that presents the texts and task on the computer screen using a masking procedure that allows the registration of the reading behavior. Participants were presented with an instructions page where they read the task according to the assigned perspective. The six documents were listed below in a google-like display, and students were told to read the sources that helped them answer their question. Afterwards, students could access the documents and a task screen to answer the assigned question. In session 3, participants performed the same trustworthiness ranking task as the one in session 1.

Analysis and Results

Trustworthiness analysis. We checked whether the experts' classification matched students' classification of sources. We performed chi-square tests, with students' rankings to each of the source (trust, 1; untrustworthy, 0) before and after the experiment (moments 1 and 2). We found significant differences for the following sources: Blog moment 1, p We also found significant differences for the sources: OMS in moment 2 and Ministerio in moment 2. These two trustworthy sources were not significantly differentiated by students before the experiment. It was only after the interaction with the contents that students could correctly classified them. Please note that this did not happen for the untrustworthy sources. **On-line and task analysis.** We analyzed how perspective affected the type of texts read and from which sources students extracted the information. We considered the percentage of perspective-related texts and percentage of trustworthy and untrustworthy texts. We performed Anovas, with independent measure Perspective and dependent measures the above variables. Results were significant for Percentage of trustworthy texts, $F(2, 50) = 15.03$, p Favor, p Neutral, p Against, p We analyzed from which sources students extracted the information. First, we considered the number of ideas from perspective-related texts. We also counted the number of ideas from trustworthy and untrustworthy documents. Results were significant for the three dependent measures.

Students in the in favor condition included more perspective-related ideas than those in the neutral condition $F(2, 50) = 7.25, p$. Discussion Our results indicate that high-school students are able to identify sources as untrustworthy without accessing the contents. However, for more trustworthy sources an interaction with the contents is required. On the other hand, it seems that perspective instructions helped students focus on trustworthy sources and induced the use of perspective-related contents from trustworthy sources. The educational implications will be discussed.

Teaching fourth and fifth graders to evaluate the authority of information sources

Monica Macedo-Rouet, @4 Teleport 1, France; Jean-Francois Rouet, Universite de Poitiers, France

The present study investigated the effects of instruction about multiple sources on students' ability to evaluate content information based on the cognitive authority of the sources. Participants were 96 students from 4th and 5th grades (mean age = 10.3 years). They received 30-minutes instruction on the authority of information sources and completed a comprehension test with questions on sources and authority one week later. A significant effect of instruction was found, as well as a significant instruction by comprehension level interaction. Poor comprehenders in the instruction group showed higher performance as compared to the control group. The number of students who were able to correctly identify source authority was higher in the instruction group than in the control group. The results are encouraging because effects could be found with one only instruction session. There are reasons to believe that this type of intervention can be easily adapted to school organization. However, other requirements, among which teacher training and adaptation to students' initial comprehension level, must be attained before this instruction can be implemented in school classes.

Recent studies show that elementary school students have a hard time evaluating information sources on the Internet, because they do not clearly distinguish advertisement from content and are misled by the complexity of information display in Web documents (Eastin, 2006; Valcke et al., 2007). Nevertheless, there is evidence that students possess selective criteria to judge the authority of people who give commands to them (e.g. the teacher, other children, etc.; Laupa, 1994). Thus, students possess selective authority criteria, but they are not necessarily efficient in evaluating sources when they are reading and searching for information.

Before they enter middle school, students have relatively few opportunities to learn how to evaluate multiple sources. Access to information sources at school has grown exponentially, but topics such as drawing pupils' attention to authors and publishers of a text, their affiliations, and the context of publication are not regularly taught in the elementary grades (Goldman et al., 2009). Dealing with multiple sources is a complex activity that requires a number of comprehension and documentary skills. Therefore, training is needed to improve students' ability in critically learning from sources (Britt & Angliskas, 2002; Rouet, 2006).

Some researchers have implemented and tested information skills training programs at the elementary school level (Gerjets & Hellenthal-Schorr, 2008; Kuiper et al., 2008; Vries et al., 2008). These studies have obtained a moderate success in enhancing students' evaluation skills. Results suggest that training programs should focus more on content than on technical issues of information search, and that students should be encouraged to reflect on their searches in order to improve their understanding of information found on the Internet.

We conducted a quasi-experimental study using a specific intervention that delivers instruction on the authority of sources and encourages students to establish links between sources and content. Our hypothesis was that instruction would have a positive effect on student's comprehension of "who said what" in the text, and on students' recognition of authority, defined as "the most knowledgeable" source. We also expected that poor comprehenders would benefit from the instruction more than good comprehenders, because of the results from prior studies (Raphael & Wonnacott, 1985).

Method

Participants were 96 students (59 male, 37 female) from 4th and 5th grade classrooms of two French elementary schools. Students' age ranged from 9 to 11 years ($M = 10.3, SD = 0.68$). Prior to instruction, students' completed a

standardized comprehension pre-test (Aubret & Blanchard, 1991) and were categorized as "good" or "poor" comprehenders.

Four argumentative texts dealing with familiar topics were developed for the purposes of the study. Each text presented a controversy between two sources of information, represented by characters in the text. We used simple texts instead of multiple documents in order to limit the quantity of information to be read and allow children to complete the exercise in a 30 minutes session. Each text was accompanied by 4-5 multiple choice questions. There were two types of question: (a) source-content comprehension ("according to the nutritionist..."), (b) recognition of authority ("who is the most knowledgeable character about [subject]?").

The instruction consisted of five steps of mediated discussion in small groups. The general goal of this approach was to encourage students to identify the multiple sources presented in the texts, to establish links between sources and content ("who said what"), and to identify cognitive authorities. Inspiration was sought in effective comprehension instruction practices, such as "reciprocal teaching" (Palincsar & Brown, 1984), from which we borrowed the techniques of asking/answering questions and making predictions.

The experiment was run in two sessions of 30 minutes each. The first session was dedicated to instruction, the second session to the post-test. Students worked in groups of eight, with one computer per pupil. Prior to the experiment, students received specific instruction (approximately 40 minutes) on how to use the online software.

Results

The mean scores for good and poor comprehenders were respectively: 83% and 70% (instruction group), and 82% and 54% (controls). A main effect of instruction was found ($F(1,91) = 3.97$, $p < .042$), as well as a main effect of comprehension level ($F(1,91) = 12.58$, $p < .021$). Additionally, there was a significant interaction between comprehension level and instruction ($F(1,91) = 4.20$, $p < .044$). Students in the instruction group outperformed controls, only if they were poor comprehenders.

Concerning the recognition of authority, 87% of the answers in the instruction group corresponded to the most knowledgeable source with a correct argument, against 74% in the control group. More interestingly, the non expert represented only 2.2% of the answers in the instruction condition and 10% of the answers in the control condition. The distribution of authority scores was analyzed with chi-square statistics. The results ($\chi^2(2) = 3.64$, p

Conclusions

The results of this study are encouraging because significant effects could be observed within a short period of time. With only two sessions (training + test) students showed progress in comprehending the perspectives of multiple sources in argumentative texts. Anecdotal data shows (a) that students adapt very easily to the instructional context because they are used to work in small groups (b) that they engage in lively discussions, especially when texts deal with subjects familiar or interesting to them. Thus, it is reasonable to think that this instruction can be easily implemented in elementary school classes, although other requirements exist in terms of teacher training and class organization. In the long run, the instruction could be adapted to the online system to allow for group discussions with automatic feedback from the system. This adaptation would require further development and observations in class, but the current system can already be used to archive texts and questions that can be used by the teacher in his regular class.

SYMPOSIUM

Causes and effects of biased teacher judgments

Chairperson: Detlef Urhahne, University of Munich, Germany

Organiser: Christian Lorenz, University of Bamberg, Germany

Detlef Urhahne, University of Munich, Germany

Discussant: Pascal Bressoux, Université Pierre Mendès-France, France

Teachers' judgments about student achievement should be as fair and objective as possible. However, there are often cases where teachers misjudge student performance or have erroneous expectations about student achievement. Among the different factors that might impact teacher judgments, characteristics of the teacher, the student, the test, and the teacher ratings have been identified. In the symposium, we will focus on some of these characteristics and examine which of them appear to be meaningful and which do not. Thereby, indications of stereotyping by teachers can be revealed and recommendations about how to overcome them can be made. Furthermore, it is well established

that erroneous teacher expectations can influence student achievement as shown by the seminal work of Rosenthal. However, whether an expectation effect can also be detected at the whole class level and if contrasting teacher expectations positively or negatively influence the achievement of whole classes is an underexplored area. Moreover, whether biased teacher judgments influence the motivation and emotions of students and to what extent the impact of erroneous teacher judgments is mediated by causal attributions has been infrequently investigated. Knowledge about the effects of biased teacher judgments has implications for how negative effects could be counteracted and how positive effects could be exploited. In this sense, the symposium contributes to strengthen the sensibility about biased teacher judgments, to reflect on the causes and effects, to elucidate the advantages and disadvantages, and to derive practical conclusions.

Teacher Judgment, Student Motivation, and the Mediating Effect of Attributions

Detlef Urhahne, University of Munich, Germany; Ji Zhou, University of Munich, Germany; Mingjing Zhu, University of Munich, Germany; Jiannong Shi, Chinese Academy of Sciences, Beijing, China

Based on Weiner's attributional theory of intrapersonal motivation, the mediating effect of attributions on teacher judgment and student motivation was investigated. In two studies, 144 German and 272 Chinese fourth grade elementary school students were tested on their mathematical achievement, causal ascriptions for success and failure, expectancy for success, self-concept, and test anxiety. Mathematics teachers were asked to estimate students' performances on the applied mathematics test, which led to either an accurate judgment, underestimation, or overestimation of students' actual performances. One year later, Chinese students were retested on their mathematical achievement. Results show that the attributional pattern of underestimated students was maladaptive compared to overestimated students. Attributions mediated the effect of teacher judgment on students' expectancy for success, self-concept, test anxiety, and, in case of the Chinese sample, mathematics achievement of the next year. The results indicate the important role of student attributions as a function of teacher judgment and imply attribution retraining as a possible intervention.

Teachers' judgments have a decisive influence on students' motivation to learn and their willingness to put effort into tasks. However, there is no simple, direct relation between teacher judgment and student motivation. Each student perceives teacher judgment differently, and students' explanations vary for why a teacher has judged a performance in a certain way (Weiner, 1986). The differences in students' causal attributions have an impact on motivational consequences such as expectancy for success, self-efficacy perceptions, and affective reactions (Weiner, 1992). Accordingly, it can be assumed that students' attributions might work as mediators between teacher judgment and student motivation.

Meta-analytic studies reveal that teachers are relatively accurate in ranking students according to their actual achievement (Hoge & Coladarci, 1989; Sudkamp, Kaiser & Moller, submitted), however, they show a general tendency to overestimate students' test performances. There is generally a larger group of overestimated students and a smaller group of underestimated students. In an investigation of fourth grade elementary students in Austria, a group of underestimated students was contrasted with a group of accurately estimated and overestimated students (Urhahne, Chao, Luttenberger, Florineth, & Paechter, in press). Research results revealed that underestimated students had the same test performance as non-underestimated students but showed lower expectancy for success, displayed lower academic self-concept, and felt more test anxiety. Two other investigations, in which underestimated and overestimated students were compared on their motivational-affective traits, confirmed these findings (Urhahne et al., 2010). Again, the pattern emerged that underestimated students had lower expectancy for success, a lower self-concept, and more test anxiety than overestimated students.

Research Hypotheses

According to Weiner's model of interpersonal motivation, it is assumed that student attributions will work as mediators between the relationship of teacher judgment and student motivation. The research hypotheses of the two studies are the following:

1. Underestimated students show different attribution patterns for success and failure in comparison to overestimated students.
2. Students' attributions work as mediators between teacher judgment of student performance and psychological and behavioral consequences for the students.
3. The mediation model can be equally supported for a German and a Chinese sample.

Method

Participants were 144 German and 272 Chinese fourth grade elementary school students who were tested with a standardized mathematics achievement test. In addition, students indicated their causal ascriptions for success and failure, expectancy for success, self-concept of ability, and test anxiety by ratings on a self-description questionnaire.

Their mathematics teachers were asked to estimate students' performances on the applied mathematics test, which led to either an accurate judgment, underestimation, or overestimation of students' actual performances. One year later, Chinese students were retested on their mathematical performance by another standardized mathematics achievement test for fifth graders. Students' retesting could only be done in China as in Germany students change after the fourth grade from primary school to different secondary schools.

Results

In Germany, underestimated students attributed success more on variable causes like chance but less to stable causes like ability. They also attributed success less on positive emotions but blamed failure more on negative emotions. In China, underestimated students attributed success more to chance and failure more to emotions, task difficulty, and effort than overestimated students. This pattern could be regarded as maladaptive as underestimated students attributed success to a variable and external cause and failure to a stable or internal cause.

Hierarchical regression analyses for the dependent variables expectancy for success, test anxiety, and academic self-concept were conducted to test the mediating effect of causal attributions. In the first step, teacher judgment was entered into the regression models. In the second step, possible attributional mediators indicated by significant correlations with teacher judgment and student motivation, were added to the regression models. In the German sample, the effect of teacher judgment on students' expectancy for success, test anxiety, and academic self-concept was mediated by students' causal ascriptions. In the Chinese sample, the effect of teacher judgment on student motivation in all three cases was largely reduced after introducing causal ascriptions into the regression models.

In a final analysis, Chinese teachers' judgments were regressed on mathematics achievement of the next school year. An initial significant beta coefficient revealed that underestimated students showed weaker performance in the follow-up test than overestimated students. In the second step of the regression analysis, causal attributions were introduced into the model and chance attribution of success and ability attribution of failure emerged as mediators. In the third step, when also psychological consequences were taken into account, the effect of teacher judgment on mathematics achievement completely disappeared. Teacher judgment was fully mediated by chance attribution of success, expectancy for success, and mathematical self-concept.

Discussion

In two studies in elementary schools, the effects of teacher judgment on student motivation were closely examined, and the assumption that the relationship is mediated by student attributions was tested. Underestimated students attributed success more to external causes and failure more to internal causes in comparison to overestimated students. In both studies and for most of the psychological consequences, ability and emotion attributions have worked as mediators.

As attributional patterns are malleable and can be changed by attribution retraining (e.g., Carr & Borkowski, 1989), underestimated students can be encouraged to reconsider maladaptive attributions and to adopt more adaptive attributions instead. Another suggestion derived from the research results is that teachers can support students' motivation by persuading them to adopt a more positive attribution style. The support can be given immediately after test results are informed to the students and can even be a part of the explanation of grades. Teachers might inform students that abilities are malleable or that emotional reactions depend upon cognitive evaluations and are under personal control. Changing students' perceptions of the controllability of the causes could prevent a decrease of motivation and performance in view of unfavorable teacher judgments.

Direct vs. indirect teacher judgments: Differences regarding students' social status and gender

Christian Lorenz, University of Bamberg, Germany; Cordula Artelt, Bamberg University, Germany

Teachers' diagnostic competence is regarded as a core competence in school settings. Nevertheless, there seem to be differences in the accuracy of teacher judgments depending on students' gender and socio-economic status as well as on the information the teacher has about the underlying tasks. In the current study it was explored to which extent teacher judgments are biased by the mentioned student attributes and assessment methods. For this sake, students from two subsamples of the Bamberg BiKS study attending grade one ($N = 385$) and five ($N = 482$) were tested in vocabulary and text comprehension, while their teachers estimated their individual achievement both directly (task specific) and indirectly (without reference to the particular tasks) by means of a questionnaire. The results for both grade levels show that there are barely significant biases depending on students' gender and socio-economic status, neither for direct nor for indirect judgments. However, direct judgments were even more objective and less biased than indirect judgments. These findings implicate that stereotypes play only a subordinated role in teacher judgments.

Teachers' diagnostic competence is sometimes claimed to be a core competence for high quality teaching. It is necessary that teachers judge their students fairly and objectively. In general, two methods of assessing teacher judgments are applied in the research field on teachers' diagnostic competence: Teachers' judgments on students' performance are either based on specific tasks that are known to the teachers and that are in fact administered to the respective students (direct or specific judgments), or these judgments refer to students' general abilities in a more or less defined area, mostly without knowing concrete tasks that are used to assess these abilities (indirect judgments). In both cases the judgments usually are compared with students' achievement in standardized tests, whereupon the extent of congruence between student performance and teacher judgment is regarded as an indicator of teachers' diagnostic competence. Studies comparing these two approaches generally found that the diagnostic competence is somewhat higher when being based on direct judgments (e.g. Feinberg & Shapiro, 2003). Nevertheless, researchers more often use indirect judgments in their studies because they are much easier to gather and teachers are less burdened when filling in the questionnaire.

Regardless of these described methodological differences many studies found that some students' attributes influence teachers' judgments, especially their social status or gender. However, the findings are heterogeneous in this regard. For instance, it was repeatedly shown that students' socio-economic background can bias teachers' judgments and especially their school recommendations after primary school (Stahl, 2007; Ditton, 1992, 1995, 2010). While many (German) studies pointed out that students with lower socio-economic status are often judged too bad in relation to their actual achievement, some other studies found no influence of the social status at all (e.g. Wigfield, Galper, Denton & Seefeldt, 1999). A similar situation holds true for students' gender. As predominantly older research findings suggest, students' gender has no influence on teachers' ratings (e.g. Hoge & Coladarci, 1989; Jussim & Eccles, 1995; Demaray & Elliott, 1998). In contrast, a series of recent studies showed, that reading competence of girls is often overestimated, while boys are often underestimated in the same performance (Hinnant, O'Brien & Ghazarian, 2009) or that girls receive better marks in German than boys with the same competence level (Bos et al., 2005). It appears that stereotypes can play an important role in teachers' judging process.

Research Hypotheses

Based on the mentioned inconsistency of findings, the current study explored the following hypotheses:

1. Does the accuracy of teachers' judgments on students' vocabulary and text comprehension vary depending on students' socio-economic background and their gender?
2. Are these variations bigger for indirect judgments than for direct judgments?
3. Do these effects appear independently of grade level?

Method

The data basis for the analyses stems from two different subsamples of the Bamberg BiKS project (BiKS is the German acronym for "educational processes, competence development and selection decisions in pre- and primary school age"). In grade level one N = 385 students (from 61 classes in primary school) and in grade level five N = 482 (from 85 classes in secondary school) students from Bavaria and Hesse participated. Students' competences in different fields (e.g. vocabulary, text comprehension, arithmetic) were measured with standardized tests, their socio-economic background (ISEI) was derived from interviews with their parents. At the same time teachers were asked to rate these competences level for each individual student, either specifically (directly) by having all the information about the underlying test items available, as well as indirectly by only giving an estimation of the general competence.

Results

In order to examine the relevance of 1) students' attributes and 2) the assessment method for measuring accuracy of the teachers' judgments, the mean discrepancy between teachers' judgments and students' achievement were calculated for each of the groups (boys/girls and high/low social status) and compared via t-tests. The results indicate that there are barely significant differences in the teachers' judgment accuracy depending on students' socio-economic background or gender, even though students' social status has a strong influence on their achievement. Nevertheless, in most competence domains and for both grade levels there are marginal but observable differences related to judgment accuracy depending on students' attributes which are consistently more pronounced for indirect than for direct judgments, as effect sizes approve.

Discussion

These findings indicate - at least for the two competence domains under study - that teacher judgments are basically accurate in that way that they are not biased by the students' gender or social status. Even if the differences are not substantial, it appears that indirect judgments that are often used in research but rarely in classes are slightly less fair, whereas direct judgments which are relevant for the regular assessment in the classes, for testimonials or school

recommendations do not favor or disadvantage special groups of students. Altogether the current study suggests that stereotypes seem to be less relevant than suspected.

Expecting the best: Teacher expectations and student academic and social outcomes

Christine Rubie-Davies, University of Auckland, New Zealand

The conception that some teachers have high or low expectations for all students has been little explored. This is despite Brophy's (1985) assertion that expectations for a whole class would have more effects on student outcomes than the oft reported expectations of teachers for individual students. The current study examined changes in student achievement and academic self-perceptions across one year conditional on whether students had a high or low expectation teacher. The teachers were identified depending on their expectations for all students. Students' academic achievement and self-perceptions were measured at the beginning and end of the year. Teacher instructional practices were observed. The academic achievement and self-perceptions of students with high expectation teachers increased substantially across one year. Contrasting findings were noted for students with low expectation teachers. Observations of teachers revealed contrasting pedagogical practices for the two teacher groups. The results indicate the importance of considering teacher factors when examining relationships between teacher expectations and student outcomes.

The teacher expectation literature has a history spanning almost five decades. Some researchers consider teacher expectations to be accurate and to have only small effects on student outcomes (Jussim, Robustelli, & Cain, 2009). However, the conception of the self-fulfilling prophecy provides an acknowledgement that teacher expectations can be inaccurate. It is an erroneous judgement of student performance that leads to the teacher interacting with students in particular ways, resulting in the fulfilment of the initially inaccurate belief (Rosenthal & Jacobson, 1968). Research that has investigated the self-fulfilling prophecy effect has focused almost exclusively on teacher expectations for individual students. Differential behaviours of teachers towards those for whom they have high or low expectations have been identified (Brophy, 1983, 1985) but a meta-analysis showed that the behaviours that most affected student outcomes (e.g., those related to the class climate) were those concerning the whole class (Harris & Rosenthal, 1985). Nevertheless, despite this finding and an assertion by Brophy (1985) that teacher expectations for the whole class were likely to be of more consequence for student outcomes than expectations held for individuals, this conception remains largely untested in the literature.

Research by Weinstein (2002) has indicated that teacher beliefs moderate their expectations. In turn, the differing beliefs result in contrasting teacher pedagogical behaviours and so the teacher expectation effects are mediated by the differential behaviours of teachers. This notion reflects Weinstein's stance that contrasting teacher beliefs should be considered when examining teacher expectation effects. When teacher beliefs are accounted for in the expectation sequence from initial formation to student achievement, there are large differential outcomes for students (McKown & Weinstein, 2008). Similarly, Babad (2009) has shown that biased teachers have far more negative teacher expectation effects on students than do non-biased teachers. However, Rubie-Davies (2008) is the only author located who has tested the idea that teachers may have high or low expectations for all students, i.e. that there are high and low expectation teachers. This perspective was examined in the current study.

Research Hypotheses

Based on Brophy's notion that class-level expectations were likely to have more substantial effects on student outcomes than those for individuals, the current study explored the following hypotheses:

1. Teachers who had very high or very low expectations for their students could be identified.
2. Student academic and social outcomes would vary depending on whether they were with a high or low expectation teacher
3. Differing teacher beliefs would lead to contrasting teacher instructional practices possibly mediating the effects of teachers' expectations.

Method

Participants were 191 primary school students (either in Year 2 or in Year 5/6), 132 of who had high expectation teachers and 59 who had lows. Student achievement and academic self-perception were measured at the beginning and end of the academic year. Teacher expectation was measured by asking 21 teachers to estimate student end-of-year reading achievement (n = 540 students) on a 1-7 Likert scale from very much below average to very much above. Only the students of teachers whose expectations were significantly above or below class-level beginning-year achievement were included in the study. Analyses verified that expectations were contrastingly high or low for all students in each respective class.

Results

Student reading achievement was measured beginning and end of one academic year. Overall, students with low expectation teachers had higher achievement beginning the year than did students with high expectation teachers. However, markedly different results were documented by year's end. Those with high expectation teachers made very large academic gains ($d = 1.05$) while those with low expectation teachers made fewer gains ($d = .05$). Similarly, there was no difference in students' self-perceptions in reading and maths at the beginning of the year. However, at year's end, the academic self-perceptions of students with high expectation teachers had risen but there was a substantial drop in the self-perceptions of students with low expectation teachers. Further, a sub-scale used to determine student perceptions of their teachers' expectations showed no difference between the two student groups at the beginning of the year. Nevertheless, student perceptions of teacher opinion for those with low expectation teachers had fallen by year's-end in contrast to the perceptions of students with high expectation teachers.

Teacher instructional behaviours were observed to determine if these might mediate between teacher expectations and student outcomes. Large differences were found between high and low expectation teachers' practices. In summary, high expectation teachers took a facilitative approach to student learning: using mixed ability grouping; spending considerable time introducing new concepts, linking to prior knowledge and establishing student understanding; providing students with choices in activities, setting clear learning goals; using questions requiring higher level thinking; and positively approaching classroom management. In contrast, low expectation teachers used a more directive approach: they emphasised procedural directions; used ability groupings for reading; asked few questions of students; frequently admonished students for behaviour; and made all decisions about whom students were to work with, when and how.

Discussion

The conception that teachers could have high or low expectations for all students was examined in this study. Academic and social outcomes were investigated for students whose teachers had contrasting expectations. Compared to students with low expectation teachers, those with high expectation teachers made large academic gains and enhanced their academic self-perceptions. Observations of teacher instructional behaviours suggested that differing pedagogical practices may have mediated the effects of teacher expectations on student outcomes.

Few studies have considered teacher beliefs (i.e. teacher factors) in the expectation literature as contributing to differential expectation effects. The current study as well those by Weinstein (2002) and Babad (2009) suggest that teacher factors are related to large differential outcomes for students and therefore should be more closely considered in teacher expectation studies. Further, considering the large gains in academic outcomes found for students with high expectation teachers, it would be prudent to consider an intervention designed to raised teachers' expectations and change beliefs and practices such that they reflect those of high expectation teachers. Thus it may be that the outcomes for all students could be enhanced.

SYMPOSIUM

An international perspective on stimulating excellence in higher education

Chairperson: Fritz Oser, Universitat Freiburg, Switzerland

Organiser: Lyndsay Drayer, Hanze University of Applied Sciences, Groningen, Netherlands

Ingrid Schutte, Hanzehogeschool Groningen University of Applied Sciences, Netherlands

Discussant: Lynn McAlpine, University of Oxford, United Kingdom

This symposium on evoking excellent achievement in higher education focuses on international comparison of research data. Research on high ability in higher education is a new field in Europe. Institutions in Finland, Germany and the Netherlands share the results of their collaboration in research. We wish to discuss empirical research findings and their implications on the institutional level, the level of teacher strategies and the level of students and programs. Presentation 1. The comparison of plans of Dutch and German universities on their aims and goals with gifted education is the central theme of the first presentation. Students are stimulated to achieve more and a higher level in different ways, leading to different learning outcomes. Presentation 2. Effective teachers' strategies to evoke excellence include three concepts; building a community, offering a certain amount of freedom and providing academic challenges. What do teachers themselves say on their strategies and which differences can be found in strategies in a regular curriculum compared to honours education? Presentation 3. Measurements on moral and cultural sensitivities of urban secondary school students favor the high ability students. Is that still the case with higher education students? We discuss the implications to further develop the instruments for cross-cultural

comparisons and to further educate the high ability students' moral sensitivities to combine excellence with ethics and citizenship for the global world.

Evoking excellence with special undergraduate programmes: a German-Dutch comparison

Julia Moeller, University of Erfurt, Germany; Lyndsay Drayer, Hanze University of Applied Sciences, Groningen, Netherlands

This presentation compares the two main gifted education programmes for undergraduate students in the Netherlands and Germany. The programmes were evaluated and will be compared in terms of the institutions involved, the educational objectives pursued, the nature of support provided to the students, and the anticipated effects (Netherlands), respectively the achieved effects (Germany). The Dutch study focuses on the Sirius Program established by the Dutch government which invited universities to submit their own plans for the promotion of student excellence. The successful applications are analysed with respect to the above mentioned criteria. The German study focuses on the ideational support means, which is a varied enrichment programme provided by several national foundations that is supported with money and guidelines by the German government. The scholarship recipients were interviewed in large online surveys (N1 = 2379 and N2 = 1614). Both programmes are endowed with public funding and thus are shaped by political objectives. Also, both programmes are conducted by non-governmental institutions: universities in the Netherlands, and basically political, religious and social foundations in Germany. Thus, the presentation provides insights in theory and practice of gifted undergraduate education in both countries. The discussion will address the impact of political objectives and organizational structures on the reality of gifted education. Strategies for educators to accumulate scientific knowledge about gifted education, about evidence-based goals and about real life limitations will be provided. The different evaluation methods will be discussed in order to find out the best practice for research.

Introduction

The aim of this presentation is the comparison of the main promotion programmes for excellent undergraduate students in the Netherlands and Germany. The programmes are compared in terms of assigned institutions, educational objectives, the nature of support provided to the students and the anticipated effects (Netherlands), respectively achieved effects (Germany). In the Netherlands, most universities now offer special programmes for talented students. The government has stimulated this process through the Sirius Program. Assessment of plans was based on the institution's own views on excellence and the anticipated achievements. This resulted in 37 applications, 19 of which were selected for funding (2008-2010). For this presentation we have analyzed these successful applications focussing on the following points: 1) the nature of the activities chosen by each university to stimulate excellence, 2) the "added value" expected for the participating students, the university and society, and 3) the anticipated effects of the excellence programmes as measured by the individual universities. In Germany, the main programmes for undergraduate gifted education are provided by institutions which are closely related to the bigger political parties, the two main churches, the labour unions, the German economy and the state as such. These institutions receive money and some guidelines from the government in order to provide scholarships and enrichment programmes for excellent and socially committed students in the tertiary sector. The enrichment programmes, called "ideational support", vary widely and are influenced by theoretical assumptions of gifted education as well as political / ideological objectives. The effects of the ideational support were evaluated (2009-2010) in a survey including 2379 present scholarship recipients and 1614 former stipendiaries, as well as other people implicated in the programmes. The evaluation focused on effects of the ideational support, self-reported by the recipients. Psychological issues such as self-regulation, self-efficacy, good work (Gardner, Csikszentmihalyi, Damon, 2002), social competence etc. were assessed as well as "objective" measures such as achievement (indicated by grades and duration of study) and social commitment.

Data and Methods

For the Dutch study, the 19 successful applications published by the institutions are publicly available (www.siriusprogramma.nl). The plans were analysed and categorised according to the nature of the activities, the number of credits awarded, the reasons for developing the activities, the anticipated added value, and the way in which the effects are to be measured. The German study applied a multi-method approach, consisting of large online questionnaires for present and former scholarship recipients, phone interviews with mentoring professors, group interviews with self-organized groups of scholarship recipients and questionnaires in which the implicated institutions reported their specific goals which should be realised in their education programme. Additionally, the main documents published by the institutions to present themselves were analysed and categorised. However, the focus lay on the online questionnaires, which were completed by 2379 present and 1614 former scholarship recipients. According to Kirkpatrick's (1998) evaluation model, reaction (satisfaction, quality of the programme

learning (knowledge, attitude), behaviour (academic and occupational achievement, civic engagement) were assessed. The data of present and former scholarship recipients were compared with each other as well as with results from studies on gifted students (Heller & Vieck, 2000; Lubinski & Benbow, 2006) and representative samples (Fischer, 2006).

Results

Netherlands (Sirius): Historically, the Dutch research universities have more experience with special programmes for talented students (often called Honours programmes) compared to the universities of applied sciences. In the Sirius Program we detect a shift from departmental research programmes for a limited number of students, to more broadly-orientated multidisciplinary Honours programmes for a larger student population. The universities of applied sciences have developed Honours programmes specifically aimed at professional excellence and stimulating applied research within the institutions. Although the contents of the programmes and the European Credits (EC's) awarded vary greatly between the institutions, the anticipated added values and effects to be measured show similarities. The performance indicators mainly focus on short term effects such as academic performance, retention and graduation rates, student satisfaction, time required to obtain the first job and starting salary. Germany (ideational support): The questionnaires revealed showed that the scholarship recipients appreciate the received ideational support much. They report effects of the ideational support in terms of development of achievement, social commitment and personal growth. The more the students participated in the ideational support, the bigger were the reported effects. Also, the effects of the different education programmes were in accordance with the goals of the particular institution.

Theoretical and educational significance

The presentation provides insights into different theoretical assumptions about gifted education found in the implicated institutions and the different political and organizational strategies to accomplish promotion of gifted students. It is of theoretical significance to learn about the assumptions and aims of given institutions in the two countries and to prove if they meet scientific knowledge about best practice in gifted education. Also, the impact of political assumptions and institutional limitations on the reality of gifted education will be discussed. The methodological add on value of the presentations will be the discussion about a best practice in the evaluation of undergraduate gifted programmes, concluding the research of both studies. The educational significance concerns the development of strategies to get together scientific knowledge about best practice as well as theoretical assumptions and the reality of political and structural limitations and guidelines in the institutions concerned with gifted education.

Teaching strategies to elicit excellence in higher education

Marca V.C. Wolfensberger, Hanzehogeschool Groningen, Netherlands; Roeland M. Van der Rijst, ICLON-Leiden University Graduate School of Teaching, Netherlands

Pedagogy for gifted and talented students in higher education is the main topic of this study. Teachers of educational programmes designed for talented or highly motivated students in higher education (here called honours programmes) are challenged to stimulate students to increase the quality of their academic achievements. However, systematically acquired knowledge on effective teaching strategies for motivated and talented students above the age of 18 is limited (Heller, Mönks, Sternberg & Subotnik, 2000). The aim of this study is to augment the existing body of knowledge. Firstly to reflect on this knowledge from different perspectives, secondly by a mix-method research, analysing multi-institutional data collected in the United States and the Netherlands about teachers perception on teaching strategies for gifted and motivated students in higher education. The theoretical perspectives behind this study focus on (1) theories about giftedness, (2) motivational theories and (3) on studies on honours programmes.

Three concepts prove to be of importance when thinking about pedagogies for excellent students: shaping of a community, allowing for (academic) freedom and providing academic challenges. The empirical section of the study is concerned with the question: which strategies teachers say to employ within honours education and regular course in the light of these three concepts. These strategies highlight effective tactics that can be used to elicit excellence. This account addresses a gap in the emerging international body of knowledge on 'honours pedagogies'. Some aspects of the honours context seem quite different from standard teaching practices and necessitate special faculty development.

Introduction

Pedagogy for gifted and talented students in higher education is the main topic of this study. Teachers of educational programmes designed for talented or highly motivated students in higher education (here called honours programmes) are challenged to stimulate gifted and motivated students to increase the quality of their academic achievements. However a systematically acquired knowledge about effective teaching strategies motivated and talented students above the age of 18 is limited (Heller, Mönks, Sternberg & Subotnik, 2000). The aim of this study is to augment the existing body of knowledge. Firstly to reflect on this knowledge from different perspectives, secondly by a mix-method research, analysing multi-institutional data collected in the United States and the Netherlands about teachers perception on teaching strategies for gifted and motivated students in higher education. The theoretical perspectives behind this study focus on (1) theories about giftedness, (2) motivational theories and (3) on studies on honours programmes. Three concepts prove to be of importance when thinking about pedagogies for excellent students: shaping of a community, allowing for (academic) freedom and providing academic challenges. The empirical section of the study is concerned with the question which teaching strategies teacher say to employ within honours education and regular course in the light of these three concepts. This study reveals that teachers employ different teaching strategies for talented and motivated students compared to regular classes.

Methodology

A systematically conducted literature study into research findings published in scientific journals included in the Social Science Citation Index (SSCI) revealed findings on effective teaching strategies for honours students. For further analysis of review studies published in the period 1959-2009 and individual reviews in the period 1999-2009 were included. These studies were complemented by publications on motivational theories and studies into honours programmes. The analysis of the publications revealed that teaching strategies emphasising community, freedom and academic competences highlight effective tactics that can be used to elicit excellence in higher education. Then, we devised a mix-method research design with a questionnaire and an interview protocol for focus groups. The questionnaire focused on specific teaching methods. Multi-institutional data were collected among faculty in the US and the Netherlands in 2006-2007. The analysis has been conducted on the basis of 442 completed questionnaires representing at least 84 higher education institutions. The respondents were experienced teachers across the US and the Netherlands. The questionnaire consisted of 20 multiple choice questions, 47 items with a 5 point Likert scale and three open questions. The focus group interview questions were conducted with teachers (N=48) at the end of each semester in a Dutch university with a relatively long tradition of honours programmes. The teachers were invited to comment on the extent to which strategies employed in honours programmes differ from those in regular educational programmes and whether faculty training was needed.

Results

The search query into reviews from the period 1959-2009 yielded 28 publications covering one or more of the themes concerned with teaching strategies for honours programmes (cf. Fliegler & Bish, 1959; Rogers, 2007) revealing two themes: teaching strategies and teaching objectives. The search query into individual studies from 1999-2009 found 60 relevant publications. Frequently occurring teaching objectives were stimulation of creativity (Heller, 2007), leadership-building and fostering of student motivation (Schick & Phillipson, 2009). Although those findings give account of different age groups, they can provide insight into students in higher education (cf. Colangelo & Davis, 2003). The findings have been embedded in perspectives of motivational theories and honours studies. This resulted in three teaching strategies potentially relevant and effective for teaching excellent and talented students in higher education: building communities, balance between giving freedom and providing structure and developing academic competences.

The results from the questionnaire and focus group suggest that there are similarities between honours and regular education. Nonetheless, significant differences remain. Teachers in honours programmes attach greater value to community building and indicate that they offer students more freedom in terms of planning and selecting of research topics. Interdisciplinarity and undergraduate research are of greater importance in honours programmes. Furthermore teachers give little reference to structural issues when teaching honors, while teachers in regular educational programmes often emphasize the need for a structure and clear explanations. Finally, little or no distinction can be made between regular and honours education in terms of the provision or application of academic

knowledge. The results of this research indicate that greater tailoring of honours programs, within a strong framework of community, would be appropriate.

Theoretical and educational significance of the research

Honours pedagogies within higher education have received little attention in previous research. The spread of programs designed for enhanced educational opportunities and outcomes makes further research critical. This research examines the strategies that teachers in higher education in the United States and the Netherlands reportedly employ in honours courses, in contrast to regular programs. These strategies highlight effective tactics that can be used to elicit excellence. This account addresses a gap in the emerging international body of knowledge on 'honours pedagogies'. Some aspects of the honours context seem quite different from standard teaching practices and necessitate special faculty development. The extent to which teachers in higher education are equipped to facilitate the creation of this kind of learning environment certainly requires further debate and study.

Combining ethics and excellence in education of gifted students

Kirsi Tirri, University of Helsinki, Finland; Ingrid Schutte, Hanzehogeschool Groningen University of Applied Sciences, Netherlands

In this paper we argue that skills in moral judgment and especially in moral sensitivity are necessary in combining excellence with ethics. High ability students have been shown to be superior in moral judgment when compared to average ability students. However, high academic ability does not always predict high moral judgment (Narvaez, 1993). Moreover, morality includes other components as well, such as sensitivity, motivation and character. Social and moral responsibility (Davies et al., 2005) and understanding the world 'from the point of view of the other' (Nussbaum, 1997, as cited by Friedman, 2000) are considered to be aspects of citizenship education for the global world. We present two instruments that have been created to measure moral and cultural sensitivities of urban school students (Tirri & Nokelainen, 2007; Holm, Nokelainen & Tirri, 2009). The instruments with a detailed description of their use and validity will be published in a book (Tirri & Nokelainen, 2011). We show the correlations between academic achievement and moral sensitivities favoring the high ability urban school students. The level of moral judgment is associated with rapid cognitive development of gifted students. The difference in self-estimated ethical and intercultural sensitivity between academically gifted and average ability students might disappear when students get older. At the conference, we will present data on higher education students. We will also discuss the implications of our work to further develop the instruments for cross-cultural comparisons and to further educate the high ability students' moral sensitivities to combine excellence with ethics.

Introduction

In this paper we argue that skills in moral judgment and especially in moral sensitivity are necessary in combining excellence with ethics. High ability students have been shown to be superior in moral judgment when compared to average ability students. However, high academic ability does not always predict high moral judgment (Narvaez, 1993). Moreover, morality includes other components as well, such as sensitivity, motivation and character. Social and moral responsibility (Davies et.al., 2005) and understanding the world 'from the point of view of the other' (Nussbaum, 1997, as cited by Friedman, 2000) are considered to be aspects of citizenship education for the global world. In this paper we present two instruments that have been created to measure moral sensitivities of urban school students (Tirri & Nokelainen, 2007; Holm, Nokelainen & Tirri, 2009). We have gathered empirical data from 4 urban schools in Finland and tested the psychometric qualities of our instruments. The level of moral judgment is associated with rapid cognitive development of gifted students. The difference in self-estimated ethical and intercultural sensitivity between academically gifted and average ability students might disappear when students get older. We examine the ethical and intercultural self-evaluations among older students (17 years and older) in

2010/2011. The instruments with a detailed description of their use and validity will be published in a book (Tirri & Nokelainen, 2011).

Data and Methods

The non-probability sample of urban secondary school students (N=249-549) was collected with the two instruments during the years 2006 and 2007 from the seventh, eighth, and ninth grade students. The non-probability sample of university students (N=500) was collected from two Dutch universities in 2010/2011. The data will be presented at the conference. The ethical sensitivity scale questionnaire (ESSQ) is based on Narvaez's operationalization of ethical sensitivity (2006). Its main purpose is to scale the pupils' orientations on ethical issues. The ESSQ measures following seven dimensions of ethical sensitivity: (1) Reading and expressing emotions, (2) taking the perspectives of others, (3) caring by connecting to others, (4) working with interpersonal and group differences, (5) preventing social bias, (6) generating interpretations and options and (7) identifying the consequences of actions and options. The instrument consists of 28 Likert-scale items with the response options from 1 (totally disagree) to 5 (totally agree). The Intercultural Sensitivity Scale Questionnaire (ICSSQ) is based on Bennett's (1993) Developmental Model of Intercultural Sensitivity (DMIS), which is a conceptual tool to situate certain reactions towards cultural difference. The DMIS consists of six stages, of which three are ethnocentric and three ethnorelative. The ICSSQ is based on the operationalization of the first five stages: (1) Denial, (2) Defense, (3) Minimization, (4) Acceptance, and (5) Adaptation. The instrument consists of 23 Likert-scale items.

Results

Academically gifted students estimated their ethical skills higher than average ability students (Tirri & Nokelainen, 2007). This finding supported other researchers' notion that gifted students hold a privileged position in the maturation of moral thinking because of their precocious intellectual growth (Andreani & Pagnin, 1993; Karnes & Brown, 1981; Terman, 1925). The results concerning cultural sensitivity showed that academically above average students estimated their intercultural sensitivity higher than average ability students. Further, the academic achievement level appeared to be related to intercultural sensitivity: all the above-mentioned variables were negatively correlated with the two lowest ethnocentric stages and positively with the two highest ethnorelative stages of the DMIS (Holm, Nokelainen, Tirri, 2009).

Significance of the research

Our research indicates that gifted secondary school students show higher scores in self-estimated ethical and cultural sensitivities than average-ability students. High ability students show interest to the scientific and research fields that require skills in ethics. Teachers and educators should nurture the moral growth of future scientists by exploring and discussing the ethical aspects of doing scientific studies. Academic work ethic is a specific domain that needs to be discussed with the future scientists (Tirri, 2011). Furthermore, as future scientists and citizens, gifted students might play a part in coming up with solutions for problems of the global society, like climate change and poverty. Future scientists need ethical expertise that includes skills in ethical sensitivity, ethical judgment, ethical motivation and ethical action. Holistic education supports the development of the whole person, rather than merely the cognitive domain. This kind of education acknowledges the importance of social and affective domains in student's development including their moral sensitivities.

SYMPOSIUM

What makes a successful learner of mathematical proof?

Chairperson: Matthew Inglis, Loughborough University, United Kingdom

Organiser: Matthew Inglis, Loughborough University, United Kingdom

Stefan Ufer, University of Munich, Germany

Discussant: Jon Star, Harvard University, United States

This symposium will present three empirically validated accounts of factors that influence how successfully students engage with mathematical proof. Such accounts are important because proof is at the heart of mathematical knowledge construction, so successful engagement with proof is one major goal of mathematics education. Although important, such accounts are rare: it has been known for decades that students struggle to comprehend and construct proofs, but we do not yet know how to design instruction to help them overcome these struggles. By presenting three such accounts together, we aim to link different strands of empirical research on the cognitive processes involved in proof comprehension and construction.

The contributions to the symposium are similar in their focus on individual acquisition of cognitive skills related to proving, and complementary in their educational levels and their research methods. At the secondary school level, Ufer, Heinze and Reiss use a correlational survey to highlight commonalities and differences in the cognitive demands of calculation and proof problems. At the university level, Inglis and Alcock use eye-tracking to identify attentional differences as experts and novices read proofs, and Mejia-Ramos and Weber use an intervention study to investigate how presentation format proof affects proof comprehension. The authors of all three contributions will discuss their findings with a focus on implications for the learning and teaching of proof across the educational levels.

Expert/Novice Differences in the Reading of Mathematical Proofs

Matthew Inglis, Loughborough University, United Kingdom; Lara Alcock, Loughborough University, United Kingdom

Learning by reading mathematical proofs is central to the study of advanced mathematics. Indeed, some philosophers have argued that professional mathematicians learn the majority of their new mathematics by reading the proofs of others. However, many educational research studies have shown that students find mathematical proofs difficult to engage with. Here we report a study in which professional research mathematicians and first year undergraduate students were asked to read, and then determine the validity of, several purported mathematical proofs. Participants' eye-movements were recorded as they read. We analysed the order in which participants attended to different components of the purported proofs. Our findings suggest that a major difference between expert and novice behaviour when reading mathematics is that experts expend considerably larger effort to looking for logical links between different statements. In addition, we demonstrate that novice readers spend proportionately longer studying formulae (compared to text) than experts. However, contrary to the predictions of earlier researchers, we found no evidence that expert readers read mathematics in a non-linear fashion.

At the heart of mathematics is the notion of proof: logical arguments that justify mathematical claims. Because of the centrality of proof to mathematics, curriculum documents and educational theorists have argued that it should be central to mathematics education at all levels of schooling. In particular, a key goal of mathematics education is to develop students' abilities to read and critique mathematical arguments (e.g., NCTM, 2000). However, even students at the undergraduate level find engaging with proof difficult, and struggle to determine whether or not a proof is valid, i.e. whether it contains any logical errors or gaps which that prevent it being accepted by the mathematical community (Selden & Selden, 2003). Consequently, researchers have suggested that deepening our understanding of how expert mathematicians read proofs could productively inform the design of effective educational interventions (e.g. Weber, 2008).

Our study was informed by theoretical analyses of what is required to effectively read mathematics (e.g. Selden & Selden, 2003; Weber, 2008; Weber & Alcock, 2005). Specifically, we tested two hypotheses: (i) novices focus more on

surface features such as algebraic manipulation, and less on logical relations than do experts; (ii) experts devote more effort than novices to finding and evaluating the logical links between different statements in proofs.

We asked 12 research-active mathematicians ('experts') and 18 first year undergraduate mathematics students ('novices') to read six number theory proofs. Participants' eye-movements were recorded by a Tobii T120 Eye-Tracker. After participants had read each argument they were asked to state whether the proof was valid, and how confident they were in their judgement. Participants were encouraged to take as long as they needed to make an informed judgement. In this contribution we focus on the eye-movement data recorded in the study.

To test Hypothesis (i) we classified each part of the proofs as being 'formulae' or 'non-formulae'. We then calculated participants' mean dwell times each area. These data were subjected to an ANOVA with one between-subjects factor (group: expert/novice) and one within-subjects factor (type: formulae/non-formulae). A significant interaction was found, $F(1,28)=8.81$, $p=.006$, a consequence of the novices (as predicted) spending proportionately longer than the experts fixating on the formulae within the proofs. These data suggest that the novices do not devote a similar level of effort as the experts to comprehending those parts of the arguments which were written in text: often the part where logical structure is explicitly discussed.

Hypothesis (ii) was tested by calculating line transition matrices (i.e. the number of saccades each participant made between different lines of the proofs). We calculated the number of saccades of distances 1, 2 and >3 (i.e. a saccade between line n and line $n+1$ has distance one, whereas a saccade between line n and line $n-3$ has distance three). These data were subjected to an ANOVA with one within-subjects factor (distance: 1, 2, >3) and one between-subjects factor (group: expert, novice). There was a significant interaction, $F(1.02,28.7)=5.22$, $p=.029$: the experts made significantly more saccades between consecutive lines than the undergraduates, $t(28)=2.24$, $p=.033$, but the differences for the other distances considered did not approach significance, all $ps>.2$. Hypothesis (ii) accounts for these additional consecutive between-line saccades by suggesting that experts more frequently conduct searches for between-line justifications. To test this prediction more explicitly we calculated the number of eye-movements made of the form Line $x+1$ to Line x to Line $x+1$. Under the assumption that such movements could be associated with attempts to find the logical link between lines x and $x+1$, Hypothesis (ii) predicts that the experts would make more of such moves than the novices where Line $x+1$ requires a justification, but not when it does not (e.g. when Line $x+1$ introduces a novel definition). This prediction was confirmed (we found a significant transition-type by group interaction on these frequency data, $F(1, 27)=4.38$, $p=.046$).

To summarise, many educational research studies have shown that students of all ages struggle with proof, and in particular with reading proofs. Here we reported the first direct comparison of expert and novice in-line proof reading behaviour. We found that novices get 'hung up' with surface features of arguments and do not devote as much effort as experts to searching for the logical links between statements. Further research is required to determine whether expert reading strategies can be explained and modelled during instruction, and whether such instruction would be sufficient to raise the efficacy of novice reading behaviour.

Cognitive predictors of problem solving in geometry – a comparison of complex calculation and proof

Stefan Ufer, University of Munich, Germany; Aiso Heinze, Leibniz Institute for Science and Mathematics Education, Germany; Kristina Reiss, Technische Universität München, Germany

Mathematics competence as described in educational standards worldwide encompasses the abilities to perform mathematical reasoning and proof and to apply mathematical rules and procedures to perform calculations. Both aspects of mathematical competence are commonly viewed as aims of secondary level instruction. Nevertheless, the relation between the cognitive processes which are necessary to construct proofs and perform complex calculations in geometry is quite unclear. In particular, it is unknown if the underlying problem solving processes require the same cognitive prerequisites or if there are specific differences. Mathematics education research tends to focus on

epistemological specifics of proof problems, but from a problem solving perspective, both task types seem to be quite similar. This research builds on theoretical ideas from dual-process theories of deductive reasoning (Evans, 2008). They typically describe a fast, intuitive and experience-based system 1 and a slow, analytic system 2 which is e.g. based on mental simulations. In a correlational study with N=230 German 10th grade students from Germany (Gymnasium), we find that abilities related to system 1 are almost equally related to performance in both task types, whereas abilities related to system 2 are primarily related to the ability to construct geometry proofs. The results cast light on two different aspects of geometric content knowledge and their role in mathematical problem solving. We will also discuss instructional ideas that might potentially foster conceptual knowledge that can be applied flexibly to solve proof problems as well as calculation problems.

Context

Mathematics competence as described in educational standards worldwide encompasses the abilities to perform mathematical reasoning and proof, on the one hand, and to apply mathematical rules and procedures to perform calculations, on the other hand. Both aspects of mathematical competence are commonly viewed as aims of secondary level instruction, and are typically treated in the context of secondary level geometry. Nevertheless, simple one-step geometric calculation tasks tend to dominate classroom activities.

Mathematics education research often focuses on the specific epistemological complexity of proof problems (Duval, 2002). Nevertheless, from a problem solving perspective, many cognitive processes seem to be common to both tasks types. Hsu (2010), for example, found no significant differences between 9th graders' ability to construct geometry proofs and to solve (parallelized) geometric calculation problems.

Both task types involve deductive reasoning processes. Dual-process theories (e.g. Evans, 2008) propose two cognitive systems for deductive reasoning. System 1 is described as fast, intuitive, and based on experience. System 2 is considered as slow, analytic, and based for example on mental simulations. Computation tasks are presumably based on system 1: Here, only one specific geometric configuration is involved. Thus, recognizing a prototypical subfigure linked to a certain mathematical property may already trigger an inference. In a proof process on the contrary, in principle, every argument has to be checked against all possible instantiations of a given geometric configuration. The latter involves the ability to manipulate the geometric configuration mentally within the constraints imposed by the proposition to be proved (mental simulations, system 2). From this perspective, the success in proof tasks can be expected to rely strongly on cognitive processes associated with system 2, in contrast to the performance in complex calculation tasks.

Aim

In our study, we aim at testing the hypothesis that mental processes related to system 1 are connected to performance in both task types, whereas processes related to system 2 are only connected to performance in proof tasks.

Methodology

We conducted a correlation study with 230 German grade 10 students (Gymnasium) and surveyed their abilities to solve complex calculation tasks (8 open items) and to construct geometry proofs (7 open items). As predictors, we used a geometric knowledge test consisting of mathematical propositions (grouped into 6 multiple-choice items) that had to be judged as true or false and, additionally, a scale of simple single-step geometric calculation problems (4 open items) to survey procedural knowledge. The tests were administered by trained assistants in two 45-minute sessions.

We assume different cognitive processes required to judge true and false propositions in the geometry knowledge test. To evaluate a true proposition (e.g. in each isosceles triangle two angles are congruent), it is sufficient to recall the corresponding theorem or, alternatively, one or more prototypes of isosceles triangles from memory to see that the proposition is correct. This is a typical application of system 1. When evaluating a false proposition (e.g. in each isosceles triangle, the bisector of each angle bisects the side opposite to the angle), a prototype might lead to a wrong conclusion, since it might represent a special case for which the proposition is true. Several possible configurations of isosceles triangles, and different angles have to be considered to see that the proposition is false. This involves cognitive processes typically associated with system 2 (e.g. mental simulations). Accordingly, we split the knowledge scale into two subscales.

The relation between the predictors and the performance in the two task types were analyzed by using regression analyses.

Findings

The scales showed sufficient to good reliabilities and distributions. The performance in single-step calculation items had no significant influence on the performance in neither proof nor complex calculation tasks. The ability to judge true propositions showed a significant relationship with both task types ($t(226)=5.79$; $pb=0.35$ for proofs, $t(226)=5.31$; $pb=0.35$ for complex calculations). In our context, this means that abilities related to system 1 are indeed connected to performance in both task types.

The ability to judge false propositions showed a significant relation with proof performance ($t(226)=4.85$; $pb=0.30$). Moreover, we found a weakly significant relation with complex calculations ($t(226)=2.07$; $pb=0.14$) which disappears when controlling for proof performance.

To sum up, we found a predictor pattern which is consistent with our theoretic assumptions about cognitive processes which are relevant for complex calculation tasks and proof tasks within elementary geometry. First, the ability to solve single-step calculation tasks does not seem to be relevant for success in both task types. Secondly, the results support the assumption that success in proof tasks relies on abilities associated with both systems of deductive reasoning. System 2 does not seem to be equally relevant for complex calculation tasks. It requires flexible mental representations of geometric concepts and the ability to manipulate them in working memory.

Discussion

If these results can be sustained, at least there are two educational implications: First, if the ability to solve single-step calculation problems is not predictive for the success in higher-order tasks, the current role of this task type in classrooms should be reconsidered carefully. They tend to make up the majority of practice problems. Secondly, existing ideas that can potentially lead to a better development of mental representations and abilities associated with system 2 should be considered as possible interventions to foster conceptual development and performance in both task types. Examples are so-called "conjecturing tasks", demanding students to explore geometric configurations and come up with a reasonable conjecture about a geometric configuration, or tasks involving the evaluation of (potentially false) mathematical propositions.

The effect of proof format on proof comprehension: are structured proofs easier to understand?

Juan Pablo Mejia-Ramos, Rutgers University, United States; Keith Weber, Rutgers University, United States

In undergraduate mathematics courses, proofs are regularly employed to convey mathematics to students. However, research has shown that students find proofs to be difficult to comprehend. Some mathematicians and mathematics educators attribute this confusion to the formal and linear style in which proofs are generally written. To address this difficulty, Leron (1983) suggested an alternative format for presenting proofs, namely structured proofs, designed to enable students to perceive the main ideas of the proof without getting lost in its logical details. However, we are not aware of any empirical evidence that such format actually helps students comprehend proofs.

Here we report preliminary results of a study that employs a recent model of proof comprehension to assess the extent to which Leron's format helps students understand proofs. This model comprises six different dimensions of proof comprehension and suggests ways in which each dimension can be assessed. Using this model we designed proof comprehension tests for two proofs, one in calculus and one in number theory. We compare the performance of twelve undergraduate mathematics students who took these tests after reading two different versions of these proofs: the traditional linear presentation and Leron's structured presentation. This study did not find evidence that structured proofs improved students' comprehension of proofs, suggesting the need for more research on the conditions under which this format may improve comprehension.

Introduction

In advanced mathematics courses, proofs are a primary way that teachers and textbooks communicate mathematics to students. However, researchers note that students find proofs to be confusing or pointless. Some mathematicians and mathematics educators attribute students' difficulties in understanding proofs to the formal and linear style in which proofs are written (e.g. Rowland, 2001).

To address this difficulty, Leron (1983) suggested an alternative format for presenting proofs: the structural method. Leron suggested that linear proofs limit students' understanding because this format masks the overarching structure of the proof. He recommended instead organizing a proof into levels with Level 1 providing a summary of the main ideas of the proof, Level 2 giving a summary of how each of the main ideas is implemented, and successively lower levels filling in more of the details of the proof. Leron claimed this format helped students comprehend proofs.

This suggestion has an obvious appeal; if changing the format of a proof can increase students' understanding of its content, then this alternative proof format provides a practical way to improve the effectiveness of lectures and textbooks in advanced mathematics courses. However, although several researchers cite Leron's structured proofs as a possible way to improve proof presentation (e.g., Alibert & Thomas, 1991), we are not aware of any empirical evidence that such proofs will help students. Indeed, in an exploratory study, Cairns and Gow (2003) present theoretical difficulties that students may encounter with a structure proof and illustrate how three students experienced these difficulties. The goal of this study is to further examine the extent to which Leron's (1983) structured proofs improve student understanding.

Methods

For this study, we interviewed twelve third-year undergraduate mathematics students. Participants were asked to study a proof and told they would be asked a series of questions about it. After they studied the proof to their satisfaction, they returned it to the interviewer. Participants were then asked to rate how well they understood the proof on a 5-point scale (with 5 indicating they understood the proof completely) and asked both open-ended and multiple-choice questions about the proof. These questions were designed employing Mejia-Ramos et al.'s (2010) model for proof comprehension at the undergraduate level (according to this model students' proof comprehension can be assessed along six dimensions including the ability to cite justifications for statements in the proof and identify the logical structure of the proof and its high-level ideas). After participants answered all questions, the proof was returned to them and they were permitted to change their answers. This process was repeated with a second proof. Participants in one group first studied a linear presentation of a proof in calculus and then studied a structured proof of a statement in number theory. Participants in the second group studied a structured version of the calculus proof and a linear version of the number theory proof. The structured and linear versions of the proof in number theory were taken with minor modifications from Leron (1983). Participants were also asked about their opinions of the structured proof, what (if anything) they found positive or negative about it.

Our analysis focuses on: (a) how well participants felt they understood the given proofs, (b) participants' performance on the proof comprehension test, and (c) their comments on the benefits and drawbacks of structured proofs. Results Combining across proofs, participants studying the linear proofs reported a mean understanding of 4.00 and answered an average of 7 of the 15 assessment questions correctly (47%), while students studying structured proofs reported a mean understanding of 3.13 and answered 4.83 out of 15 assessment questions correctly (32%).

Among the twelve participants, two reacted positively to the structured proof format, citing that it made explicit the goals of the proof and the relationships between its different parts. The remaining ten participants cited drawbacks with the approach, with some claiming they found it generally confusing.

Discussion

In summary, this study did not find evidence that structured proofs improved students' comprehension of proofs. When participants read a structured proof as opposed to a linear proof, they reported less understanding and performed worse on the assessment questions. Only two participants cited more benefits of structured proofs than drawbacks, with the remaining participants citing that the difficulties in following the structured proofs hindered their understanding.

We note that our results about students' difficulties with structured proofs are consistent with the findings of Cairns and Gow (2003). We also note there are no empirical studies that offer any evidence that structured proofs do improve understanding. We are not arguing such studies cannot be done, but we believe they would take careful thought to design, maybe including instruction for students on how structured proofs should be read. We contend such studies are necessary if alternative formats for presenting proofs are to continue to be proposed as a means of increasing students' proof comprehension, both because claims of this type in mathematics education should require

empirical support and because a study of this type can offer practical pedagogical direction for teachers who wish to incorporate proofs in their own classrooms.

SYMPOSIUM

Perspectives of competence measurement in VET

Chairperson: Frank Achtenhagen, Institute for Business and Human Resource Education, Germany

Organiser: Esther Winther, University of Paderborn, Germany

Frank Achtenhagen, Institute for Business and Human Resource Education, Germany

Discussant: Franz Eberle, University of Zurich, Institut fuer Gymnasial- und Berufspädagogik, Switzerland

Competence measurement in the fields of vocational education and training do actually not exist in Germany and other European countries (cf. Baethge, Achtenhagen, Arends, Babic, Baethge-Kinsky & Weber, 2006). Major problems are given by the fact that competence measurement in VET has mainly to cope with the effective and efficient fulfilment of actions at the workplaces. This leads to a multitude of measurement problems of which central perspectives shall be discussed.

The symposium treats three perspectives: First, an approach to constructing educational assessments in terms of modeling actions and conceptual understanding for mastering real-life tasks at the worksite. This also includes the analyses of test fairness with respect to both the individual characteristics of the students and the companies' properties. Second, perspectives of recent developments in modeling a complex sample of abilities and its high-dimensional structures as well as advantages and disadvantages of diagnostic models will be discussed. Third, competence measurement for VET has to be integrated into a comprehensive, general measurement model of competence. The link between a complex ability construct and the performance in real-life situations can be modelled using sophisticated statistical methods like generalizability theory.

The contributions to this symposium bring together decisive perspectives of competence measurement in the fields of VET. A central aim is to present and discuss research standards which support performance studies in these fields that are comparable to those of PISA studies in compulsory education.

Competence-oriented assessments in VET

Esther Winther, University of Paderborn, Germany; Frank Achtenhagen, Institute for Business and Human Resource Education, Germany

Performance studies in vocational and professional education and training, comparable with the PISA studies on scholastic education, do not yet exist in Germany and other European countries. Therefore, the proposal aims to transfer the methods and evaluation standards applied in the PISA studies to the area of VET and professional development. For this purpose, approximately 1,800 final examinations for industrial clerks (after 3 years of apprenticeship) are analyzed. Based on that analysis scientifically founded evaluation models are developed. Simultaneously, there is a need to learn more about complex situations and its descriptive components to design competence-oriented assessment. This also includes a deep insight into the modeling and scaling approach, but also a constructive discussion about theoretical assumptions regarding the competence construct that is measured. Two aspects of interests will be discussed: A reconstruction of the item development under a pedagogical content knowledge (or subject didactic) perspective, and based on DIF analyses aspects of fairness in formative and

summative testing as well as for the use in instructional processes to foster learning and teaching in the specific domain of economic sciences. The DIF analyses are done in different ways: comparing individual characteristics as well as comparing companies' properties.

(1) Aims and methodology

According to the „Standards for educational and psychological testing“ (AERA, APA & NCME, 1999) the development of tests is based on four different phases: „(1) delineation of the purpose(s) of the test and the scope of the domain (content and skills) to be measured; (2) development and evaluation of the test specifications; (3) development, field testing, evaluation, and selection of items and scoring guides and procedures, and (4) assembly and evaluation of the test for operational use“ (ebd., p. 37). Compared to the PISA studies for the compulsory school system, measurement of competencies in VET has to take into account not only relevant knowledge, but also abilities to fulfill work-related actions in an effective and efficient way. To control this precondition it is necessary to reconstruct (and revise) the theoretical assumptions, which led from the training program to competence measurement under aspects of pedagogical content knowledge as well as under psychometrical aspects. This includes the control (and revision) of the developmental chain with regard to concept map, construct map, item development, outcome space, and measurement procedure (four building blocks, Wilson, 2005). Results of such analyses will be presented. They can be used for the interpretation of test results of different test takers and for the construction of revised test versions. In addition to that there are a number of person-related principles, which should apply: Respect for the students/examinees, responsibility, fairness, reliability, validity and collaboration among the parties involved. In other words, a test developer has to ask: What efforts are made to ensure that the assessment results are accurate and fair? Professionals in learning and instruction should provide and use tests that are fair to all test takers regardless of personal characteristics. Therefore, fairness is a primary consideration in all aspects of testing. Fairness concerns are often framed in terms of both test and item bias favoring or disadvantaging groups of test takers. Two approaches to examining potential measurement bias are identified: (a) judgmental, and (b) statistical. Judgment methods rely solely on one or more expert judges' opinions to select potentially biased items. Clearly, this is more a heuristic methodology. Instead of the sole reliance on expert (i.e., content area) judges, the recommendation to rely on statistical techniques for investigating generates potential bias because this method's defensibility is given. The statistical technique then flags potentially biased items (e.g. Clauser & Mazor, 1998; Zumbo, 1999).

(2) Findings

Primarily results of analyses of test items under the pedagogical content knowledge perspective will be presented (e.g. neglect of process aspects of actions). This is the starting point for the discussion of fairness which is relevant for both the formative as well as the summative use of assessments. Based on the analysis of 1,776 final examinations of industrial clerks the continuum of variation of students' professional competence is discussed. The continuum of variation is an essential part of modern test theory and it not only helps define Differential Item Functioning (DIF) but it also helps us interpret DIF results and their use in learning and instruction. DIF refers to the different statistical properties of an item between groups. DIF analyses here are done in three ways using the Rasch model for DIF: pre-orientation in economic courses vs. no formal trainings, male vs. female, large-scale enterprises vs. smaller companies.

Rasch model for DIF: (Appendix 1)

Competence measurement in VET is not considered fair if it advantages or disadvantages groups of test-takers. Winther (2010) considers that a major concern in the design and development of competence measurement in the domain of VET and professional development is to minimize the effects of the factors that are not part of the actual professional ability to understand and to act in complex professional situations. Some of these factors are described by the test-takers characteristics; some of them are addicted to companies' properties. For example, there is substantial bias comparing the solving of economic problems by naive individuals (with no formal trainings in economics) and novice individuals (with pre-orientation in economic courses). The bias is – surprisingly – in that direction that the groups of novice individuals are less likely to answer an everyday economic item correctly than examinees of the other group (mean DIF-effect .438 logits). The results suggest that classroom instruction in economics does not necessarily lead to superior performance in everyday economic tasks. The examinees from those two groups show differing probabilities of success on the everyday economic items after matching on the underlying ability that the items are intended to measure even after three years of learning and working together. With respect to companies' properties trainees of large-scale enterprises have higher probabilities of responding correctly to an economic item than those trainees working in smaller companies (mean DIF-effect .529 logits). Both effects mentioned have meaningful impact on both the design of tests in the economic domain as well as on the learning and instructional processes.

(3) Theoretical and educational significance

With respect to the design of tests to measure competence in the domain of economics a fundamental issue is that DIF is a necessary, but not sufficient condition for item bias. Therefore, a very important decision is whether to consider items exhibiting DIF as biased items until proven valid or unbiased items until proven biased (Schumacker, 2005). Item bias differs in terms of whether group differences are based on relevant or irrelevant characteristics (respectively) of the test. DIF requires that members of the groups be matched on the relevant underlying ability before determining whether members of the two groups differ in their probability for success. And finally, adverse impact simply describes disproportionate workplace decisions based on test performance, for instance (e.g. Zumbo, 1999). Using the empirical results of DIF for discussing implication on learning and instruction (as a formative use of assessments) it has to be considered that first of all under the pedagogical content knowledge perspective an adjustment of students' prior knowledge, of the skills and strategies students' are using in learning and performing, and of the understanding of underlying economic concepts is necessary.

Do diagnostic models hold more promise than they deliver?

Matthias von Davier, Educational Testing Service, United States

Recent developments in modeling complex student response data utilize multidimensional discrete skill variables. These variables represent latent mastery/non-mastery levels that need to be inferred by observed responses to a series of items. Models of this type have been developed as extensions of latent class approaches, and are often referred to as models for cognitive diagnosis, or diagnostic classification models. The class of models presented here is suitable for binary and ordinal observed response data, and allows modeling the latent structure as a combination of quantitative and qualitative latent variables. Applications of this general diagnostic modeling framework to analysis of test and questionnaire data from areas such as cognitive skills assessments, large scale surveys, longitudinal analysis, and the analysis of multidimensional personality tests (Big 5) will be discussed. The presentation will give an overview of the field, and will talk about promised advantages of using these models as well as limitations of the utility of these models.

(1) Introduction

The presentation will give an overview of latent variable models for cognitive diagnosis. von Davier, DiBello and Yamamoto (2006) provided a selective review of these models tracing the history of diagnostic models from Tatsuo's Rule Space Methodology (RSM) to the General Diagnostic Model (GDM, von Davier & Yamamoto, 2004, von Davier, 2005) As Rupp & Templin (2008) point out, the roots of the currently discussed or rediscovered models go back three decades or more. I chose the term general diagnostic model for my developments, which are no exception here. A new name for a family of models may help to distinguish the approach, but may also be counterproductive in helping to understand relationships to existing approaches. Other names used in the field are aside from cognitive diagnosis models terms such as skill profile models, cognitively diagnostic models, and other variations and for more specific models such as NIDA, DINA, NIDO, etc. All these new terms cannot hide the fact that latent structure analysis (Goodman, 1974; Haberman, 1979; Lazarsfeld & Henry, 1968) is the foundation of all these approaches. This can be easily expressed in terms of a slight variation of the latent class model equation. Some well known properties are preserved, for example, many approaches assume local independence of response variables given the latent class. In addition, one may assume that the latent variable takes on a specific form. In the vast majority of diagnostic models, the latent structure is broken down into a product space of several mastery/non-mastery variables. In this case, we speak of the latent structure as representing binary latent skills, each of which can take on two states. Haberman & von Davier (2007) discuss limitations of these models for the use on item response data based on test instrument that were not designed for the identification of multiple skills.

(2) Modeling high-dimensional structures

However, if highly multidimensional tests are subjected to analysis with diagnostic models, the multidimensional skills-space used in these models may need to be constrained in order to maintain the ability to estimate these models without excessively large sample sizes. DeLaTorre & Douglas (2004) design a higher-order diagnostic model, in which the skill space distribution depends on a higher order latent trait, which makes the binary skills into unobserved 'super-items' and relates in consequence all responses, the observed and the unobserved binary 'skill responses' to a uni-dimensional IRT model. von Davier & Yamamoto (2004) suggested a model that was used by Xu and von Davier (2006) to parameterize the high-dimensional skill space more parsimoniously utilizing log-linear models for multidimensional binary and ordinal data. This model allows for interactions and higher order marginal moments, while reducing the burden on estimated quantities necessary for these models by a large extent, and has proven to be more flexible in fitting the data than, for example, discrete-ized multidimensional normal ability variables.

(3) Utility for factorial and typological theories

Subsequent research (Haberman, von Davier & Lee, 2008) has shown that diagnostic models and multidimensional IRT (MIRT) models can hardly be told apart when looking at the fit of these models to real data. This implies that the multidimensional quantitative skill variable used in MIRT models can very often be successfully approximated by a discrete skill variable with very few (2 or 3 are often sufficient) skill levels per dimension. This finding corresponds with conceptual discussions of the DIMCAT framework (DeBoeck, Wilson & Acton, 2005), as well as with findings reported by Lindsay, Clogg & Grego (1991) as well as de Leeuw & Verhelst (1986) and Formann (1985, 2003). The consequence is that the GDM can be viewed as a general latent variable modeling framework that covers binary, ordinal, and continuous latent variables.

The talk will elaborate on these findings and will give examples of applications of the GDM, and will present research-grade software that is publicly available for non-commercial purposes.

On a General Competency Measurement Model

Richard Shavelson, Stanford University, United States

Across multiple societal sectors, demand is growing to measure individual and group competencies. This paper unpacks Hartig et al.'s (2008) competency definition as a complex ability construct closely related to real-life-situation performance to make it amenable to measurement. Unpacked following the assessment triangle (construct, observation, inference), competency measurement is exemplified by vocational and educational research from business, military and education sectors. Generalizability theory, a statistical theory for modeling and evaluating the dependability of competency scores, is applied to several of these examples. The paper then pulls together the threads into a general competency measurement model.

(1) Aims and Methodology

This talk provides one possible vision, or more formally, model of what the measurement of competencies—be they in education, work, or everyday life—might look like and how such a measurement might be developed and evaluated. It addresses, in part, the challenge posed by Hartig, Klieme and Leutner (2008, p. v): The theoretical modeling of competencies, their assessment, and the usage of assessment results in practice present new challenges for psychological and educational research. The paper is conceptual. It draws on a variety of statistical methods, especially Generalizability Theory (Cronbach et al., 1972).

(2) Findings

The presentation is organized along the lines of the assessment triangle (Figure 1; National Research Council, 2001): Construct—Observation—Interpretation. What is measured, indirectly, is typically called a construct—in our case, the construct is competence or competency. Competence is a "... complex ability ... [construct] that ... [is] closely related to performance in real-life situations" (Hartig, Klieme, & Leutner, 2008, p. v). Note that the construct, competency, is an idea, a construction created by Western societies. It is hypothetical and cannot be observed directly. It can only be inferred from a person's behavior.

Figure 1. The Assessment Triangle. (Appendix 1)

Competencies may be simple (e.g., fastening a bolt) or complex (e.g., troubleshooting a malfunctioning engine). Underlying performance and competence are a complex set of abilities. These abilities are cobbled together when a person attempts to meet task and response demands. The ability complex changes over the duration of task performance as sub-goals are met and new goals are set. These complexes are inextricably intertwined and while psychologists untangle them, analyze them separately, and add them up to provide a measure the whole, this is not the case of competency measurement. Rather, competency measurement focuses on real-world tasks and responses to them recognizing a multitude of abilities are involved in performance and pulling them apart distorts the performance of greatest interest (e.g., McClelland, 19973; Shavelson, Roeser et al., 2002).

From this construct, a task, or problem or stimulus can be identified that is thought to evoke the construct. By engaging in the task, a person's behavior—her response—can be observed. Either the presence or absence of the construct can be observed, or the person's level of performance can be observed. The universe of possible tasks and responses for observing competency performance, then, logically follow from the definition of the construct. For the purpose of building an assessment, a sample of the tasks/responses is drawn from this universe.

Having created an assessment and observed behavior on the sample of tasks and responses, the question remains: Do the scores actually measure—reliably and validly—the construct? That is, can one reliably and validly interpret (infer) from a person's behavior on the assessment the presence or absence of the construct, or the level of performance on the construct? Evidence is presented in Table 1.

Table 1. Generalizability Analysis of Scores from the Navy Machinist Mates Hands-on Assessment (data from Webb, Shavelson, Kim, & Chan, 1989). (Appendix 2)

The talk presents one possible definition of the construct, competence, in a preliminary way. From that definition, concrete examples of how that definition might be put into practice are provided. These examples are drawn from business, military and education. From this characterization, a statistical theory for modeling performance on competence measurements is briefly described. It is then applied to several of the example assessments and some general findings of competency measurement are summarized. The entire package is put together in a final concrete example of an operational assessment of college students' learning. The talk concludes with one possible synoptic model for developing measures of competency.

(3) Theoretical and educational significance

Research and development activities directed at the measurement of competence need to be based on one or several models of competency measurement. The model presented in this paper (or some other model) serves as a beginning of a conversation as to the nature of competency measurement. If adopted across research and development groups involved in measuring competency, there is a chance that our findings and experiences can accumulate and progress over time. In this way, a center of gravity will be created and new advances in one domain will most likely inform measurement in another competency domain. The goal, in the end, is to create continuous improvement in both our measurement methods and our theories of competency.

SYMPOSIUM

On the Design of Visualizations for Learning

Chairperson: Marije van Amelsvoort, Tilburg University, Netherlands

Organiser: Marije van Amelsvoort, Tilburg University, Netherlands

Discussant: Mireille Betrancourt, University of de Geneva, Switzerland

A great deal of educational research aims at a better understanding of learning with and from visualizations, for example by comparing text and pictures, or static and dynamic graphics. Visualizations refer to static and animated visual displays that depict conditions, situations, processes, places or events as they appear in maps, diagrams, graphs, pictures, schematics, data-based spatial or linear renditions, and immersive virtual environments. Although visualizations are widespread in education, the results of learning with visualizations are often mixed, arguably because learning scientists have mostly ignored the importance of informed design of visualizations. Despite much work in graphics design, we know surprisingly little about what a good visualization for learning should look like or what makes a visualization more effective than another. This symposium aims at an inventory of principles, functionality, and aesthetics in the design of visualizations for learning. Three studies are reported that investigate different kinds of visualizations (metaphorical depictions, physics and geography graphics, and argument diagrams). Schwartz et al. investigate whether a decorative picture increases learners' understanding when the graphic is designed to convey a metaphorical message. De Vries and Ashraf solicit teachers' expertise in determining the existence of different categories of visualizations and their function across cultures and domains. Van Amelsvoort and Maes investigate learners' spontaneous construction and understanding of argument visualizations. Through the presentation of these studies, as well as through energetic debate with the discussant, the symposium will give rise to a list of research-based guidelines for the design of visualizations for learning.

Metaphorical Visualizations: Their Influence on the Emotional Intensity of Expository Text Themes

Neil Schwartz, California State University, United States; Robert Danielson, California State University, United States; Sevil Gonen, California State University, United States; William Vallado, California State University, United States; Maryam Falahi, California State University, United States

A series of four experiments across three investigations are reported which describe the influence of decorative graphics on learners' ability to extract the underlying themes of narrative and expository text. When decorative graphics are metaphorical depictions of textual themes, learners use the graphics to guide their interpretation of text at a level deeper than literal passage facts. However, text themes are not equally salient in the emotional arousal they

evoke in learners, and the graphics influence thematic text comprehension differently relative to that arousal. Specifically, the more a graphic is capable of metaphorically depicting text theme, the better the passage will be learned. However, the effect is most predominant well after learning and depends on the emotional salience of the thematic concept.

Background to the Investigation When graphics are paired with text, text comprehension is reliably improved. The finding is robust and well documented across a wide variety of visualization graphics (Schnotz & Bannert, 2003; Mayer, Hagerty & Mayer, 2005; Schwartz & Collins, 2008). However, not all visualization graphics function in the same way, particularly when the graphics are intended to decorate a page. In a meta-analytic review, Levin, Anglin, and Carney (1987) found moderate to strong effect sizes for graphics used to inform text by representing all or part of text content, but weak to non-existent effect sizes for graphics used for decoration. Elia, Gagatsis, and Demetriou (2007) found that graphics used principally for adornment fail to increase learners' understanding of related tasks or deepen their comprehension of instructional material. And yet, decorative graphics are common in educational materials, and publishers still persist in incorporating them. The presumption is that publishers believe that learners will be more drawn to text if it is visually interesting and attractive. The problem is that instructional designers need to know if decorative graphics actually make a difference beyond the aesthetics of text, and what features of the graphics influence comprehension. In the present paper, we discuss four experiments demonstrating that when decorative graphics are metaphorical depictions of underlying text themes, learners use the graphics to guide their interpretation of text at a level deeper than surface processing. (Danielson, Schwartz, Krause & Lippman, 2010; Mortensen & Schwartz, 2009; Schwartz, Battinich, Lieb & Mortensen, 2008; Schwartz, Lieb, Battinich & Kuinke, 2007; Schwartz & Collins, 2008). Schwartz and Collins (2008) demonstrated that learners summoned personally relevant prior knowledge based on the theme of the text made salient by a decorative graphic. Mortensen and Schwartz (2009) found that learners' comprehension of both literal details and deeper-level text themes were increased when decorative graphics were visual metaphors of the underlying themes of a narrative text. Danielson et al. (2010) revealed that learners remembered more neutral passage material in the presence of a decorative graphic when the graphic was a metaphorical depiction of the text theme—significantly more than a graphic showing the geographic region in which the text information took place, or no graphic at all. The Danielson et al. investigation was designed to replicate Mortensen and Schwartz (2009) with expository, as opposed to narrative text, since expository text is more commonly found in textbooks and mainstream media. Two types of text themes (Genocide vs. Civil War) were crossed with four types of metaphorical graphics (Genocide vs. Civil War vs. Geographic Location vs. None) to demonstrate that thematically-consistent metaphorical graphics influence what is remembered from text. The experimental passage was an 839-word expository text describing the current conflict in Darfur, written to reveal two socio-political themes—civil war and genocide. The civil war theme described how Darfurian factions fight for territory and influence. The genocide theme described actions centering around ethnic cleansing. The passage contained 40 neutral, 20 civil war, and 20 genocide idea units. Neutral idea units provided the reader with contextual background of the conflict, geographic information, and a historical timeline. Civil war idea units consisted of rebel groups uniting against a corrupt government for representation. Genocide idea units consisted of a planned extermination or removal of a group of individuals. The graphics depicting genocide, civil war, and geographic location were visual metaphors of the theme and are shown in Figure 1. Metaphorical depiction was defined as a visual representation of an object in action (the target) capable of being understood in terms of another object (the source—in this case the concept underlying the text theme) (Van Weelden, Cozijn, Maes, & Schilperoord, 2010). The analysis yielded significant differences in memory for the genocide theme relative to the theme of civil war, but only in the no graphic condition, with the genocide theme significantly better remembered. Thus, the themes inherent in the text were not equivalent in their salience (Figure 2).

The Present Investigation In the present investigation, we designed two experiments—one a test of the theme of genocide, and the other as a test of the theme of civil war—since the themes were determined to be nonequivalent emotionally. The experimental passage constructed for both experiments was 431 words in length and comprised of 24 sentences, three rated high for the genocide or civil war theme, respectively, in the context of the Darfur conflict. The passage with the genocide sentences was used for experiment 1; the passage with the civil war sentences for experiment 2. The graphics were the same as Danielson et al. (2010) but re-normed for their metaphorical depiction of the genocide or civil war theme, respectively. Only the genocide graphic required modification to reach a statistically significant level of metaphorical depiction. Participants were randomly assigned to one of four graphics (civil war; genocide; geographic location; none) in each experiment. In experiment 1, learners read the passage with the salient genocide theme; in experiment 2, the passage with the salient civil war theme was used. Learners in both experiments were directed to write an essay immediately following reading and a second essay one week later. Results from both experiments suggest that graphics, when they are metaphorical depictions of theme, make text material more memorable when the material can be associated with the theme. However, text themes are not always equivalent, evoking different levels of emotion that mediate the extent to which the graphics influence learners' ability to extract themes for comprehension. The graphics with metaphorical depiction of theme also exert their greatest effect some time after learning. Taken together, the findings reveal that graphic

visualizations, when they are carefully-constructed metaphorical depictions of underlying text themes, influence what learners learn from text. The graphics may appear decorative, but they are interpreted by learners at a level deeper than their literal appearance. Learners attempt to make meaning of the graphics they see by drawing metaphorical associations between the underlying meaning of the text and the underlying meaning of the graphic.

Unpacking Visualisations: A Study of Teacher Conceptions

Erica de Vries, Université Pierre-Mendes-France, France; Muhammad Ashraf, University of Grenoble, France

Visualisations gain more and more importance in pedagogical material, in text books and in computer programs. Despite the co-existence of many different types of visualisations or graphical genres, learning research only has taken into account the distinction between text and pictures. The current study aims at unpacking what, at least in learning research, seems to be one single holistic indivisible category of visualisations. The presented approach focuses on teacher conceptions on the existence of different types of visualisations and their presumed function in teaching and learning. Twenty teachers from two different countries (France and Pakistan) and of two different subject matters (physics and geography) were interviewed. Amongst others, results showed that teachers are confident about student comprehension for generic categories such as tables, line graphs, and maps. However, the transparent nature of hybrid visualisations was called into question. This is an important finding given the fact that technological means have considerably enlarged the spectrum of visualisation possibilities. The design of educational graphics therefore involves reasoned use of advanced visualisation techniques.

Introduction

Visualisations gain more and more importance in pedagogical material, in text books and in computer programs. Despite the co-existence of many different graphical genres, learning research only has taken into account the distinction between text and pictures by studying their spatial and temporal arrangement. Thus, much less attention has been devoted to the educational efficacy of different types of visualisations (or texts!). Thus, the verbal and the visual presentation modes appear as two holistic indivisible categories. To begin with, very diverse systematic taxonomies of visualisations would be possible depending on the particular classification criteria adopted: graphical form, content domain, pedagogical function, signification mode, or nature of the projection of world to visualisation. Bertin (1983) for example distinguishes diagrams (bar charts, histograms, and scatter plots), maps (geographical maps and diagrams with projected topological relations), networks (trees, path, node-and-link), and symbols (signs, icons, pictograms). A more pedagogically oriented categorisation distinguishes representational, organisational, interpretational and transformational pictures (Carney & Levin, 1998). Such distinctions have not gained much importance either in educational research or in teacher training as part of the body of professional knowledge of teachers. The current study aims at an inventory of existing knowledge on visualisation types through an exploration of teacher conceptions on the pedagogical use of visualisations.

Theoretical background

Visualisations are widely used in everyday life, in professional practice, in science and technology, as well as in teaching and learning. Thus, just like reading and writing for texts, interpreting and constructing visualisations seem to be important skills. Roth, Pozzer-Ardenghi, and Han (2005) even argue for the necessity of developing "critical graphicacy", i.e. the ability of constructing and deconstructing inscriptions, in other words to disentangle form, content, and purpose of representations (see also MRC, diSessa, 1995). Such skills clearly go beyond the objectivist functions of visualisations of recording, communicating and processing information (Bertin, 1983). On the other hand, compared to text, visualisations are acclaimed for their transparency, their concreteness, and their support for perceptual inferences (Larkin & Simon, 1987). In short, today's citizens are thought to be able to spontaneously and intuitively read off information because visualisations rely on analogy, on resemblance relations, on iconic as opposed to symbolic representation (Schnotz, 2001). However, educational settings may be considered as a special case of communication characterized by a knowledge disparity between participants. In particular, teachers and learners differ in prior experience with representational conventions (de Vries, 2010), which coins the question of the nature of such representational knowledge especially in teachers. Within the iconic presentation mode, are teachers aware of different types of visualisations? Are teacher conceptions domain-dependent? For example, graphical representations are traditionally widely used in geography (Bertin, 1983) and in physics but for essentially different reasons. Furthermore, teacher conceptions are likely to be culture-dependant. For example, French teachers select, organize and construct their own teaching material, whereas Pakistani teachers use textbooks which contain mostly text, some tables, and very few maps (geography) and diagrams (physics). The aim of the interview was to extract teacher conceptions on visualisation genres, their function in teaching, and on student comprehension.

Method

The study involved an inventory of teacher conceptions through a detailed, semi open-ended interview of ten French and ten Pakistani secondary school teachers in geography and physics. The sample was selected through snowball sampling method and teachers were interviewed in their home country. The interview consisted of seven questions for each of a set of eight different visualisations from geography and physics text books from Pakistan and France. Transcripts of the interviews were scored with the help of an analysis grid.

Summary of the results

Labelling graphics All eight visualisations received more than one category name in the set of teachers. The most clear-cut categories were "table", "map" and "line graph", but even visualisations within these categories were sometimes called "illustration" or "diagram". Only physics teachers used the category name "illustration".

Function of graphics The most important function of graphics, as indicated by teachers, is to present specific information on a topic. Furthermore, graphics are used in order to compare between text and graphics, and for students to be able to study subject matter. Teachers in both disciplines and from both countries did not feel that the presented graphics would motivate or attract students. All teachers stated that they use generic categories such as line graphs, tables, and pictures (such as an image of the solar system). Pictograms are not much used.

Student comprehension All teachers were confident on student comprehension of visualisations like the ones presented with the exception of a map-histogram hybrid that only the better students would understand. All students are thought to be able to understand line graphs and tables. Pictures and pictograms received mixed results. Some teachers think only good students will understand those, whereas others think any student will understand them.

Conclusions and future work In this study, the idea of visualisations as an opaque category was questioned and teachers were interviewed in order to extract their expert knowledge on visualisation types and functions in teaching. The results show that no clear cut categories can be identified. Category names such as "line graph", "diagram", "map" and "illustration" were not univocally attributed and no clear indication as to their function was established. Furthermore, although teachers were confident about student comprehension for generic categories such as tables, line graphs, and maps, there is also reason to doubt the transparent nature of hybrid visualisations, i.e. combinations of different types. This is an important finding given the fact that technological means have considerably enlarged the spectrum of visualisation possibilities. The design of visualisations of learning therefore involves finding the balance between full exploitation of new visualisation techniques and the anticipation of their pedagogical appropriateness. Future research should inquire into the nature of representational knowledge in general and for pedagogical purposes. Furthermore, future work should tackle the question of proper teaching of representational knowledge in teacher training and in school curricula.

Spontaneous Visualization of Argumentation

Marije van Amelsvoort, Tilburg University, Netherlands; Alfons Maes, Faculty of Humanities Tilburg University, Netherlands

Argument diagrams show argument in a non-linear way. They may help students to see relevant relations and to communicate their argumentative positions. However, research on learning with argument diagrams has shown mixed results. We argue that studies thus far did not take into account enough the design quality of argument diagrams. In two studies, we aimed to find design principles for argument visualization. In the first study, twenty participants had to visualize their position (either pro or contra) of an issue on a whiteboard with color pens. Then they were shown the drawing of another participant and asked to explain whether it was created by a proponent or opponent. All participants used textual, spatial and graphical features to visualize their standpoint, and all correctly identified the other's standpoint. Although participants created different types of visualizations, design principles seem to exist that are recognized by others. In the second study, we wanted to find out to what extent the graphical features support understanding of the argumentation. Four versions of the visualizations (1 original, 3 manipulated to contain text only, blurred text only, or graphics with blurred text) were exposed to 120 participants, twice very shortly, a third time for a longer period. Participants had to answer questions on sign, quality, attractiveness and clarity of the visualizations. We found that learners spontaneously use graphical features when creating argument visualizations. The meaning of these features is recognized by others, and strengthens the message. Our studies can help improve computer tools for argument visualization.

Students are sometimes asked to visualize argumentation in diagrams to help them learn about a topic. Researchers have argued that visualizing argumentation in diagrams helps for overview, shows relations, illustrates the structure of argumentation, and promotes reflection of alternative perspectives (e.g., Baker, 2003; Suthers & Hundhausen, 2003). However, visualizing argumentation is hard. Students are taught for years how to read and write, but hardly any attention is paid to how to read and draw visualizations. Asking students to visualize argumentation is therefore

oftentimes not helpful in remembering or understanding the argument. We actually don't know much about how students produce and interpret argument visualizations, and so far, there are hardly any shared conventions in visualizing argumentation (Buckingham Shum & Okada, 2008). Several software tools have been created to visualize (collaborative) argumentation, such as Reason!Able (Van Gelder, 2000), and Drew (Corbel et al., 2003). These tools make argumentation visible, but constrain learners at the same time. In Drew for example, learners must use rectangles to put arguments in and cannot use colors. We asked participants to create a visualization on a whiteboard in any way they liked in order to find spontaneous designs. The goal of our studies is to (1) investigate how students spontaneously create visualizations, and (2) how different graphical features of visualizations contribute to the understanding of argument visualizations.

In our first study, twenty participants were assigned a position (for or against) and asked to make a drawing of twelve given arguments to convince someone else of their standpoint. They could design the drawing in any way they liked, as long as they used all arguments for and against. Results show that all visualizations were different, though seventy percent could be defined as web-like or table-like (Figures 1 and 2). All participants used textual, spatial and graphical elements to visualize their standpoint. The visual language matrix (adapted from Kostelnick & Roberts, 1998) was used to identify what and how many elements were used. In this matrix, 15 graphical, textual and spatial features are distinguished on a local level (i.e., small-scale, such as size for important words) and global level (i.e., large-scale, overall level such as general shape of the visualization). Two researchers independently analyzed 285 features, rating 4% differently. All features were used in more than one visualization, but not in all visualizations. For example, the visualizations contained on average 4.81 arrows ($SD = 5.53$), and 3.21 different colors ($SD = 0.79$) at a local level. The number and type of graphical features inform us of what participants spontaneously use, but do not explain what the features mean. Therefore, we have asked the twenty participants to read the visualization of another participant and decide whether it was made by a proponent or opponent. Table 1 displays perceptual features (space, graphics, and text manipulations) that were used in more than half of the visualizations to meet their argumentative goal. For example, colors were used consistently to show pro and contra arguments.

Participants all correctly identified the standpoint in visualizations created by others. We also compared explanations readers gave for how they decided upon the standpoint to answers the designers gave on how they visualized the argument. For example, one designer explained that she circled her most important argument and put an exclamation mark in front of it. The reader said: "I think the designer was against, because this counter argument is in a red square with an exclamation mark in front of it" (see Figure 2). Study 1 showed that participants use perceptual features in visualizations (space, graphics and text manipulations) consistently to a large extent, and that these are recognized by others, even though very different types of visualizations were created.

In study 2, we investigate to what extent these perceptual features are responsible for understanding argument diagrams, as well as evaluating their attractiveness and persuasiveness. For the experiment, we constructed four versions of each of the visualizations produced in study 1; (a) the original version, (b) graphics with blurred text, (c) text only, and (d) blurred text only. 120 participants were asked to carry out three tasks, twice (task 1 and task 2) looking at the visualizations one by one for only 4 seconds on screen, a third time by looking at the visualizations all together without time limit. In task 1, they had to decide whether the visualization was from a proponent or opponent. In task 2, they rated the attractiveness and clarity of the visualization. In task 3, they answered more in-depth questions about the quality of the visualizations using a selection task. We expected that the graphical features help participants in deciding pro or contra when they have only four seconds to decide, and that participants evaluate visualizations with graphical features more positively. The graphical features of each visualization in study 1 were correlated to participants' evaluations in study 2, in order to find those features that are important for understanding argument visualizations. Preliminary results indicate that graphical features help learners identify arguments faster, but not understand them better. In sum, learners spontaneously use textual, graphical, and spatial features when creating argument diagrams. The meaning of these features is not only recognized by others, but also strengthens the message. Design principles are derived from learners' own use of graphical features to improve tools for argument visualization. Future research should take into account how people create and interpret specific aspects of argument visualizations to gain insight into how representations guide learning.

SYMPOSIUM

Learning by means of comparing and contrasting

Chairperson: Lennart Schalk, ETH Zurich, Switzerland

Organiser: Elsbeth Stern, ETH Zurich Institute for Behavioral Sciences, Switzerland

Discussant: Alexander Renkl, University of Freiburg, Germany

Encouraging students to compare different examples of problems and/or solution methods has recently gained attention because it has proven to be a powerful mechanism for meaningful learning particularly in formal areas such

as science and mathematics. Systematic comparisons involve processes of structural alignment and mapping that support learning by abstraction, inference-projection, or difference-detection. As a consequence, comparisons can support the extraction of a common relational scheme inherent in different examples. Another possibility is that comparisons do help to contrast important features that should not be confused. In this symposium, three different experimental studies will be reported that investigated learning by means of comparing and contrasting. The first study by Schalk and Saalbach demonstrated that a broad transfer performance can be achieved by comparing multiple examples in the domain of propositional logic. The second study by Ziegler revealed that contrasting superficially similar problems in the domain of basic algebra helps to highlight the differences which prevents from confusing the underlying concepts. The third study by Durkin and Rittle-Johnson showed that comparing correct and incorrect solution methods helps to learn key concepts and correct procedures about decimal fractions. Overall, the studies demonstrated that initiating comparison and contrasting activities foster the acquisition of conceptual and procedural knowledge and their transferability. The discussion will integrate these new empirical findings and provide critical reflections on how the findings can be used to develop learning material.

Designing learning material to foster transfer: Which route to take?

Lennart Schalk, ETH Zurich, Switzerland; Henrik Saalbach, ETH Zurich, Switzerland

We evaluated different ways of how to design learning materials to foster the flexible use of general principles. One possibility is to directly present the abstract representation of a principle; another is to present concrete examples which instantiate the principle and prompt comparison of them. Both the use of worked examples and the prompting of comparison processes have been shown to support learning and transfer. In contrast to previous studies, we evaluated the transfer potential of a variety of learning materials with multiple transfer tasks. In Experiment 1, four different ways of learning the principles of propositional logic were tested against each other: (1) learning the abstract representation, (2) comparing the abstract representation with one worked example, (3) comparing two worked examples, (4) learning two worked examples without comparison. We found that students learning material (3) showed better transfer performance than students using (1), (2), or (4). Surprisingly, students comparing the abstract representation with one worked example (3) were least successful. Given the importance of mapping abstract representations onto concrete examples in school learning, we explored a way of supporting this mapping. In Experiment 2, we therefore tested whether comparing the abstract representation with two worked examples (5) instead of one would result in a better transfer performance. We found that learning with (5) resulted in the best transfer performance. We suggest that this kind of comparison should be considered when designing learning materials to foster transfer of general principles.

A major aim of education is to enable learners to apply their content knowledge to solve a large variety of problems. Knowledge acquired in educational contexts often consists of general principles applicable to superficially dissimilar phenomena. For example, principles of propositional logic should be considered when evaluating the validity of a philosophical argument, but also when comprehending the functions of logic gates in digital circuits. Teaching thus requires that the principles taught in school are transferable to new problems and do not remain tied to specific characteristics of the learning situation.

Different approaches have been proposed to achieve this aim. One approach to foster transfer of general principles suggests directly teaching the abstract representation of the principle (e.g., a formula). It is argued that abstract representations are likely to emphasize non-perceptual relations among entities while containing no (distracting) extraneous information (e.g., Kaminski, Sloutsky, & Heckler, 2008). Another approach emphasizes the self-construction of the principle by comparing concrete examples (e.g., worked examples). Comparing examples is said to promote the generation of a more general and complete relational schema (e.g., Gentner, Loewenstein, & Thompson, 2003). Finally, a third approach suggests learning simultaneously from different representational formats (e.g., a formula and a worked example). Here it is argued that integrating multiple representations supports conceptual understanding by active translation between representations (e.g., Ainsworth, 1999). However, results of research investigating these different approaches are difficult to compare.

A comprehensive evaluation is difficult due to two reasons. First, conceptualizations of transfer differ between researchers. Mainly, dichotomies such as near versus far transfer have been used without explicitly specifying the conceptual distance between learning and transfer task. This becomes even more problematic because, second, transfer is commonly measured only with a single task. Hence, the advantage of the learning material used in previous studies may be restricted to the specific kind of transfer tested. The aim of the present research was therefore to evaluate the transferability of general principles taught by different materials by means of a wide range of transfer tasks with different representational formats.

Experiment 1

In Experiment 1, we developed materials presenting the principles of propositional logic in four different ways. Groups of students learned the principles either by (1) directly learning the abstract representation of the principles, (2) comparing the abstract representation with one worked example, (3) comparing two worked examples, or (4) learning two worked examples without comparison. (4) served as the baseline group, which should be outperformed by the other groups. Group (3) might be provided with the most effective learning material since learners are trained on the translation between different representations and the different transfer tasks are based on various representational formats.

Method:

Undergraduates (N=114) were randomly assigned to learning materials. Students worked through the materials individually. To engage students in active processing they were instructed to write short self-explanations. Learning lasted one hour. One week later, students were given a transfer test consisting of seven types of tasks.

Results

Students comparing two worked examples gained the highest transfer score (65%). This score was significantly higher than the score of students comparing the abstract representation with one worked example (54%, $d = .72$) and the score of the baseline group (58%, $d = .46$). Directly learning the abstract representation resulted in the second best transfer score (61%). This group was significantly superior to the group comparing the abstract representation with one worked example ($d = .51$), however, they did not outperform the baseline group.

Discussion

Comparing worked examples resulted in the best transfer performance. Although students learning the abstract representation did not perform significantly worse than students comparing two worked examples, they failed to perform better than the baseline group. The results thus suggest that learning principles by the means of comparing worked examples has the highest transfer potential.

Surprisingly, however, comparing the abstract representation with one worked example resulted in the least successful transfer performance. Given the importance of mapping abstract representations onto concrete examples in school learning, we explored a way of supporting this mapping in the second experiment.

Experiment 2

We tested whether comparing the abstract representation with two worked examples (5) instead of one would result in a better transfer performance. We compared performance of this group to groups (1), (2), and (3) of Experiment 1.

Method

Twenty-seven undergraduates learned the principles of propositional logic by comparing the abstract representation with two worked examples. The students were tested on the same transfer test used in Experiment 1. The procedure was the same as in Experiment 1.

Results and Discussion

Learners of material (5) gained the highest transfer score (66%). This group significantly outperformed students who (1) learned only the abstract representation ($d = .31$) and students who (2) compared the abstract representation with one worked example ($d = .82$). No differences between learners of material (5) and students who (3) compared two worked examples were found. Our results suggest that using multiple representations when learning general principles is only efficient when the abstract representation needs to be aligned with multiple worked examples.

General Discussion

Overall, we found that comparing worked examples (3, 5) is more effective than merely learning an abstract representation (1) or aligning two different representational formats (2) with respect to transferring general principles such as propositional logic to a broad range of tasks. Our results therefore suggest that a specific advantage of learning environments with multiple representations can only be reached when they incorporate multiple worked examples (5) instead of a single one. This allows for deep abstraction from superficial features of the learning materials. Because learning principles is common in mathematics and science instruction the present findings have implications on developing learning materials.

Learning similar concepts in mathematics: Contrasting as a way to make differences more salient

Esther Ziegler, ETH Zurich, Switzerland

Numerous studies have shown the positive effect of comparisons on concept learning. Comparisons seem to affect a deeper processing of learning materials. Previous studies used comparing examples with dissimilar surfaces to abstract a principle that subsequently can be applied to solve a novel problem. However, to understand closely-related concepts, it may be helpful to compare objects with similar surfaces to make differences more salient, in the sense of a contrasting. The aim of this study was to explore whether comparisons used as contrasts can help to better understand the difference between superficially similar concepts. A training study was conducted with a self-learning program for the introduction of two mathematical concepts: addition and multiplication in algebra. A total of 157 sixth-graders (mean-age= 12.4) were randomly assigned to two conditions: (1) in the contrast condition they were presented addition and multiplication tasks simultaneously with the instructions to compare them, (2) in the sequential condition they practiced addition examples for two days, followed by two days of multiplication training. In both conditions, exactly the same learning material was used. In accordance with our hypotheses, all three post-tests (one day, one week, ten weeks later) showed a significant effect of contrasted learning compared to sequenced learning, although students in the contrast condition performed worse in the immediate learning tests. Thus, this study demonstrated that contrasting is a promising learning method to differentiate superficially similar concepts in the domain of algebra in a school setting, although such learning leads to more errors at the beginning.

Many students have substantial difficulties in learning algebra. The main problem seems to be the uncertainty in handling the rule system which may be responsible for prevalent confusion of similar concepts ($ab+ab=2ab$ and $ab \cdot ab=a^2b^2$). Two reasons for confusion errors are discussed: procedure memorizing without understanding underlying concepts (Stephens, 2008) and the misleading focus on surface features instead of paying attention to structural characteristics of concepts (Chi et al., 1981). Comparisons seem to affect a deeper processing which help to overcome this focus on the surface and to gain insight into causal structures of concepts. The benefit of comparison has been shown in numerous studies with comparisons to learn complex concepts (Kurtz et al., 2001; Loewenstein et al., 2003). Therefore, comparing examples with dissimilar surfaces helps to abstract a common principle which subsequently can be used to solve novel problems. However, to understand closely-related concepts, it may be helpful to compare objects with similar surfaces to make differences more salient, in the sense of a contrasting. Concepts are frequently built on precedents and therefore often differ only in a few aspects, which may also be the reason why concepts are usually introduced gradually. But there is no research that investigated a simultaneous and contrasted introduction of concepts. Hence, the aim of this study was to examine whether such contrasting helps to distinguish between superficially similar concepts. On this account, we have chosen the two concepts addition and multiplication in algebra. We expected to find learning benefits of the contrasted introduction compared to the sequential introduction. In addition, we were interested in whether contrasting can be established as a general instruction principle in school settings.

Method

We constructed a self-learning program for the introduction of the two concepts: addition and multiplication in algebra. The programs were processed in 2-hour learning sessions on four successive days where students had to work through 9 work sheets. These sheets consisted of worked examples and a self-study part. After every sheet, students did a test as an indicator for immediate learning. A total of 157 sixth-graders (mean-age= 12.4, 54.5% girls) participated and were randomly assigned to one of two conditions. In the contrast condition, students were presented worked addition and multiplication tasks simultaneously with the instruction to compare them. In the sequential condition, students practiced addition examples for two days, followed by two days of multiplication training. In both conditions, exactly the same learning material was used only presented in another order.

All students participated in three post-tests (one day, one week, ten weeks later), where procedural and conceptual knowledge, including misconceptions, were assessed as indicators for long-term learning. Conceptual knowledge was further analyzed for the number of defining features students reported in their written explanations. In addition, we assessed the passive learning of the alphabetical-ordering convention which was not explicitly taught.

We conducted two successive experiments with different participants and with an adapted post-test instruction: "control all tasks after finishing the test".

Results

As the main effect of group was similar in both experiments, we merged the two experiments into one evaluation. We used repeated measurement ANOVAs with the factor Group (contrast versus sequential) x Time (T1: one-day, T2: one-

week, T3: ten-weeks) for all the post-test measures. A multivariate ANOVA was conducted for the immediate learning measures.

There was a main effect of group for all post-test measures in favor of the contrast group: for procedural knowledge ($p = .094$) and for conceptual knowledge ($p = .077$) both with significant post-hoc tests at all points of measurement and for misconceptions ($p = .102$) with significant post-hoc tests at T2 and T3. These results indicate that contrast learning improves long-term memorization. The sub-analyses of conceptual knowledge showed only significant differences in reporting defining concept features, but not in reporting secondary features.

Surprisingly, the contrast group performed worse in immediate learning (p

There was a main effect of time for most of the post-test measures (p

Discussion

Our findings support contrasting as a promising learning method to differentiate superficially similar concepts in the domain of algebra in a school setting. The contrast group performed better in most of the post-test measures, mainly in the one- and ten-weeks post-tests, indicating a clear long-term learning gain.

In immediate learning, however, the sequential learners showed better results which may mislead one to conclude they learned better. However, knowledge acquisition needs to be considered on a long-term basis. An implication may be that some errors must be done in concept learning to differentiate between concepts. Furthermore, the fact that contrast students scored higher in the defining features of conceptual knowledge indicates that contrasting instruction leads to a focus on the essential aspects of concepts that need to be learned. This focus on defining features may be the key to manage distinction between similar concepts. Together with the worse performance of contrast learners in not explicitly taught conventions it may indicate that sequential processing of material requires less cognitive load. Thus, this reduced cognitive load may promote the perception of secondary concept features, but seems to distract from the more central defining features.

The effectiveness of comparing incorrect and correct examples

Kelley Durkin, Vanderbilt University, United States; Bethany Rittle-Johnson, Vanderbilt University, United States

Many studies have examined the benefits of comparison when learning mathematics. Comparing common mathematical errors to correct examples may be one type of comparison that prevents such errors from being made in the future. In two experiments, we examined whether comparing correct and incorrect solution methods was more effective than comparing two correct solution methods when learning about decimal magnitude. In Experiment 1, students ($N=74$) in Grade 4 and 5 were randomly assigned to one of two conditions: 1) incorrect and correct examples or 2) correct examples only. Comparing incorrect and correct examples helped students learn correct procedures and remember key concepts more than comparing correct examples. Students' explanations during the intervention revealed that those in the incorrect and correct condition more frequently discussed correct concepts (e.g., the magnitude of a decimal; identifying a misconception). In Experiment 2, students ($N=54$) in Grade 4 and 5 were provided with instructional explanations or additional practice to evaluate the different benefits of each when learning from incorrect examples. Students were randomly assigned to one of three conditions: 1) incorrect and correct examples with explanations, 2) incorrect and correct examples with additional practice, or 3) correct examples only with additional practice. Preliminary analyses suggested that exposing students to incorrect and correct examples was more effective than studying only correct examples when learning about decimal magnitude. Also, additional practice seemed to be more beneficial than instructional explanations. Overall, having students compare incorrect and correct examples seems beneficial for learning, especially when paired with procedural practice.

Intuition suggests that exposure to incorrect examples reinforces an incorrect response. However, the learning of science literature has robustly shown that misconceptions in science persist even in older students, and discussing these misconceptions is an important step towards correcting them (e.g., Eryilmaz, 2002). In a similar fashion, comparing common mathematical errors to correct examples may prevent such errors from being made in the future.

It may improve students' ability to use and transfer effective solution methods (procedural knowledge) and to understand key concepts (conceptual knowledge). In particular, this type of comparison emphasizes the critical attributes of correct examples (Grope & Renkl, 2007) and helps students correctly update their schemas for important decimal concepts (VanLehn, 1999).

Students have common and persistent misconceptions in the domain of decimal fractions (Irwin, 2001; Resnick et al., 1989), so we examined incorrect examples in this domain. Students often treat decimals as if they are whole numbers (e.g., they think 0.25 is greater than 0.7) or do not understand how a zero affects the magnitude of a decimal (e.g., 0.08 and 0.250). We used a number line task to teach students about decimals. This was a relevant but novel task for most students, and the National Math Panel Report (2008) suggests using number lines for supporting understanding of decimals.

In Experiment 1, we investigated whether comparing incorrect and correct examples (incorrect condition) promoted greater learning than comparing two correct examples (correct condition). We randomly assigned students ($N = 74$) in Grade 4 and 5 to a condition. All students completed a pretest that focused on students' knowledge of decimal procedures and concepts. The procedural knowledge assessment included number line problems in a variety of formats. The conceptual knowledge assessment focused on students' understanding of decimal magnitude (e.g., which is bigger?). Students then worked individually on a 25-minute intervention during which they studied 12 worked example pairs and answered questions about the examples. During the intervention, students in both conditions also solved four practice problems. After the intervention, students completed an immediate posttest. About two weeks later, students completed a retention test.

Comparing incorrect and correct examples led to greater procedural knowledge at posttest and greater conceptual knowledge on the retention test. This was partially due to these students making fewer whole number misconception errors on the retention test. Thus, comparing incorrect and correct examples does help students learn correct procedures and remember key concepts above and beyond the general benefits of comparison. During the intervention, comparing incorrect and correct examples encouraged students to more frequently discuss misconceptions and mention correct concepts. These findings suggest that exposure to incorrect and correct examples may cause students to notice salient, correct concepts more so than comparing only correct examples.

Even with the learning gains in Experiment 1, students were still making errors on 40% of the problems. When students are learning in a domain with many misconceptions, such as decimal magnitude, they are faced with competing concepts (Huang, Liu, & Shiu, 2008). Instructional explanations emphasize important conceptual structures, which may be a way to eliminate this competition (Renkl, 2002). Also, when a correct procedure is learned, the incorrect procedure remains, and this results in competing procedures (Siegler, 2002). Giving students sufficient procedural practice may decrease competition and improve selection of correct procedures (Siegler, 2002). Consequently, more instructional explanations and more opportunities for procedural practice throughout the intervention might be beneficial for reconciling these competing concepts and procedures, which we wanted to investigate in Experiment 2.

In Experiment 2, we examined three conditions: (1) learning from comparing an incorrect and a correct example with instructional explanations (incorrect-explanation), (2) comparing an incorrect and a correct example with additional practice problems (incorrect-practice), and (3) comparing two correct examples with additional practice problems (correct-practice). We slightly modified the assessment and used the same pretest-intervention-posttest-retention test design as in Experiment 1. During the intervention, students ($N = 54$) studied 12 worked example pairs and answered questions about the examples. Students in the incorrect-explanation condition received an instructional explanation for each worked example pair and solved 4 practice problems. Students in the incorrect-practice and correct-practice conditions completed 28 practice problems, in an effort to control for time on task.

After preliminary analyses, it seems that comparing incorrect and correct examples led to greater procedural knowledge at posttest and greater conceptual knowledge at posttest and retention test. In addition, spending time on practice problems led to greater retention of procedural and conceptual knowledge than spending time on instructional explanations. Comparing incorrect and correct examples appears to be a promising instructional tool, and providing opportunities for practice may help students benefit most from such comparisons.

SYMPOSIUM

Effects of home environment and early child care on social development of young children

Chairperson: Andrea G. Eckhardt, German Youth Institute, Germany

Organiser: Andrea G. Eckhardt, German Youth Institute, Germany

Discussant: Hans Guenther Rossbach, University of Bamberg, Germany

A major topic in early childhood education is the social development of young children. However, the findings of the effects of home environment and center based care are inconsistent. New insights in influences of social development in early childhood are presented from multiple perspectives. In the first paper, Melhuish et al. present new findings from the EPPE-Project focusing on long term influences of demographic characteristics, early years home learning environment, and pre-school experience on social development of children at age 11. While this paper looks at individual and combined influences of the developmental context of children, the following presentations provide insight on the effect of institutional care on the social development of children. In the second paper Leseman, de Haan & Elbers examine social-emotional development in targeted and mixed culturally diverse preschools for disadvantaged children, with special interest in the effects of classroom ethnic-cultural composition and degree of interethnic peer interaction on extraversion, work attitude, sociability and emotional stability. Finally, results from a systematic review by Eckhardt & Egert present the effectiveness of early childhood programs on social development of children. The symposium contributes to existing knowledge in confirming the long term consequences of family environment and quality of center based care on positive aspects of social development. At the same time, it provides new insights from research on the effects of institutional care that result from groups with children from diverse cultural backgrounds. Additionally, it highlights differential effects depending on individual characteristics of children, care settings or program features.

The effects of early experiences at home and pre-school on social/behavioural development at age 11

Pamela Sammons, University of Oxford, United Kingdom; Edward Melhuish, University of London, United Kingdom;

Kathy Sylva, University of Oxford, United Kingdom; Iram Siraj-Blatchford, Institute of Education - University of London, United Kingdom; Brenda Taggart, University of London, United Kingdom

This paper explores the contribution of the demographic characteristics, early years home learning environment and pre-school to children's social/behavioural development. While much existing research relates aspects of children's environments or experiences to social development, there has been little work that is with a large enough longitudinal sample, with sufficiently detailed data, to delineate the independent long-term effects of demographics, home and pre-school. This paper contributes to the literature by presenting findings from the Effective Pre-school and Primary Education (EPPE) Project, a longitudinal study on a representative sample of 3000 children in the UK. While the study has extensive longitudinal information on cognitive, educational and social/behavioural development, this paper will focus on the predictors of social/behavioural development at age 11. The home learning environment and pre-school are important predictors of social/behavioural development and the interaction of these effects is also explored.

Aims:

This paper aims to explore the contribution of the demographic characteristics, early years home learning environment and pre-school to children's social/behavioural development. While much existing research relates aspects of children's environments or experiences to social development, there has been little work that is with a

large enough longitudinal sample, with sufficiently detailed data, to delineate the independent long-term effects of demographics, home and pre-school. This paper uses findings from a longitudinal study on a representative sample of 3,000 children in the UK. While the study has extensive longitudinal information on cognitive, educational and social/behavioural development, this paper will focus on the predictors of social/behavioural development at age 11.

Methodology:

The EPPE project is Europe's largest longitudinal investigation into the effects of pre-school and primary education on children's developmental outcomes, and uses mixed methods. Using multilevel modelling, the authors examined the contribution of child, family, home environment, and school characteristics to children's social/behavioural development at age 11 years. Research questionsThe research questions addressed in this paper are as follows: a. Does the early years home learning environment (HLE) have an independent effect on children's social behavioural development?

b. Does pre-school have an independent effect on children's social/behavioural development?

c. Does pre-school quality influence children's social/behavioural development?

d. Do the effects of home and pre-school on children's social/behavioural development remain until age 11 years?

e. How do pre-school effects and home learning environment effects interact to shape children's social/behavioural development?

Sample

Five regions in the U.K were strategically selected to include urban, suburban and rural areas, some including social and ethnic diversity. A total of 141 centres were randomly selected from different types of provisions (e.g., playgroups, nursery schools, private day nurseries). Over 2,800 children were recruited at age 3 and followed until school entry (age 5), when they were joined by an additional 310 'home' children with no pre-school experience. Approximately 2,700 of these children were then followed for a further six years until the end of Primary school (age 11). Child assessmentsSocial/behavioural development was measured at several ages through standardized questionnaires completed by a teacher (or other staff) who were familiar with the child in pre-school or school environments. When children were aged 11 we used the Strengths and Difficulties Questionnaire (Goodman, 1997) plus additional items from other questionnaires to measure different features of children's social/behavioural development. The social/behavioural child profile was completed by a teacher who knew the EPPE 3-11 child well. Principal component analysis and confirmatory factor analysis were used to identify the main underlying dimensions of social behaviour at age 11. The main four dimensions of social behaviour were self-regulation, pro-social behaviour, hyperactivity and anti-social behaviour. Home Learning Environment measureBased on data collected from parental interviews, an index of the Early Years Home Learning Environment (HLE) was constructed, consisting of the following items rated on an 8-point scale (anonymous, 2001):

Reading to child	Painting and drawing with child
Playing/teaching numbers/shapes to child	Library visits with child
Playing with letters/numbers with child	Playing/teaching alphabet/letters
	Playing/teaching of songs/nursery rhymes etc.

Pre-school quality measure: Early Childhood Environment Rating Scale-Revised (ECERS-R) (Harms, Clifford,& Cryer, 1998) Early Childhood Environment Rating Scale-Extension (ECERS-E) (Sylva, Siraj-Blatchford & Taggart, 2003). Co-variables: Child and family variablesParental interviews and questionnaires were conducted at ages 3 and 7. Information was collected on parental characteristics (socio-economic status, educational level, employment and age), family characteristics (lone parent family and number of children), and child characteristics (ethnicity, birth weight, perinatal difficulties, child's first language, early developmental problems). Analytic strategyIn order to take account of the clustering of children within the same pre-school centre or school multi-level models (Goldstein, 2003) were used to investigate children's development as a function of home, pre-school and school factors as well as a wide range of EPPE 3-11 and family characteristics.

Findings:

The positive benefits of pre-school education have largely persisted through to age 11. Attending a pre-school compared with not attending (the 'home' group) showed a positive effect on children's pro-social behaviour at the end of Year 6, but there were no statistically significant differences for other aspects of social behaviour. Also the quality of the pre-school had a statistically significant impact on all four social/behavioural outcomes at age 11. The findings suggest that attending a high or medium quality pre-school has a lasting effect in promoting or sustaining better social/behavioural outcomes, in terms of increased 'Self-regulation', higher 'Pro-social' behaviour and lower 'Anti-social' behaviour levels at age 11. There was a continuing strong influence of the Early years Home Learning Environment. After controlling for child and family characteristics, Early years HLE had a significant net effect on children's self-regulation, pro-social behaviour and hyperactivity at age 11. Only self-regulation had significant interactions between early years HLE and pre-school quality. Controlling for other background characteristics, a combination of high Early years HLE and attendance at a medium or high quality pre-school is a strong predictor of higher self-regulation. In addition, high Early years HLE seems to act as a protective factor for children who do not

attend pre-school helping them achieve higher levels of self-regulation. Similarly, high quality pre-school seems to protect against the disadvantage of a low Early years HLE and promotes children's later self-regulation. Theoretical and educational significance: This study has shown that children who have more beneficial experiences in the home and in pre-school before they enter school have better social/behavioural development and these effects are still apparent at the end of primary school. These beneficial effects upon social/behavioural development contribute to the child's overall well-being and are likely to promote social and educational success in later years. The benefits of early experiences are long-lasting and fundamentally change children's longer-term development. These findings add further weight to arguments for: (1) pre-school education for all 3 and 4 year old children (2) ensuring good quality of pre-school education, and (3) supporting parents in providing a high quality HLE.

Social-emotional development in culturally diverse preschool and kindergarten classrooms

Paul Leseman, Utrecht University, Netherlands; Annika de Haan, Utrecht University, Netherlands; Ed Elbers, Utrecht University, Netherlands

A major issue in early educational intervention policy for low income and ethnic-minority children concerns the pros and cons of targeted versus mixed and universal programs. Whereas recent evidence indicates that mixed and universal programs are more effective in the domains of cognitive and language development compared to targeted approaches, less is known about similar differential effects on social-emotional development. The question is especially relevant for social-emotional skills that relate to interethnic interaction and to the establishment of enduring interethnic relationships, because a major criticism on targeted approaches is that they tend to reinforce segregation between majority and minority communities. The present study examined the effects of targeted versus mixed early childhood education programs on interethnic interaction and social-emotional development in a sample of 116 3-6-year old children. The results show, as was expected, that mixed (i.e., heterogeneous) classrooms have a higher the degree of interethnic interaction. Furthermore, the results indicated a positive effect of targeted (i.e., homogenous) classrooms on social-emotional development: a lower level of extraversion and impulsivity, a higher level of positive play-work attitude in more targeted, homogenous classrooms, and negative effects of peer interethnic interaction: a higher level of extraversion and impulsivity, a lower level of positive work attitude in classrooms with a relatively high degree of interethnic peer interaction. The findings together suggest that interethnic interaction may present difficult social contexts for young children from various ethnic-cultural backgrounds. The difficulties may arise from communication problems and conflicting norms and expectations about interaction and communication.

Aims

In the face of the persistent education gap, most industrialized countries provide pre-school education programs targeted at low income and ethnic minority groups. Two main types of intervention can be distinguished: universal versus targeted. Universal interventions provide care and education for all children. Targeted interventions, in contrast, are specifically provided to eligible groups only, such as particular ethnic and sociolinguistic minority groups. Targeted interventions seem most cost-effective, but tend to reinforce societal segregation tendencies with at least two possible negative consequences. First, the educational effectiveness of the preschools serving mainly disadvantaged children with an immigrant background may be reduced (Lee & Loeb, 1995; Schechter & Bye, 2007). Second, due to the lack of contact between members of minority and majority communities, mutual prejudices and discrimination may increase (Allport, 1954). First (indirect) evidence suggests that a mixed classroom composition promotes inter-ethnic interaction and that positive inter-ethnic interaction promotes social skill development (Johnson et al., 2000), positive inter-ethnic peer relations (Hamre & Pianta, 2001), positive attitudes towards minority communities (Henry & Rickman, 2007), and multicultural sensitivity and positive intergroup attitudes (Aberson et al, 2004). However more evidence is needed. The present study will contribute to this by examining the effects of ethnic-culturally targeted versus mixed-universal preschools on interethnic interaction and on social-emotional development among 3- to 6-year-old immigrant and low income native children.

Method

The participants in this study, 116 in all, were selected from a larger sample of children participating in a longitudinal study on the effects of mixed preschools in the city of Utrecht, The Netherlands. At the first measurement wave the sample consisted of 52 children (28 boys) from 8 preschool classrooms and 64 (31 boys) children from 8 kindergarten classrooms. The mean age of the preschool children was 2.8 years ($SD = .30$); 53.7% had a native-Dutch ethnic background and 72.6% came from low SES families. The mean age of kindergarten children was 4.3 years ($SD = .23$); 63.9% was native Dutch and 58.5% came from low SES families. A norm-referenced structured questionnaire, filled out by the teacher, was used to assess children's extraversion, play-work attitude, sociability, and emotional stability. Furthermore, teachers were asked to report the size and ethnic cultural composition of the class. Based on school

records, children whose parents were born and raised in the Netherlands were considered native-Dutch. Children with one or two parents born in another country were considered ethnic-minorities. Classroom processes were observed on four half days using a cyclic-interval-coding approach. In each classroom a representative subsample of six children were selected as targets for the observation study. For each observation interval, inter-ethnic interaction was coded if the target child was native-Dutch and verbally interacted with at least one ethnic minority child during that interval or if the target child was an ethnic-minority and verbally interacted with at least one native Dutch child in that interval. The scores of the six target children were averaged over intervals and aggregated to the class level as percentage interethnic interaction of the total classroom time.

Preliminary findings

Preliminary statistical analyses were conducted using MANOVA with classroom composition (two levels: > 50% ethnic minorities), interethnic interaction (two levels based on median split: > 10 % of the total time) and age-cohort as factors, and the social-emotional measures as dependents. The results indicate a statistically significant main effect of classroom composition, a borderline significant main effect of interethnic interaction, and significant interaction effects with cohort on extraversion and work attitude. The mean level of extraversion is lower and the mean level of positive play-work attitude is higher in classrooms with comparatively more ethnic minority children. The mean level of extraversion is higher and the mean level of positive work attitude is lower in classrooms with a comparatively high level of interethnic interaction. The main effects are stronger in the younger cohort than in the older cohort.

Summary and significance

The present results suggest that more homogenous targeted classrooms provide a better basis for social-emotional development in young children attending early childhood education programs than (deliberately) mixed classrooms. The fact that, in addition to the main effect of classroom composition, interethnic interaction was negatively related to social-emotional outcomes, suggests that interethnic interaction may present difficult social contexts for young children from various ethnic-cultural backgrounds. The difficulties may arise from communication problems and conflicting norms and expectations about interaction and communication. Although mixed programs may have a positive influence on language and cognitive development, the same may not hold for social-emotional development. The results pertain to an important issue of current education policy regarding the contribution of targeted and universal early childhood education to the integration of ethnic-cultural minorities.

Differential effects of early childhood education programs on social development of young children

Andrea G. Eckhardt, German Youth Institute, Germany; Franziska Egert, German Youth Institute, Germany

Over the last decade, several studies investigated the effects of early childhood education programs on the cognitive and social development of young children. In general, there is a strong evidence for positive effects of early education programs on the cognitive and academic domain, whereas the findings on the social development are less conclusive. Results suggest positive effects in some studies and no or negative effects in others. Although, some systematic reviews have been conducted recently, more research is needed providing information on differential effects on the social development of children. To understand the inconsistent effects of program effectiveness on social development, a systematic review was conducted. Approximately 70 articles were identified that report studies with (quasi-)experimental designs and aim at the social development of children from 0-6 years. Of all identified articles, the full text was coded by two independent reviewers using an extensive coding schema.

Aims

Research on the impact of early childhood education on the social development of children has yielded inconsistent findings. Systematic reviews on this topic indicate overall small positive effects of participation in early child care/intervention programs on social development. However, less is known on differential effects on social development depending on child characteristics, program features or setting characteristics. For a better understanding of the effectiveness of early child care/intervention programs, a systematic review was conducted to examine effects of child, program and setting characteristics. This paper investigates the differential effects of early child care/intervention programs on social development. The purpose of this presentation is to (1) illustrate the search process and (2) to present findings from this systematic review.

Methodology

To understand the inconsistent effects of program effectiveness on social development, a systematic review of existing studies was conducted that investigates child characteristics and program features due to program impact. Therefore, an electronic search in relevant databases such as ERIC, PsycINFO, Francis, ProQuest Dissertations and Theses and, additionally, a hand search of publications were conducted and approximately 3.000 relevant citations found. Titles and abstracts were reviewed from all references and about 700 articles were identified that provide information on the development of children up to 6 years of age. Using a short screening form, approximately 70 articles were identified that a) report studies with (quasi-)experimental designs, b) aim at the social development of children from 0-6 years, and c) met the selection criteria for research quality (e.g. sample size, assignment, outcome measurements). These studies are included in the systematic review. Of all identified articles, the full text was coded using an extensive coding schema extracting information on the following aspects: intervention program, target population, types of study, outcome measures, sample, characteristic of settings and personnel. The coding process at all stages was completed by two independent reviewers. Disagreements between the two reviewers in the coding process were resolved through discussion. Effect size estimations were conducted using the statistical software Comprehensive Meta-Analysis 2.0 by Borenstein, Hedges, Higgins, and Rothstein (2005). Results are based on the calculation of random-effect models.

Findings

At time of submission only preliminary results are available. The final results presented at the symposium will be based on the complete sample. Preliminary results were calculated on the basis of 19 studies, containing 25 group comparisons. The overall effect of child care on the development of children below seven years is $ES = 0.199$ with a 95% confidence interval of $0.109 \leq CI \leq 0.29$. To test the influence of individual studies on the combined effect size, an analysis was conducted with each study removed. The results confirm the overall effect size. Depending on the study removed, the overall effect size varies between $ES = 0.177$ and $ES = 0.217$ indicating only small changes. In sum, early child care/intervention programs have a small positive effect on the social development of children below seven years. Some studies contained mixed age groups ($N = 9$) and others homogenous groups ($N = 10$). Random-effect models were conducted to test for differences depending on the groups of children. Children classified in settings with mixed age groups had a lower increase in social development ($ES = 0.129$; $0.019 \leq CI \leq 0.239$) compared to children classified in homogenous age groups ($ES = 0.272$; $0.152 \leq CI \leq 0.392$). Finally, it was tested if children at risk profited more from child care/intervention programs compared to children without being at risk. This analysis identified a positive effect in social development of children independent of their at risk status. However, children without being at risk seem to benefit more from their participation in child care/programs ($ES = 0.213$ vs. $ES = 0.183$; $0.109 \leq CI \leq 0.317$ vs. $0.029 \leq CI \leq 0.338$).

Summary and Significance of Research

Preliminary findings of small effect sizes are consistent with recent systematic reviews on the overall effect of early child care/programs on social development (e.g. Anderson et al. 2003; Camilli, Vargas, Ryan, & Barnett, 2010; Nelson, Westhues, & MacLeod, 2003). In addition, results reveal some differential effects depending on individual characteristics of children, care settings or program features. The analysis of the complete sample is expected to provide an even more detailed understanding of the effect of social development on children in early child care/programs. The systematic review offers new insights on social development of small children depending on child characteristics, program features and setting characteristics. Knowledge of differential effects for specific groups of children or children in care with certain setting characteristics are relevant for policy makers who develop early intervention programs.

SYMPOSIUM

Causal Effects in Educational Research

Chairperson: Michael Becker, Potsdam University, Germany

Organiser: Michael Becker, Potsdam University, Germany

Discussant: Olaf Koeller, Leibniz Institute for Science and Mathematics Education, Germany

Causal inference is of central importance for educational and developmental scientists: For example, programs for school improvement or the elimination of risk factors for maladaptive scholastic development require that researchers identify causal factors and mechanisms which determine educational outcomes and estimate their impact on normal, optimal, or pathological development. In most areas of educational research experimental manipulation, often considered as the gold standard of causal research, is practically and/or ethically not feasible. Instead, observational data has to be used to estimate causal effects. Recently, the question how to appropriately address causality in non-experimental research has drawn substantial attention in educational and developmental research (e.g., Foster, 2010; Schneider et al., 2007), picking up ideas and techniques from other disciplines such as econometrics. In the symposium, leading scientists in the field present promising approaches for causal effect estimation, e.g. regression discontinuity, instrumental variables, and elaborate their potential and limitations, both from a theoretical and applied perspective. The major goal is to emphasize the utility (and benefit) educational research can (and should) expect from modern design and data analysis techniques.

A comparison of quasi-experimental analysis methods for causal inference in large-scale assessment

Eckhard Klieme, Deutsches Institut für Intern. Pädagogische Forschung, Germany; Ulf Kroehne, DIPF, Germany; Johannes Hartig, German Institute for International Educational Research (DIPF), Germany

Bilingual education understood as teaching academic content in a secondary language is implemented as an educational program in many educational systems. Compared to students with similar initial baseline conditions bilingual instruction is expected to gain English competence, especially for German grammar schools and high schools. The aim of the paper is twofold: Firstly, we discuss the identification of a causal effect of bilingual instruction on the theoretical level and introduce the definition of a treatment effect which can be estimated drawing on the data available from a German large-scale assessment of students' language competencies, named DESI (German English Student Assessment International, Beck & Klieme, 2007). Secondly, we present a methodological comparison of different quasi-experimental analysis methods applied to the estimation of a treatment effect at the school level. In particular, we compare different propensity score based adjustment procedures (propensity score matching, propensity score weighting and propensity score sub-classification) with generalized analysis of covariance for estimating the causal effect of bilingual instruction. We highlight why the different approaches, even when applied to same data and based on an identical set of covariates, are expected to yield different treatment effect estimators. A positive adjusted treatment effect for bilingual instruction at the school-level is found consistently for all measured outcomes. It is concluded that the bilingual instruction is an effective treatment at the school-level, even if the competence is averaged across students. In the closing discussion the methodological limitations of the presented analysis and further research questions are discussed.

For the investigation of causal effects large-scale assessments are not well-suited because usually they are observational studies with cross-sectional designs. However, results from large scale assessments often attract a great deal of attention and findings from large-scale assessments, for instance, observed differences between groups of students, are often discussed in a causal manner. Accordingly, there is a gap between the large scale assessments' important contributions to educational research at the one hand and the traditional approaches to causal inference and program evaluation at the other.

In this presentation we discuss the identification and the estimation of the causal effect of bilingual instruction on students' English competence based on empirical data from a German large-scale assessment of students' language competencies, named DESI (German English Student Assessment International, Beck & Klieme, 2007). Bilingual education - understood as teaching academic content in a secondary language - is implemented as an educational program in many educational systems. Compared to students with similar initial baseline conditions bilingual instruction is expected to gain English competence, especially for German grammar schools and high schools. For the evaluation of bilingual instruction the unadjusted difference between students with and without bilingual instruction has no causal interpretation because the assignment of individual students to the bilingual instruction was not randomized. Therefore, additional assumptions are needed for identifying a causal effect of bilingual instruction, i.e. in order to adjust for existing baseline differences between treated and untreated students. However, in case important and pre-ordered covariates are not measured or if further assumptions of the quasi-experimental adjustment methods are violated, the treatment effect cannot be identified at all. Moreover, even if a causal effect can be identified, the estimated treatment effect might be sensitive to additional assumptions of the analysis method used to estimate the adjusted treatment effect.

Therefore the aim of the paper is twofold. Firstly, we discuss the identification of a causal effect of bilingual instruction on the theoretical level and introduce the definition of a treatment effect which can be estimated based on the data available from the DESI large-scale assessment under more reasonable assumptions. For this purpose we re-define the treatment variable and consider the bilingual instruction as a treatment implemented at the school-level. In addition we discuss the substantial interpretation of the resulting average treatment effect and highlight the appropriateness of this treatment definition with respect to typical violations of the Rubin Causal Model in educational research, such as the violated stable unit-treatment value assumption (Stuart, 2007). Secondly, we present a methodological comparison of different quasi-experimental analysis methods applied to the estimation of a treatment effect at the school level. In particular, we compare different propensity score based adjustment procedures (propensity score matching, propensity score weighting and propensity score sub-classification) with generalized analysis of covariance for estimating the causal effect of bilingual instruction. We highlight why the different approaches, although applied to the same data and based on an identical set of covariates, are expected to yield different treatment effect estimators. The resulting differences between the estimated treatment effects are discussed as a region of uncertainty, i.e. a measure of the treatment effect estimator's robustness with respect to the utilization of a particular adjustment method.

For the re-defined treatment effect at the school-level we present the suggested region of uncertainty for the different outcomes and compare the estimated treatment effects for the different discussed adjustment methods. A positively adjusted treatment effect for bilingual instructions at the school-level is found consistently for all measured outcomes. It is concluded that the bilingual instruction is an effective treatment at the school-level, even if the competence is averaged across students. In the closing discussion the methodological limitations of the presented analysis and further research questions are discussed.

Generalizing Causal Inferences: Test Validity and Meta-Analysis

Derek Briggs, University of Colorado, United States

Estimating the causal effect of program X on outcome Y is a challenging task, but it is a task that is, in principle, solvable through some combination of experimental design and statistical adjustment. In contrast, the generalization of causal inferences is more art than it is science. In this presentation I focus attention on what might be viewed as a precondition for generalizing the effect of an intervention in educational research—the construct validity of a test score when it has been used as an outcome variable. Meta-analysis is often considered the primary "scientific" means by which the effects of educational interventions across different outcomes can be synthesized. Yet this activity hinges upon the assumption that the outcome variables for which effects have been estimated can be compared on a common scale once effect size statistics have been computed. Such an assumption is only plausible if test scores represent interval measures of a common underlying latent variable. Because this is only assumed and never

evaluated, it may well raise some difficult questions about the meaningfulness of causal generalizations that result from meta-analytic research.

Estimating the causal effect of program X on outcome Y is a challenging task, but it is a task that is, in principle, solvable through some combination of experimental design and statistical adjustment. In contrast, the generalization of causal inferences is more art than it is science. In this presentation I focus attention on what might be viewed as a precondition for generalizing the effect of an intervention in educational research—the construct validity of a test score when it has been used as an outcome variable. Meta-analysis is often considered the primary "scientific" means by which the effects of educational interventions across different outcomes can be synthesized. Yet this activity hinges upon the assumption that the outcome variables for which effects have been estimated can be compared on a common scale once effect size statistics have been computed. Such an assumption is only plausible if test scores represent interval measures of a common underlying latent variable. Because this is only assumed and never evaluated, it may well raise some difficult questions about the meaningfulness of causal generalizations that result from meta-analytic research.

This point is illustrated in this paper using test score data gathered between the Fall of 2008 and the Fall of 2009 by visiting the web sites for 22 states reported to have developmental score scales in the annual "Quality Counts" issue produced by American publication Education Week in 2008. For 9 of these states, it was possible to locate both the mean scale scores and standard deviations on the state's large-scale math and reading assessments for the grades 3 and 8. In all of these cases item response theory methodology was used to create and maintain a "developmental" scale such that the scores of the same student in a higher or lower grade could be compared in absolute sense. Over the past 30 years, the quality of developmental score scales in the United States have been evaluated on an operational basis, consistent with the scaling theory that makes no presumption that the resulting scale has interval properties. What this means in practice is that one examines the empirical patterns of grade by grade means and standard deviations (SDs) after tests have been calibrated onto a common scale. In order to compare observed growth patterns across multiple states, it is customary to place each state's test scores onto a common scale using an effect size metric (cf. appendix A). With grade to grade growth in an effect size metric nested within each state, it becomes possible to conceptualize the task of comparing growth patterns within and across states as one of meta-analysis. Table 1 (cf. appendix B) summarizes the descriptive results from taking such an approach with the data described above.

What stands out in Table 1 is the variability in these estimates of growth across scales within each of the four adjacent grade combinations (e.g., grade 3 to 4, 4 to 5, etc). Mean growth in student performance for any pair of adjacent grades ranges from a low of .30 SDs (grade 3 to 4 Reading) to a high of .65 SDs (grades 5 to 6 Reading). This variability is much larger for tests of reading than tests of math. With respect to the reading vertical scales, it is also clear that there is greater variability among the four states with scales created by one testing company (Harcourt) than there is among the five states with scales created by another (CTB). For math tests, one sees a trend from grades 3 through 8 consistent with that of decelerating growth—in general, effect sizes decrease in magnitude with increasing grade. There is no such discernible trend for the reading tests.

As is typical in application of meta-analytic techniques, as a next step one would be inclined to look for other factors germane to the creation of each state's test that could help to explain the variability in growth from state to state. For example, perhaps the answer can be found in differences in the triangulation of content standards, curricular emphasis, and test design from state to state? Can differences in growth be explained by something schools within a given state are doing to effect learning? One might ask certainly ask these questions, but if the test score scales being synthesized in each state only contain ordinal information, will the results be meaningful? In this presentation I raise this question and suggest that there is good reason to believe that the answer will, unfortunately, be "no."

Instrumental variable regression techniques to estimate effects of schooling and age on achievement

Jan-Eric Gustafsson, University of Goteborg, Sweden; Christina Cliffordson, University West, Sweden

The main purpose of the paper is to examine the relative effects of schooling and age on achievement in mathematics and science by the use of a regression discontinuity design, augmented with an instrumental variable (IV) approach. The regression discontinuity design relies on the assumption that there is a sharp age-based decision rule for grade assignment of students, but this assumption is typically violated, which in turn causes biased estimates. A previous study based on the Swedish TIMSS 1995 data showed that an IV regression approach, using formal school start-age as an instrument, can be used to obtain unbiased estimates of the grade and age effects when the assumption of a sharp age-based decision rule is violated, thereby creating a fuzzy RD design. In the present study, the applicability of this IV-

approach is investigated for all the countries participating in the TIMSS 1995 study. All together, around 40 countries investigated science and mathematics achievement in 7th and 8th grades, and around 20 countries also participated with 3rd and 4th grade. The rules for school start and grade repetition vary greatly between countries, so in a first step it is investigated for which countries an age-based decision rule leading to a fuzzy RD design is used, and in the next step the IV regression analysis is conducted for the countries for which this is possible.

Issues of causal inference have not been a strong focus of interest in educational research since the 1980s. However, lately there are signs of a growing interest, such as an increasing use of experimental designs and an increasing interest in methods for causal inference from observational data (see, e.g., Schneider, et al., 2007). Given that other disciplines within the field of social and behavioral research have kept a focus on issues of causality, it also is possible to take advantage of developments made in disciplines such as economics, sociology, and statistics. Within econometrics, in particular, there has been a strong development of methods for establishing causal relations in observational data (e.g., Blundell & Costa Dias, 2009).

One of these methods is instrumental variables (IV) regression, which is commonly used to deal with two of the main threats to causal inference in observational data, namely reversed causality (or more broadly, endogeneity) and errors of measurement. The idea is to find a variable (an 'instrument') that is related to an endogenous variable X , but not to the dependent variable Y apart from the indirect effect via X . The treatment effect can then be identified through the part of the variation in X that is triggered by the instrument. Estimation is typically done with two-stage least squares, where the first step involves predicting X from the instrument, and the second step involves predicting Y from the variation in X due to the instrument.

IV regression has only rarely been applied in educational research, but given the frequent need to address problems of reverse causality in educational research there should be a great potential for application of this method. The current paper uses IV regression to deal with reverse causality in regression discontinuity designs used to separate the effects of age and schooling on achievement.

It can easily be observed that students in a higher grade have a higher level of achievement than students in the adjacent lower grade, with an effect size typically around $d = .40-.50$. This effect is due to the combined effect of another year of schooling and another chronological year, and it is of great theoretical and practical interest to separate the effects due to schooling and age. Given that these factors tend to be completely confounded, this is no easy task, but it has been demonstrated that under certain circumstances this can be done with the between-grade regression discontinuity (RD) design. In this design, the age effect is estimated through the age variation within grades, and the schooling effect through the grade effect, controlling for age (e.g., Cahan & Cohen, 1989).

However, for this approach to give correct results grade assignment must be strictly based on age, for example through the rule that school starts during the year the child becomes 7 years old. However, this rule is typically not strictly followed, because certain children are allowed to start school a year early, while others have their school start delayed by a year. Furthermore, in certain school systems there is grade repetition for poorly achieving students. Such deviations from the strict decision rule required by the RD design turns the design into a so called "fuzzy RD design" and these deviations tend to cause severe bias in the estimates of the effects of schooling and age. The reason for this is that the fuzziness is due to reverse causality, the actual grade that a student attends being determined by level of achievement. One approach to deal with this problem is to exclude students who are not of normal age for their grade. When the frequency of such cases is low, this approach works well (Cliffordson, 2010), but such an ad hoc approach is not optimal. However, Cliffordson and Gustafsson (2010) demonstrated on Swedish data from the TIMSS 1995 study that an IV regression approach used on all cases yielded reasonable estimates. In these analyses, the instrument was taken to be the age the student was expected to have if normal-aged for the grade, so the instrument expresses "intention to treat".

In the paper, the applicability of this IV-approach is investigated for all the countries participating in the TIMSS 1995 study. In this study, around 40 countries investigated science and mathematics achievement in 7th and 8th grades, and around 20 countries also participated with 3rd and 4th grades. The rules for school start and grade repetition vary greatly between countries, so in a first step it is investigated for which countries a fuzzy RD design is applicable. In the next step the IV regression is conducted for the countries in which this is possible, and in the final step the estimates obtained are assembled and evaluated.

SYMPOSIUM

Discursive practice and knowledge construction in mathematics classrooms in different cultures

Chairperson: Fritjof Sahlstrom, University of Helsinki, Finland

Organiser: David Clarke, University of Melbourne, Australia

Discussant: Oskar Lindwall, University of Gothenburg, Sweden

The three papers in this symposium employ different analytical approaches to the study of classroom discourse and knowledge construction in particular Asian and Western mathematics classrooms. Comparison across such culturally-disparate sites poses powerful questions regarding the nature of social interaction and the social processes whereby knowledge is constructed and performed. The symposium combines a focus on classroom patterns of participation with fine-grained analyses of associated patterns of communicative exchange and negotiation of meaning. Each paper sees mathematics learning in terms of participation in forms of social practice. In the first paper, analysis of classrooms in eight culturally-diverse settings examines student participation in different forms of discursive practice and their developing capabilities with regard to both discursive practice and mathematical reasoning. The second paper reports a Bakhtinian analysis showing that mathematical activity in one Japanese classroom was characterized by a monologic suppression by authoritarian voice, rather than by a dialogicality of voices. In the third paper, classroom participants are shown to be highly sensitive to nonverbal epistemic claims and their ongoing interaction is shaped by moment-by-moment adjustments in relation to these. The participants are shown to orient to slight changes in the production of discursive tokens in determining whether a shared understanding of the learning task at hand is arrived at. This in turn is shown to have consequences for the co-construction of knowledge and the constitution of trajectories of learning.

In combination, the three papers address fundamental questions about the social construction of knowledge in mathematics classrooms.

The Cultural-Specificity of Discursive Practice and Learning Outcomes: Connected Contingencies

David Clarke, University of Melbourne, Australia; Lihua Xu, The University of Melbourne, Australia; May Ee Vivien Wan, University of Melbourne, Australia

This paper reports research into the nature and occurrence of mathematical discourse in well-taught classrooms in Berlin, Hong Kong, Melbourne, San Diego, Seoul, Shanghai, Singapore and Tokyo and into the possible associated learning outcomes arising (or likely to arise) from such discursive practices. The paper combines analyses of the relative contributions made by teachers and students to the public classroom discourse, the use of technical mathematical terms by students, both publicly and privately in class and in their post-lesson reflections on their learning. The analysis determined the number of utterances occurring in whole class and teacher-student interactions in a sequence of five lessons from each of the classrooms studied (a total of 110 lessons from twenty-two classrooms), together with the frequency of public statement of mathematical terms and, in a separate analysis, the number of utterances and spoken mathematical terms in the context of student-student (rather than public) interactions. Also analyzed was student use of technical mathematical terms in 191 post-lesson interviews in which they described classroom activities and their mathematics learning.

Student-student spoken interactions were frequent in the classrooms studied in San Diego, Singapore and Melbourne, and non-existent in Shanghai and Seoul, and student use of mathematical terminology varied significantly. Such variations in practice problematise any simplistic characterization of "the Asian classroom." Student spoken facility with the technical language of mathematics can be achieved through either public or private discourse, however student facility with mathematical discourse, in a broader sense, may be enhanced or restricted by cultural contingencies.

In this paper, we summarize analyses of 110 lessons documented in twenty-two classrooms located in Australia (Melbourne), China (Hong Kong and Shanghai), Germany (Berlin), Japan (Tokyo), Korea (Seoul), Singapore and the USA (San Diego). A stratified analysis was conducted in five stages focusing on the significance of the situated use of spoken mathematical language in these classrooms. The results of the first and second analytical stages focused on public oral interactivity (frequency of public utterance) and public mathematical orality (spoken use of key mathematical terms). We distinguish private student-student interactions from whole class or teacher-student interactions, both of which we consider to be public from the point of view of the student. Our major concern in the first four stages of the analysis was to document the opportunity provided to students in the mathematics classroom for the oral articulation of the relatively sophisticated mathematical terms that formed the conceptual content of the lesson and to distinguish one classroom from another according to how such student mathematical orality was afforded or constrained in both public and private classroom contexts. The fifth stage of our analysis examined student use of mathematical terms in post-lesson video-stimulated interviews.

A total of 110 videotaped lessons were analyzed. The 'Asian' data set analyzed included three sequences of five lessons from three mathematics classrooms in Shanghai, three similar sequences from Hong Kong, Tokyo, Seoul and Singapore. 'Western' classroom practice was represented in this analysis by three sequences of five lessons from Melbourne, two sequences from Berlin and two sequences from San Diego. The data from San Diego 3 and from Berlin 3 were excluded because of difficulties in distinguishing "public" and "private" statements in those classrooms.

Spoken Mathematics in the Classroom

The prevalence of spoken mathematics in the twenty-two classrooms studied differed in the following respects:

- the frequency of public utterance
- the relative prominence of the teacher or the students' voices in public discourse
- the frequency of public use of spoken technical terms, most particularly by students
- the differences in the extent to which student use of spoken mathematics was strategically facilitated by teachers
- the extreme differences between classrooms in the occurrence of student-student (private) use of spoken mathematics.

In the fifth stage of our analysis, the transcripts of student post-lesson interviews were examined for the occurrence of the key terms that constituted the instructional focus of the lesson, together with those mathematical terms closely related to the key terms (related terms). In addition, we also coded other terms employed by the student to describe or explain some aspect of their classroom activity.

In conducting the post-lesson interviews, students were asked to comment on what they had learned or felt was important from that day's lesson. Following which, the video for the lesson was played and the student could pause, fast forward or rewind to any parts of the lesson that they felt were important or that they wanted to comment on. After viewing the video, the students were asked if they had any other comments about the lesson before ending the interview session.

Conclusions and Speculations

As a result of this research, we were able to compare the discursive practices of twenty-two mathematics classrooms in eight cities in seven countries. Many hypotheses emerged and these have been variously investigated.

- If student facility with technical mathematical vocabulary is the targeted outcome, then the analysis of the post-lesson interviews suggests that the public scaffolding of student technical fluency (eg Shanghai 1) can be as effective as the encouragement of student-student spoken mathematics (eg San Diego 2) in developing this facility.
- Where the classroom provided students with no opportunity for spoken mathematics (Seoul), there appeared to be little inclination (and possibly capacity) to do so, even in interview situations where the invitation to use spoken mathematics was explicit ("Tell me what the lesson was about").
- Student inclination to employ other mathematical terms ('other terms') in addition to those specific to the lesson could indicate a form of interconnected knowing.
- The level of student participation in the social modelling of particular forms of argumentation could afford or constrain individual's development of particular reasoning capabilities.

Our work suggests that the theories of teaching/learning by which contemporary (largely Western) instructional advocacies are rationalized may themselves be culturally-specific. Fine-grained analysis of the discursive practices of mathematics classrooms in contrasting cultures may hold the key to connecting social discursive practice with specific forms of individual performative capability.

Analysis of “Voice” in a Japanese Mathematics Classroom

Minoru Ohtani, Kanazawa University, Japan

This study investigates how a Japanese mathematics classroom is discursively constituted. The investigation focuses on the ways that teacher and students coordinate their purposes and maintain a predictable sense of the ongoing discourse. The discussion consists of two parts. The first part involves an indication of the theoretical framework and the justification for the methodology used. The theoretical framework, which is grounded on the Bakhtinian perspective, is applied to the study of classroom discourse in which the concept of “voice” and “speech genre” play significant roles. The second part involves description and interpretation of an episode that occurred in the classroom during participant observation. A year-long participant observation was conducted. Utterances which the classroom teacher and students addressed to me are recorded. These utterances give the participant observer an opportunity to have access the under-represented voices in ordinary classroom practice. Analysis of the episodes shows that classroom mathematical activity is characterized by a monologic suppression by authoritarian voice, rather than by a dialogicality of voices. Teacher's utterances suggest that he sends a strong implicit message that homogeneity among students activity should be attained. Students were constrained to limited expression through the monologic speech genre of formal schooling, and this was reflected in their assumption that there is only one true formulation of a mathematical task.

This paper investigates how a Japanese seventh grade mathematics classroom is discursively constituted. The investigation focuses on the ways that teacher and students coordinate their purposes and maintain a predictable sense of the ongoing discourse. The following discussion consists of two parts. The first part involves an indication of theoretical framework and the justification for the methodology used. The second part involves description and interpretation of an episode that occurred in the classroom during participant observation.

Theoretical framework which is grounded on the Bakhtinian perspectives is taken to the study of classroom discourse in which the concept of “voice” and “speech genre” play significant roles.

Bakhtin, contemporarily with Vygotskii, shared the basic idea that communicative practice is situated in social practice (Wertsch, 1991). Unlike many scholars of language, especially contemporary linguists who concern themselves primarily with linguistic form and meaning abstracted from the actual conditions of use, Bakhtin focused on the utterance, the real unit of communication. Speech can exist in reality only in the form of concrete utterance by the individual speaking subject. The speaking subject is called “voice” (Bakhtin, 1982). Voice refers to more than vocal-auditory signal. It involves the much more general phenomenon of “the speaking personality” in particular social practice. Utterance is an activity that enacts different values, perspectives, conceptual horizons, intentions, and world views. Bakhtin stresses the idea that voice reflects “speech genre” (Bakhtin, 1986), which involves particular social and cultural categories.

A year-long participant observation was conducted. Every lesson was audio-video taped for later analysis. “Voices” which the classroom teacher and students addressed to me are essential. According to Bakhtin, any utterance entails the idea of addressivity. An utterance reflects not only the voice producing it but also the voices to which it is addressed. Furthermore, the voices to which an utterance is addressed may be temporally, spatially, and socially distant. Thus, utterances of teacher and students involve their motives, beliefs, situations of definitions, and opinions before, during, and after the lessons. These utterances give the participant observer (voice to be addressed) an opportunity to have access the underrepresented voices in ordinary classroom practice.

Analysis of the episodes shows that classroom mathematical activity is characterized by a monologic suppression by authoritarian voice, rather than by a dialogicality of voices (Wertsch & Rupert, 1993). Teacher's utterances suggests that he sends a strong implicit message that homogeneity among students activity should be attained, even if another form of description or perspective could be used to describe an object or event more appropriately and usefully in their activity settings. Teacher's use of the register of formal instruction surfaces at many points and in many guises in classroom discourse. One of the characteristics of the monologic speech genre of formal schooling is directiveness. Teacher's utterances were directives designed to get the student to participate in formulating the problem in the right way. Another characteristic is a tendency toward a certain kind of rationality. This derives in part from the institutional framework within which formal instruction take place. Formal instruction has to perform a degree of rationalization of what it transmits. Thus, in place of diversity or heterogeneity, it puts explicit, standardized taxonomies, which are expressly inculcated and therefore conserved in the memory as knowledge that can be reproduced in virtually identical form by all the agents subjected to its action. A further characteristic of this speech genre in formal instructional settings is a tendency of homogenization created by such rationality. An underlying assumption of the lesson is that one must not introduce alternative formulations unless specifically invited to do so. This functions as if

an invisible barrier has been placed around the topical space that is eligible for discussion. The title of the worksheet becomes directive of an imperative that he is expected to follow. The title functioned to regulate his mathematical activity in ways that are appropriate for the classroom setting. By responding to the directive, the student engages in a process sanctioned and regulated by the teacher.

The voices of most students can be seen as the internalized voice of the authorized teacher. Through months of classroom practice, students would gain adequate facility and flexibility in the patterns of privileging a particular speech genre deemed appropriate in mathematics lessons. These voices are reflected in the assumption that there is only one true formulation of mathematical task. The mastery of this privileging pattern of the monologic speech genre of formal schooling was clearly revealed in many episodes.

Dialogicality of voices was detected in some students. A student wrote that: "Unlike ordinary lessons, today's lesson was interesting. Because, I can formulate my answer by myself." Kinds of dialogicality that are temporally and spatially distant become apparent in his voice. The voice involves not only positive attitude toward the lesson, but also negative opinion associated with the way the teacher organized preceding lessons.

Embodied epistemic claims in educational settings

Helen Melander, Uppsala University, Sweden; Fritjof Sahlstrom, University of Helsinki, Finland

The focus for this paper is a concern with how people in interaction in educational settings claim to know things, and how these claims, as integrated aspects of learning, can be found to change. Epistemic stances are the primary means by which students and teachers can establish, sustain, and question intersubjectivity in teaching situations. Previous work shows that participants use a variety of resources, including verbal and non-verbal (e.g. prosody, gestures and other embodied displays) epistemic stance markers, for situating their actions within a trajectory of past, concurrent, and projectable change.

Drawing on analyses of video recorded interaction between teachers and students in mathematics education and pilot training, our results show that participants are highly sensitive to nonverbal epistemic claims and the ongoing interaction is shaped by moment-by-moment adjustments in relation to them. This in turn is shown to have consequences for the co-construction of knowledge and the constitution of trajectories of learning.

The identification of evidence of knowing is the basis of, amongst other things, assessment in classrooms. Hence, a more developed understanding of how teachers and students – relying upon non-verbal resources – establish, sustain, challenge, and change epistemic claims is of immediate relevance for the practical activity of teaching.

The focus for this paper is a concern with how people in interaction in educational settings claim to know things, and how these epistemic stances, as an integrated aspect of learning, can be found to change over time. The analysis is situated within recent understandings of learning and development as social and situated (e.g. Enfield & Levinson, 2006; Lave & Wenger, 1991).

Epistemic stances, that is, participants' ways of marking attitudes toward knowledge and how it was obtained, are the primary means by which students and teachers can establish, sustain, and question intersubjectivity in teaching situations. Moreover, they are an important resource for teachers when assessing student's actions. Epistemic stance emerges from interaction between participants in particular dialogic and sequential contexts; it is a public action that is shaped by the talk and stances of other participants in sequentially unfolding turns-at-talk (Karkkainen, 2006). Participants thus socially establish epistemic ecologies of teaching and learning.

Recently completed and on-going work (e.g. Melander, 2009; Sahlstrom, forthcoming) shows that participants use a variety of resources for situating their actions within a trajectory of past, concurrent, and projectable change. These resources include verbal and non-verbal epistemic stance markers, such as syntax and prosody, and gestures and other embodied displays.

Previous research has shown that human action is built through the use of many different kinds of interactional resources. Participants use semantic, syntactic, and prosodic features of talk, gestures, gaze, and body posture, and resources in the surrounding material environment when participating in social interaction (e.g. Goodwin, 2000). Most commonly, analysis of epistemic stance has been focused on verbal aspects of knowledge claims. In this paper, we intend to expand notions of epistemic stance beyond the verbal and lexically oriented analyses and, in line with the above-mentioned research, focus on the role of gesture, prosody, and the use of and interaction with artifacts in the epistemic ecologies of the studied situations (cf. Goodwin, 2007).

Providing empirical ground for the analyses are video recordings of mathematics lessons focusing how teachers and students are working with linear equations. In the analyses we demonstrate how epistemic stance is produced and oriented to and how the student in different ways is positioning himself as knowing some things and as being ignorant of others. This in turn has consequences for how the participants co-construct the content of learning. These results are contrasted with analyses of pilot training where a trajectory of learning is constituted over time through a study of how the student's epistemic claims change over three consecutive lessons, carried out both on the ground and in flight.

The participants are demonstrated to be highly sensitive to nonverbal epistemic claims and the ongoing interaction is shaped by moment-by-moment adjustments in relation to them. The participants have a number of resources available to them, not least prosodic, where they are shown to orient to slight changes in the production of discursive tokens (mhm, yes, etc.) displaying in minimal albeit efficient ways whether a shared understanding of the learning task at hand is arrived at. This in turn is shown to have consequences for the co-construction of knowledge and the constitution of trajectories of learning.

The identification of evidence of knowing is the basis of, amongst other things, assessment in classrooms. Hence, a more developed understanding of how teachers and students – relying upon non-verbal resources – establish, sustain, challenge, and change epistemic claims is of immediate relevance for the practical activity of teaching. This study builds on the substantial cumulative findings of prior studies, to focus on the nature of classroom knowing. It contributes to the empirical resolution of questions on how to identify and analyze successful learning, and how to identify and distinguish accomplished teaching.

SYMPOSIUM

A Cognitive Load Picture Tells a Story about Multimedia Learning

Chairperson: Birgit Karoline Imhof, Knowledge Media Research Center, Germany

Organiser: Gabriele Cierniak, Knowledge Media Research Center, Germany

Discussant: Paul Ayres, University of New South Wales, Australia

Much is known about how to design multimedia materials to optimize learning (see Ainsworth, 2006; Schnotz, 2005). Highly influential has been Sweller's cognitive load theory (CLT; Sweller, 2005) and Mayer's cognitive theory of multimedia learning (Mayer, 2005). Both theories consider the influence of cognitive load. However, there remain a number of unanswered conceptual questions, as well as unidentified conditions, pertaining to the use of multimedia materials. The papers in this symposium investigate some of these issues. The first paper examines the impact of disfluency. Diemand-Yauman, Oppenheimer and Vaughan (in press) found that the inclusion of unintelligible text can facilitate learning, in spite of expected increases in cognitive load. This paradoxical finding is investigated in a multimedia environment that distorts diagrams as well as text. The second paper investigates two plausible explanations for the segmentation effect. CLT argues that segmenting animations is advantageous because the need to process transitory information in working memory is reduced (Ainsworth & van Labeke, 2004; Ayres & Paas, 2007). An alternative explanation is that segmentation acts as a form of temporal cueing, breaking the animations into meaningful units (Arguel & Jamet, 2009; Schwan, Garsoffky, & Hesse, 2000). Few CLT studies have investigated learners with any form of special needs. In the case of learners in pain, working memory capacity can be reduced, consequently multimedia materials may be especially important for this group of learners. The final paper examines the impact of multimedia materials on this population.

Disfluency Research Meets Cognitive Load Theory: When a Bad Layout Leads to Good Performance

Tim Kuhl, Knowledge Media Research Center, Germany; Alexander Eitel, knowledge media research center, Germany; Katharina Scheiter, Knowledge Media Research Center, Germany; Peter Gerjets, University of Tuebingen, Germany

According to Cognitive Load Theory (CLT), instructional material should be designed in a way to decrease unnecessary demands on working memory that, for instance, may be caused by a low legibility. In contrast, recent research on disfluency in educational settings showed that less legible text even leads to better learning outcomes. However, research on disfluency was yet only conducted using texts as stimuli, but not multimedia materials. Therefore, the aim of the current study was to investigate which of these abovementioned two contradicting assumptions would hold true in learning with text and pictures: Would a less legible text also be beneficial when accompanied by pictures, and what would be the role of less legible pictures? To address these questions, participants were randomly assigned to one of four conditions resulting from a 2x2-Design with text layout (legible vs. less legible) and picture layout (legible vs. less legible) as independent variables. Learning outcomes were measured by means of a retention test, a transfer test, and a pictorial test. Extraneous cognitive load (ECL) was assessed by one item referring to task difficulty. Results revealed that a less legible text layout led to better performance on transfer tasks, which is in line with disfluency research. However, a less legible picture layout led to worse performance on pictorial tasks and to higher subjective ratings of ECL, which is in line with CLT. These results stress the importance to take a closer look when and for which purposes legibility may be important.

According to Cognitive Load Theory (CLT; Sweller, van Merriënboer, & Paas, 1998), instructional material should be designed in a way that unnecessary demands on working memory (i.e., extraneous cognitive load, ECL) should be avoided. While in general there is strong empirical support for the CLT, there are certain areas which are rather neglected in this research area, such as the influence of legibility of the instructional material. Nevertheless, following CLT, one would recommend designing the layout of the instructional material in a way that it can easily be perceived. However, this view has recently been challenged by research on “disfluency” in educational settings (Diemand-Yauman, Oppenheimer, & Vaughan, in press). These authors argue that a certain amount of illegibility – which is termed disfluency - leads to a deeper engagement and processing of the text, resulting in better learning. They showed that harder-to-read fonts (e.g., Haettenschweiler) lead to higher learning outcomes compared to easier-to-read fonts (e.g., Arial). However, the current research on disfluency is restricted to text processing, and no study has yet investigated the role of disfluency in learning with multimedia instructional material. Hence, the role of disfluency when learning from text and pictures is yet unclear: Is a disfluent text also beneficial when accompanied by pictures, and do even disfluent pictures foster learning? Or is disfluency harmful and leads to higher ECL, as could be derived from CLT? To address these questions, we manipulated the legibility of text and pictures in the current experiment, and investigated its impact on learning outcomes and cognitive load.

Method

Seventy-two university-students were randomly assigned to one of four conditions which resulted from a 2x2-Design with text layout (legible vs. less legible) and picture layout (legible vs. less legible) as independent variables. The instructional material was adapted from a study by Mayer, Hegarty, Mayer, and Campbell (2005, Exp. 2). It was paper-based (fitting on one page) and consisted of four key pictures depicting the mechanisms of a toilet flush and a text below describing how a toilet flush works. Participants received six minutes to process the instructional material. The experimental variation of the text layout consisted of either a legible text layout or a text layout, which looked like a low quality photocopy of a normal text (less legible; i.e., wavily deformed and blurred). Similarly, the experimental variation of the picture layout consisted of either a legible picture layout or a picture layout, which looked like a low quality photocopy of these pictures (less legible; i.e., wavily deformed and blurred). Learning outcomes were measured by means of a retention test, a transfer test, and a pictorial test. Cognitive load was assessed by one item referring to difficulty (“How difficult was it to learn with the material?”), which was supposed to measure ECL.

Results

Concerning retention, a 2x2-ANCOVA (controlling for prior abilities) revealed neither differences for text layout, nor for picture layout, nor an interaction. With regard to transfer, a 2x2-ANCOVA revealed a main effect for text layout (p With respect to the ECL-item, a 2x2-ANCOVA revealed a main effect for picture layout (p Summary & Discussion). In this study, we investigated whether making instructional text and/or instructional pictures disfluent would decrease learning outcomes, as could be derived from CLT, or improve learning outcomes, as would be predicted from current disfluency research. In line with disfluency research, a worse text layout led to a deeper understanding (as measured by transfer tasks), suggesting that a disfluent text may have led to a deeper processing of the content. However, designing pictures in a disfluent way did not lead to better transfer performance. By contrast, less legible pictures tended to lead learners to a worse pictorial model of the content, as indicated by the lower performance on pictorial tasks. In connection, learners receiving less legible pictures found it more difficult to learn with the material than learners receiving more legible pictures. These latter findings are basically in line with CLT. Taken together, while a less

legible layout of the text led to a better understanding of the content, less legible pictures on the other hand may have led to a worse pictorial mental model. By this first attempt to incorporate disfluency research in multimedia learning scenarios, this study may be considered as – at least partly – a challenge to CLT. However, it has also demonstrated that the global question whether a low quality layout leads to better performance does not seem to be very fruitful. Rather, a more sophisticated differentiation between the legibility of text layout and of picture layout and their impact on different learning outcome measures seems reasonable.

Explaining the Segmentation Effect in Learning from Animations: The Role of Pausing and Cueing

Ingrid A. E. Spanjers, Maastricht University, Netherlands; Tamara Van Gog, Erasmus University Rotterdam, Netherlands; Jeroen van Merriënboer, University of Maastricht, Netherlands; Pieter Wouters, Universiteit Utrecht, Netherlands

Segmentation, that is, showing an animation in pieces rather than continuous, has been shown to improve the effectiveness of animations in terms of cognitive load and learning. Two alternative (but not mutually exclusive) explanations can be given for beneficial effects of segmentation. First, pauses, which are usually inserted between the pieces, provide learners with the possibility to perform necessary cognitive processes on smaller units of information. Secondly, segmentation breaks the animation down in meaningful pieces, which is a form of cueing, and may support learners in perceiving the structure underlying the information. This experiment investigated with a 2 (pauses or no pauses) x 2 (cues or no cues) design which explanation is the most plausible. The participating 161 secondary school students first completed a pretest, then studied animated worked examples on probability calculation, and finally made a posttest. Results showed that studying animated worked examples with pauses led to higher posttest achievement than studying animated examples without pauses. However, studying animated examples segmented by cues required less investment of mental effort during study than examples without cues, without decreasing posttest performance significantly. Thus, results provide some evidence for both explanations.

Animations are increasingly used in education. Information in animations is often transient. Consequently, learners have to process information currently presented, while simultaneously maintaining information presented earlier in working memory to be able to link it with new information (Ayres & Paas, 2007; Lowe, 1999). This may lead to a high cognitive load, which may hinder learning from complex animations. Therefore, it is important to search for guidelines to increase the effectiveness of complex animations by reducing this high cognitive load. One of the guidelines proposed is segmentation, that is showing animations in pieces (e.g., Ayres & Paas, 2007; Wouters, Paas, & Van Merriënboer, 2008). A number of studies have found positive results on learning from segmented animations (e.g., Hasler, Sweller, & Kersten, 2007; Spanjers, Wouters, Van Gog, & Van Merriënboer, in press). Two (alternative, but not mutually exclusive) explanations can be given for these positive effects. First, in previous studies pauses were inserted between the pieces. These pauses provide learners with time to perform necessary cognitive activities and to perform them on smaller units (Mayer, 2009). Secondly, segmentation can be seen as a form of temporal cueing, since it breaks animations into meaningful units (cf. Arguel & Jamet, 2009) which may support people in mentally breaking the events shown into units (see Schwan, Garsoffky, & Hesse, 2000). Since the natural boundaries are made more salient through the segmentation, searching for them may impose less cognitive load and learners may be supported in perceiving the structure underlying the process or procedure shown and stimulated to self-explain the information shown, which enhances learning (cf. Catrambone, 1998). This study investigated which of these processes is the most plausible explanation for the beneficial effects of segmentation. Therefore, learning outcomes and cognitive load with non-segmented animated worked examples and animated examples segmented by pauses, cues or pauses and cues are compared to each other. In addition learning efficiency scores (equal/higher learning outcomes with lower/equal investment of mental effort; see Van Gog & Paas, 2008) was also compared.

Method

The participating 161 secondary education students (51 % females; mean age = 14.79, SD = 0.49) were randomly assigned to one of the conditions (non-segmented (n = 42), segmented by cues (n = 41), segmented by pauses (n = 40),

and segmenting by pauses and cues ($n = 38$)). First, they completed a pretest consisting of probability calculation problems. Subsequently, they studied four animated worked examples, in which it was demonstrated and explained how probability calculation problems can be solved (cf. Spanjers et al., in press). The segmented examples were divided into five or six segments by pauses of 2 seconds and/or cues (i.e., slightly darkening the screen temporarily). Finally, the students completed the posttest consisting of probability calculation problems. After each example and test problem, the participants rated the amount of mental effort invested.

Findings

Two-by-two ANCOVAs with pretest scores as covariate showed that learners who studied animated worked examples with pauses ($M = 6.46$) achieved better than learners who studied examples without pauses ($M = 5.80$), $F(1,156) = 3.96$, $p = .05$. There was no significant main effect of cueing nor a significant interaction between cueing and pausing. For mental effort invested in the posttest no significant main effects nor a significant interaction was found. Analyses on the mental effort data during example study showed that studying examples with cues ($M = 2.19$) required less mental effort investment than studying the examples without cues ($M = 2.73$), $F(1,156) = 5.65$, $p = .02$. There was no significant main effect of pausing nor a significant interaction between pausing and cueing. Conclusion This study replicated the findings of previous studies (Hasler et al., 2007; Spanjers, Wouters et al., in press) that segmentation enhances learning from animations. Furthermore, this study investigated the plausibility of two explanations for the segmentation effect by comparing learning outcomes and cognitive load of four types of animated worked examples. Learners studying animated examples with pauses attained higher posttest scores than learners studying examples without pauses, without differences in investment of mental effort during example study. Thus, pauses influence the efficiency of the learning outcomes positively. On the other hand, studying animated examples with cues required less mental effort than studying examples without cues, without differences in posttest scores. So the insertion of cues also influenced the efficiency of the learning process positively. These results provide evidence for both explanations: pausing between segments enables learners to perform necessary processes on smaller information units, leading to better learning, and providing temporal cueing by making natural event boundaries more salient lowers cognitive load.

Does the multimedia principle hold true for chronic pain learners?

Angela Smith, University of New South Wales, Australia

Much is known about how pain reduces working memory capacity, but little is known about how instruction can be designed to compensate. Cognitive load theory (Sweller, 2005) and the cognitive theory of multimedia learning (Mayer, 2005) have both shown that a multimedia approach can overcome some working memory limitations. This paper investigated the impact of multimedia learning materials on learners who experience chronic pain. Sixty school teachers (30 with chronic pain, 30 pain-free) were randomly assigned to one of two learning materials written (W) or written with visuals (W+V). Following instruction on how lightning forms, participants completed retention, transfer, and matching tasks. Overall, pain-free learners scored higher than chronic pain learners; and the multimedia combination of W+V was more effective than the single W strategy. However, these results were moderated by the

task and the learner. For pain-free learners there was a consistent advantage to the W+V strategy. However, for chronic pain learners, the advantage of the W+V strategy was only found on one transfer task. Chronic-pain learners demonstrated impaired cognitive performance; and the effectiveness of multimedia materials was moderated by task requirements. This study adds to multimedia learning theory by extending the research into population of learners with special needs. The study may have implications for information representation to individuals with chronic pain in broader contexts.

This paper investigates the impact of multimedia materials on learners with chronic pain. It aims to show that these learners experience impaired cognitive performance compared with pain-free learners, and interact differently with multimedia materials. Learners with chronic pain essentially operate in a dual-task, split-source paradigm. Key areas of the brain involved in attentional resource allocation, modulation of sensory and affective components of pain, and amplification and attenuation of pain response, are associated with widespread activation in the anterior cingulate (ACC) and prefrontal cortices (PFC; Gilbert & Sigman, 2007). Such cortices are also activated during a variety of higher order processes including cognitive control, behavioural flexibility, and performance adaptation (Collette & Van der Linden, 2002). Importantly, the ACC and PFC are sensitive to working memory (WM) load and susceptible to interference when the processing of stimuli is increased. The sum of such conditions suggests that learners with chronic pain are vulnerable to impaired cognitive performance, particularly in contexts that require knowledge acquisition, problem-solving and transference. Although, the influence of pain on WM is well documented, little has been explored to improve cognition through instructional design manipulation. Cognitive load theory (CLT; Sweller, 2005) and cognitive theory of multimedia learning (CTML; Mayer, 2005) have identified various design principles that should be followed to optimize multimedia learning environments. Both theories directly link WM demands to multimedia design, arguing that a dual mode approach (visuals and text) can overcome some WM limitations. The application of these theories has predominantly been conducted with mainstream learners. However, are these design principles effective for a population of learners demonstrating episodes of reduced WM capacity? Do learners with chronic pain require greater access to multimedia materials to maximize understanding? This study investigates if the multimedia principle holds true for a population of learners with chronic pain. Mayer's multimedia principle states: "People learn more deeply from words and pictures than from words alone" (p. 31; Mayer, 2005). Two predictions were made. First, similar to pain-free learners, chronic pain learners would benefit from instruction that integrated visual and textual information. Second, that pain-free learners would learn more effectively than chronic pain learners. To test these predictions, a 2x2 factorial design was used where the first factor was participant pain status (presence vs. absence) and the second factor was instructional strategy (written vs. written + visual).

Method

Participants. 60 academic staff were recruited from a Sydney school. 30 reported that they had chronic pain and 30 reported no form of chronic pain. Each group was randomly assigned to one of the two treatment conditions: written only (W) or written with visuals (W+V). Each of the four cells had 15 participants.

Materials. The materials were a reproduction of those used by Mayer and colleagues that explain lightning formation. In the W group, written instructions were provided; in the W+V group, instructions included written text and diagrams. Following the learning phase, participants were required to take a retention test; a transfer test that included four different types of problem-solving questions, and a matching test that required causal-element identification. Prior to this phase a prior knowledge test was given, that served as a covariate throughout. Demographic data on pain duration, intensity, and depressive symptoms were also collected but are not reported here because of space restrictions.

Procedure. Participants received 8 minutes to process the instructional material before being presented the series of timed tests: retention (6 minutes), transfer (3 minutes each question), and matching task (3 minutes).

Results

An ANCOVA on the retention task indicated a significant strategy effect. The W+V strategy outperformed the W strategy: $F(1,53)=4.09$, p

Conclusion

For pain-free learners, there was a consistent advantage for the dual mode strategy. More learning occurred when both written text and diagrams (W+V) were presented compared with written text (W) alone. For learners with chronic pain the modality effect was moderated by the type of transfer task required. On tasks that required an explanation of the relationships among elements in the scientific system (transfer tasks 1 and 2) no advantage was observed. On a task that required making changes to the scientific system in order to achieve a particular goal (transfer task 3), a large effect was observed. Possible causes of this interaction will be discussed in more detail during the presentation. The findings of this study extends the theory on multimedia learning to a unresearched population of learners. The interaction findings suggest that chronic pain reduces WM capacity and that the effectiveness of

multimedia materials varies according to task requirements. The study may have significant implications for the way in which information is represented to learners with chronic pain in clinical and vocational contexts.

SYMPOSIUM

Facets of teachers' competences and teachers' perceptions

Chairperson: Eveline Wuttke, Goethe-Universitat Frankfurt, Germany

Organiser: Eveline Wuttke, Goethe-Universitat Frankfurt, Germany

Juergen Seifried, Universitaet Konstanz, Germany

Discussant: Monika Waldis, University of Applied Sciences, Switzerland

Aims of the symposium

Current discourse surrounding teacher competence and its development has established that teacher competence is a primary requirement for high level performance in the classroom. It has also established that this competence covers a variety of types of knowledge that a teacher should ideally possess (Shulman, 1987). Bromme (1992, 1997) has taken up and further developed Shulman's classification, which, from his perspective, also contains value systems (philosophy of the school subject, convictions, teachers' perception of learners etc.). In our symposium we focus on three central facets of teachers' competence and perception, namely diagnostic competence of teachers, professional error competence of teachers, and teachers' perception of ability and effort.

Scientific and educational relevance

As students' learning from errors depends on how teachers deal with errors and as diagnosing is an everyday task at school and the demand to foster students individually increases, such concepts prove to be helpful both in further education and earlier in teacher education when implemented in the curriculum. We furthermore need to know more about teachers' perceptions of learners abilities because teachers are among the most significant adults with whom children interact daily at school and we know that children easily assimilate teachers' perceptions as a part of their own self-concept.

Can Diagnostic Competences of Teachers be fostered by Training and the use of Diary?

Julia Klug, TU Darmstadt, Germany; Mara Gerich, Institut fuer Psychologie TU Darmstadt, Germany; Stefanie Jauch, Institut fuer Psychologie TU Darmstadt, Germany; Simone Bruder, DIPF, Germany; Bernhard Schmitz, Technical University of Darmstadt, Germany

Diagnosing is one of teachers' key tasks at school. So far, particularly students' academic achievement has been investigated in prior empirical research on teachers' diagnostic competence. However, there's a request to shift the focus to diagnosing learning behavior and a call for further education programs to foster new facets of teachers' diagnostic competence. The aim of the present study was to develop and evaluate a training program including a standardized diary, which was based on a three-dimensional process model of teachers' diagnostic competence concerning learning behavior. N=47 secondary school teachers participated in the longitudinal training program which combined pre- and posttest measures with time-series data. Results of our study show that the training in fact enhances teachers' diagnostic competence, especially when it comes to the processing while diagnosing and to diagnostic action before the actual judgment is delivered. The standardized diary proved to be a useful instrument to measure diagnosing in everyday work at school and also showed an additional intervention effect for the processing while diagnosing. As diagnosing is an everyday task at school and the demand to foster students individually increases, the training concept proves to be helpful both in further education and earlier in teacher education when implemented in the curriculum.

Theoretical framework and aim of the study

In their daily job, teachers are faced with multitasking and highly complex work (Brante, 2009). Diagnosing is one of their key tasks as they "are challenged to meet diverse learning needs and to adapt their teaching to heterogeneous academic ability as well as to multiple interests and motivations" (Vogt & Rogalla, 2009).

Looking at prior empirical research, students' academic achievement in particular has been investigated, from the 1970s until today. So far, accuracy in teachers' judgments has been measured by correlating judgments with results of standardized tests (e.g. Coladarsi, 1986; McElvany et. al., in press). However, there's an ongoing request in theoretical literature to shift focus from diagnosing achievements to diagnosing learning behavior which allows didactic action afterwards like fostering students individually and adapting class to their needs (e.g. Abs, 2007; Kretschmann, 2009). Klug, Bruder & Schmitz (in preparation) developed and empirically tested a model of teachers' diagnostic competence concerning learning behavior which closes the gap between previous empirical research and recent theoretical demands. It describes diagnosing learning behavior as a three-dimensional process (Jäger, 2007), consisting of a preactional, an actional and a postactional phase (Schmitz & Wiese, 2006). In preactional phase, teachers should intentionally aim at watching individual students learning process and at fostering students due to the diagnosis. Furthermore, teachers' basic diagnostic skills (knowledge about methods for gathering information, knowledge about psychological quality criteria of tests, knowledge about judgment formation) are activated. In actional phase, acting systematically is most important, including making predictions, gathering information from different sources, choosing relevant information, interpreting data and coming to a concluding diagnosis. In postactional phase, pedagogical action that follows out of the diagnosis like giving feedback, writing plans for students' promotion and adapting class by means of teaching appropriate learning strategies shall be implemented. Knowledge, professional identity and reflected experience are responsible for the development of diagnostic competence in the model.

Klieme et al. (2003) call for further education programs to foster new facets of teachers' diagnostic competence. Nevertheless, there are no such programs yet (Laukart, 2004). The aim of the present study was to develop and evaluate a training program including a standardized diary based on the described model to foster diagnostic competence concerning learning behavior.

Methodology

N=47 secondary school teachers with a mean age of 40.4 years and a mean school-teaching experience of 14.76 years (min=1, max=38) participated. 66 % were female and 7 had already taken part in a further education program on diagnostics. The longitudinal training design combined pre- and posttest measures with time-series data. Experimental group 1 (n=15) completed pretest, then got three weekly training sessions and completed posttest afterwards. Experimental group 2 (n=15) additionally worked on a standardized diary, starting one week before the first training session and finishing one week after the last session. The waiting control group (n=17) participated in pre- and posttest and got a shortened training program afterwards.

Pre- and posttest were composed of three instruments which were tested in a former study. First, a scenario-test measured diagnostic competence. It described a case of a pupil with learning difficulties followed by twelve open questions based on the model. Answers were rated each from zero to three points. Interrater-reliabilities were between ICC=.67 and ICC=.95. Of a maximum of 36 points, M=14.28 (SD=4.59) points were reached. Second, a knowledge test in multiple-choice-format with item difficulties between .33 and .82 measured knowledge on diagnostics. Third, a six-point likert-scale-questionnaire measured reflected experience (4 items, α =.75) and professional identity (12 items, α =.77).

The standardized diary contained 12 items on the content of the model, four on professional identity and one item on reflected experience, each formulated as states.

Findings

Multivariate ANOVAS with group as independent and the pre-post difference as dependant variable showed significant differences in case scenario measures for the total score of diagnostic competence ($F=12.43$, $df=2$, p

Theoretical and educational significance

Results of our study show that teacher training in diagnostic competence concerning learning behaviour in fact enhances teachers' diagnostic competence, especially when it comes to preactional and actional diagnosis action. However, postactional content needs to be broadened in later training programs. The standardized diary proved to be a useful instrument to measure processing while diagnosing in everyday work at school even though it did only show an additional intervention effect for actional variables. As diagnosing is an everyday task at school and the demand to foster students individually increases, such training concepts prove to be helpful both in further education and earlier in teacher education when implemented in the curriculum.

How to deal with student errors – Findings from a teacher training study

Juergen Seifried, Universitaet Konstanz, Germany; Eveline Wuttke, Goethe-Universitat Frankfurt, Germany

It is often said that students – or people in general – learn from errors. But we argue that this does not happen automatically, that teachers must support students in learning from errors, and that a teacher needs specific competences to do so. First, teachers need to know what typical errors can be made in a certain domain. Then, after errors have been discovered, teachers need to know how to give constructive and elaborate feedback about more successful ways to solve a problem. Therefore, the objectives of our studies are:

- To find out what teachers know about typical student errors.
- To analyse how teachers handle errors, if they get to the bottom of errors and if they are able to give elaborate feedback in order to support students in learning from errors.

The presentation will report the first findings from a video vignette study.

SYMPOSIUM

Understanding mechanisms and quality of students' questions

Chairperson: Albert Logtenberg, University of Amsterdam, Netherlands

Organiser: Albert Logtenberg, University of Amsterdam, Netherlands

Discussant: Baruch Schwarz, Hebrew University, Israel

This symposium brings together three empirical studies that investigate how students ask questions. Research in student questioning faces two problems. Firstly, students in education do not ask many questions and the quality of the questions leaves much to be desired. Secondly, there is more need for empirical knowledge of how questioning processes elapse in different domains. The aim of this symposium is to discuss methodological and empirical issues and contribute to theory on student questioning. In questioning theory variables such as prior knowledge readers' goals play an important role. The first paper discusses the impact of domain-specific prior knowledge on number and quality of students' questions (N=26, aged 21). Students of the experimental group received prior knowledge on the topic 'emotion and learning'. Their questions are compared to the questions of the control group that did not receive prior knowledge. The second paper studies questioning with 33 students (aged 15) that read a historical introductory text. In order to determine the quality of a historical question indicators of questioning ability in History are described. The third paper discusses how readers' goals affect the detection of reading obstacles and the generation of questions on scientific texts. Results show that students in the understanding condition detected more explanation obstacles than the students in the experimenting condition. The discussant will discuss the contribution of these studies to theoretical understanding of questioning processes and how this understanding can help develop learning activities that foster the development of student questioning skills and domain-specific understanding.

The influence of domain-specific prior knowledge on the number and quality of students' questions

Frauke Kammerer, University of Erfurt, Germany; Helmut M. Niegemann, University of Erfurt, Germany

Questioning as a learning technique can improve learning outcomes because it helps the learner to better integrate new knowledge into prior knowledge. However, the influence of domain-specific prior knowledge on the number and quality of questions has not yet been made clear. We aim at empirically based statements about the influence of prior knowledge on the number and quality of questions. We therefore conducted an experiment with two groups: the experimental group (n=13) received prior knowledge on the topic "emotion and learning" (high prior knowledge). The

control group (n=13) did not receive prior knowledge on that topic (low prior knowledge). To judge the number and quality of questions students in both groups read a text on the topic "emotion and learning" and were asked to write down all their questions while reading. The first results indicate that both groups differ significantly in their domain-specific prior knowledge. Further analysis may show if this difference in has an influence on the number and quality of their questions

Aims.

Questioning as a learning technique can contribute to better learning outcomes. Previous studies have shown the positive effects of questioning (e.g., Graesser & Person, 1994). But there are inconsistent results concerning the influence of domain-specific prior knowledge on the number and quality of learner's questions (e. g., Miyake & Norman, 1979; van der Meij, 1990). To contribute to this knowledge gap we designed an experiment with two groups: one group that received prior knowledge on the topic 'emotion and learning' and another group that did not receive any prior knowledge. Firstly, we want to find out if both groups differ in the number they ask on another text about emotion and learning. Secondly, we consider the quality of their questions in relation to their domain-specific prior knowledge.

Theoretical framework

We judge the quality of questions according to the PREG model (Otero & Graesser, 2001). This model predicts the occurrence of questions during text understanding on three different cognitive levels:

Text surface: learners seek to understand the meaning of a certain word, e.g., 'What is the meaning of exam nerves?'

Text base: learners seek to understand the relation of propositions in a text, e.g., 'How are the two components of exam nerves related to each other?'

Situation model: learners seek to construct relations between propositions in a text and their prior knowledge, e.g., 'What is the relation between emotions during learning and the depth of information processing?'

Research question and hypothesis

This paper deals with our research question concerning the number and quality of student questions: How does domain-specific prior knowledge influence the number and quality of students' questions? We expected students with high prior knowledge (experimental group) to ask more questions on a higher cognitive level than students with low prior knowledge (control group) (Hypothesis 1). We expected both groups to differ in the number of questions they ask (Hypothesis 2).

Method

Participants and design.

The participants were 26 students of a German university majoring in education, special education or psychology (2 male, 24 female). The mean age was 21.58 years (SD=2.56). All of the participants studied in the second semester. They were randomly assigned to one of the experimental conditions.

Experimental conditions.

We designed an experiment with one experimental and one control group (1x1 design). The experimental group received prior knowledge to the topic of emotion and learning. The control group did not receive domain-specific prior knowledge on that topic.

Learning materials

As learning materials we used two texts about emotion and learning: one text that explicitly induced prior knowledge on the topic (prior knowledge text) and one text that was read by both groups (main text).

In the first text that was given to the experimental group before reading the main text important concepts of the topic "emotion and learning" were explained (e.g. exam nerves, worry-component of exam nerves). The explanation of certain concepts should reduce the number of questions on text surface. Thus, students in the experimental group should have more cognitive resources to concentrate on questions on higher cognitive levels. Before reading the main text the control group received a text about the oil catastrophe in the Gulf of Mexico (control text). We wanted to make sure that both groups read the same amount of words before turning to the main text.

We took the main text on emotion and learning from an educational psychology textbook. We analysed the text into propositions and manipulated the text on the three levels of understanding according to the PREG model. These manipulations should make the text inconsistent and thus, provoke questions on the three levels of understanding according to the PREG model. Students were told to read this text and try to understand it. If they had difficulties in understanding they should formulate and write down their questions.

Prior knowledge test.

After they had finished reading the first text (prior knowledge text and control text) students of both groups completed a criterion-oriented prior knowledge test.

Dependent variables.

To measure the influence of prior knowledge we gathered the following variables: number of questions, quality of questions and learning outcome.

Results

Manipulation check.

We conducted a t-test for independent samples to check if both groups are different regarding their prior knowledge. The mean score of the experimental group in the prior knowledge test was $M=3.23$ ($SD=1.166$), the mean score of the control group was $M=1.85$ ($SD=1.281$). The t-test showed that both groups differed significantly in their domain-specific prior knowledge ($t(24)=2.882$; $p=.008$). Cohen's $d=1.13$ showed a strong effect in favour of the experimental group.

Number and quality of questions.

The data concerning number and quality of questions have not yet been fully analyzed. To judge the quality of questions we analyzed them into propositions. Two independent raters will judge the quality of questions according to the PREG model. To compare the means of the questions on each level we will conduct t-tests. The results will be presented at the conference.

significance and future work

As stated earlier, we try to contribute to fill in the gaps of previous studies examining the influence of prior knowledge on the number and quality of questions. We also collected data on interest, level of understanding (self-assessment) and invested effort. We should also pay further attention to the influence of these variables on the number and quality of questions.

Students' questioning in History: indicators of the ability of formulating historical questions

Albert Logtenberg, University of Amsterdam, Netherlands; Carla Van Boxtel, University of Amsterdam, Netherlands; Bernadette Van Hout-Wolters, University of Amsterdam, Netherlands

This study aims at deeper insight into students' ability to ask historical questions after reading a historical introductory text and at the identification of possible indicators of this ability. The study draws on domain-specific and more general theories on questioning. We depart from the idea that historical questions are related to historical thinking and reasoning. Furthermore, we use a three-stage model of questioning (onset, formulating and answering) for designing this study. 33 students in secondary education were instructed to underline text segments they found striking. Then, students were instructed to formulate questions and were asked whether they could give an answer. Finally students were interviewed about their most interesting and important questions. We used four indicators for students' questioning ability to analyze the data; the ability to formulate a question out of an experience of perplexity, the quality of the questions asked, students' questioning goals, and the extent to which students have an idea of an answer. Our analysis shows that the four indicators proposed in this study can help to determine students' ability in asking historical questions and the problems students face. The data also support the idea that the model of questioning is not always linear; a question can function as a start but also as a result of historical reasoning. Implications for improving students' ability to ask historical questions are explored.

In History, questioning can be seen as an 'engine' of historical reasoning (Reference removed for review). Interpreting a historical phenomenon implies a search for explanations ('why did it happen?'), differences and communalities ('what changed?') and historical context ('was it common in that time?'). When we want to enhance students' ability to ask historical questions, it is important to investigate how students perform on a questioning task. The aim of this study is to provide an insight into students' questioning ability and to identify indicators of students' ability to ask historical questions.

Yang (2006) argues that research on questioning assumes incorrectly that 'the cognitive process type needed by each question is fixed in itself.' (pp. 198). Most research on questioning disregards the mechanisms of question generation and the domain-specific characteristics of questioning (Otero, 2009). Although researchers in history education state that questioning plays an important role in historical reasoning empirical research is scarce.

Van der Meij (1994) describes three stages that characterize the questioning process : (1) the onset (perplexity), (2) development (formulating) and (3) processing of an answer (answering). The stage of formulating questions knows many difficulties and opportunities (Van der Meij, 1994). Ideally, students should be able to recognize their experience of perplexity (onset) and put this perplexity into the right words. In History, students' perplexity is sometimes the result of considering past events and actions as strange, reasoning from a present-oriented perspective. Having an idea about the answer is considered an important component of questioning ability. The task to formulate questions can be interpreted differently. Questions can function to express interest, to foster text-comprehension or to create a representation of the phenomena the text is about (Chin & Osborne, 2010).

Summarizing, this study focuses on questions asked by students in secondary education. We describe the domain-specific characteristics of student questioning processes in order to be able to do more sophisticated claims about what constitutes students' ability to ask historical questions. Potential indicators are 1) students' ability to formulate the experienced perplexity into a question; 2) the domain-specific quality (historical question types), 3) students' ability to formulate an answer and 4) students' questioning goals.

In order to validate and specify these indicators, we investigated students' questioning after reading an historical introductory text. These questions are addressed to describe possible indicators of students' ability to ask historical questions:

1. To what extent do students' formulate a question out of experiences of perplexity?
2. To what extent do students formulate historical questions and what type of historical questions?
3. To what extent have students an idea of a possible answer?
4. What are students' questioning goals?

Method

Participants

33 students in higher secondary education (mean age = 15.6, 10 boys, 23 girls) are recruited from a sample of 174. Selection criteria were high, medium and low scores on variables prior knowledge and interest in History.

Procedure

The introductory text about the Industrial Revolution (770 words) composed for this study contains narrative and problematizing characteristics. Participants were instructed to read and underline text segments that were striking or unclear to them. After reading students were instructed to ask questions. After each formulated question, students were asked to answer it. Students were interviewed about their most important question.

Analysis

We used the analyses of types of perplexity in terms of prior knowledge, affect and historical reasoning (Reference removed for review) to determine whether students put their perplexity into a question. Secondly, we determined the type of questions (descriptive, comparative, explanative (causal) and evaluative questions). Furthermore we distinguished questions aiming at text comprehension and questions aiming at understanding a historical phenomenon. Finally we analyzed the preliminary answers that students gave and analyzed the explanations they gave for choosing their most important question.

Results & Conclusions

Not every experience of perplexity during reading was formulated into a question after instruction. Spontaneously asked questions during reading were not always (re)formulated after instruction. For example, perplexity that was characterized with emotions, such as indignation, was not always transformed into a question. In some cases students verbalize perplexity, but resolve it by reasoning historically (e.g. contextualize an event or situation) when they are asked to explain their perplexity.

Students formulated 117 (M = 3.5) questions after instruction. Most questions were descriptive (N= 60) and explanative (N = 47) questions and aimed at historical understanding (76%). Many of these questions go beyond the text and seek for more general information about the Industrial Revolution, such as 'How did the Industrial Revolution start?'

On 79 (67.5%) of the questions students tried to formulate an idea of an answer. Ideas contained information from the text, lessons on the topic or world knowledge. In some cases students formulated follow-up questions while

reasoning about a possible answer. Analysis of the explanations for choosing certain question as most important revealed that students think the most important questions are questions that helps them to understand the topic and that focus on the most significant issues of the historical topics. Sometimes, personal interest is also seen as an important motivation for a question.

Summarizing, the indicators proposed in this study help to determine students' ability in asking historical questions and the problems students face. Students' reflection on their questions reveals important aspects of cognitive and affective goals and historical aspects of the ability of questioning. The data also support the idea that the model of questioning is not always linear: a question can function as a start but also as a result of a historical reasoning.

Effect of an understanding task versus an experimenting task on detection of obstacles and questions

Paula Fernandes, University of Coimbra, Portugal; Piedade Vaz, University of Coimbra, Portugal; sanjose vicente, University of Valencia, Spain; Jose Otero, Universidad de Alcala, Spain; Maria Morgado, High School of Tomar, Portugal

Question asking may be conceptualized as a request for information in order to overcome an obstacle to achieve a certain goal. This study examined the effect of two reading tasks, and corresponding goals, on the detection of obstacles and question asking on scientific passages. Two types of obstacles and corresponding questions were considered in the study: explanation obstacles and association obstacles. A typical example of the former are difficulties in establishing causal relations, while the latter correspond to difficulties in characterizing the entities described in a text and their features. A sample of secondary school students read passages for understanding or, alternatively, to do an experiment, with instructions to ask questions if necessary. The results showed that students in the understanding condition detected more explanation obstacles, according to the questions asked, than the students in the experimenting condition. The opposite was true for association obstacles and association questions.

Asking an information seeking question may be conceptualized as a request for information in order to overcome an obstacle to achieve a certain goal (Reference removed for review). In this study, we examined how readers' goals affect the detection of reading obstacles and, subsequently, the generation of questions on scientific texts. These three elements, reading goals, obstacle detection and question asking are closely interrelated. Goals influence the type of mental representation attempted by readers. The attempted mental representation, in its turn, is one key element defining the comprehension obstacles found, and these obstacles influence the questions asked. Two types of obstacles and corresponding questions were considered in the study: explanation obstacles and association obstacles (Reference removed for review). A typical example of the former are difficulties in establishing causal relations, while the latter correspond to difficulties in characterizing the entities described in a text and their features. A sample of secondary school students read the same short passages for understanding or, alternatively, to do an experiment, with instructions to ask questions if necessary. Given a particular text and a reading task, the immediate goal of a reader consists in building an internal representation of discourse appropriate for the attempted task.

Therefore, these two tasks were hypothesized to correspond to different mental representations attempted by the students under the two conditions. Reading for understanding involves representations of discourse where explanations and causal relations play an important role. This expectation is supported by models such as the constructionist theory of discourse comprehension of Graesser, Singer and Trabasso (1994), and by many other studies that have demonstrated the importance of causal or goal-based explanations in the mental representation of narratives (Klin, 1995; Suh & Trabasso, 1993; Van den Broek, 1990), and of expository texts (Millis and Graesser, 1994; Singer and Gagnon, 1999; Wiley and Myers, 2003).

A different mental representation and different obstacles would be expected when someone reads a text to perform a procedure. For instance, reading about a physical system in order to carry out an experiment involves attempting a representation where objects and processes are elaborated in enough detail so that the operation of the system could

be predicted (Norman, 1983). In addition, school practical work is frequently considered by students as mainly manipulative and relatively devoid of theoretical content (Abrahams and Millar, 2008). Students focus on manipulative activities with less regard for the ideas providing meaning and relevance to the events taking place in the laboratory. Therefore explanations and causal relations may be regarded less important under this condition. In contrast, knowing the objects and processes involved in a procedure are expected to be central components of the mental representation built. Therefore obstacles in representing these entities, i.e., association obstacles, are expected to be more frequent when reading to perform an experiment than when reading for understanding.

In accordance with this, we hypothesized that less explanation obstacles and less explanation questions should occur in the experimenting condition than in the understanding condition while the opposite should occur for association obstacles and association questions.

One hundred and twenty four 12th grade students, in 6 classes, and 72 9th grade students, in 4 classes, participated in three experiments. The students read 4 different short science passages under understanding or experimenting conditions, with instructions to ask questions if necessary.

The results showed that obstacles and questions depended in a predictable way on the proposed tasks and corresponding reading goals of the students. Students in the understanding condition asked significantly more explanation questions than the students in the experimenting condition - a result replicated across the experiments. In contrast, students in the experimenting condition tended to ask significantly more association questions than the students in the understanding condition. These results suggest that understanding and experimenting tasks give rise to different concerns in science students. The relation between these concerns and deep understanding merits further attention.

SYMPOSIUM

Developmental dyscalculia interventions and fMRI measures – A combined approach

Chairperson: Dominique Arndt, University of Duisburg-Essen, Germany

Organiser: Dominique Arndt, University of Duisburg-Essen, Germany

Katleen Sahr, University of Duisburg-Essen, Germany

Discussant: Daniel Ansari, University of Western Ontario, Canada

Arithmetic competencies are an important predictor for children's later success in their educational career. Thus, developmental dyscalculia - which is defined as a specific learning disability that affects the acquisition of mathematical skills in children with normal intelligence and age-appropriate school education - needs to be investigated more often especially in young children. The aim of this symposium is to present a combination of

different research methods in the field of developmental dyscalculia, which is quite new. In the research of all presenters the findings of a mathematical training condition for children aged five to ten years were replicated by means of functional magnetic resonance imaging (fMRI). The papers differ in their kind of mathematical training and the sample of children (e.g. formerly preterm children versus children taken from ordinary primary school).

Imaging and behavioral effects of an arithmetic training for young children

Katleen Sahr, University of Duisburg-Essen, Germany; Dominique Arndt, University of Duisburg-Essen, Germany; Maria Opfermann, Duisburg-Essen University, Germany; Annemarie Fritz, University of Duisburg-Essen, Germany; Detlev Leutner, University of Duisburg-Essen, Germany; Helga Krinzinger, RWTH Aachen University Hospital, Germany; Jan Kötter, RWTH Aachen University Hospital, Germany; Kerstin Konrad, RWTH Aachen University Hospital, Germany; Klaus Willmes - von Hinckeldey, Medical Faculty RWTH Aachen University, Germany

Our longitudinal study investigated, whether early arithmetic competencies can be validly and reliably assessed with a screening instrument and fostered by means of an adaptive training. In addition, we aimed at supporting these behavioral findings by investigating whether the changes in arithmetic competencies are accompanied by neurological changes as well, that is, shifts in brain activation patterns. Secondly, children were tested for their arithmetic and cognitive competencies. Based on these results, we classified children into those who showed average arithmetic and cognitive performance, low arithmetic but average cognitive performance or both, low arithmetic and low cognitive performance. The low arithmetic achievers were then assigned to one of three training groups: an individual adaptive training of arithmetic competencies, a computer-based working memory training and a group-based training of social skills, whereby all trainings took place three times a week over seven weeks. It was found that the arithmetic training led to significant increases in arithmetic competencies compared to the other two training groups and that such effects remain stable over several months, but not after a year. This implies that, although the seven-week-training was obviously effective, continuous support is needed to keep low achieving children's arithmetical competencies on a level that allows them not to fall behind their age-related peers. This was also supported by the finding that brain activation patterns changed with increasing and decreasing arithmetic competencies.

Early arithmetic competencies are an important predictor for children's later success in school. (Krajewski & Schneider, 2009). Detecting missing competencies and correcting them as early as possible might thus be considered one of the main goals of education. In this regard, our longitudinal study focused on three main questions: (a) How do arithmetic competencies develop in early childhood and how can this be tested? (b) Can missing competencies be overcome by means of an adaptive training? (c) Are there indicators other than pure performance improvements that show children's arithmetic development, e.g., shifts in brain activation patterns?

When looking at the arithmetic development of children, it can be seen that even toddlers are already able to deal with amounts and numbers and that such abilities become more sophisticated the older the children get, even without specific training. The model of arithmetic development by Fritz, Ricken and Balzer (2009) proposes five levels that children aged about four to eight years naturally run through when building up their arithmetic skills. For instance, during the first level, children are able to distinguish small sets (that is, they do not count but can decide which of two sets is bigger), while during the fifth level, they already have a relational understanding of numbers (for instance, they can solve tasks like "What number is 5 less than 9?").

Based on this model, we tested 1363 children aged 4 to 8 years with a screening instrument the tasks of which correspond to the skills that Fritz et al. (2009) propose to be developed within the respective levels. In addition, cognitive abilities (CPM) were assessed. Out of this sample, 256 children were selected, who either showed average arithmetic and cognitive performance (Group A), low (PR

Repeated measures ANOVAs revealed - in comparison to the working memory and social training groups - a stronger impact of the arithmetic training on arithmetic performance (interactions of time and type of training), which referred to retention (p

Over the course of a year we tested and scanned 40 first- to third graders showing low arithmetic performance (PR. These 40 children as well as 16 age-matched controls completed four different numerical tasks in the scanner (Siemens Trio; voxel size: 3.5mm; TR: 1.6 sec; block design): a symbolic magnitude comparison task, a non-symbolic magnitude comparison task, a symbolic exact addition task ("Add these two numbers up to 7, yes or no?"), and a non-symbolic exact addition task. For all four tasks, the same stimulus combinations (stimuli ranging from 2 to 5) were used comprising 24 items per task.

Brain activation differences between low-achieving children and controls as well as specific and unspecific training effects on brain activation patterns will be presented and discussed.

Our behavioral results from both studies indicate that an adaptive training of arithmetic competencies can strongly improve children's immediate retention and transfer skills and such effects even last for a certain amount of time. However, since these effects were only found for the first, but not the second follow-up, a continuous training of children, whose arithmetic skills are below age-related expectations, seems more advisable than a one-time intensive push.

Training in Children with Developmental Dyscalculia

Karin Kucian, University Children's Hospital, Switzerland; Ursina Grond, University Children's Hospital, Switzerland; Claudia Schonmann, University Children's Hospital, Switzerland; Barbara Henzi, University Children's Hospital, Switzerland; Stephanie Rotzer, University Children's Hospital, Switzerland; Markus Galli, Methods in Action GmbH, Switzerland; Michael von aster, german red cross hospitals Berlin; neuroscience center zurich, Germany; Ernst Martin, University Children's Hospital, Switzerland

Recent studies in human neurosciences indicate that developmental dyscalculia is linked to a deficient development of spatial number representation, i.e. the mental number line. This study evaluated a computer based training program of this basic number representation with neuropsychological as well as imaging (fMRI) basis. It was shown, that children benefited from the training regarding to their representation and arithmetic ability. Different activation patterns between dyscalculics and control children could be shown, as well as a main effect of training in decreased frontal lobe activation. Furthermore there is indication for a differential training effect on dyscalculic children, who showed an increase in parietal activity. This is a clear indication of a remedy to deficient brain activation patterns by the means of a custom-designed training program.

Background

Developmental dyscalculia is a specific learning disability that affects the acquisition of mathematical skills in children with normal intelligence and age-appropriate school education. Estimated prevalence rates range from 3 to 6%. One essential step in the development of mathematical understanding is the formation and automated access to a spatial representation of numbers. Many children with Developmental dyscalculia show a deficient development of such a mental number line.

Aim

The present study aimed to develop and evaluate a computer-based training program to improve the construction and access to the mental number line. The efficiency of the training was evaluated by means of neuropsychological tests and functional magnetic resonance imaging (fMRI).

Methods

Sixteen children with Developmental dyscalculia aged 8-10 years and 16 matched control children completed a 5-weeks computer training called 'rescue calcularis'. Main goal of the training was to gear a rocket, on which Arabic numbers, additions, subtractions, or sets of dots were displayed, to a corresponding landing place on a number line from 0 to 100. All children played the game 15 minutes a day on 5 days a week. Different behavioural data related to number processing and other cognitive abilities such as spatial working memory, as well as fMRI during a number line task was measured before and after training. Developmental dyscalculia and control children differed significantly according to standardized measures of number processing and calculation. Differences in verbal IQ were due to differences in the subscore 'arithmetic' and disappeared when comparison was controlled for arithmetic.

Results

In general, children with and without Developmental dyscalculia could benefit from the training indicated by (i) improved spatial representation of numbers and (ii) the number of correctly solved arithmetical problems.

Regarding the initial pattern of brain activation control children activated the typical fronto-parietal network associated with number processing (Figure 1.A). In contrast, dyscalculics showed main activation in medial frontal areas (Figure 1.A). Statistical group comparison corroborated that children with Developmental dyscalculia showed less activation in bilateral parietal regions (Figure 1.B). The main effect from pre-post training comparison was a decrease of frontal lobe activity after training in both groups (Figure 1.C). An increase of parietal activity in Developmental dyscalculia children was evident after a second follow-up 4 weeks after training was completed.

Conclusions

In general, children with and without Developmental dyscalculia showed a benefit from the training indicated by (a) improved spatial representation of numbers and (b) the number of correctly solved arithmetical problems. Regarding initial group differences in brain activation, children with Developmental dyscalculia showed less activation in bilateral parietal regions which might reflect neurophysiological deficits in pivotal regions for number processing. Both groups showed a clear reduction in the recruitment of relevant frontal brain regions after the training which can be attributed to automatization of cognitive processes necessary for mathematical reasoning and may indicate reduced demands on executive functions. Moreover, results point to a parietal remediation of deficient brain activation in dyscalculic children after consolidation of acquired and refined number representation. To conclude, the present study represents the first attempt to evaluate a custom-designed training program in a group of dyscalculic children and results indicate that the training leads to an improved spatial representation of the mental number line, which facilitates processing of numerical tasks, and a modulation of neural networks.

Brain-imaging guided intervention of numeracy skills in primary school children born prematurely

Liane Kaufmann, UMIT-Private University for Health Sciences, Medical Informatics and Technology, Austria; Marc Starke, Innsbruck Medical University, Department of Pediatrics IV, Austria; Silvia Pixner, UMIT-Private University of Health Sciences, Medical Informatics and Technology, Austria; Christian Kremser, Innsbruck Medical University, Department of Radiology I, Austria; Thomas Trieb, Innsbruck Medical University, Department of Radiology I, Austria; Ursula Kiechl-Kohlendorfer, Innsbruck Medical University, Department of Pediatrics IV, Austria

The term developmental dyscalculia denotes severe calculation difficulties despite average intellectual abilities and good schooling. Prematurely born children are known to be at high risk to develop learning disorders including dyscalculia and thus are an ideal population to study developmental pathways of numerical cognition. Main aim of the present study is to investigate training-induced changes as regards behavioral performance and functional imaging (i.e., blood-oxygenation-level-dependent/BOLD response) in 6 to 7 year-old children born prematurely. Neuropsychological assessments (including a standardized calculation test) are conducted prior training and after termination of training. The experimental training condition comprises specific training of basic number skills and consists of eight training sessions, each lasting 30 minutes. A control training focusing on phonological skills is offered to participants in a waiting group design. Both training programs are comparable with respect to duration, materials and sensory modality. To the present, data collection is still ongoing. Data analyses will be as follows: Calculation skills will be used as a covariable. Beyond quantifying behavioral training effects, training-induced changes in neurofunctional response patterns (i.e., fMRI signal strength) upon processing number tasks will be measured.

Aims

Individuals with significant calculation difficulties have a considerable disadvantage in both academic and occupational activities. The term developmental dyscalculia (DD) denotes severe calculation difficulties despite average intellectual abilities and good schooling. According to influential authors, impaired number magnitude (i.e., numerosity) processing should be considered a key cognitive deficit of affected children. Most studies on developmental dyscalculia are based upon adult calculation models which may not provide an adequate theoretical framework for

understanding and investigating developing calculation systems. Moreover, despite the fact that recent technological advances enable us to visualize the neurofunctional correlates of numerical cognition, many researchers are skeptical as regards the educational implications of neuroscience research. Recently, an increasing effort to bridge the gap between neuroscience and education can be observed, as reflected in scientific journals devoted to this subject (i.e., *Mind, Brain and Education*; first compiled in 2007). In particular, it has been stressed that neuroscientific endeavors might be potentially fruitful for educational sciences by going beyond behavioral analyses (and thus contributing to a better understanding of the brain-behavior relationship of the cognitive function of interest).

The present study is among the first to systematically investigate the effects of number skill training in young children. Our research efforts are targeted at prematurely born children because the latter are at high risk to develop learning disorders including developmental dyscalculia. Consequently, by recruiting prematurely born children aged 6 to 7 (first graders), we may ensure to have both average and poor math performers in our sample. Thus, beyond investigating training effects at both the behavioural and neuroimaging level, our design will allow us to investigate whether mastery (i.e., average versus poor performers) modulates training extents (by looking at the behavioural, at the neural and at both levels).

Methodology

Study participants are 6 to 7 year-old, formerly preterm children with a gestational age of

The experimental training condition comprises specific training of basic number skills and consists of eight training sessions, each lasting 30 minutes. A control training focusing on phonological skills will be offered to participants in a waiting group design. Both training programs are comparable with respect to duration, materials and sensory modality. Training effects will be measured behaviorally (i.e., calculation test administered prior and after training; as well as behavioral data of the experimental task employed in the scanner) and by means of neuroimaging (i.e., fMRI responses in number-relevant brain regions).

The experimental task to be employed in the scanner is a physical Stroop task requiring children to classify the physically larger (font-size) of two to-be-compared one-digit numbers by button press. Generally, incongruent items (physical and numerical size interferes) are more difficult than congruent ones, as reflected in higher error rates and slower response times. However, the so-called congruency effect may be less pronounced or even absent in children who have imprecise number magnitude representations (as expected in poor math performers). The task is presented in box-car fashion (5 stimuli per block; stimulus duration will be 3000 msec; inter-stimulus-interval varying between 1000 and 3000 msec). Experimental blocks are interspersed with rest blocks (18000 msec each) and preceded by an instruction picture (4000 msec). The instruction picture is defined as predictor of no interest. Within blocks, stimuli are presented in randomized order. Data analyses are performed using SPM5 (<http://www.fil.ion.ucl.ac.uk/spm/software/spm5/>) and are hypotheses driven: fronto-parietal areas being the regions of interest. A whole-brain regression analysis will be performed to examine which brain regions correlate significantly with behavioral performance during scanning. Finally, correlation and regression analysis will be conducted to assess the association between neurocognitive (i.e., behavioral training effects) and brain imaging measures (i.e., neurofunctional training effects).

Findings

Please note that currently, we are still in the stage of data collection. Our working hypotheses are as follows. First, behavioural training effects are specific (i.e., larger gains in number knowledge observable in children participating in the number skill training compared with children attending the non-numerical training). Second, beyond behavioural training effects, training effects are expected to arise at a neural level (preferentially in number-relevant fronto-parietal brain regions). Third, skill level (i.e., mastery of number knowledge) may modulate the extent of training effects (possibly at both the behavioural and the neural level). In particular, poor math performers (i.e., experimental group consisting of preterm children with poor calculation skills) are expected to show larger training effects compared to average performing peers (i.e., control group consisting of preterm children with average calculation skills).

Theoretical and educational significance of the research

Our findings will be taken as an example to discuss how neuroscience findings may impact on educational sciences and classroom interventions. In particular, we expect that the findings of our intervention study will enhance our current understanding of the link between skill level and training extents on the one hand and will aid in characterizing the interplay between behavioural and neurofunctional training effects on the other hand. In particular, knowledge about the close interlink between behavioural performance and neural responsiveness may inspire pedagogical practice to go beyond well-established teaching methods, encouraging the development and evaluation of novel teaching attempts that take into account the brains' responsiveness to training.

SYMPOSIUM

The assessment of reading literacy: new measurements and technological developments

Chairperson: Helge Stromso, University of Oslo, Norway

Organiser: Eduardo Vidal-Abarca, Universidad de Valencia, Spain

Danielle McNamara, University of Memphis, United States

Discussant: Johannes Naumann, German Institute for International Educational Research, Germany

The concept of reading literacy has expanded in the last decade. It now includes competencies to use very different documents that combine verbal and pictorial information covering very different contents with very different purposes (e.g., accessing, retrieving or integrating information). These competencies can take advantage of technological developments that allow automated analysis of document information as well as the reader's behavior when reading documents. The aim of this symposium is to show recent studies that have explored how these competencies can be assessed, and how technological developments can be used for the assessment. Thus, two contributions explore the measurement of two important reader's competencies, that is, text-picture integration and the use of document within a task-oriented reading approach, whereas the third one measures text difficulty, an important component of any assessment procedure. Regarding technological developments, two contributions explore the use of information technology to analyze: (a) text difficulty with Coh-Metrix, and (b) the reader's competencies to use documents with CompLEC, whereas the third one provides a theoretical and empirical basis to analyze text-picture integration with an automated tool. The ultimate goal of this symposium is to build bridges between research advances in reading and document literacy and practical solutions for education and assessment.

CompLEC: A computed-based test to assess task-oriented reading competencies of high-school students

Eduardo Vidal-Abarca, Universidad de Valencia, Spain; Tomas Martinez, Universidad de Valencia, Spain; LADISLAO SALMERON, UNIVERSITY OF VALENCIA, Spain; Ramiro Gilabert, Universidad de Valencia, Spain; Ana .C. Llorens, Universidad de Valencia, Spain; Amelia Mana, University of Valencia, Spain

CompLEC is a computer-based test that assesses students' ability to use complex documents to solve a series of questions, which correspond to the skills promoted by PISA and PIAAC, two recent international reading literacy assessment programs. CompLEC presents the information with a masking procedure, so that it can evaluate students' reading and search behavior. The test has adequate psychometric properties, as revealed by data from 794 students collected in 7 different Spanish regions. Preliminary analyses with hierarchical linear equations based on on-line data suggest that students' initial reading and search efficiency are strong predictors of performance. From a practitioner's perspective, CompLEC provides information not only of students' question success, but also of critical reading and search behavior, which allows for a more fine-grained intervention in task-oriented reading.

Two recent international reading literacy assessment programs, i. e., PISA (Program for International Students Assessment, OECD, 2009) and PIAAC (Program for International Adult Assessment Competencies, OECD, 2010), have been implemented to assess reading comprehension with a task-oriented reading approach. The emphasis in this approach is on the use of different documents (i. e., continuous texts, like a novel or an expository text, and non-continuous, like a graph or a table) to answer different kind of questions to prompt different types of cognitive processes (e.g., retrieving and integrating information) having the document available.

Two characteristics of task-oriented reading are essential. First, only information that is pertinent to the task is relevant to the reader. Second, the reader interacts with the text in a particular way, going back and forth from the text to the task, and vice versa, until she determines that the task has been achieved. Therefore, task-oriented reading places specific self-regulatory demands on readers (e. g., how to read a text according to the question, when and where to reference a document, what piece of text to read, and when to stop searching to answer a question). This interaction between the reader and the text can be recorded on-line, which gives information to make inferences about the reader's skills and strategies.

Vidal-Abarca and colleagues have developed a technological tool to record this interaction called Read&Answer (Vidal-Abarca et al., 2010). They also have conducted different studies using this tool to analyze the impact of different kind of questions on comprehension (Cerdan, Vidal-Abarca, 2008; Cerdan, Vidal-Abarca, Martinez, Gilabert & Gil, 2009), or the difference between skilled and less-skilled readers (Vidal-Abarca, et al., 2010), which contribute to explain the readers' performance in task-oriented reading.

Features of CompLEC
