CompLEC, the tool we present in this symposium, is based on Read&Answer technology and the main results of the above-mentioned studies. It follows PISA and PIAAC framework regarding text materials and type of questions. CompLEC is a test to assess reading literacy competencies at the individual level. It provides practitioners with information about the product of reading (i. e., performance) and the processes and strategies the readers follow when reading a document. An important advantage of CompLEC is that it provides all this information automatically. Next, we explain the main characteristics of CompLEC and the main results of a first application to a large population of high-school students.

CompLEC is composed of five short documents (~400 words) and 20 questions (5 retrieve, 10 interpret, 5 reflect questions). Documents represent different structures (3 continuous and 2 non-continuous documents) and deal with several topics (Climate change, nuclear energy, language of the bees, traffic accidents and good chairs). Students are given one hour to use the documents to answer the questions. They can read either the text or the questions first.

The tool presents information following a masking procedure, so that students have to click on text segments to make them readable. This procedure allows to record students' on-line behavior. CompLEC automatically derives a series of indexes based on those data, such as reading speed, number of searches, search regulation, search efficiency, and global reading strategy.

Psychometric and on-line analyses

We collected data from 794 7th to 9th grade students, from schools or 7 Spanish regions, which allowed us to analyze the test's psychometric properties and the relationships between on-line reading behavior and performance.

Psychometric properties of the test were obtained after data from 794 students from 7th to 9th grade, from schools located in 7 Spanish regions. Reliability of the text was fair, as revealed by a Cronbach alpha of .80. Construct validity was assessed by comparing students' scores with CompLEC with those obtained in a standardized comprehension skills test (TEC). Correlation between tests' scores was high: $r = .52$, $p < .001$. Finally, predictive validity was considered by predicting students' class scores through students' scores in CompLEC. Correlations were moderate to high: mathematics $r = .32$, $p < .001$, natural sciences $r = .44$, $p < .001$.

In addition, we are currently testing a series of hierarchical linear equations using on-line indices as predictors of final test scores. Preliminary results suggest that initial reading time had a positive relation with performance. In addition, students' decisions to search were associated to lower performance. This suggests that students regulate their search initiatives, so that they would not search when they are positively confident on a question response (Vidal-Abarca et al., 2010). Once students decided to search, time on task had a differential effect. Time searching text segments that include relevant information for a question had a positive relation with performance, whereas the opposite relationship was found for inefficient search time. Finally, the results seemed to be modulated by question difficulty and comprehension skill.

Conclusions

CompLEC is a test to assess high-school students' reading literacy competencies similar to those measured by PISA and PIAAC. It is based on well-grounded research studies on how students deal with task-oriented reading. CompLEC provides practitioners with automatic information about the product and processes when readers reading complex documents to answer different types of questions. This information can be used to improve the student's strategies when using complex documents.

Coh-Metrix Measures of Text Difficulty: Moving Towards Improving Comprehension Assessment

Danielle McNamara, University of Memphis, United States; Arthur Graesser, University of Memphis, United States; Jonna Kulikowich, Penn State, United States

We focus on the importance of considering the nature of the text in comprehension assessment, and discuss a new methodology for doing so that is currently being considered for adoption by the Common Core State Standards in the United States. Traditional readability measures such as Flesch-Kincaid, Lexile, and Degrees of Reading Power measure text difficulty at the word and sentence levels. These measures assume that when words are less frequent in language and when sentences are more syntactically complex, the text is more difficult to process. However, discourse psychologists have identified multiple levels of language and discourse differentiating the surface code (words and syntax), explicit textbase, situation model, genre and rhetorical structure, and pragmatic communication. We developed Coh-Metrix, which automatically analyzes text on measures associated with these levels, except for pragmatic communication. This study examined 53 Coh-Metrix measures for 37,520 texts in a corpus representing

what typical students have read. A principal components analysis revealed that the components were closely aligned with the theoretical levels, accounting for 67.3% of the variance: word concreteness, syntactic simplicity, referential cohesion (textbase), situation model cohesion, and narrativity (genre). The results support the claim that there is an objective and theoretical foundation for scaling texts on difficulty, one of the major goals in literacy research. The presentation will discuss how these components can be used to characterize the complexity of particular passages that students encounter in K-12 classrooms and how these components might be used to enhance our ability to more accurately gauge reading proficiency.

There is a heightened awareness in text comprehension assessment concerning the need to consider the nature of the text, and particularly the difficulty of the text. Whereas there has been a good deal of focus on the nature of the assessment questions, there has been little on characterizing and controlling the difficulty of the text beyond the use of traditional readability formulas. The purpose of this project is to explore the use of advanced measures of linguistic characteristics of text and discourse provided by an automated tool called Coh-Metrix in order to assess text difficulty (cohmetrix.memphis.edu; see csep.psyc.memphis.edu/vita.htm for publications). The scaling of texts on difficulty has enormous practical value in education in addition to advancing scientific theories of reading and comprehension. There are times when students need to be challenged by assigning them texts on difficulty levels that push the envelope on what they can handle. There also are times when students need a self-confidence boost by receiving easy texts that they can readily comprehend. In most situations, however, the texts should not be too difficult or too easy for students, but rather at an intermediate zone of difficulty. The appropriateness of a text is a particularly important factor in the assessment of comprehension ability. A widespread assumption is that the texts or tests should be sensitive to the individual students' proficiency profiles. This study explores the potential of going beyond traditional measures of text readability for this purpose by incorporating linguistic indices inspired by theories of text and discourse comprehension.

Advances in psycholinguistics, discourse processes, and cognitive science provide a theoretical foundation for scaling texts on multiple levels. Multilevel theoretical frameworks have identified the representations, structures, strategies, and processes at multiple levels of language and discourse. These multilevel frameworks have typically included the following levels: words, syntax, the explicit textbase, the referential situation model (sometimes called the mental model), the discourse genre and rhetorical structure (the type of discourse and its composition), and the pragmatic communication level (between speaker and listener, or writer and reader). Coh-Metrix was developed to analyze and measure text on the first five levels of discourse.

In order to discover what aspects of texts account for text complexity, a principal components analysis assuming an orthogonal loading of components with Varimax rotation was conducted on Coh-Metrix indices for 37,520 texts in a corpus provided by Touchstone Applied Science Associates (TASA). Because there was a large number of texts and Coh-Metrix measures, a high Kaiser criterion of 2.0 was adopted to determine the number of principal components. This analysis converged on 53 measures of linguistic features of text.

The texts were single paragraphs with a mean length of 288.6 words ($SD = 25.4$). The TASA corpus represents the texts that a typical senior in high school would have encountered kindergarten through 12th grade in the United States. The texts are scaled on Degrees of Reading Power, which can approximately be translated into grade. Most of the text genres were classified by the TASA researchers as being in language arts, science, and social studies/history, but other categories were business, health, home economics, and industrial arts.

The principal components analysis of the corpus revealed that the following 8 dimensions (in order of percentage of the variance explained) accounted for 67% of the variability among texts.

1. Narrativity. Narrative text tells a story, with characters, events, places, and things that are familiar to the reader. Narrative is closely affiliated with everyday oral conversation. Informational texts on unfamiliar topics would lie at the opposite end of the continuum.
2. Referential cohesion. High cohesion text contains words and ideas that overlap across sentences and the entire text, forming threads that connect the explicit text together for the reader.
3. Syntactic complexity. This component reflects the degree to which the sentences in the text use complex, unfamiliar syntactic structures, which are more challenging to process and understand.
4. Word abstractness. Abstract words represent concepts that cannot be visually represented. Text that contains more abstract words is more challenging to understand.
5. Situation model cohesion. Causal, intentional, and temporal connectives help the reader to form a more coherent and deeper understanding of the text.

6. Verb cohesion. This component reflects the degree to which there are overlapping verbs in the text. When there are repeated verbs, the text likely includes a more coherent event structure that will facilitate and enhance situation model understanding.
7. Logical cohesion. This component reflects the degree to which the text contains explicit additive and comparative connectives to express relations in the text. This component is related to the reader's deeper understanding of the relations in the text.
8. Temporal cohesion. Texts that contain more cues about temporality and that have more consistent temporality (i.e., tense, aspect) are easier to process and understand. In addition, temporal cohesion contributes to the reader's situation model level understanding of the events in the text.

We consider the first five of these components to be most highly associated with text difficulty (and they were the most robust components, accounting for 54% of the variance). Using the results of the analysis, we can compute percentile scores on text complexity for individual texts based on the five components. A percentile score varies from 0 to 100%, with higher scores meaning the text is likely to be more challenging to read than other texts in the corpus. For example, a percentile score of 80% means that 20% of the texts are more difficult and 80% are easier. Four such texts including two narrative texts and two science texts are presented in Figure 1.

The presentation will further discuss how these components can be used to characterize the complexity of particular passages that students encounter in K-12 classrooms and how these components might be used to enhance our ability to more accurately gauge reading proficiency. These results support the claim that there is an objective and theoretical foundation for scaling texts on difficulty, one of the major goals in literacy research.

Assessment of Text-Picture Integration Difficulties in Reading Comprehension

Wolfgang Schnotz, University of Landau, Germany; Mark Ullrich, University of Koblenz-Landau, Germany; Holger Horz, Goethe-University Frankfurt, Institute of Psychology, Germany; Thorsten Rasch, University of Koblenz-Landau, Germany; Nele McElvany, Max Planck Institute for Human Development, Germany; Katrin Lintorf, Technical University of Dortmund, Germany; Jurgen Baumert, Max Planck Institute for Human Development, Germany

Reading comprehension frequently requires integrating text and picture information into coherent knowledge structures. To investigate how students' competencies for text-picture integration develop, a representative sample of integration tasks was selected from German schoolbooks and used for the construction of items, which were presented to 1060 students from grades 5 to 8 attending different types of German schools. Based on item-response theory, 186 items requiring integration at different hierarchical levels were selected according to a 1-parameter logistic test model. The increase of competencies across grades was significant, but nevertheless relatively low given the large differences between school types. Cognitive item analysis revealed that text-picture integration can be performed based on a limited set of cognitive operations. Further analysis showed that combining structural task characteristics and procedural item characteristics allowed relatively successful predictions of item difficulties according to item-response theory, explaining about half of the variance associated with item difficulty.

Textbooks often combine written text with schematic diagrams or various kinds of graphs that visualize and explain complex and more abstract subject matter. When learning from such materials, students are expected to integrate verbal and pictorial information for the construction of mental representations of the learning content (Ainsworth, 1999; Mayer, 2005).

The model of integrated text and picture comprehension (Schnotz, 2005) was used for the analysis of integration requirements in textbooks. This model assumes that text and picture integration takes place in a working memory, which has a limited capacity (Baddeley, 1986) and includes different channels for processing verbal and pictorial information (Paivio, 1986). Integrating verbal and pictorial information requires mappings between corresponding elements in the text and the picture. Surface structure mappings include interrelations between words and graphical elements based on cohesive devices such as color coding, common numbers, symbols or labels. Deep structure mappings include interrelations between conceptual structures and mental models of the learning content. Within deep structure mapping, a distinction can be made between different levels of extracting information from text and pictures: Level 1 refers to extracting detail-level information, level 2 refers to extracting simple relations, and level 3 refers to extracting complex relations.

Assessment of Students' Competencies

We randomly selected 48 text-picture integration units from a representative sample of biology and geography textbooks in Germany in grades 5 to 8. Text length per task unit varied from 38 to 160 words. The number of pictures

per task unit varied from 1 to 3. For each unit we created 6 multiple-choice test items: Two items on level 1, two items on level 2, and two items on level 3. This resulted in a total of 288 test items. The items were presented via a multiple matrix design to 1060 students from 48 classes in Germany from grade 5 to grade 8. The three tracks of the German schooling system (Hauptschule: low, Realschule: medium, Gymnasium: high) were represented by the same number of classes.

The correlation between the theoretical hierarchy level of items and their empirical difficulty revealed a significant Kendall's Tau of .55. This value can be considered as satisfactory because the need for the stochastic independency of each item had to be taken from a different local hierarchy, and the different local hierarchies cannot be expected to have the same difficulty levels. Accordingly, the distinction between the three theoretical hierarchy levels was sufficiently supported by the empirical data. Students' item responses were then analyzed with regard to the dimensionality of text-picture integration competency. Although a 2-dimensional model had the lowest Bayes Information Criterion (BIC) value and thus the best model fit, the two latent variables ('extracting details' and 'extracting relations') had an extremely high correlation of $r=.95$. Thus, we decided for pragmatic reasons to proceed with a 1-dimensional model.

Assessment of Item Difficulties

In order to find out what makes some items more difficult than others, we performed a rational task analysis of all selected items. On the one hand, this analysis included a structural analysis of the text, a structural analysis of the pictures, and a description of the text-picture cohesion per unit. On the other hand, we performed a procedural analysis of the required cognitive operations per item.

The structural analysis of the text included text length and number of content concepts. The structural analysis of the pictures included number and type of pictures, number of graphical entities and number of variables within pictures. Furthermore, we measured text-picture cohesion in terms of number of overlaps between color codes, labels, symbols and numerical values. For the procedural analysis of the required cognitive operations, we identified based on experts' judgments a set of operators for integrating text and picture information:

- IDPICT = identification of relevant picture
- EMap = element-mapping (name, symbol, color, numerical value)
- IDENT-AT (candidates, attributes, results) = identification of sets of entities based on attributes
- READ = reading of attributes
- IDENT-IT = identification of sets of entities based on item response alternatives
- IT-MATCH = complexity of pattern-matching with item response alternatives

For the procedural analysis of the required cognitive operations per item, we determined the frequency of applications for each operator within the rational task analysis, which resulted in an operator-application profile for each item.

Regarding the structural features of text-pictures units, item difficulty correlated highly significantly only with text length ($r=.37$; $p=.003$), whereas the other features did not uniquely add to the explained variance of item difficulty. Item difficulty also correlated significantly with the cognitive hierarchy level of the items ($r=.50$; $p<.001$). Combining text length and cognitive hierarchy level as predictors for item difficulty resulted in a multiple correlation of .63, which was also highly significant ($p<.001$). To get a more detailed view of the procedural requirements associated with the different cognitive hierarchy levels, we computed multiple regressions between the application frequency of each operator according to the rational task analysis as predictors and the cognitive hierarchy level as dependent variable. The combination of the number of element mappings (EMap), the number of identifications of sets of entities based on attributes (IDENT-AT), the reading of attributes (READ), and the complexity of pattern-matching with item response alternatives (IT-MATCH) resulted in a multiple correlation of .70 ($p<.001$) with the hierarchy level of items.

Theoretical and Practical Relevance

Challenges associated with text-picture integration seem to be closely related to structural and procedural item characteristics. This result is promising, because it suggests that it is possible to build 'bridges' between measurement theories and cognitive research on comprehension processes. Such bridges are relevant for assessment, because they could allow in the long run an automated assessment of item difficulties. They are also relevant for the fostering of students' competencies, because they provide us with a better understanding of what makes some items more difficult than others, what kinds of cognitive procedures are required, and how adequate strategies of integrating text and picture information can be taught.

Children's agency in research — across settings and as co-investigators

Chairperson: Kristiina Kumpulainen, National Board of Education, Finland

Organiser: Kristiina Kumpulainen, National Board of Education, Finland

Ola Erstad, University of Oslo, Norway

Discussant: Roger Saljo, Goteborg University, Sweden

The dominant discourse of most educational and psychological research on children, learning and development conceives of children as subjects of study, done by adults studying children, as a process of measuring and normalising childhood (e.g., Marr & Malone, 2007). However, developments in recent years focus more on positioning children as active co-producers of meaning (Fleer & Hedegaard, 2010; Fleer, Hedegaard, Bang & Hviid 2008) and the formation of identities across different settings and contexts (Moje & Luke, 2009; Wortham, 2006). As a consequence, several researchers are involving children as active agents in the research itself and as co-investigators. Building on a situative and socio-cultural framework on human agency (Greeno, 2006; Holland, Lachicotte, Skinner & Cain, 1998; Martin, Sugarman & Thompson, 2003), we maintain that validating and making use of this aspect of participation in research is a crucial factor in building more ecologically valid educational and psychological research.

The aim of this symposium is to present different ways of researching with children in family practices and across different contexts of learning. Moreover, it presents a specific methodological investigation of the use of video cameras when researching with children, along with reflections on ethical considerations, challenges and possibilities in involving children more actively in research. Specifically, the aims of the different presentations are to contribute different experiences and approaches from research.

Learner video, learner voice: reflections on self-directed research by younger learners

John Potter, Institute of Education, University of London, United Kingdom

This presentation reflects on two completed studies which positioned children of primary school age (between 7 and 11) as researchers of their own experiences using self-authored video as a central tool for reflection. In the first project (Potter, 2010) fieldwork was carried out in two schools among children taking part in video projects on themes of self-representation and identity. The findings in this study suggested that this new media literacy practice can be metaphorically conceived as a form of "curatorship" in the organisation of digital media assets and that this connects to an important set of dispositions and skills in lived culture. In the second case study (Selwyn, Potter & Cranmer, 2010), video recording under the control of younger learners was used as part of a set of mixed methods to explore the differences between children's experience of new media technology at school and at home. The findings in this study suggested that the desire to engage with the "learner voice" approach in their video research was representative of a deeper need to see their experience of lived culture reflected and acknowledged within pedagogy. Self-authored video in the project provided some of the participants with the means to present their learning lives.

The third and last presentation puts the emphasis on how children (age between 6 and 11) as learners relate to other people and objects, drawing on deeper trajectories or narratives of the self as it exists within and outside the immediate learning contexts. Using a mix of methods and drawing on cultural studies and identity theory, Potter examines how personal histories and future orientations are used to create "narratives of the self". And it is these selves (or their narrativisations) which are central to productive learning.

This presentation reflects on two completed studies which positioned children of primary school age (between 7 and 11) as researchers of their own experiences using self-authored video as a central tool for reflection.

In the two UK projects (Potter, 2010), fieldwork was carried out among children in two primary schools taking part in video projects on themes of self-representation and identity. The findings from the first case study suggest that this literacy practice can be metaphorically conceived as a form of curatorship in the organisation of digital media assets and that this connects to an important set of dispositions and skills in lived culture (Williams, 1979). In the second case study (Selwyn, Potter & Cranmer, 2010), video recording under the control of younger learners was used as part of a set of mixed methods to explore the differences between children's experience of new media technology at school and at home. The findings in this study suggested that the desire to engage with the learner voice approach in their video research was representative of a deeper need to see their experience of lived culture reflected and acknowledged within pedagogy. Self-authored video in the project provided some of the participants with the means to present their learning lives.

The presentation reflects on how a future research agenda might be constructed in the light of the findings. With these lenses on interactional data, as well as video clips and photographs made by the children themselves, the intention in this presentation is to put an emphasis on learning as the capacity to adapt to changing roles within

different contexts. With data from these three case studies as a point of departure, we hope to contribute to broader discussions of how children initiate and perform their agency and identity as learners across different settings. Altogether, these different lenses and perspectives explore how children perform their agency and identity across different settings.

AGENTS – Children as video researchers

Jaakko Hilppo, University of Helsinki, Finland; Kristiina Kumpulainen, National Board of Education, Finland; Lasse Lipponen, University of Helsinki, Finland

This project explores the potential of video research in promoting children's agency in the formal and informal contexts of childhood. The idea of "efficacious agency" is that children are not merely reactive, passive and controlled by either environmental or biological forces but they can make themselves more efficacious, proactive and self-regulating. Within the "children as researchers" approach video research is used as means of eliciting the voice of the child, but not pursued or developed as a participatory method in its own right. This implies that Kumpulainen et al pays attention to innovative and new methods for collecting data from the children's perspective, by digital video compositions, written annotations and other data produced by the children.

This presentation explores the potential of video research in promoting children's agency in the formal and informal contexts of childhood. The idea of "efficacious agency" is that children are not merely reactive, passive and controlled by either environmental or biological forces but they can make themselves more efficacious, proactive and self-regulating. Further, we argue that through co-produced video stimulations it is possible for the children to learn to control their actions from outside, express their own perspectives on efficacious agency and hence also participate in the research process.

Building on a situative and socio-cultural framework on human agency (Greeno, 2006; Holland, Lachicotte, Skinner, & Cain, 1998; Martin, Sugarman, Thompson, 2003; Vygotsky, 1978), we maintain that validating and making use of this aspect of participation in research is a crucial factor in building more ecologically valid educational and psychological research.

Within the "children as researchers" approach (e.g., Kellet, 2005; Christensen & James, 2008), video research is used as means of eliciting the voice of the child, but not pursued or developed as a participatory method in its own right. Our objective is to develop and refine video research methods that recognise children as active research partners. In this, we draw on the work of Goldman-Segall (1998), who has shown that children can take part in video research as competent actors and stakeholders. In this approach, children have not only an epistemological, but also a strong ontological position.

Our method consists of a cycle of six steps (1–6). The first three steps (1–3) are researcher driven and the focus is on the identification and joint group reflection of efficacious agency in context. In steps 4–6, with the use of mobile phones and other hand-held video devices, children create video episodes of their authentic life in diverse contexts (e.g., episodes from school, playground or museum). As in steps 1–3, children observe and discuss video data in peer groups and develop and design ideas to be further used with parents in home settings. Steps 4–6 will focus on empowering children's own views and voices of efficacious agency in their worlds.

As data, we will present and discuss the preliminary findings from two ongoing empirical cases from elementary school and daycare contexts in the Helsinki Metropolitan area. Participants of each empirical case formed focus groups of three to five children, comprising four to six groups per case and, in all, fifty children. Our focus in the presentation will be on questions of engaging children as co-researchers in designing, producing and interpreting video episodes from their authentic life in diverse contexts. We will also look into whether implementing our method has had any effect on the children's efficacious agency.

Learning identities and pathways: Using video to study children across settings

John Potter, Institute of Education, University of London, United Kingdom; Oystein Gilje, Department of Educational Research, Norway; Ola Erstad, University of Oslo, Norway

This presentation elaborates on issues related to children as co-researchers. The data was gathered as part of the ongoing Learning Lives project which focuses on three transitions (cohorts) within the educational system in one community in the eastern part of Oslo, Norway. The transitions are in the age-groups 5-6 years (1), 15-16 years (2) and 18-19 years (3), and all of the informants will be followed for at least one year. The data presented here stem from cohort 1, which put an emphasis on preschool children's learning identity in the transition from kindergarten to first grade in primary school. The overall aim in the project is two-folded. First, we aim to make explicit the mobilization of resources or affordances within specific contexts at the same time as focusing on an approach which characteristics learning as the capacity to adapt to changing roles within different contexts (Holland et al., 1998; Hull and Shultz, 2002). And secondly, our emphasis is on how the individual learner relates to other persons and objects, in order to grasp processes occurring between people, which we find significant for young people's identity and learning. With this perspective, the presentation here aims at describing learning among preschool children within and across

different learning sites exploring the positioning and re-positioning of the learner identity across these different contexts.

Gilje, Erstad and Potter elaborate in their presentation the overall theme in the symposium by drawing upon data from three case studies. This presentation reflects on two completed studies and one ongoing study. These three studies put an emphasis on the children's use of video cameras as a tool for making narratives about themselves across different settings like the kindergarten, the primary school and the home.

We study children in kindergarten and primary school (ages between 6 and 11) and ways of involving them as researchers of their own experiences using self-authored video as a central tool for reflection. The presentation puts the emphasis on how children as learners relate to other people and objects, drawing on deeper trajectories or narratives of the self as it exists within and outside the immediate learning contexts. Using three different case studies, we examine how personal histories and future orientations are used to create "narratives of the self", and it is these selves (or their narrativisations) which, we suggest, are central to productive learning.

Using three different case studies, we examine how personal histories and future orientations are used to create "narratives of the self", and it is these selves (or their narrativisations) which, we suggest, are central to productive learning.

In the two UK projects (Potter, 2010), fieldwork was carried out among children in two primary schools taking part in video projects on themes of self-representation and identity. The findings from the first case study suggest that this literacy practice can be metaphorically conceived as a form of "curatorship" in the organisation of digital media assets and that this connects to an important set of dispositions and skills in lived culture (Williams, 1979). In the second case study (Selwyn, Potter & Cranmer, 2010), video recording under the control of younger learners was used as part of a set of mixed methods to explore the differences between children's experience of new media technology at school and at home. The findings in this study suggested that the desire to engage with the "learner voice" approach in their video research was representative of a deeper need to see their experience of lived culture reflected and acknowledged within pedagogy. Self-authored video in the project provided some of the participants with the means to present their learning lives.

The Learning Lives project in Norway elaborates further on this perspective, describing learning among preschool children within and across different learning sites exploring the positioning and re-positioning of the learner identity across these different "locations" (Erstad, Gilje, Sefton-Green & Vasbø, 2009). The data reported on in this case study is part of an ongoing project studying three different cohorts in one community in the eastern part of Oslo.

The data presented here stem from cohort 1, which consist of video data and the observations of a small number of children followed during the last six months in kindergarten. The data consist of observations during different settings at kindergarten, in their community and at home. In addition, the children are supposed to make short video clips about places in their local environment.

With these lenses on interactional data, as well as video clips and photographs made by the children themselves, the intention in this presentation is to put an emphasis on learning as the capacity to adapt to changing roles within different contexts. With data from these three case studies as a point of departure, we hope to contribute to broader discussions of how children initiate and perform their agency and identity as learners across different settings.

SYMPOSIUM

Understanding the social, situated and dynamic transactions among teachers and students

Chairperson: Nancy Perry, University of British Columbia, Canada

Organiser: Julianne Turner, U. of Notre Dame, United States
Discussant: Susan Nolen, University of Washington, United States

Although psychological and educational research has acknowledged the social, situated, and dynamic aspects of learning and engagement, researchers have mostly focused on individual differences in cognitions and beliefs. Partly, this situation results from a dearth of theory and methods to examine such complex processes. In this symposium, presenters investigate the socially situated and dynamic nature of teacher-student and student-student transactions using theoretical and methodological tools that capture interaction. Theoretical constructs include 1) situated learning (Greeno & Gresalfi, 2008; 2) co- and shared regulation (Volet, Vauras, & Salonen, 2009); and 3) dynamic systems theory (Thelen & Smith, 1994). Methods include using the activity as unit of analysis and the State Space Grid (SSG) (Hollenstein, 2007) technique. SSG uncovers (mis)matches in participants' behavior patterns and their (in)stability over time. Presentations will examine interpersonal coordination in three educational settings: small group of students, small group with teacher, and whole class instruction. Scientific relevance includes the use of theory and methods to analyze bidirectional and reciprocal regulatory processes, flexible shifts of agency, and sharing and transfer of responsibility between the participants in shared learning contexts. Analyses uncover how matches and mismatches develop and settle into patterns. Educational relevance involves insight into more or less optimal interpersonal transactions. Discussions will address how suboptimal transactions might be disrupted or redirected through examination of patterns and professional development.

Elementary School Students' Regulation of Science Learning While Solving a Fictional Murder Mystery

Nancy Perry, University of British Columbia, Canada; Carolyn Thauberger, University of British Columbia, Canada; Lynda Hutchinson, University of British Columbia, Canada; Cansel Kadioglu, Gaziosmanpasa University, Turkey; Cindy Lau, University of British Columbia, Canada; Ahmed Rahim, University of British Columbia, Canada

Research on the regulation of learning has mainly focused on individuals and independent activity, but learning in elementary school classrooms is rarely a solo event. In fact, evidence suggests children develop self-regulation through a process of co-regulation and effective co-regulation enhances both self and shared regulation of learning. Hence research about inter-individual forms of regulation is needed. We examined students' co and shared regulation as they worked collaboratively to solve a fictional crime. Primarily, we focused on what instrumental supports students provided one another for regulating learning, how co and shared regulation developed across time, and how regulation supported understandings about forensic science. Initially, students' interactions were characterized as "knowledge sharing/reporting." Co-regulation was limited to one student keeping the group on track, self-regulation occurred outside the group, and shared regulation was not observed at all. Over time, however, students began to "regulate in unison," and co-regulation became more instrumental to individual and group goals. Our findings indicate collaborative tasks that prompt dynamic, coordinated, and interdependent work afford opportunities for regulation of learning to occur. However, our findings also indicate students may struggle to interact productively in collaborative contexts, highlighting the need for more research about how features of tasks, instructional practices, and interpersonal processes afford and constrain all forms of regulation

Aims. We examined student-student interactions during collaborative work for evidence of self, co and shared regulation. Primarily, we focused on (a) what instrumental supports students provided one another for regulating learning, and (b) how students' co and shared regulation developed across time and supported understandings about forensic science.

Theoretical framework. Research involving elementary school children supports the view that self-regulated learning (SRL) develops in contexts where children gradually gain control over learning through co-regulation (Perry, 2004; Perry, Hutchinson & Thauberger, 2007). Models of co-regulation build on Vygotskian and neo-Vygotskian perspectives emphasizing the importance of instrumental interaction and activity in learning and higher psychological processes, such as SRL (McCaslin & Good, 1996; McCaslin, 2009). Co-regulation involves support giving and receiving and presumes at least one party in a transaction has knowledge or skill the other(s) need to learn. The "co-regulator" role can shift across time and tasks, depending on who has expertise in a situation. Shared regulation is "regulation in unison" and describes how participants co-construct understandings about tasks through shared metacognition, motivation and strategic action (Hadwin et al., 2010). Co and shared regulation can illuminate how children collaborate to complete tasks or solve problems. We argue successful collaboration depends not only on (a) self-regulatory skills and strategies that individuals contribute to the group; but also on (b) support members provide that boosts the self-regulatory competence of their peers (co-regulation); and (c) shared or collective regulation of learning that involves metacommunicative awareness and successful coordination of strategies (Winne et al., in press).

Methodology. The data presented here are from a larger study of self, co, and shared regulation among students working collaboratively to solve a fictional crime presented through The Crime Kit, an electronic learning kit constructed in gStudy, now nStudy, software (Winne, Hadwin & Beaudoin, 2010). Eight lessons each presented a blog by Detective Silver describing case developments and scaffolding student navigation to experiments, evidence, forensic information such as fingerprint analyses, and interviews with experts. Groups of three students followed the blog and recorded case observations in "Suspect Notes," summarized learning from experiments in "Summary Notes," evaluated learning and SRL in "Self-Evaluation Notes," and represented predictions about the case in a "Concept Map." gStudy recorded students' on-line actions. Digital recordings captured group discussions. The larger study involved 24 grade 5 students (8 groups; Mean Age = 10.85 years, ethnic minorities = 58%, identified disabilities = 8%) attending a low-SES school in a large sub-urban district near Vancouver, Canada.

Space prevents an in-depth presentation of our data in this proposal. Here we focus on results from one group's discussions of two Summary Notes: Lesson 3, Interviewing Witnesses, and Lesson 5, Leaf Analysis and show changes in the group's regulation over time. Transcripts were divided into four segments, corresponding to the group's interactions about four summary questions that loosely followed Bloom's Taxonomy (Bloom, 1956), with two questions at the levels of knowledge or comprehension and two at higher levels. Table 1 shows whether and where instances of self, co, and shared regulation were observed in the transcripts. Forms of regulation were further refined, so that processes were identified as metacognitive, motivational, and strategic, and related to task understanding, planning, goal setting, monitoring, problem-solving, and evaluating. Data will be discussed at this level of detail at EARLI.

Findings.

Initially, students in Group 2 answered Summary Note questions before meeting to discuss them. Until Lesson 3, their interactions involved mainly knowledge sharing with individuals reporting their answers to the group (e.g., S2: I wrote, "Ask questions about the crime." S3: I wrote ...). Co-regulation was limited to one student keeping the group on track (e.g., "Let's start with question 1 ... Read number 2 ... S2?), self-regulation occurred outside the group and shared regulation was not observed. Then, while discussing question 4 in Lesson 3 a shift occurred. Students stopped reporting, "I wrote ..." and began discussing options and correcting and building on one another's responses to . Eg.:

SX: (asking about options proposed) So what's the right [answer] to be?

S2: ... they need proof to get evidence the person actually committed the crime.

S1: (elaborating) 'Cause you can't just blame one person ... You can't just say, 'She did it.'

By Lesson 5, Group 2's process of shared regulation was seamless. One student led the discussion, another read the questions, and the third recorded answers in the Summary Note template. "Regulation in unison" was evident and co-regulation became more instrumental to individual and group goals. E.g.: Students supported one another to read and understand challenging vocabulary, and to find key information in the Crime Kit ("Just go to Notes? ... And go to browser ... Go all the way up ... Now, go to Information ... let's see. A broad leaf. Where's a broad leaf?). For both lessons, Group 2's actual Summary Notes indicate good understanding of the science needed to solve the crime (e.g., in Lessons 3 and 5, tactics for interviewing witnesses, evidence from analyzing leaves).

Significance. Research on the regulation of learning has mainly focused on individuals and independent activity, but learning in elementary school classrooms is rarely a solo event. Hence understandings about inter-individual forms of regulation are needed. Collaborative tasks present opportunities to study students' co and shared regulation. They can prompt dynamic, coordinated, and interdependent work, and illuminate how collaborative teams leverage individuals' unique and distributed expertise to achieve something that could not be achieved by individuals alone (Winne et al., in press). However, consistent with previous research, our findings indicate students may struggle to interact productively in collaborative contexts (we will provide evidence for this from other groups in our EARLI presentation). Research is needed about how features of tasks, instructional practices, and interpersonal processes afford and constrain all forms of regulation.

How do Teachers Scaffold Low-Achievers in Reading Comprehension?

Anu Kajamies, University of Turku, Finland; Marja Vauras, University of Turku, Finland; Riita Kinnunen, University of Turku, Finland

This paper discusses a study of special needs teachers and their low-achieving students during the implementation of a reading comprehension intervention. The intervention was designed to support matching, growth-promoting instructional discussions between the students and their teacher. We aim to show whether teachers created opportunities for the low-achieving students to reach higher levels of independent functioning, and to illustrate how dynamic instructional match/mismatch can be analyzed with the State Space Grid technique (Hollenstein, 2007;

Vauras et al., 2009b). Low-achieving students were selected from 437 fourth grade, 10-year-old mainstream students on the basis of the pre-test scores in reading comprehension. The quantitative results from the pretest, posttest, and follow-up test indicate significant effects for the intervention students' reading comprehension during the intervention. Detailed analysis of the results shows that the lowest-achieving students progressed the most. We focus on the strategy practice of two teachers, in particular on how they created and took up growth-promoting opportunities. Preliminary analysis shows that teachers had difficulties in finding a dynamic match. Reading comprehension was mainly practiced at low levels and few opportunities were created at higher levels. It was easier for the teachers to create growth-promoting opportunities for the lowest achieving students than for the more skilled low-achievers. Detailed findings and implications for the challenges involved in instructional interaction and teacher training will be discussed in the presentation

Aims and Background

Scaffolding the reading comprehension of motivationally vulnerable low-achievers poses a challenge to teachers (Guthrie et al., 2004; Vauras et al., 1999). Optimal scaffolding presupposes sensitive and flexible teachers, who create a dynamic match between their moment-to-moment support and the students' constantly varying functioning, and growth-promoting opportunities within the students' zones of proximal development (ZPD) (Salonen et al., 2005; Vygotsky, 1978). This paper discusses a study of special needs teachers and their at-risk, low-achieving students during the implementation of a reading comprehension intervention to support growth-promoting instructional discussions. Special needs teachers were assisted in implementing the interventions, aimed to provide intensive, systematic, and explicit teacher scaffolding to promote the growth of cognitive, metacognitive, and motivational activities involved in skilful reading comprehension (Vauras et al., 2009a; Pressley, 2005). This paper aims to show whether teachers succeed in creating opportunities (Gresalfi, 2004) for the low-achieving students to reach higher levels of independent functioning, and to illustrate how dynamic instructional match/mismatch can be systematically detected and analyzed with the aid of State Space Grid (SSG) technique (Hollenstein, 2007; Vauras et al., 2009b). Further, we discuss the implications of instructional (mis)matches in the development of reading comprehension skills in the case of low-achieving students.

Method and Analysis

Experienced special needs teachers ($n = 11$) participated in a half-year-long intervention to foster low-achieving students' reading comprehension skills, self-regulatory and coping skills, and motivational engagement in reading. Training and counseling were provided to advance teacher scaffolding. Low-achieving students ($n = 57$) were selected from the total sample of 437 fourth grade, 10-year-old mainstream students on the basis of the pre-test scores in reading comprehension. This paper concerns the interventions that the teachers carried out in 18 hours in small groups (3 trainees /group) in core comprehension skills (such as, selecting, integrating, transforming, and summarizing information). The intervention was strongly built around a mystery book (Threat in the Desert Island, written for the purposes of the program, and including tasks and problems of increasing difficulty). In all respects, ethical code for scientific research is followed, according to the guidelines of the ethical committee of the University of Turku.

All intervention sessions were videotaped, and this paper illustrates the scaffolding patterns of two teachers, differing in their level of creating opportunities for their students. We applied the dynamic-analytical State Space Grid (SSG) technique (e.g., Granic & Patterson, 2006; Hollenstein, 2007) to analyze (mis)matches and opportunities offered in scaffolding in real-time interaction patterns. SSGs provide a visual aid (temporal scatter plot) to depict the relationship between the activity of a teacher and a student (/group) synchronized in time. The observed data (selected target phases) were transmitted to The Observer XT (Noldus Information Technology), and then, behavioral events were coded and exported from Observer XT to GridWare. The level of creating (teacher) and taking-up (students) growth-promoting opportunities (Gresalfi, 2004) in scaffolding the strategy practice was classified into high and low levels (in creation of categories, the work of Kintsch and Kintsch, 2005; Taylor et al., 2002; Vauras et al., 2009b are used), plotted on a 5 (teacher) x 5 (students) grids (coding ranging from 'none' to 'strong'). At high levels, the teacher creates growth-promoting opportunities within the ZPD, and strategies are practiced by building links between the strategy principles and situational factors (different tasks, prior knowledge and experience). Metacognitive regulation is integrated at the highest level of scaffolding, and if the student take-up is high, they are involved in discussions at the level of how, when and why strategies can be used in various real-life situations. At low levels, teacher scaffolding focuses on mechanical practicing of the strategies, which are treated as isolated elements in the reading activity. No real opportunities for learning and motivation are created when the focus of interaction is on things irrelevant for understanding.

Findings and Significance of the Outcomes The quantitative results from the pretest, posttest, and follow-up test indicate significant effects for the intervention students' reading comprehension during the intervention ($1, 435$) = 8.56 , p Preliminary interaction analysis shows that teachers had difficulties in acting sensitively and flexibly and finding

a dynamic match in spite of the guidance provided to them in implementing scaffolding principles and new materials. Reading comprehension was mainly practiced in low levels and few opportunities were created at the higher levels. Instead of instructional discussions, the interactions were tightly led by the teacher, full of simple question-answer chains, accompanied with disconnected situational or content demands. The teachers typically stayed in secure/comfortable interaction, where students' skills may become consolidated, but further progress is slow (cf., Vauras et al, 2009b). It was easier for the teachers to create growth-promoting opportunities for the lowest achieving students than for the more skilled low-achievers. Further, the teachers had difficulties taking up opportunities provided by the (often the more skilled) students: they neither carefully listened to students' suggestions, nor did they try to understand their thinking or establish links to the discussed topics. Much of the time was spent on incidental matters. Students were over-controlled, under-demanded and unsupported despite these experienced teachers' genuine interest in scaffolding students and expanding their own expertise. The significance of the findings lies in the development of advanced methods in analyzing instructional interactions and in their theoretical and educational impact for implementing special needs interventions. Detailed findings with implications for challenges inherent in instructional interaction and teacher training will be discussed in the presentation.

The Change in Teacher-Student Interactional Patterns in Eight Classrooms over One School Year

Julianne Turner, U. of Notre Dame, United States; Sara Fulmer, University of Notre Dame, United States

We investigated the dynamic nature of teacher-student interaction over one year. In particular, we analyzed patterns of opportunities offered by teachers to make connections among content ideas, and how their students took them up. Instruction was observed and coded 12 times each in 8 middle school classrooms. Teacher opportunities and student uptake (coded as none, weak, moderate, strong) were plotted on a 4x4 grid representing all possible behavioral combinations to show trajectories of interaction during real time. Interactional patterns differed in classrooms of weak vs. strong teachers. All classrooms showed a wide range of teacher-student interaction in the first quarter. By second semester, patterns had stabilized. Weak teachers offered mostly weak opportunities (e.g., practicing procedures) and student uptake was weak. Strong teachers offered mostly moderate to strong opportunities to connect ideas, and students took up the offers. Findings imply that, over time, teachers' and students' behaviors may invite certain kinds of reciprocal behaviors from each other and these sequences may lead to certain forms of stable patterns. Studying classrooms as dynamic systems can provide information about how patterns develop, and how interventions might interrupt stable patterns of low quality interactions. Teachers might study patterns and redesign opportunities such as tasks or questioning practices or study interactions in high quality instruction.

Aims

The goal was to investigate patterns of stability and change in teacher-student interaction about content over the school year in eight middle school classrooms. In particular, we examine the quality of opportunities offered by teachers to make connections among content ideas, how students took up these opportunities, and patterns of interactions.

Theoretical Perspective

We take the theoretical perspective that learning and engagement develop as teachers and students participate together (Turner & Patrick, 2008; Vauras, Salonen, & Kinnunen, 2008). Therefore, classrooms are dynamic systems (Thelen & Smith 1994). Over time, teachers' and students' behaviors may invite certain kinds of reciprocal behaviors from each other and these sequences may lead to certain forms of stable patterns (Gurtman, 2001). Teachers provide opportunities for student participation of different levels of quality. For example, if certain kinds of scaffolding require that students connect ideas (e.g., compare-contrast), then students might be more likely to offer explanations or ask questions that attempt to make connections. Conversely, if teachers focus on isolated facts or procedures alone, students may practice skills, but not relate them to disciplinary content. In another situation, teacher opportunities and student uptake may be unbalanced; students may respond to a weak opportunity with a high quality response, or may not respond to a strong opportunity. In those situations, patterns could be perturbed, opening up the possibility for change in interaction patterns (Thelen & Smith, 1994). These assumptions lead us to take social interaction rather than individual teacher or student behaviors as the unit of analysis (Rogoff, 1997).

Methodology

Teachers participated in a year-long intervention to foster student engagement in middle school. We introduced four theoretical principles that support engagement: supporting students' competence, autonomy, belongingness, and making learning meaningful. Teachers learned instructional strategies (e.g. asking open-ended questions) to enact the four principles and were encouraged to implement them in their daily instruction.

Observations (n=12) were conducted in each of the 8 classrooms during the school year. The observation instrument was designed to capture teacher-student interactions. Instructional interactions were coded by activity segments, which were defined by the intended product in the activity. Activity segments ranged from 1 to 4 during observed classes.

The eight teachers were first classified on one variable, Responsive Assistance in Thinking (RA-T), which indicated teachers' propensity to scaffold instruction, (Rivera & Tharp, 2004). RA-T was coded "present" when the teacher 1) determined students' current level of performance/understanding, and 2) adjusted instruction to enable an advance in learning. The presence or absence (i.e., 1 or 0) of teachers' use of RA-T was separately recorded for each activity segment during the 12 observations, and then were averaged across the 12 observations. Teachers differed significantly on the mean level of RA-T [$t(6) = -3.61, p$

Then interaction patterns for the teacher groups were contrasted on one observation category, the source of opportunities to work on content (adapted from Gresalfi, 2004). This variable is coded for both teacher and student. These ratings were plotted on a 4 x 4 State Space Grid (none, weak, moderate, strong; Hollenstein, 2007) such that teacher offers and student uptake could be plotted together in the same cell (e.g., teacher opportunity might have been moderate, but student uptake was weak). Activity segments for one class were connected by lines with arrows showing the direction of interaction over that class period.

Findings

Weak teachers

In the first quarter of the school year, teacher-student interaction was in the lower (southwest) quadrant, indicating a pattern of none/weak opportunities and none/weak uptake by students. In the second through fourth quarters, classroom interaction formed a stable pattern, with both teacher offers and student uptake mostly rated "weak." In the fourth quarter, teacher offers varied from none to moderate, but student uptake remained mostly weak, as did the overall interaction pattern.

Strong teachers

In the first quarter, teacher-student interaction was somewhat unstable, ranging from "weak" to "strong" for teacher offers and from "none" to "strong" for student uptake, with weak being the most common student response. During four activity segments in quarter 1, both teachers and students were rated "strong" (3 different teachers). By the second semester, teacher-student interaction became more stable around the upper (northeast) quadrant, representing moderate to strong levels of opportunity and uptake. Examples of tasks and teacher-student dialogue will be presented to illustrate teacher offers and student uptake.

Theoretical and educational significance

This research demonstrates the social and dynamic nature of classroom interaction both within class periods and over time. In addition, it illustrates how patterns became stable over time. Teachers and students established interaction patterns, which tended to invite reciprocal behaviors from each other. Students tended to take up the kinds of opportunities offered; that is, weak opportunities were associated with weak uptake and strong opportunities often supported students in making content connections. Participation patterns varied the most at the beginning of the year when teachers and students were becoming acquainted.

Analyses point to the potential of understanding how classroom dynamics develop and how one might intervene to improve instruction. Teachers might study their patterns, relate them to specific instructional activities, and strive to change interaction patterns by redesigning tasks and ways of questioning and explaining ideas. Based on this study, students would be more likely to take up stronger opportunities if offered, thus supporting both engagement and learning

SYMPOSIUM

Cross-cultural aspects of learning technology acceptance

Chairperson: Armin Weinberger, Saarland University, Germany

Organiser: Nicolae Nistor, Ludwig-Maximilians-Universität München, Germany

Armin Weinberger, Saarland University, Germany

Discussant: Heinz Mandl, Ludwig-Maximilians-University Munich, Germany

Education in a global networked society implies the wide use of educational technology, which in turn requires learners' technology acceptance. The previous educational research has given little attention to the acceptance and use of learning technology in international or intercultural context. In this symposium, we present three empirical studies of technology acceptance by adult learners. All three are based on an acknowledged acceptance theory (i.e. the Unified Theory of Acceptance and Use of Technology, UTAUT, Venkatesh et al., 2003), and aim at applying it in contexts where different cultures are involved. The first deals with the introduction of a virtual learning environment at a Swedish, a Norwegian, and a Lithuanian university. The second examines the use of a learning management system at a Spanish university, distinguishing technological from non-technological culture as context of the technology use. The third is a large survey of general attitudes and use of computers for learning in Germany and Romania, considering both ethnical and professional culture. In each of them, the findings widely correspond with the previous acceptance theories, i.e. learners' expectations and the social influence determine their attitudes, which further determine the technology usage. Additionally, the cultural diversity highlights influences such as, e.g., individualism, uncertainty avoidance or computer anxiety, which can change both the values of the acceptance variables, and the relationships between them. Based on these evidences, the three studies provide a deeper insight into the interconnections between culture – in the national/ethnical, as well as in the professional sense – and learning technology acceptance.

A comparative case study of technology acceptance at three Northern European universities

Christina Keller, Jonkoping International Business School, Sweden

Virtual learning environments have in recent years become an important tool in higher education, in distance learning as well as on campus. This study analyzed factors influencing acceptance of virtual learning environments among academic staff and students in blended learning environments. The study was performed as a comparative, explanatory case study at three universities providing master education of public health in Sweden, Norway and Lithuania. The findings of the case study showed that national culture was powerful in influencing acceptance of virtual learning environments, positively as well as negatively. High degrees of performance expectancy and social influence affected acceptance of virtual learning environments positively. The high degree of social influence was hypothesized to be transferred by the values of the national culture. The high degree of acceptance of virtual learning environments in Lithuania was hypothesized to be due to high degrees of the cultural values of power distance and uncertainty-avoidance.

Aims

The aim of the study was to analyse factors influencing acceptance of virtual learning environments among students and staff in blended learning environments and different national settings.

Methodology

The research setting of the study was public health master education at three case universities: Nordic School of Public Health, Sweden, University of Tromsø, Norway, and Kaunas University of Medicine, Lithuania. The data collection was performed from 2004 until 2007, by interviews with key persons of the implementation process, for example, deans, project managers, and teachers. The interviews focused on the general level of acceptance of the virtual learning environment (VLE) at the university, as well as the core constructs of Unified Theory of Acceptance and Use of Technology (UTAUT) (Venkatesh et al., 2003); performance expectancy, effort expectancy, social influence and facilitating conditions.

105 students in the public health master programs of the three universities responded to a survey questionnaire, capturing the core constructs of UTAUT. Both the interview questions and questionnaire items were phrased by adapting the original items used in estimating UTAUT (Venkatesh et al., 2003) to a research setting of online learning. The statements were graded on a scale from 1 (I don't agree at all) to 5 (I agree completely). The students were also able to state their opinions about advantages and disadvantages in two open survey questions.

Findings

The general acceptance of the virtual learning environment was found to be low at the Swedish university, medium at the Norwegian university and high at the Lithuanian university. In table 1, the findings of the interviews and survey questionnaires on the core constructs of UTAUT are summarized.

The particularly negative perceptions from the Swedish university seemed to be due to a strong tradition of teaching on campus, which regarded the virtual learning environment as something negative. Lithuanian students regarded the web platform as a means of improved communication with teachers. Swedish students, on the other hand, associated the virtual learning environment with reduced communication with teachers: "Fronter [the virtual learning

environment] could never substitute the inspiration and response that you get from meeting teachers/tutors and other students face to face. Fronter is aimed at cognitive tasks, not for building relations.” (student, Swedish university, 2005). Norwegian teachers and students seemed to regard the web platform as an adequate tool for storage and retrieval of course material, and for postings of assignments, but nothing more: “It doesn’t make me a better teacher in any way, but the technology works...” (teacher, Norwegian university, 2005). On the other hand, students of the Lithuanian university were enthusiastic about the opportunity to interact with teachers by the e-mail feature in the virtual learning environment: “Now, at last we can speak to teachers one to one.” (student, Lithuanian university, 2004). The enthusiasm was shared by the university management: “This is the future of education, something new to offer our students” (dean, Lithuanian university, 2004).

Theoretical and educational significance

Technology acceptance research has shown that behavioural models, like TAM and UTAUT, do not universally hold across national cultures (Srite & Karahanna, 2006; Bandyopadhyay, & Fraccastoro, 2007). Hofstede (2001) defines national culture as “the collective programming of the mind that distinguishes the members of one group or category of people from another” (p. 9). In this study, national culture is defined as the shared norms, values and behaviours that distinguishes the members of one group or category of people from another. Applying Hofstede’s cultural values, Sweden and Norway are individualistic, feminine countries with a low degree of power distance. The degree of uncertainty-avoidance is somewhat higher in Norway (index value = 50), than in Sweden (index value = 29). Lithuania display another pattern of cultural values with high scores on uncertainty avoidance and masculinity, and medium scores on power distance and individualism (Sarvutyte & Streimikiene, 2010). Sweden and Norway are among the lowest rated nations in the world (index value = 31) on the cultural value of power distance. Lithuania has a higher degree of power distance (index value = 45), which i.e. means that decisions from university management are obeyed. In the two Scandinavian countries, staff and students generally take on a critical stance towards top-down decisions from university management. The high degree of uncertainty-avoidance in Lithuania (index value = 67) may also lead to obedience to university management, as this behavior reduces individual risk-taking. Moreover, a strong social norm, measured by the core construct of social influence was evident in explaining the positive perceptions of the virtual learning environment.

An analysis of the influence of students’ technological culture on their technology acceptance

Santiago Iglesias-Pradas, Universidad Politecnica de Madrid, Spain; Angel Hernandez-Garcia, Universidad Politecnica de Madrid, Spain; Felix Pascual-Miguel, Universidad Politecnica de Madrid, Spain; Oscar Lorenzo Duenas-Rugnon, Universidad Politecnica de Madrid, Spain

The increasing implementation of learning management systems (LMS) in educational institutions during the last decade has raised the interest among the research community on the acceptance and use of these systems by both teachers and students. At first, the implementation of LMS was based on their technical design and the adaptation of the learning processes to the virtual environment, neglecting students’ characteristics when the systems were deployed, which led to expensive and failing implementations. The Unified Theory of Acceptance and Use of Technology (UTAUT) proposes a framework which allows the study of the acceptance and use of technology that takes into consideration the students’ characteristics and how they affect the acceptance and the degree of use of educational technology. This study questions the role of the user’s attitude towards use of LMS and uses the UTAUT to examine the moderating effect of technological culture in the adoption of LMS in Spain. The results from the comparison and analysis of three different models confirm the relevance of attitude towards use as an antecedent of intention to use the system, as well as the important moderating effect of gender and technological culture. The discussion of results suggests the need for a more in-depth analysis and interrelations of cultural dimensions in the adoption of educational technologies and learning management systems.

1 Introduction and research objectives

During the last twenty years a wide range of theoretical models for analysing technological acceptance have been used, mainly Davis's Technology Acceptance Model (TAM) [1], based on Fishbein and Ajzen's Theory of Reasoned Action (TRA) [2]. This study applies a TAM-followup, the Unified Theory of Acceptance and Use of Technology (UTAUT), an integrative model by Venkatesh et al. [3], as a ground for our research model. UTAUT consolidates features of eight different acceptance models and proposes a unified model with four core constructs that determine IT use behaviour, and which takes into account the moderating role of gender, age, experience and voluntariness of use. UTAUT is a relatively new theory, and the effect of cultural elements, a key factor in learning processes, is not yet taken into consideration in its original formulation [4].

This research then focuses on two aspects seldom covered by UTAUT studies: (1) the mediation role of attitude towards use as a predictor of behavioural intention to use and (2) the attitudinal differences between students with technological and non-technological background education and culture. The first one is a topic in which no consensus has been achieved yet [5]; the second examines a moderating variable on the adoption of e-learning technologies from a cultural perspective, an approach that has not been introduced in UTAUT studies until recently.

While the influence of experience in technology use and the role of computer literacy have been widely studied, the issue of technological education background as a cultural trait with shared beliefs and differential characteristics has been neglected in the technology acceptance literature for a long time. However, some recent studies have begun to take it into account, confirming the relationship between technological background and lower levels of anxiety, as well as more positive attitude towards use and intention to use the system [6].

2 Research Design and Methodology

Three different models have been analyzed in order to achieve the research goals: a basic TAM-based model, an extended UTAUT model – which also considers anxiety and self-efficacy – with attitude towards use as a predictor of behavioural intention to use and the extended UTAUT model without the attitude towards use construct. The second and third models included technical background education as a moderator variable.

In order to test the model, online surveys have been completed by 79 graduate, post-graduate and lifelong learning Spanish students – 62 of them belonging to the technologic culture – who already used a Learning Management System (Moodle). Results of these surveys have been analyzed with structural equation modelling with a partial least squares approach, for which PLS Graph 3.0.1130 and SPSS 18 software packages have been used.

3 Conclusions

After verifying the model and reformulating some constructs to assure the consistency and reliability of the measure instrument, the main results reveal the attitude towards use as a mediator between both performance expectancy and social influence, and behavioural intention. However, effort expectancy was not found to have a significant relevance for any of the models, contradicting thus prior literature.

While no moderation effect was found from experience – either Moodle-, LMS- or ICT-related –, age or voluntariness of use, the differences between technological and non-technological culture, together with gender differences, arised as strong moderators for the intention to use the LMS. This is an important finding which emphasizes the appropriateness of considering cultural factors to study the acceptance of technology in education – particularly, both moderating variables have been entwined in the Spanish educational system, where the majority of technological degree courses have traditionally comprised male students, in contrast to non-technological studies.

The study confirms that, for students belonging to a non-technological culture, higher levels of performance expectancy and social influence lead to a more positive attitude towards using a learning management system. Furthermore, facilitating conditions become, more than attitude, the determinant factor of the intention to use the LMS in the case of non-technological culture.

These results emphasize the importance of the existing support infrastructure – both technical and human – when delivering courses via LMS in order to reach a higher audience and expand to all educational disciplines. Also, the comparison between our research results and those found by Nistor et al. [7] with a larger sample of technical and non-technical participants suggests a balance between facilitating conditions and anxiety in the acceptance of ICT-based LMS, so that this reciprocal relation may not be explained only by psycho-social factors perceived by the individual, but also depend on the inherent socio-cultural dimensions.

The influence of culture and infrastructure availability on learners' technology acceptance

Nicolae Nistor, Ludwig-Maximilians-Universitat Munchen, Germany; Thomas Lerche, Ludwig-Maximilians-Universitaet Munich, Germany; Ciprian Ceobanu, Universitatea Alexandru Ioan Cuza Iasi, Romania; Armin Weinberger, Saarland University, Germany

Technology-enhanced learning is increasingly used in international and multicultural contexts. However, little attention has been paid to learner characteristics and attitudes towards technology within different ethnical and professional cultures. This study attempts to integrate culture (in sensu Hofstede, 2001) and infrastructure availability into an established technology acceptance model (the Unified Theory of Acceptance and Use of Technology, UTAUT; Venkatesh, Morris, Davies & Davies, 2003). Relying on a relatively large sample (N = 2834) of technology users from Germany and Romania, we examine the differences in terms of culture, infrastructure availability and technology acceptance between sample subgroups. With respect to culture dimensions, we use an adapted test that estimates variances and the statistical significance of the differences in group values, which was not possible with previous methods. The collected data reveals significant cultural differences both between countries and regions, and between professions. Both culture and infrastructure availability significantly influence technology acceptance. Their influences can be discerned with respect to only one variable, i.e. individualism, which affects the perceived facilitating conditions, which further co-determines the technology use. The theoretical significance of our contribution lays in the first steps towards integrating Hofstede's culture model into the UTAUT. For the educational practice, it suggests a starting point of dealing with cultural discrepancies in the context of technology-enhanced learning.

Rationale

Technology-enhanced learning is increasingly used in international and multicultural contexts. However, little attention has been paid to learner characteristics and attitudes towards technology within different ethnical and professional cultures. A usual, implicit assumption seems to be that technology use implies the same acceptance mechanisms in every culture; there is however not yet sufficient empirical evidence to what extent this is true. Therefore, our study examines the influence of learners' culture on their learning technology acceptance (LTA), which may obviously interact with the availability of the technology infrastructure. More precisely, we attempt to integrate culture dimensions and infrastructure availability into an established acceptance model.

Theoretical background

Learning technology acceptance. The Unified Theory of Acceptance and Use of Technology (UTAUT; Venkatesh, Moris, Davis, & Davis, 2003) is a powerful acceptance model describing technology use as a consequence of the use intention, further determined by performance expectancy, effort expectancy and social influence. Additionally, the facilitating conditions directly determine technology usage. In a larger, socio-political context, some of these predictors are likely to be influenced by culture.

Culture. Hofstede (2001) defines culture as patterns of thinking, feeling and potential acting, which may be determined by both nation and culture. Hofstede identifies five dimensions of culture: power distance, collectivism/individualism, femininity/masculinity, uncertainty avoidance, and long/short-term orientation. Recent research (e.g. Venkatesh & Zhang, 2010) attempts to identify connections between these dimensions and the LTA variables.

Infrastructure availability. Besides cultural differences, material conditions vary between Eastern and Western European countries and regions (Eurostat, 2009). Thus, there are major differences between Germany and Romania, and also within both countries, i.e. between Southern and Eastern Germany, and, within Romania, between Moldavia and the rest of the country. These discrepancies are connected with differences in infrastructure availability and technology diffusion, probably with different technology acceptance, as well.

Aims of the study

Against the background of a hypothesized research model that states the influence of culture and infrastructure availability on the UTAUT acceptance variables, we examine:

(RQ1) the difference between geographical regions and professions in terms of culture

(RQ2) the influence of culture on the acceptance variables

(RQ3) the influence of infrastructure availability on the acceptance variables.

Methods

Within this scope, we conducted a correlation study, recording longitudinal data in a one-shot survey, from undergraduate and graduate students and faculty/teachers, from universities, technical colleges, and adult education centres. We collected a sample ($N = 2834$) of Romanian ($n = 1016$) and German ($n = 1818$) students and professionals of technological ($n = 861$) and non-technological disciplines ($n = 1972$).

Since Hofstede's (1994) culture dimensions are defined only for sample sizes over 50, they may not be processed using statistical methods such as t-test or regression analysis. Therefore we developed a method (Lerche & Kiel, submitted) that allows estimating the variance of the cultural dimensions with the use of Carmer's theorem and a correction factor depending on the sample size. This method allows the application of Welch's test for the difference in culture dimensions (e.g. uncertainty avoidance) by two subsamples, drawn by use of a median split of the dependent variable (e.g. technology use). Instead of regression analysis or correlation, we split the sample according to the values of the dependent variable (e.g. technology use) and we test the difference in the independent variable (e.g. uncertainty avoidance) for the two subsamples. Against an appropriate theoretical background (e.g. a rationale proposing that uncertainty avoidance leads to less technology use), we assume that a significant difference will suggest a significant influence of the independent on the dependent variable.

Results

The collected data reveals cultural differences both between countries and regions, and between professions (RQ1). Culture dimensions appear to have diverse influence on the LTA variables. Individualism, masculinity and uncertainty avoidance display wide effects, influencing many of the LTA variables; power distance and long-term orientation restrict their effect to one LTA variable, i.e. social influence and respectively performance expectancy (RQ2). Insufficient infrastructure appears to significantly decrease expectancies and the technology usage, while increasing the use intention, which thus develops under social influence and is associated with anxiety. Since infrastructure availability has no significant effect on the perceived facilitating conditions, this important predictor of the technology use appears to be determined only by culture, i.e. by individualism (RQ3).

Discussion

The validity of these results is enhanced by the relatively large sample, and its appropriate variance of the independent variables geographical location, profession, culture dimensions, and infrastructure availability. The use of an adapted statistical test for Hofstede's variables (Lerche & Kiel, submitted) is new and confers special methodical significance to the study. However, we must keep in mind that this statistical approach has not yet the strength of a regression analysis. Also, the influences of culture and infrastructure availability may be confounded with respect to some of the UTAUT variables.

This study places main emphasis on theory, making the first steps towards integrating Hofstede's (2001) culture model into the UTAUT (Venkatesh et al., 2003). In this respect, our findings are in line with the previous research (e.g. Venkatesh & Zhang, 2010), while enlarging and deepening the view of the culture influence. With respect to the educational practice, the study suggests acceptance and culture dimensions as a starting point of dealing with cultural discrepancies in the context of technology-enhanced learning.

SYMPOSIUM

Assessment and Learning Implications of the Predictive Classification of Academic Performance

Chairperson: Eduardo C. Cascallar, Katholieke Universiteit Leuven, Belgium

Organiser: Eduardo C. Cascallar, Katholieke Universiteit Leuven, Belgium

Discussant: Mien Segers, Maastricht University, Netherlands

This symposium will summarize and integrate three highly successful and pioneering studies using a predictive systems approach in educational assessment. Given the complexity of the variables involved in the field of education and educational assessment in particular, it is possible to take full advantage of predictive systems in order to improve the quality of educational assessments. In particular, neural networks, with their superior potential for pattern recognition and classification are particularly well suited to use available data to give a much broader expectation of academic performance, based on a wider set of predictors which lead to increase validity, accuracy, and utility of the construct, while also increasing the accuracy of the resulting classifications. A predictive systems approach, and the resulting operational models can lead to better assessment programs and improved learning outcomes, improved diagnostic and placement evaluations, and an opportunity for "continuous assessment". Two studies involved the modelling of expected general academic performance and mathematics performance in higher education using basic cognitive, motivational, learning strategies, and background variables. The other study reports an applications of a predictive classification system of writing performance in secondary education. In all of these applications accuracy in classification was very high. In summary, these models are proposed as valuable alternatives to develop more comprehensive and accurate assessemnt systems which can increase the validity and the accuracy of assessment procedures, thus achieving higher levels of fairness and efficiency, while also increasing the understanding of the processes involved and those involved in reaching better learning outcomes.

Predicting and explaining writing outcomes: Neural network methodology at work

Monique Boekaerts, Leiden University, Belgium; Eduardo C. Cascallar, Katholieke Universiteit Leuven, Belgium

The study was set up with two objectives in mind, namely to understand the variables that influence writing performance and to be able to predict future high and low writing performance. Approximately 1500 vocational school students participated. Background variables provided information about students' home and personal environment, activities outside school, classroom environment, and daily (writing) practices. Questionnaires were used to collect this information. Writing process and writing outcome variables were measured on-line with specially designed software. Authentic writing tasks were selected to assess the quality of students' writing performance as well as the way they tried to steer and direct the writing process. Cues on the screen probed about their motivation to write, their emotions, meta-cognitive strategy use, self-efficacy, and use of external regulation. The traces that students left behind were also studied (e.g., time spent writing the letter, consulting the instruction). Teachers were involved in setting standards for assessing the students' writing performance. The data were analyzed with the neural network methodology, which allowed us to examine large amounts of data in an integrated fashion. It helped us to identify students who are and who are not at risk of becoming poor writers. Using cluster analyses, multi-dimensional scaling and other techniques we identify patterns of differences in core variables among different groups of writers. We will address the predictive and the exploratory aspects of the study.

In class, students find themselves in and create specific learning and working environments that are based on a multitude of factors that affect each other in multiple ways. We assumed that the writing environment that poor writers create is fundamentally different from the environment that good writers create for themselves. We argued that it is insufficient to single out a small set of variables that is assumed to affect writing outcome and study the extent to which higher scores on these variables affect students' writing performance. As Salomon (2006) correctly

pointed out, such an approach only allows us to look at patterns of differences between variables in good and poor writers but does not allow us to study how each of the core variables affects the nature of the writing environment. The research was aimed at predicting vocational students' level of writing performance on the basis of a large set of variables, including variables pertaining to the home context, students' beliefs about writing as a domain, and the quality of their actual writing process. Self-report questionnaires were used to assess aspects of the home context, the writing activities they engage in daily, the type of employment and the number of hours spent at work per week, reading habits, and being with friends. We used Boekaerts' six component self-regulation model to identify writing process variables. Authentic writing tasks were selected to assess the quality of students' writing performance as well as the way they tried to steer and direct the writing process. The interactive soft-ware program that was designed allowed us to measure writing performance on-line. Students engaged in two writing sessions, each lasting an hour, and completed several questionnaires in an additional one-hour session. They logged on to our Internet site and their responses were automatically submitted. Students were asked to write a letter to the editor and they also completed a sentence condensing task (Zimmerman & Kintsantas). They were asked to transform single sentences into the shortest possible Dutch sentence that conveyed the same meaning. On-line task probes appeared on screen to assess their cognitions, affects and strategy use, as well as their use of external regulation. The students' self-efficacy, learning intention, and affect prior to starting on each of the writing tasks were assessed. During each of the tasks their strategy use, the frequency of using the scaffolds and the writing tools provided (e.g., frequency of using the spellers, the model example, the instructions) were also assessed. After the tasks were completed, the traces left behind, such as the time taken to complete the letter and the sentence, the time taken to revise the letter and the sentence, and the number of revisions they had attempted, were noted and analyzed. In a separate session, students completed the questionnaires asking for their domain-specific beliefs about writing, their daily habits, and their meta-cognitive strategy use in relation to three writing genres (e-mail, term paper, and application letter). Students' access to meta-cognitive writing strategies was assessed in relation to the orientation, execution, and reflection stages of each of these writing genres. A neural network approach (NN) was used as a model building technique in order to maximize predictive accuracy. The NN was trained on a sub-sample and the weakest inputs were pruned back. The final solution was used to make a predictive classification into two main categories: students who were and those who were not at risk of having poor writing performance. This classification was then compared against observed writing outcomes in order to calculate accuracy of classification. The NN predicted with 96% total accuracy that students would be in the at-risk group and with 100% accuracy that they would not be. Looking at the classification of the students does not reveal the interactions between the variables that the NN discovered. Remarkably, none of the inputs showed considerable strength singly, but it was the aggregate of predictors in meaningful patterns that provided the NN the strength in prediction and classification. We conducted Ward's cluster analyses on the students in the at risk group to see whether it concerned a homogeneous group. This yielded three separate groups. Multi-dimensional scaling revealed that these groups differed mainly on the time spent writing the letter, tool use, access to meta-cognitive strategies, and affective variables. Using cluster analyses, multi-dimensional scaling and other techniques we identified patterns of differences in core variables among different groups of writers. We will address the predictive and the exploratory aspects of the study, highlighting the different insights that predictive methodology affords.

Cognitive processes, self-regulation and mathematical performance: Application of Neural Networks

Mariel Musso, Katholieke Universiteit Leuven, Argentina; Eva Kyndt, Katholieke Universiteit Leuven, Belgium; Eduardo C. Cascallar, Katholieke Universiteit Leuven, Belgium; Filip Dochy, K.U.Leuven, Belgium

There is substantial research which has investigated the influences of: working memory; attention, motivation, and learning strategies, on mathematical performance and self-regulation in general. However, these studies have looked at the separate effects of these components. We have little understanding about how they impact on the performance when taken together, understanding their interactions, and how much each can predict a mathematical performance. On the other hand, new methodologies and technologies, and the emergence of predictive systems, have focused on the possibility of assessments which use a wide range of data or student productions to evaluate their performance without the need of traditional testing (Boekaerts & Cascallar, 2006). This research addresses to understand different cognitive patterns and complex relations between cognitive variables, motivation and background variables, for different levels of mathematical performance, using Artificial Neural Networks (ANN). Sample: over 700 beginning university students, both genders, ages 18-25. Two neural networks were developed to identify the lowest 30% and highest 30% of estimated future performance in a mathematics test. Both models were able to reach 100% correct identification of all students, both in the target group for each network. They showed interesting differences in the pattern of relative normalized importance of those variables with the highest participation in the predictive model. For Low performers, basic cognitive variables were most important, while self-

regulation and background variables were good predictors for High performers. Their impact on educational quality and improvement, as well as accountability is highlighted.

Although there is substantial research which has investigated the influences of: (a) working memory (Adams & Hitch, 1997; Ashcraft, 1995; Geary, 1990; Geary & Widaman, 1992; Hitch, 1978; Lemaire, Abdi, & Fayol, 1996; Logie, Gilhooly, & Wynn, 1994; Passolunghi, Cornoldi, & Di Liberto, 1999; Passolunghi & Pazzaglia, 2004; Pickering, 2006; Widaman, Geary, Cormier, & Little, 1989); (b) attentional systems (Posner & Rothbart, 1998; Rueda, Posner, & Rothbart, 2004); and (c) motivation, on mathematical performance and self-regulation in general, these studies have looked at the separate effects of these components. Therefore, we have little understanding and data about how they impact performance when taken together, understanding their interactions, and how much each can predict the mathematical performance in an integrated model (Cascallar & Musso, 2008; Musso & Cascallar, 2009). On the other hand, new methodologies and technologies, and the emergence of predictive systems, have focused on the possibility of assessments which use a wide range of data or student productions to evaluate their performance without the need of traditional testing (Boekaerts & Cascallar, 2006). The purpose of this research was to develop predictive classification models that could identify with sufficient precision two groups of students corresponding to the highest 30% and lowest 30% of estimated future performance in a mathematics test, utilizing only cognitive, motivational and background variables, with no assessment of the mathematics content present in the test. It was expected that results would enable the development of an "early warning" system which would allow early and prompt intervention with those students most in need of support and remediation in mathematics (at the level of exit from secondary education, and beginning of university studies). Similarly, this approach could serve to identify top or advanced students and improve their placement and/or career choice. The sample included over 700 university students, of both genders, ages between 18 and 25, attending the first or second year in several different disciplines (Psychology, Engineering, Medicine, Law, Social Communication, Business and Marketing), academic year 2009-2010. After giving informed consent, all the participants completed the following cognitive tasks, during the first session (60 minutes): 1) Attention Network Test (ANT) (Fan, McCandliss, Sommer, Raz, & Posner, 2002), and 2) Automated Operation Span (Unsworth, Heitz, Schrock & Engle, 2005). In a second session (90 minutes) participants completed the Learning Strategies Questionnaire (LASSI, Weinstein, Schulte & Cascallar, 1982; Weinstein, Palmer, & Schulte, 1987), the Online Motivation Questionnaire (OMQ) (Boekaerts, 2002) before- after the math task and were given a mathematics test consisting of 65 items (50 items from a national mathematics test calibrated at exit from secondary education, and 15 items from the 12th grade TIMSS test administered worldwide). In addition, a questionnaire was applied in order to collect background variables, including individual and family characteristics.

Procedure: It had been used a back propagation network, that is, a multilayer network composed of nonlinear units, which computes its activation level by summing all the weighted activations it receives and which then transforms its activation into a response via a nonlinear transfer function. The results obtained were very successful in terms of the effectiveness of the two predictive classificatory models developed. Both models were able to reach 100% correct identification of all students, both in the target group for each network (Highest 30% of scores or Lowest 30% of scores, respectively) and those "not belonging" to the target group. Both networks showed interesting differences in the pattern of relative normalized importance of those variables with the highest participation in the predictive model. For the Low performers (those predicted to be in the lowest 30% of scores), several basic cognitive variables were most important, such as "reaction-time" and "working memory capacity". On the other hand, results from the predictive model for those expected to be in the Highest 30% of the scores, the top predictors with the most significant participation were self-regulation and background variables. Besides the evident predictive power of both neural networks to model the expected performance of the low and high performance groups, this methodology has also detected important differences in the factors that seem to underlie the students' performance. Among the lowest 30% of the student group, the main determinants of performance appear to be the basic cognitive processing variables, indicating the degree to which they represent the areas of relative weakness in the group, and more discriminating from the rest of the students. On the other hand, among the high 30% of the student group, the main determinants appear to be self-regulation and background variables (particularly how interested they were in the task, and social indicators such as parents' occupations), leaving the cognitive variables at much lower levels of importance, probably also due to the fact that they are more evenly represented in the group and are therefore less discriminating. The predictive systems approach allows for the understanding of the students' individual characteristics, in addition to the prediction of expected performance levels. This opens major possibilities for improvement of evaluation procedures and the planning of interventions. In addition it has implications for the application of these methods in educational research and in the implementation of diagnostic "early-warning" programs in educational settings, as well as informing cognitive theory and the development of automated tutoring and learning systems. The capacity to very accurately classify students, which is also what tests attempt to do (usually with much less success in terms of accurate classifications), without the performance sampling issues of traditional testing is a major step in using a much broader picture of a student's overall inputs into any attempted performance,

and therefore a much more valid approach to educational evaluation. In turn, this new approach allows for the conceptualization and development of new modes of assessment which could facilitate breaking away from traditional forms of testing while at the same time improving the quality of the assessment (Segers, Dochy & Cascallar, 2003).

Predicting academic performance in higher education: Role of cognitive, learning and motivation

Eva Kyndt, Katholieke Universiteit Leuven, Belgium; Mariel Musso, Katholieke Universiteit Leuven, Argentina;

Eduardo C. Cascallar, Katholieke Universiteit Leuven, Belgium; Filip Dochy, K.U.Leuven, Belgium

There is a substantial body of literature investigating academic performance. Former research has shown that a variety of student characteristics both states and traits effect academic performance. In this research study we will predict general academic performance in the first bachelor year educational sciences, based on students' motivation, approaches to learning, working memory capacity and attention, by means of a neural network analysis. Since the goal of a neural network analysis is classification it allows us to investigate the predictive value of the different variables for different categories of students. In this study three neural network analyses are performed for three categories of academic performers: the top 20%, the bottom 20%, and the 60% middle group of students. The relative importance of the variables will be examined in order to determine whether or not every variable is important for every category of students. Participants in this study were 128 university students. Results show that working memory capacity and attention are both good predictors of academic performance, especially for the best and weakest performers of the group. Students' motivation and approaches to learning were good predictors for the group of students whose performance was in the middle 60%.

A substantial body of literature has been dedicated to the educational achievement of students and what influences it (Lehto, 1995; Vansteenkiste, Simons, Lens, Sheldon & Deci, 2004). This study will investigate whether working memory capacity, attention, motivation and students' approaches to learning can provide enough information for a correct predictive classification of their academic performance. Research using traditional methods, has shown that all of these variables are related to students' academic achievement (Lehto, 1995; Trigwell & Prosser, 1991; Vansteenkiste et al., 2004). Neural network (NN) analysis has been utilized in business and social sciences as a statistical methodology for classification and recognition of patterns (Detienne, Detienne & Joshi, 2003; Neal & Wurst, 2001). However, when focusing on educational literature very few studies apply neural network analysis (Cascallar et al., 2006; Wilson & Hardgrave, 1995). Preliminary research applying NN-analysis suggests that NN-analysis may substantially improve the validity of the classifications and increase the accuracy and predictive validity of test (or other educational) information (Musso & Cascallar, 2009; Perkins, Gupta & Tammana, 1995). When applying NN-analysis, it is important to realise that although neural networks can address some of the same research issues as regression, it is inherently a different mathematical approach (Detienne et al., 2003). In this study, we will carry out predictive classifications of students that score high, low or around the mean. Moreover, for each of these categories we will look at the relative importance of the different predictors in this study. In total 236 university students, enrolled in the second bachelor year of educational sciences, participated in the study of whom the majority was female. For all independent variables validated measures were used. Approaches to learning were measured by means of the R-SPQ-2F (Biggs, Kember & Leung, 2001). Students were asked to answer the questions according to how they usually studied in the first bachelor year. For motivation, an adapted version of the Self-Regulation Questionnaire (Ryan & Connell, 1989) was administered. Working memory capacity was assessed by the 'Automated Operation Span Task' (Unsworth et al., 2005) and Attention was measured by the 'Attention Network Test' (Fan et al., 2002). Finally, the dependent variable academic performance equals the average percentage that students achieved in their first year in the bachelor program of educational sciences. In total three neural networks were carried out predicting the top 20%, bottom 20% and middle group of academic performers. The evaluation of the neural network is based on the precision, sensitivity, specificity, ROC curves and accuracy. The evaluation of the first network predicting the top 20% scores of academic performance can be considered very good. The precision of the network equals .86. The network's sensitivity equals 1 and can be described as perfect. The specificity of the network amounts .83. The area under the ROC curve equals .956. The accuracy of this first neural network amounts 82.6% in the training phase, in the testing phase the accuracy increased to 100%. The actual weight and normalized importance of the different predictors indicate that orienting attention, overall attention, and processing speed are the most important predictors. When adding the variables motivation and students approaches to learning to the network, the accuracy and overall evaluation of the model declined. The network including motivation and approaches to learning is evaluated as weak, especially in contrast with a network with only the cognitive capacities of the students as input. The second NN-analysis was designed to predict the bottom 20% of academic performance. The precision of this second neural network equals .77. The network's sensitivity equals 1. The specificity of the network amounts .70. The area under the curve equals .897. In the training phase accuracy reached 76.5%, while in the testing phase the

predictive accuracy achieved equaled 100%. Working memory capacity, processing speed and orienting attention are the most important predictors for students with scores in the bottom 20%. For this network, adding students' motivation and approaches to learning also declined the evaluation of the network. Indicating that these variables decrease the predictive accuracy of the network rather than adding valuable information. The third and final neural network focused on predicting the academic performance of the group of students with the middle 60% scores. The precision of this third neural network equals .56. The network's sensitivity equals .79. The specificity of the network amounts .27. The area under the curve for this network equals .681. This indicates that the prediction of this middle group could be more complex and requires additional variables. In the training phase accuracy was 74.5%, while in the testing phase the predictive accuracy reached 79.3%. In this final network processing speed, a surface approach to learning, working memory capacity and controlled motivation are the most important predictors. It is important to notice that in this network students' motivation and approaches to learning did add valuable information to the network. This study faces some limitations for generalisation. The first limitation is the sample composition and size. Due to practical constraints, more specifically the administration of the cognitive tests, our sample size was limited to 236 students. Moreover, the vast majority of the sample was female. Former research does not offer a clear indication of whether or not this disproportion affected our results (Cano, 2005; Castagnetti & Rosti, 2009; Lynn & Irwing, 2008; Mattick, Dennis & Bligh, 2004; Naglieri & Rohjahn, 2001). Another limitation of this study is the fact that we chose to investigate 'only' four independent variables while NN-analysis has the ability to handle a large amount of input variables. Future research could include more variables when predicting academic performance by means of NN-analysis. This study supports the idea that the use of predictive systems could contribute to the prediction of future academic performance, which in itself could be a useful construct in tasks like selection for academic admission, academic advising, and placement in general. At a theoretical level these results confirm the contribution of cognitive variables in the measurement of academic performance and refines the body of knowledge concerning approaches to learning and motivation.

SYMPOSIUM

Investigating domain-specific epistemological and learning beliefs

Chairperson: Bettina Roesken, Ruhr-Universität Bochum, Germany

Organiser: Bettina Roesken, Ruhr-Universität Bochum, Germany

Csaba Csikos, University of Szeged, Hungary

Discussant: Krista Muis, McGill University, Canada

Students' epistemological beliefs and beliefs about learning play an important role in their academic achievement. In Hofer's (2001) and Muis' (2007) models, students' epistemological beliefs have a fundamental, albeit often indirect effect on school-related academic factors. Previous research on student epistemological beliefs has primarily focused on general epistemic beliefs, i.e., what counts as knowledge, and how it is constructed in general (cf. Hofer and Pintrich, 2002; Swe Khine, 2008). Nevertheless, there are some domains where specific inventories have been developed, i.e., in mathematics (see De Corte, Op 't Eynde & Verschaffel, 2002; Schommer-Aikins, 2008), science (see Elder, 2002), reading (see Mokhtari and Reichard, 2002) and EFL/ESL learning (see Horwitz, 1985). Developing high reliability paper-pencil questionnaires on both levels of general and domain-specific epistemological beliefs requires considerations of validity issues like the question of congruity between Likert-scale propositional statements and real-world activities to which those statements pertain. The aim of this symposium is to demonstrate how domain-specific belief systems can be assessed, and what role they can play in academic achievement. In the first paper, by means of a questionnaire, comprehensive data was collected that gives an overview on Finnish students' beliefs related to their experiences as learners of mathematics. The second paper focuses on reading-related beliefs based on the MARS questionnaire (Mokhtari and Reichard, 2002). Self-referential statements about what one usually does were matched with general epistemic statements about what people usually should do in different reading-related situations. The third study focuses on how statements formulated in first person and third person differ not only in their means, but in the structure of the belief system that they manifest.

Structuring students' beliefs about learning mathematics

Bettina Roesken, Ruhr-Universität Bochum, Germany

For more than twenty years now, the influence and significance of beliefs have been in the focus of research in the field of mathematics education. Even nowadays, students' beliefs about mathematics and its teaching and learning are key since they are a decisive parameter for engagement and success in school. To approach the structure of students' mathematics-related beliefs we have used a questionnaire to collect and analyze data from a sample of secondary school students in Finland. We explored what dimensions describe their beliefs of learning mathematics, how they are related and what structure they generate. By means of factor analysis we obtained seven dimensions that are

described by reliable scales, which allow drawing an average image of Finnish students' beliefs about learning mathematics. We further analyzed relations between the dimensions and what structure they generate. Thereby a core of three high correlating dimensions could be identified. Participants in our study were 1436 randomized chosen students of secondary school, grade 11, from overall Finland.

Students' mathematics-related beliefs are a decisive parameter for engagement, motivation and success in school. The study of students' beliefs about mathematics and its teaching and learning has received much attention in recent years and many results have been presented. These studies are in most cases descriptive, for example reporting typical beliefs held by students (e.g. Ma & Kishor, 1997). Some of the studies compare student beliefs in different countries (e.g. Pehkonen, 1994) or according to background variables such as gender (e.g. Frost, Hyde and Fennema, 1994). Most of the studies of beliefs have been carried out with a separate focus on cognitive, motivational or affective aspects and only few contributions address explicitly belief systems. However, Op 't Eynde, De Corte and Verschaffel (2002), consider explicitly the structure of beliefs about mathematics. They provide a framework of students' mathematics-related beliefs that is based on the constitutive dimensions of object (mathematics education), self, and context (class), which further lead to several sub-categories. In our study, we focus explicitly on studying the structure of students' mathematical beliefs. To approach the subject, we have used a questionnaire to collect and analyze data from a sample of secondary school students. We explore what dimensions describe their beliefs of learning mathematics, how they are related and what structure they generate. The view of mathematics indicator has been developed in 2003 as part of the research project "Elementary teachers' mathematics" financed by the Academy of Finland (project #8201695). It has been applied to and tested on a sample of student teachers and was slightly modified for the present sample. The statements in the questionnaire are grouped around the following topics: · Experiences as mathematics learner · Image of oneself as a mathematics learner · View of mathematics and its teaching and learning The items also comprise a self-confidence scale containing ten items from the Fennema-Sherman mathematics attitude scales (Fennema & Sherman, 1976). The students were asked to respond on a Likert scale (5 point, agree to disagree) to statements such as the following: · I have worked hard to do mathematics · My family has encouraged me to study mathematics · I can get good grades in mathematics or · I would have needed a better teacher. The participants in our study came from fifty randomly chosen schools from overall Finland, including classes for both, advanced and general mathematics. The respondents were in their second year course for mathematics in grade eleven. Altogether 1436 students filled in the questionnaire and gave it back. Factor analysis led us to differentiating seven dimensions describing students' beliefs about learning mathematics. Those dimensions can be assigned to different topics around their experiences with mathematics. Three factors relate to personal beliefs since a clear self-relation aspect regarding ability (F1), effort (F2) and success (F7) can be found. Although the factors ability (F1) and success (F7) both deal with capacity to learn mathematics, they clearly broach different issues. F1 describes a more static view on ability while F2 stands for a more dynamic view mentioning student's expectations about future success. Two factors relate primarily to students' support by their teacher and family (F3: teacher quality, F4: family encouragement), one to emotions (F5: enjoyment of mathematics) and one to mathematics as a subject (F6: difficulty of mathematics). In terms of the framework suggested by Op't Eynde et al. (2002, 2004) the dimensions can be assigned to all main categories and, on a finer grain, to most of the subcategories. Nearly all dimensions correlate significantly with each other. Further, the correlation matrix indicates that three of the factors, that is ability (F1), difficulty of mathematics (F6) and success (F7), are closely related and form a core of students' beliefs about learning mathematics. When we studied the relations between the dimensions, we were able to identify a core of view of mathematics (Green, 1970) with a large value of covariance. This core consists of the dimensions ability, difficulty of mathematics and success. In addition, there is a moderate correlation of enjoyment of mathematics (F5) to this core. Hence, a student with a positive view believes him or herself to be talented in mathematics, to do well in the future, experiences mathematics as easy and also likes to do mathematics. These dimensions are crucial for view of mathematics and even form an obstacle for students when they do not feel able to do mathematics and simultaneously experience mathematics more and more difficult. Thus, the present study supports previous research on mathematics-related beliefs structure. In our analysis we found evidence for an extended conceptualization of beliefs as a system. By means of factor analysis we determined useful and statistically robust dimensions of students view of themselves as learners of mathematics.

Measuring beliefs on language learning

Csaba Csikos, University of Szeged, Hungary; Eva Bacsa, University of Szeged, Hungary

This study presents the process of developing a questionnaire on beliefs concerning language learning. The research aimed at developing a Hungarian questionnaire that (1) can be used as a means of formative evaluation in the classroom (2) utilizing items of English language instruments and (3) contains self-referential statements about ESL learning, and – being parallel in its content – contains statements about one should do when learning English. The primary objective of the present study is to focus the attention such a validity problem of questionnaire development that has not been emphasized in the literature – to the differences of self-referential statements and general epistemological statements which occurs at the wording of the questionnaire items. The findings of the two-round assessment process clearly indicates that the wording of the statements is a factor to be considered when developing a new instrument. Linguistic inconsistencies might deteriorate the validity of instruments intending to measure students' beliefs.

Introduction

Victori and Lockhart (1995, p. 224) define beliefs about language learning as "general assumptions that students hold about themselves as learners, about factors influencing learning and about the nature of language learning". Several research findings draw attention to the importance of beliefs in the process of mastering a foreign language (Horwitz, 1989; Cotteral, 1999; Diab, 2006; Rieger, 2009). However, the means and methods of exploring beliefs have been subject to serious debates from the beginning of research in this field (Cotteral, 1995; Kuntz, 1996; Sakui & Gaies, 1999; Nikitina & Furuoka, 2006). Different viewpoints have been articulated concerning the measurement of beliefs and about whether they could be treated as elements of metacognitive knowledge. The majority of research in the field uses the Beliefs About Language Learning (BALLI) (Horwitz, 1987) questionnaire, or its modified versions (Sakui and Gaies, 1999; Amuzie and Winke, 2009; Rieger, 2009), albeit both its reliability and its validity are questionable and the results are difficult to interpret. The major problem is the lack of statistical analysis of the domains defined by the author (Kuntz, 1996), hence the comparison of the scales are impossible, and the results might only be compared on the item level. Further problems with the instrument include overlap between the individual dimensions and the appearance of latent factors (Piniel, 2009). In addition, there is a need for formal and content analysis of the original instrument. Some of its items should be revised, since modern linguistic aids and authentic sources are getting more and more available to the students and it would be important to map students beliefs in these fields as well. Furthermore, the original instrument as well as the modified versions operate diverse linguistic formulae that lack consistency, hence causing validity concerns.

The research

The instrument presented here is the improved Hungarian version of Beliefs About Language Learning (BALLI) (Horwitz, 1987) questionnaire. The development was done in two steps. **Study 1** In the first step of developing the instrument, a 60 item questionnaire was constructed using two ways of wording for each item that are distributed among three questionnaires. The instrument adopted 25 items from BALLI (Horwitz, 1987), 7 items from Sakui and Gaies (1999) and contained another 28 newly developed items. Versions A, B, and C each included 40 items 20 of which were written in first person singular 20 written in third person singular. The instrument is sensitive to Hungarian specialities of language learning and to the beliefs about more modern technological and authentic possibilities of language learning. Our sample consisted of 210 students. The aim of the study was to compare the two kinds of wordings. It was hypothesized that the two versions measure the same beliefs. Significant differences were detected between the means of the two versions. More statements in third person got higher scores, however, while secondary students preferred this format, elementary students scored higher in the items where first person was used. The results suggest that the validity of an instrument is influenced by the wording of its items, hence research was continued. **Study 2** In the following step, the number of items was reduced, and a singular version of the instrument contained 16 pairs of items with the same content, but different wording (first vs. third person) along with another 18 single items with first person subject. The item pairs were the ones previously showing the largest differences, the single items were those with highest reliabilities. The second data-collection was conducted on a sample of 363 17-year-olds. Data were analysed using descriptive and comparative statistics, factor and cluster analyses. Data analysis was done on the set of all items and on the sub-questionnaires as well. (Third person item pairs and single

items together are referred to as sub-questionnaire A, while first person item pairs and single items together as sub-questionnaire B.) The hypotheses were as follows: 1. No significant difference can be detected between the item means of the sub-questionnaires. 2. Items of sub-questionnaire A and B can be expressed in a single scale. 3. Sub-questionnaires are statistically identical, i. e. they measure the same beliefs. Both the whole questionnaire (.88) and the sub-questionnaires (A: .81, B: .84) had acceptable reliabilities. Item pairs were compared with paired sample t-test to test the first hypothesis. It resulted in significant differences in item preference in 12 (75%) of the 16 cases, which differences are distributed equally among the first and third person versions. Thus, it can be stated that there are significant differences between the item means of the two versions. Factor analysis was conducted involving the sub-questionnaires to test the second hypothesis. The KMO indices (A: .82, B: .84) and the number of the factors (A: 10, B: 9) were high in both cases. The interpretation of the factors was not difficult in case of the B version, it covered mostly the pre-set categories. Version A, however, was problematic. Item distribution among the factors are mostly found random, difficult to interpret. The comparison of the two factors resulted in some form of correspondance, which means that the items of the two sub-questionnaires might not be expressed on the same scale. The third hypothesis is tested by the other two and some additional analyses (cluster analysis and analyses with merged variables). They show that the sub-questionnaires do not measure the same construct, which raises validity concerns. These results contribute to the verification of the existence of a validity concern that has not been stressed above, namely that there are differences between self-referential and general epistemological beliefs. This means that in the development of any further instruments, item wording has to be a central issue.

Investigating reading-related beliefs among vocational secondary school students

Csaba Csikos, University of Szeged, Hungary; Aniko Molitorisz, University of Szeged, Hungary

Analyzing epistemic beliefs is recently girdled with an increasing scientific interest (Hofer, 2001; Bromme, Kienhues & Stahl, 2008). Besides the measurement of general epistemic beliefs about knowledge and learning, questionnaires to assess students' domain specific beliefs has also been designed (mathematics: De Corte, Op't Eynde & Verschaffel, 2002; EFL/ESL: Horwitz, 1985). The questionnaire we applied in our present study contains 19 statements transformed from Mokhtari and Reichard's (2002) Metacognitive Awareness of Reading Strategies Inventory and three additional statements based on the study by O'Sullivan (1992). The aim of this investigation is to assess the reading-related beliefs of 10th grade vocational secondary school students by our questionnaire. Three hypotheses were tested: (1) The questionnaire is a reliable measure of reading-related epistemological beliefs. (2) Students believe that rereading and effort making are more useful than adaptive strategies like going back and forth in the text to find relationships in it or adjusting the reading speed. (3) Students' reading-related beliefs are connected with background variables such as the attitude of reading. Our sample consisted of 302 10th grade students from three vocational secondary schools in Budapest. The reliability of the instrument was acceptable. Results showed that students assign more importance to rereading and effort making while reading. Significant correlations were found with background variables like the attitude of reading and the use of the internet for finding the meaning of unknown words while reading. The educational implications and consequences are discussed.

Introduction

Theoretical background

There has been an increasing scientific interest on the analysis of students' epistemic beliefs in order to get a closer understanding about what students think about knowledge and learning (Hofer, 2001; Bromme, Kienhues & Stahl, 2008). According to Muis (2007) and Muis and Franco (2009), epistemic beliefs influence school achievement through achievement goals and learning strategies. Besides studying general epistemic beliefs, assessment tools for measuring domain specific epistemic beliefs have also been developed (mathematics: De Corte, Op't Eynde & Verschaffel, 2002; EFL/ESL: Horwitz, 1985). In reading, O'Sullivan (1992) studied the relationship between reading beliefs (including teachers' and parents' beliefs) and reading achievement. She found that students' beliefs about reading influenced significantly their achievement. Mokhtari and Reichard's (2002) Metacognitive Awareness of Reading Inventory (MARSI) was developed after a review of the literature concerning the preceding methods for assessing reading strategy use. Their questionnaire contained thirty self-referential statements about what one usually does while reading academic or school-related materials and its purpose was to examine the students' degree of awareness of their own processes involved in reading. While constructing our questionnaire about reading-related beliefs, 19 statements were based on the MARSI scale and three additional statements were formulated upon O'Sullivan's (1992) study. Items from MARSI were transformed from personal strategy use to general belief: e. g. 'I take notes while reading to help me understand what I read.' was transformed to 'Taking notes while reading helps better understanding.' or 'I underline or circle information in the text to help me remember it.' was transformed to 'Underlining or circling information in the text while reading helps the reader remember it.' Based on O'Sullivan's

study, we constructed a statement concerning the effort made while reading. We also applied two statements about parents' and teachers' beliefs concerning the student's reading ability (e.g. 'My parents believe I am a good reader.')

Aims and hypotheses

The aim of our research was to measure students' reading-related beliefs while reading academic or school-related materials. The following hypotheses were tested: (1) Our questionnaire is a reliable measure of reading-related epistemological beliefs. (2) Students believe that rereading and effort making are more useful than adaptive strategies like going back and forth in the text to find relationships in it or adjusting the reading speed. (3) Students' reading-related beliefs are connected with background variables such as the attitude of reading or the use of the internet in order to find the meaning of unknown words or expressions.

Methods

Participants 302 students of 10th grade filled in the inventory in three vocational secondary schools in Budapest in June 2010. Test and procedure Our questionnaire had two parts. The first part contained questions about socio-cultural and reading-related background variables including sex, number of siblings, number of books at home, attitude of reading, the use of the internet for searching the meaning of unknown words or expressions while reading etc. The second part contained the 22 epistemic statements about what people usually should do while reading academic or school-related materials for a better comprehension. Students had to answer on a five-point Likert-type scale by marking to what extent they agree with the statement. Results Our questionnaire about reading-related beliefs showed acceptable reliability (Cronbach-alpha: .78). Factor-analysis showed to be appropriate (Kaiser-Meyer-Olkin index = .75) and the statements were separated into seven different factors explaining 56 percent of the variance. The statement with which students agreed the most was 'If one puts more effort in reading, one can better understand what one is reading.' Students agreed the least with the following two statements: 'Trying to guess the meaning of unknown words or phrases while reading helps understanding.' and 'It is worth trying to guess what the material is about while reading.' (for the first and last three statements see table 1) As for the relation with background variables, the frequency of using internet to find the meaning of unknown words or expressions showed statistically significant relation with reading-related beliefs ($r = .23$). Significant correlation was also found between students' beliefs about reading academic materials and their attitude of reading ($r = .20$). Those students who talk about books with their family or friends, expressed significantly stronger agreement in the case of seven statements than those who don't talk about books.

Discussion – Theoretical and educational significance

The results confirmed our hypotheses. The reliability of the instrument was acceptable. The means of the items showed to which activities students assign more/less importance while reading academic materials. Significant correlations were found with background variables like the attitude of reading and the use of the internet for finding the meaning of unknown words while reading. In accordance with the literature, we suppose that the assessment of reading-related beliefs fosters more precise understanding of epistemic beliefs about learning and our results also can be used in designing more effective comprehension development programs.

SYMPOSIUM

Utilizing assessment information for (in)formative feedback

Chairperson: Dominique Sluijsmans, HAN University of Applied Sciences, Netherlands

Organiser: Anders Jonsson, Kristianstad University College, Sweden

Anton Havnes, Oslo University College, Norway

Discussant: Dai Hounsell, University of Edinburgh, United Kingdom

In order to support student learning, feedback is of crucial importance, since the students need to be informed about their current performance if they are to perform better in the future. The nature of feedback and its effects on student learning has been extensively investigated, as seen for instance by the large number of meta-studies and literature reviews on the subject. This research has, however, produced somewhat intriguing and sometimes even contradictory results, making it difficult to get a general view of this field of knowledge and even more so to create a simple set of guidelines for effectively supporting student learning. Clearly, more research is needed on this topic, investigating not only the effects of feedback, but also how students respond to feedback. The aim of this symposium is therefore to bring different contributions focusing on this topic together, providing: (1) a "state of the art" picture of the research, (2) a discussion about the conceptual underpinnings of the criteria for students' use of feedback, and (3)

examples of empirical research exploring students' use of feedback in a learning context. With these presentations, and by including perspectives from four different countries (Sweden, The Netherlands, Norway, and Scotland), we hope to create favourable conditions for a dialogue about a – until now – largely neglected area of research.

Students' use of feedback in higher education: a literature review

Anders Jonsson, Kristianstad University College, Sweden

This paper investigates what research evidence can be found on how students use information about their performance on assessment tasks, as provided by tutor feedback. A broad search was performed in several online databases, including recent empirical studies on feedback use in higher education, after which the reference lists in these studies were used to find further studies, going back to 1990. In total, less than 100 studies were found. The results from the review show that there are very few studies addressing students' use of feedback, and also that most of these rely on students' own statements in interviews. Only a hand full of studies have investigated what students actually do with their feedback. As indicated by these studies, some students do seem to have effective strategies for using feedback, but there are also a number of students who seem to have rather vague strategies, such as having to "work harder". Yet another group of students seem to have no strategies at all, or use the feedback in counterproductive ways, such as erasing or avoiding problematic areas. As compared to studies investigating how students use feedback, there is a much larger number of studies investigating factors that might promote or impede students' use of feedback. Examples of such factors are timing and relation to criteria. Most notable, however, is the fact that there are seldom any real possibilities for students to use the information they receive about their performance.

According to Sadler (1989), key premises for students to be able to "alter the gap" between current performance and the performance aimed for are that: (1) They must know what performance is aimed for; (2) They must be able to assess their performance in relation to some standard(s); and (3) They must possess some strategies to modify their performance in the light of the information provided by the comparison. While the second premise might well be fulfilled by the teacher assessing the student, thereby gathering the necessary information about current performance and passing it on to the student, the third premise inevitable involves the student. It must be the student that uses the information to adjust her performance, even if this process can also be aided by the teacher to some extent. Still, very little is known about how students use the feedback they receive and this paper therefore investigates what evidence can be found in the research literature on how students use information about their performance on assessment tasks, as provided by tutor feedback. The following questions have guided the review: (1) How do students use feedback? and (2) Which are the factors that promote or impede students' use of feedback?

Method

Research on students' use of feedback was searched by starting from a number (36) of recent publications on the topic, found by searching broadly online in a number of databases. The reference lists in these articles were then used to find new articles, continuing iteratively throughout the review process. Only studies explicitly reporting on empirical research on students' use of feedback in higher education were included and the search has been limited to include only printed and peer-reviewed material, such as articles in journals, edited books, research reports, and dissertations. Furthermore, a time limit was set to 1990, and studies published before that date has not been included.

Findings

In total, less than 100 studies were found. The majority of the studies included in this review were published as journal articles, followed by chapters in edited books, and research reports. The studies included vary across academic subject, but the feedback considered is almost exclusively written comments on students' written work. Research designs encompass mostly questionnaires and interviews, sometimes in combination. A number of studies have complemented students' perceptions with analyses of examination results or tutor feedback. The results from the review show that there are very few studies addressing students' use of feedback, and also that most of these rely on students' own statements in interviews. Only a hand full of studies have investigated what students actually do with their feedback. As indicated by these studies, some students do seem to have effective strategies for using feedback, but there are also a number of students who seem to have rather vague strategies, such as having to "work harder". Yet another group of students seem to have no strategies at all, or use the feedback in counterproductive ways, such as erasing or avoiding problematic areas. As compared to studies investigating how students use feedback, there is a much larger number of studies investigating factors that might promote or impede students' use of feedback. Examples of such factors are timing and relation to criteria. Most notable, however, is the fact that feedback is often used in accordance with a transmission model, rather than a feedback loop, and that there are seldom any real possibilities for students to use the information they receive about their performance. What becomes evident,

therefore, is that merely following a set of guidelines for producing high-quality feedback – even if it means providing the students with large amounts of personalized and detailed feedback – will probably still not do the job. This is because, although some students do possess strategies to modify their performance in the light of the information provided by feedback, many students seem to lack such strategies – and teaching strategies for using feedback does not generally seem to be a part of the curriculum. Instead, what seems to be needed is the active engagement of the students with feedback in relation to their own work, for instance through the use of model answers or exemplars, so that the students learn what high-quality work looks like, but also the active engagement with criteria and standards through peer- and self-assessment, so that they become able to assess their own work. Therefore, strategies for actively engaging in feedback have to become an integrated part of the curriculum, if most students (as opposed to only some of them) are to be able to "alter the gap".

Following recommendations: differential use of feedback information

Harm Tillema, Universiteit Leiden, Netherlands

To date, many studies on feedback have looked into the conditions and methods of feedback provision; however, often without clear specification of its utilization criteria, i.e. the outcomes or effects of feedback on learning. This study provides a conceptual reinforcement of utilization criteria and looks into the variables that govern the process of use of feedback, viewed as: a) Acceptance of feedback, which is subsequently linked to b) Following recommendations. Furthermore this study explored utilization outcomes on student learning relative to the way assessment information was provided to these students by experimentally varying two formats of assessment provision of feedback, i.e. the portfolio method (instructor provided and individually targeted) and peer assessment (peer provided and generically targeted). A model is presented in which different influencing feedback provision variables in assessment are specified in relation to factors governing acceptance of feedback and the following of recommendations. Analysis of data in a field experimental pre test post test design, using one group of student teachers (subjects as their own control) (n=47) in learning to teach, showed that assessment format has a differential effect on acceptance of feedback (mainly on clearness and trust) which subsequently is related to following recommendations (mainly compliant and proficient use). Interaction effect revealed that the portfolio instrument addresses different acceptance criteria (trust) than peer assessment (feasibility) as well follow up criteria (adaptive use as compared to compliant use). This finding indicates that assessment tools can be utilized to provide a targeted impact from feedback.

"Feedback is only feed-back when it is processed", i.e., being used. To date, many studies on feedback have looked into the conditions and methods of feedback provision (Hattie & Timperley, 2007); however, often without clear specification of its utilization criteria, i.e., the outcomes or effects of feedback on (subsequent) learning. Student satisfaction with feedback would be an insufficient criterion to determine change in learning or achievement (Sadler, 2010). This study provides a conceptual reinforcement of utilization criteria and looks into the variables that govern the process of use of feedback, viewed as a) acceptance of feedback, which is subsequently linked to b) following recommendations. Furthermore, this study explored feedback utilization outcomes on student learning relative to the way assessment information was provided to these students by experimentally varying two formats of feedback provision by way of different assessment tools, i.e., the portfolio method and peer assessment (Tillema & Smith, 2009). A model is presented in which different influencing feedback provision variables in (formative) assessment tools are specified in relation to factors governing a) acceptance of feedback (London, 2003) by specifying different levels of user recognition, adoption, and approval of provided assessment information (Shute, 2008); and b) following recommendations, by specifying different levels of use as the recognized or evidenced implementation of advice and comments made by independent raters; using the Hall and Loucks' theory of Levels of Use (1977). As influencing factors to determine feedback effects different formats of assessment information delivery were used: By contrasting peer assessment as a format in which a) evaluative perceptions of b) fellow students on c) observable classroom behaviours with portfolio assessment as a format in which a) reflection of b) the student him/her self on c) self selected evidence collection

Method

A field experimental pre-test post-test design was deployed using one group of student teachers (subjects as their own control) (n=47) who participated in a training course on learning to teach/teacher preparation in practice schools. During their practice teaching semester students received as their treatment an account of assessment information (written report) on their individual lesson performance which consisted in case of peer assessment of an evaluative scoring by their fellow students of the student's teaching performance and in case of the portfolio assessment of a

written evaluation form with feedback comments from their mentors/supervisors. After receiving assessment information from their assessors on their initial teaching lesson the students filled out the Acceptance of Feedback questionnaire consisting of three scales (based on instrument developed by Tillema & Smith, 2009). After giving a subsequent lesson by the student-teacher assessors (peers or mentors/supervisors depending on the assessment tool used) filled in the Levels of Use questionnaire, specifying the adoption of comments from the initial lesson appraisal (rating scale based on Hall & Loucks' LoU instrument) and a rating scale on student teaching performance for the individual lesson. Pre measurement was conducted using the TPL instrument on student teachers' beliefs on self regulation in professional learning (Tillema, 2010). Analysis of data consisted of Log-linear regression analysis (influence of self-regulation beliefs on assessment condition/instrument) and both criterion variables; as well as Ancova analysis on differences between measurements. The intervention was conducted during one semester with subsequent administration of peer assessment (first) followed by portfolio assessment.

Findings

The results showed that assessment format has a differential effect on acceptance of feedback (mainly on clearness and trust) which subsequently is found to affect following recommendation (mainly on compliant and fidelity of use; but hardly on proficient or expert use). Regression analysis showed a moderate effect ($\beta=.34$). Interaction effect revealed that the portfolio instrument addresses different acceptance criteria (mainly trust) than peer assessment (feasibility); this is also the case for the follow up criteria (peer assessment being related to adaptive use as compared to portfolio assessment with compliant use). Additional regression analyses will be performed on the covariate relations, and change measures: i.e., assessor difference in performance rating between lessons and (improvement in) competence checklist teaching performance.

Conclusion

This finding indicates that assessment tools can be utilized to provide a targeted impact as a result of giving feedback. In essence this study lends support to the argument that assessment information is filtered through the tools by which it is provided which can have far reaching effects on the adoption and subsequent utilization of assessment information (Kluger & de Nisi, 1996). Bridging feedback with subsequent learning builds on the acceptance of feedback as a multi-facetted variable which can be "manipulated" through specific instruction and teaching approaches. Feedback therefore can be framed by the intention and purpose the provider has in mind, and by varying feedback provision tools differential effects can be obtained on subsequent learning.

Assessment and feedback: Making learning visible

Anton Havnes, Oslo University College, Norway; Kari Smith, University of Bergen, Norway; Olga Dysthe, University of Bergen, Norway; Kristine Ludvigsen, University of Bergen, Norway

The main focus of this study is to what extent and how assessment information is received and attended to in educational settings. By empirically investigating how students and teachers use assessment and feedback information, we are generating new knowledge that will bring the international discourse on assessment and feedback forward. The research is linked to a two year intervention project involving six Norwegian upper secondary schools, and with a particular focus on vocational training and the three core subjects English, Norwegian, Mathematics. Data have been collected from three schools, including both vocationally and academically oriented education. The data consists of teacher (N=192) and student (N=391) surveys in all schools, providing a baseline for teachers' structuring of students' use of assessment information and feedback. Other sources of data are focus-group interviews from three of the schools, involving school leaders and teachers (one group of each from each school) and two groups of students from each school (all attending their first year of upper-secondary school). The interviews explore teachers' and students' conceptions of assessment and feedback, as well as how assessment information and

feedback is used to support students' learning, in greater detail. Findings from the study show that there are significant differences in the way students and teachers perceive feedback and the practice of feedback. There are also significant differences between boys and girls, as well as within the various school subjects. Students experience feedback in a more positive manner in practical subjects than in the more traditional academic subjects.

By calling attention to the influence of assessment and feedback on students' learning activities, this project addresses the challenge of improving the quality of teaching and learning. While the focus of assessment research has primarily been on how teachers assess and provide feedback to student (Hattie, 2007; Hattie & Timperley, 2007; Shute, 2008), our focus is on what happens in the wake of assessment: To what extent and how do teachers and students use assessment information in further teaching and learning? The above referenced meta-studies have revealed that at this point there is a gap in existing research knowledge. Instead of taking assessment as an end-point of a teaching-learning process, the focus of the current project is to regard it as a starting point for further learning and development.

Research question

The research question is: How is information from assessment and feedback used by students and teachers in upper secondary school to support students' learning processes and to improve their learning outcomes? The main focus is on what happens in the wake of assessment – to what extent and how assessment information is received and attended to in educational settings. By empirically investigating how students and teachers use assessment and feedback information, we are generating new knowledge that will bring the international discourse on assessment and feedback forward

Context of the study

The paper reports on a two year research and development project in collaboration with the regional county. The project focuses on feedback practices in the three core academic subjects in Norwegian secondary schools: English, Norwegian, and Mathematics. In addition to differences across subjects, we also look at potential differences of feedback in academic programs and vocational education (e.g. cookery, carpentry, hairdressing, car mechanics, etc). Six upper secondary schools are involved. The schools are all situated in the Western part of Norway. To participate in the project all upper secondary schools in the county were invited to apply, and the six project schools were selected according to the following criteria:

Mixture of rural and city schools

Mixture of academic and vocational oriented schools

Mixture of small and larger schools willing to emphasize assessment for learning in the school's development plan

The research project runs parallel to the developmental project. Quantitative survey data have been collected from five of the schools, and qualitative data from three schools, including both vocational training and academic oriented schools.

Study design

The research part of the project consists of two stages. The current paper focuses on an early stage in the project, while the schools were planning interventions in their feedback system and practices. A post intervention study will be carried out in autumn 2011. The early stage interventions mapping consist of: A survey questionnaire to teachers in the five schools teaching Norwegian, English, Mathematics, and Vocational subjects in the first year of upper secondary school (N=192). A survey to all students in the first year of upper secondary schools in the five schools (N=391). Focus-group interviews with groups of teachers and school leaders (one group of each from each school), and two groups of students (separately) in the three research schools. The quantitative data provides a baseline for teachers' structuring of students' use of assessment information and feedback on projects, assignments, and tests. Interview data explore in more details teachers' and students' conceptions of assessment and feedback and how assessment information and feedback is used to support students' learning.

Data analysis

SPSS was used for analysing the quantitative data. Using factor analysis allowed us to condense a large set of variables to four categories; 1) Perceived quality of feedback, 2) Students' use of feedback, 3) Peer feedback, and 4) Student involvement in assessment practice. Correlation analysis was used to examine significant differences between teachers and students in each of the four categories in the various subjects.

Findings

While students express great interest in feedback from teachers and the majority find feedback they get useful, there is no systematic use of feedback. There are only some rare cases where students' use of feedback is structured. Students are not involved in discussing assessment criteria. Moreover, the findings show there are significant

differences between teachers and students in how feedback practice is perceived; what teachers say they do and what students experience. Additionally, it seems that assessment-related activities are to a large extent viewed as an individual activity, and the engagement with peers in relation to assessment is minimal. While there are no differences in feedback practice in the two language subjects (Norwegian and English), there seems to be significant differences between the language subjects and mathematics, and mathematics and vocational subjects. Feedback is more specific in the latter cases. The analysis of the interview data elaborates on leaders', teachers', and students' perception on feedback practices.

Implications

These results go beyond tests, assignments, and projects, and the study addresses feedback as an element in ongoing classroom practice and students' learning activities, in this way providing a broad perception of feedback. The study suggests that more research on how feedback is perceived and used by learners is needed internationally, as well as in the Norwegian context. We therefore see the current study as a starting point in engaging in international comparative research-based discussion as part of the process of developing a deep knowledge base on "what happens with feedback", which is currently missing.

SYMPOSIUM

Neuroscience and education: Examples from the field of mathematics learning

Chairperson: Daniel Ansari, University of Western Ontario, Canada

Organiser: Bert De Smedt, University of Leuven, Belgium

Daniel Ansari, University of Western Ontario, Canada

Discussant: Andrew Tolmie, Institute of Education - London, United Kingdom

The potential contribution of cognitive neuroscience to research on learning and instruction remains a hot and debated issue. In this SIG-Invited Symposium, the field of mathematics learning is taken as a case study to illustrate how transdisciplinary research in the field of neuroscience and education is emerging. Three empirical studies that combine behavioral and neuroscientific methods to answer educational research questions in the field of school-taught mathematics learning are included. The symposium covers a variety of methods, comprising neuroscientific methods, such as functional magnetic resonance imaging and electroencephalography, as well as behavioral methods, such as large-scale longitudinal cohort-sequential designs. Two ways of connecting neuroscience and education are illustrated: (1) Neuroimaging data might provide a level of analysis and measurement that cannot be accessed by behavioral studies alone, adding new insights to theories of arithmetic fact development (2) Neuroimaging data are used as an input to design large-scale studies to examine the development of algebraic mathematical problem solving skills in relation to cognitive demands of existing pedagogical practices, and to investigate the origins of atypical mathematical development. Two contributions originate from Centres for Educational Neuroscience, partially located in Education departments, and will reflect on their general research policy in this new field. All empirical papers will address the theoretical and educational implications of their findings. The discussant will end with a critical discussion from an educational point of view on how the presented studies may or may not contribute to educational research and practice.

Brain activation during arithmetic in children with low and average levels of arithmetical fluency

Bert De Smedt, University of Leuven, Belgium; Ian Holloway, University of Western Ontario, Belgium; Daniel Ansari, University of Western Ontario, Canada

Most studies on mathematics learning in the field of neuroscience and education have investigated the neural correlates of very elementary numerical processing skills in children. Little is known about more complex mathematical skills that are formally taught in school, such as arithmetic. Using functional magnetic resonance imaging (fMRI), we investigated brain activity during arithmetic problem solving in children with different levels of arithmetical fluency. Participants were 28 children aged 10-12 years. During scanning they completed a single-digit arithmetic task, in which they had to select the correct answer to an arithmetic problem. These problems systematically differed in terms of problem size (small vs. large) and operation (addition vs. subtraction). Commensurate with adult data, large problems and subtractions activated a fronto-parietal network, including the intraparietal sulci, the latter of which indicates the influence of quantity-based processes during

procedural strategy execution. Different from adults, we observed that the left hippocampus was active during the solution of those problems that are expected to be solved by means of fact retrieval (i.e. small problems and addition). Children with low levels of arithmetical fluency showed higher activation in the right intraparietal sulcus during the solution of problems with a relatively small problem size, indicating that they continued to rely to a greater extent on quantity-based strategies on those problems that the children with relatively higher arithmetical fluency already retrieved from memory. This might represent a neural correlate of fact retrieval impairments in children with mathematical difficulties.

Background

The field of mathematics learning has been put forward as an ideal workspace for interdisciplinary research in the field of "Neuroscience and education" or "Mind, Brain, and Education" (De Smedt et al., 2010). The majority of studies in this field have focused on the neural correlates of very elementary numerical processing skills, such as the comparison of numerical magnitudes (see Houdé et al., 2010 for a meta-analysis). Less is known about the neural correlates of more complex mathematical skills that are formally taught in school, such as arithmetic, and particularly about how individual differences in arithmetical competence modulate the neural processes recruited by solving arithmetic problems. Against this background, the current study used functional magnetic resonance imaging (fMRI) to investigate how arithmetic problem solving affects brain activation in children who are in the process of becoming arithmetically fluent and how such neural processes differ between children with different levels of arithmetical fluency.

Methodology/Research design

Participants were 28 children aged 10-12 years, who all attended grades 5 to 7. All children completed standardized tests that assessed their mathematical ability (Woodcock-Johnson (WJ) III Math Fluency and Calculation), reading ability (WJ III Letter-word Identification and Reading Fluency), verbal IQ (WISC-IV Vocabulary), and nonverbal IQ (WISC-IV Block Design). Performance on the WJ Math Fluency test was used to define two competence groups. Children were included in the low arithmetical fluency (LAF) group if their standardized score on the WJ Math Fluency test was 1SD below the standardization sample mean. Children were included in the typical arithmetical fluency (TAF) group if their performance on the WJ Math Fluency was within the normal range, i.e. within 1SD of the standardization sample mean. The two competence groups did not differ in chronological age, months of education, reading ability and IQ.

During scanning, all children completed a single-digit arithmetic task, in which they had to select the correct answer to an arithmetic problem. The administered problems systematically differed in terms of problem size (small vs. large) and operation (addition vs. subtraction).

Functional imaging data were collected by means of an event-related fMRI design, which allowed us to examine brain activation during only those problems that were solved correctly. The imaging data were analyzed with Brain Voyager QX, version 2.1 (Brain Innovation, Maastricht, The Netherlands). We calculated a 2 (Problem Size: small vs. large) \times 2 (Operation: addition vs. subtraction) \times 2 (Group: typical vs. low arithmetical fluency) full factorial ANOVA with Problem Size and Operation as within-subject factors and Group as between-subjects factor to examine brain activity during the arithmetic task.

Findings

Analysis of the behavioral data revealed consistent effects of problem size and operation on arithmetic performance: small problems were solved significantly more accurately ($p < .001$).

Commensurate with adult data, large problems and subtractions activated a fronto-parietal network, including the intraparietal sulci, the latter of which indicates the influence of quantity-based processes during procedural strategy execution. Different from adults, the present findings revealed that particularly the left hippocampus was active during the solution of those problems that are expected to be solved by means of fact retrieval (i.e. small problems and addition), suggesting a specific role of the hippocampus in the early stages of learning arithmetic facts. Children with low levels of arithmetical fluency showed higher activation in the right intraparietal sulcus during the solution of problems with a relatively small problem size, indicating that they continued to rely to a greater extent on quantity-based strategies on those problems that the children with relatively higher arithmetical fluency already retrieved from memory.

Theoretical and educational significance

Being fluent and efficient in performing basic calculations is regarded as an important building block for one's mathematical development (Kilpatrick et al., 2001), yet children with mathematical difficulties are known to be delayed in mastering these basic number combinations (Geary, 2004). The current study provides evidence that such

slower development might also be found at the brain level, representing a neural correlate of the retrieval difficulties in children with mathematical difficulties. The present findings also highlight that predictions derived from adult neuroimaging studies may not always be adequate for characterizing functional brain organization in children, by clearly illustrating that the brain regions in children that subserve the computations of problems with a high probability of the use of retrieval strategies are not the same as those reported in previous studies with adults. In view of this, it can be speculated that retrieval is a graded phenomenon, with different levels in the automaticity of arithmetic fact retrieval being associated with different brain regions. Behavioral measures, such as verbal reports, might not always capture such different levels of arithmetic fact retrieval. Neuroimaging data might provide a level of analysis and measurement that cannot be accessed by behavioral studies alone, adding new insights to (educational) theories of arithmetic fact retrieval development in children.

Development of algebraic problem solving skills: math precursor skills and executive functions

Kerry Lee, National Institute of Education, Singapore; Ng Swee Fong, National Institute of Education, Singapore; Rebecca Bull, University of Aberdeen, United Kingdom

Although there are a large number of studies on the teaching and learning of algebra, few are devoted to the development of algebraic thinking with respect to children's cognitive proficiencies. We report findings from a 4-year longitudinal study that examined the relationships between algebraic problem solving, its precursor skills, and children's developing executive functioning capabilities. We also report findings from two neuroimaging studies that examined the cognitive demands of existing pedagogical practices. In the longitudinal study, we used a cohort-sequential design. 650 children (5, 7, 9, and 11 year olds) were administered annually tests of executive functioning (updating, inhibition, switching) and precursor skills believed to be important for algebra (e.g. computation, pattern recognition). Older children were also administered arithmetic and/or algebraic word problems. Preliminary findings showed that updating predicted performances on the mathematical measures for both the younger and the older children. For the 10 and 11-year-olds, the relationship between updating and algebraic proficiency was fully mediated by proficiencies on the computational and pattern tasks. The neuroimaging results showed that even for adults who are competent in algebra, differences between two methods commonly used for solving algebra word problems differ mostly in their demands on attentional or updating resources. These findings suggest that in addition to instructions on the specific content demands of algebra, a focus on the updating demands of algebra and its precursor tasks may be beneficial.

Developmental dyscalculia: Domain specific and domain general contributions

Denes Szucs, University of Cambridge, United Kingdom; Amy Devine, University of Cambridge, United Kingdom; Fruzsina Soltesz, University of Cambridge, United Kingdom; Alison Nobes, University of Cambridge, United Kingdom

Developmental dyscalculia (dyscalculia) is a badly defined concept. Here we define dyscalculia as a selective impairment of mathematics performance. Currently there are contrasting opinions about whether dyscalculia is related to the impairment of a domain-specific number representation in the intraparietal sulci of the brain or whether it may be related to other, more domain general processes, like working-memory, attention or inhibition skills. Here we report the initial stages of a large-scale investigation of dyscalculia. We have screened 926 children from 21 different schools in Cambridgeshire in the United Kingdom. After a thorough assessment of the properties of score distributions we classified about 6% of the sample as potentially having dyscalculia. These children and age, gender and school-class matched controls performing at an average level on mathematics were examined with an extensive battery of tests. Tests investigated variables related to the intraparietal magnitude representation of the brain as well as domain general skills. Systematic differences in performance patterns between children with dyscalculia and control children will be discussed.

Developmental dyscalculia (dyscalculia) is a badly defined concept. Currently there are contrasting opinions about whether dyscalculia is related to the impairment of a domain-specific number representation in the intraparietal sulci of the brain or whether it may be related to other, more domain general processes, like working-memory, attention or inhibition skills. Here we define dyscalculia in a theory-neutral way as a selective impairment of mathematics performance.

On the one hand, mathematics performance is thought to be related to the function of a basic representation of magnitude embodied in the intraparietal sulci. On the other hand, it is clear that success in mathematics requires the interplay of several skills beyond the understanding of magnitude. In previous studies we mapped the development of access to the magnitude representation and compared performance on magnitude tasks to mathematics performance. First, by using electro-encephalography (EEG) and event-related brain potentials (ERPs), in a series of studies [1,2], we found clear evidence that access to the magnitude representation is as effective in 6 to 9 year old children as in adults. In general, when using one digit number comparison, access to the magnitude code seems to

happen at around 200 ms after stimulus presentation in both young children and in adults. In one ERP study we compared access to the magnitude code in adolescents with dyscalculia and in controls in a one digit number comparison task. We found no difference in the ERP markers of access to the magnitude code at 200 ms after stimulus presentation. However, we found a difference at 400 ms after stimulus presentation. In addition, there were differences in group performance on tests of executive functions but there was no robust difference in the most frequent behavioural marker, the numerical distance effect. The data was interpreted to show that the early automatic stages of number comparison are similar in dyscalculics and controls and processing differences arise in later stages of magnitude analysis when executive functions are mobilized. This study gives some indication of more complex, domain general, rather than specific, magnitude representation-related impairments in dyscalculia. In another, behavioural study we mapped the co-development of behavioural markers of the intraparietal magnitude representation in kindergarten [3]. We found all typical magnitude representation markers reported in the literature. However, we found no relationship between magnitude representation effects and several measures of mathematical performance. A factor analysis also identified the magnitude representation measures in a standalone factor, unrelated to mathematical skills.

Overall, our previous studies indicate that the developmental landscape in mathematics is complex and most probably cannot be reduced to the development of a single representation. Hence, dyscalculia probably cannot be explained by the impairment of a single representation. In order to understand dyscalculia, large scale and complex studies are needed, taking into account several potential explanatory factors. This was the motivation for the current study. We report the initial stages of a large-scale investigation of dyscalculia. We have screened 926 children from 21 different schools in Cambridgeshire in the United Kingdom. After a thorough assessment of the properties of score distributions we classified about 6% of the sample as potentially having dyscalculia. These children and age, gender and school-class matched controls performing at an average level on mathematics were examined with an extensive battery of tests. Tests investigated mathematical and domain general skills. Systematic differences in performance patterns between children with dyscalculia and control children will be discussed.

SYMPOSIUM

Measuring Outcomes of Professional Education

Chairperson: LEIF CHRISTIAN LAHN, UNIVERSITY OF OSLO, Norway

Organiser: Susanne Weber, Ludwig-Maximilians-Universität-München, Germany

Discussant: Richard Shavelson, Stanford University, United States

Various socio-economic and technological changes have a decisive implication on job requirements, on the demand for skills and competencies as well as on the processes of skill acquisition in different institutions (schools, universities, vocational training, workplaces). With regard to changes within the service sector we can observe a shift towards the requirement of more flexible jobs as "creative knowledge workers", "entrepreneurs" with corresponding claims for more general, more analytical, managerial, entrepreneurial competencies and skills like teamwork, networking, autonomous acting, self-regulation, self-organized learning and business planning etc. To keep pace with these developments in the world of work it is necessary to investigate learners' characteristics (not only as traits but also as states), the specific learning and knowledge acquiring processes in different settings and phases as well as the output and outcome of workplace learning. In the first paper the different learning and knowledge construction outcomes of engineering students are investigated when confronted with the instructional measure of internships at the workplace. The second paper reports on investigating decisive personality traits and states relevant for launching a firm. In the third paper the focus is on teaching business planning as a decisive entrepreneurial skill by implementing new instructional designs of entrepreneurship education in higher education. Hereby different aspects of entrepreneurial competencies are measured as a result of the treatment.

Individual differences in learning during internship in engineering education

Vincent Donche, University of Antwerp, Belgium; David Gijbels, University of Antwerp, Belgium; Piet Van den Bossche, University of Antwerp, Belgium; Peter Van Petegem, University of Antwerp, Belgium; Ingrid Ilsbroux, Internationale Hogeschool Leuven, Belgium

To increase our understanding of the quality of learning at the workplace, we investigated how future engineers differ in their engagement in cognitive and regulative activities during their internship in companies. Using the framework of dynamic sources of regulation of student learning during internship (Oosterheert & Vermunt, 2001) we aim to broaden current understandings about the quality of self-regulation and knowledge construction in workplace learning contexts. In an exploratory study we questioned how individual differences in learning are present among engineering students (N = 66) taking part at a long term internship during engineering education. The study indicated a considerable variety in how students regulate their learning and how they construct knowledge during internships. Five different dimensions of knowledge construction (KC) were distinguished: (1) KC through external regulation; (2) KC through self-regulation, (3) KC by actively relating theory to practice, (4) KC in close collaboration with co-workers, and (5) no knowledge construction or avoidance behaviour. The ways in which engineering students learn were also found to be associated with their motivational drive. This study underlines the importance of investigating the multi-dimensionality of regulation behaviour and knowledge construction during internships at the workplace. For practice, the results point at the importance of taking individual differences in learning into account when (re-)constructing effective workplaces for learning.

Extended summary Introduction and aims.

In today's rapidly evolving society, we are confronted with an exponential increase in information, a growing need for innovation, and the requirement to develop sufficient skills. In line with a rapid evolution towards a global knowledge society, our contemporary job market is making new demands on students and professionals at work. As Dall' Alba (2009, p. 4) describes very clearly: "Professionals in many countries around the globe are working in a context of continual change, including advances in biotechnology, computers and the internet, globalisation of the economy, expanding knowledge- and service-based industry, heightened threats to national and international security, and increased professionalization of the workforce. The ensuing context of flux and uncertainty presents new and pressing challenges for professionals, while reliance upon their skilful participation in society is heightened. Professionals are being required to take new issues into account before those issues can be fully grasped, while continuing to make judgements, acting on the basis of those judgements, and facing the consequences of their actions". Being successful in a job these days often implies being capable of operating in ill-defined and ever-changing environments, dealing with non-routine and abstract work processes, handling decisions and responsibilities and working in teams. Formal learning programmes alone aren't able to keep up with rapid changes (developments) in society to provide (future) workers with all necessary knowledge, skills and attitudes. Therefore, learning at the workplace, is increasing in importance for retaining a productive workforce and for the employees themselves in retaining their employability. Everyday work practice is full of potential learning processes. These learning activities during work can be very effective and necessary for the purposes of becoming more expert in a profession. Despite the theoretical reasoning, research on work-related learning and its antecedents has remained rather scarce. In many professional fields, internships are provided as an indispensable part of the education towards professional competence. It is suggested that the confrontation with the workplace triggers learning. To increase our understanding of the quality of learning at the workplace we investigated how future engineers differ in their engagement in cognitive and regulative activities during their internship in companies. Using the framework of dynamic sources of regulation of student learning during internship (Oosterheert & Vermunt, 2001) we aim to broaden current understandings about the quality of self-regulation and knowledge construction in workplace learning contexts. Two research questions are central: (1) Which dimensions of knowledge construction and regulation can be distinguished during internship?(2) Can distinct groups of learners be distinguished using dimensions of knowledge construction and regulation?

Methodology.

In an exploratory study we questioned how individual differences in learning are present among engineering students (N = 66) taking part at a long term internship during engineering education. Hereto, a selection of scales of the ILTP-questionnaire (Oosterheert, Vermunt, & Denessen, 2002) used to map differences in student teacher learning during internships was translated to the specific context of learning during engineering internships. In addition, the goal orientation questionnaire was administered. Exploratory factor analyses, correlation, and regression analyses were applied to investigate the interrelatedness and predictivity between the constructs under study. Hierarchical cluster analyses were carried out to explore learner group differences. Results. The study indicated a considerable variety in how students regulate their learning and how they construct knowledge during internships. Five different dimensions of knowledge construction (KC) were distinguished: (1) KC through external regulation; (2) KC through self-regulation, (3) KC by actively relating theory to practice, (4) KC in close collaboration with co-workers, and (5) no knowledge construction or avoidance behaviour. The ways in which engineering students learn were also found to be associated

with their motivational drive. Especially mastery oriented students undertake active and self-regulatory learning activities when learning at the workplace and they learn in close interaction with colleagues, which is in line with the research body on students' approaches to learning and achievement goal theory. Person oriented analyses techniques show the presence of different groups of engagers and avoiders regarding knowledge construction during internships. Theoretical and educational significance. This study underlines the importance of investigating the multi-dimensionality of regulation behaviour and knowledge construction during internships at the workplace. The practical relevance of this study can be situated on different levels. First of all, the study provides further evidence for a valid, reliable, and convenient questionnaire to map different cognitive and regulative activities among learners during internships at the workplace. Second, the results point at the importance of taking individual differences in learning into account when (re-)constructing decent workplaces for learning.

On diagnosing the capacity to launch a firm: A test for entrepreneurial competences

Fritz Oser, Universität Freiburg, Switzerland; Heiko Bergmann, Universität St. Gallen, Switzerland; Thierry Volery, Universität St. Gallen, Switzerland; Nuria Del Rey, University of Fribourg, Switzerland.

The education of young entrepreneurs is often based on the results of diagnostic instruments. The main question is, to predict the founding volition of a person and her founding realization by means of personality traits. Such questioning bears the danger that educational policy makers believe that there is an inborn personality structure that "automatically" leads to set up a company. – We developed a new instrument, which is not only based on psychological traits like general achievement motivation or on specific personality sets like innovation affinity, but also on specific beliefs, competences, knowledge, opportunities to learn and launching intentionalities. This new instrument was tested in a pre-version and in a main investigation. The online questionnaire was linked to participants in "Venture Challenge" courses (A), "Venture Ideas" workshops (B) and to students of the universities Fribourg and St. Gallen (C), who were rather not interested in business foundations. A total of 21 scales were generated. In the first analysis we compared persons without intention for company creation with persons who are interested in company creation and finally with persons that already founded a company. The second comparison was taken from the three groups mentioned above. The results are convincing: In all scales persons having experience with launching an enterprise scored significantly higher than the other two groups. Subjects participating in the venture lab scored also significantly higher than "normal" students. The results will be used for the development of a valid and reliable instrument for distinguishing founders from non-founders.

Aim

Until today most of the diagnostic instruments for predicting entrepreneurial capacities deal with personality traits (Gartner, 1988; and meta-analysis' from Collins et al. 2004; Rauch & Frese, 2007; Zhao & Seibert, 2006). But from daily experience we know that the entrepreneur is the important motor for launching a firm, and that personality traits are certainly not enough for it. It is needed optimal contextual conditions, it needs staying power, and it needs financing, planning, marketing and legal knowledge (Fýglistaller et al. 2008; Carsrud & Brännbeck, 2009; Walter & Walter, 2009). Our question is whether it is possible to develop an instrument, which includes more than personality concepts and thus leads to higher predicting validity. Especially the launching success or at least beliefs about it should be taken into consideration with a new instrument. Whereas until now researchers measured especially psychological traits like self-efficacy beliefs, general achievement motivation, stress resistance etc. or specific personality sets like entrepreneurial achievement motivation and self efficacy beliefs, search for autonomy, risk attendance, innovation affinity etc., we now wanted to go beyond such restrictions. We wanted to integrate specific beliefs about success and overcoming problems, competences, that are needed for a start up, knowledge on economical and legal issues,

opportunities to learn in settings where someone had founded already a firm and launching intentionalities, that means internal planning of becoming independent.

Method I

A first step we developed a set of questionnaire items taken partly from an instrument we developed 2 years ago, taken from other personality questionnaires and developed by our own experience with founders having launching knowledge. Some few interviews helped us to validate some of our item propositions. Especially the dimensions beliefs, competences, knowledge, opportunities to learn and launching intentionalities were completely new. The thus developed new instrument was tested twice, in a pre-study and a main study. The questionnaire was developed in an on-line format. It was linked to participants in a "Venture Challenge" course A (n=76), to participants in a "Venture Ideas" workshop B (n=389) and to students of the universities Fribourg and St. Gallen C, who rather were not interested in business and business foundations. A total of 179 cases emerged, A=82, B=62 and C=35 (this total consisted of data from the pre- and main data collection, because of identical item numbers and item structure). The descriptive statistics reveals that the difficulties of the items range from 1 to 3. An item with the mean of 0.6 is of high difficulty because only few persons answered it in the sense of entrepreneurial shape. An item with the value 2.6 would be an item easy to solve because most of the respondent answered to it in the sense of entrepreneurial shape. The inter item correlation laid between 0.3 and 0.7; the Cronbach's alpha ranged from .62 to .92. In total we had 21 scales with item numbers ranging from 2-10. For the knowledge items no Cronbach's alpha is given, because of the scale format. From the 5 belief scales (desirability, realization possibility, optimal setting conditions, personal benefit and subjective norms) the optimal setting conditions had a too low Cronbach's alpha and had to be cut off.

Results

The interesting question was about differences between the reference groups. As said up off we compared on one hand real entrepreneurs with subjects who were interested in launching a firm and "normal" students trying to answer the questionnaire as a testing exercise. On the other hand we differentiated between participants of a venture challenge course with participants of a short venture ideas workshop and "normal" students. Let's take two examples of each group. With respect to the belief variable, "realization possibility", students elicit a value of .88, interested subjects 1.71, and entrepreneurs 2.39 (p in both comparisons). With respect to further research we would like to suggest first a scale reduction in the sense that this entrepreneur test lasts not more than 25 Minutes. In addition we would like to create a program that gives each individual feedback about his/her entrepreneurial competences. For that issue we must discuss further entrepreneurial benchmarks and optimal entrepreneurial competence clusters.

Assessing "Networking" and "Teamworking" within Entrepreneurship Education

Susanne Weber, Ludwig-Maximilians-Universität-München, Germany; Stephanie Starke, University of Munich, Germany; Sabine Funke, Human Resource Education & Management, Germany

Entrepreneurial activities are linked with economical growth (European Commission, 2004; KOM, 2006; Sheshinski, Strom & Baumol, 2007). Therefore, entrepreneurship education is set on the agenda of educational programs for all levels. This is especially the case for academic programs (Audretsch, 2007; KOM, 2006), because the impact of academic entrepreneurs is higher than those with lower grades: academics tend to employ more people, make higher investments, perform better and create important spill-over effects for the regional economy (Harhoff, 1999; von Gravenitz, Harhoff, & R. Weber, 2010). For coping with these different challenging entrepreneurial tasks a lot of skills and competencies are required. Studies show that central entrepreneurial tasks are better be solved if individuals possess and can refer to social capital (Walter & Walter, 2006; Volery & Shaper, 2007; De Carolis, Litzky, & Eddleston, 2009). This can be built and developed by activities of "networking" (Wolff & Moser, 2006) and "teamworking" (Stevens & Campion, 1994). Within our paper we operationalized these two concepts, try to foster them within an innovative real-life business planning course for business students on the tertiary level and assessed the output and structure of "networking" and "teamworking".

Aims

Business Planning as a complex task within entrepreneurship education can better be managed and solved by a team rather than alone (Aronson et al., 1998; Baron & Byrne, 1997; Figl, 2010, 12-13). The ability of "networking" (Wolff & Moser, 2006, 162) and "teamworking" (Stevens & Campion, 1994) gets indispensable. The corresponding literature is extensive and diverse, with multiple roots. Here we understand "networking" as a skill: It "circumscribes a syndrome of behaviours that are aimed at building, maintaining and using informal relationships that possess the (potential) benefit of facilitating work-related activities of individuals by voluntarily granting access to resources and maximizing common advantages" (Wolff & Moser, 2006, 162). Studies on entrepreneurship show that networking leads to bigger and more valuable networks with abundant, non-redundant resources which is a comparative advantage for

entrepreneurs. Granovetter (1973, 1361-1369) differentiates with regard to the quality of networks between so-called "strong-ties" and "weak-ties". "Strong ties" represent very narrow, time intensive and emotional connections where the persons involved have commonly shared knowledge at their disposal. "Weak ties" represent rather loose connections where persons involved have different knowledge and information. Social networks with "strong ties" are typical for entrepreneurs in start-up phases (Jack, 2005; Volkmann & Tokarski, 2006), but are also of disadvantage for innovative acting (Elfring & Hulsink, 2003). One decisive criterion for running different strategies of "networking" is the individual's perception of group potency (Guzzo et al., 1993; Stajkovic et al., 2009), whereby a high degree of group potency is a valid predictor of team success (Gibson, Randel & Early, 2000, 67-68). Successful entrepreneurs use networking for generating social context, tying entrepreneurial resources to bunches, building up organizational structures (Slotte-Kock & Coviello, 2009). We understand "teamworking" as two or more individuals' interacting within or between ("work" and "learning") teams (Johnson & Johnson, 2006, 18-21; Gladstein, 1984). They share common goals, are aware of their positive interdependence for striving achievement, and also aware of who is and is not member of a team, they have specific roles or functions to perform, and desire a productive outcome (Baker et al., 2005). Effective and high performance groups feel responsible for the common success, have a high degree of commitment and outperform their expectations. They also exhibit synergy and achieve "more than the sum of its parts" (Johnson & Johnson, 2006, 18-21). Such teams are built for start-ups as the tasks for business planning are complex and include lots of task types (e.g., additive, compensatory, disjunctive) which are better managed and solved by a team than alone (Steiner, 1972; Fischer & Wiswede, 2002; Aronson et al., 1998; Baron & Byrne, 1997; Figl, 2010, 12-13). Individual resources of "knowledge", "skills" and "abilities" are required beside personality traits, technical skills or resources on a collective team level (Tannenbaum Beard & Salas, 1992; Stevens & Campion, 1994, 503; Figl, 2010, 14-15). Reviews show that the process of "effective teamwork" is mainly represented by the two broad dimensions of "task management" (task reflexivity) on the one side with subdimensions of "goal setting", "planning" etc. and "interpersonal interaction" (social reflexivity) on the other side with subdimensions like "communication", "collaboration" and "conflict management" etc. (West, 1994; Stevens & Campion, 1994, 505; Kauffeld, 2001; Figl, 2010). Individuals holding such teamwork competencies are more successful (Rader, 1989; Stevens & Campion, 1994); they end up with high task effectiveness, good mental health and perform long-term viable solutions (West, 2004, p. 3). Furthermore, by more complex group tasks and more collaboration team members learn more about such attributes of teamwork (Kotey, 2007). As both "networking" and "teamworking" can be trained (Wolff & Moser, 2006) our research questions are: (1) Is it possible to increase these two competencies by a business planning course in a tertiary entrepreneurship program? (2) How do students engage in networking behaviour and which kind of relations are used when students are faced with a challenging task? (3) Is networking used as a compensatory approach when teams report low group potency? (4) Does the course result in positive effects concerning the entrepreneurial intention of students?

Methodology

Within our study we implemented a pre-post-experimental-control-group design in a German School of Management (N=429; average age 24,4 years (SD = 2,35); 210 females). In a first step we measured "networking"-behavior by a 12-items Likert scale by Wolff & Moser (2006) combined with the "willingness to communicate" scale of Mc Crosky (1992) (20 items), and "group potency" by an 8-items Likert scale (Guzzo et al., 1993). "Teamworking"-competence was measured in a second step by the cognitive achievement test of Stevens & Campion (1994) (35 items) as well as the team attitude scale (15 items) by Baker et al. (2005). The treatment was a one semester business planning course, where the students had to modify and advance the business plan of a real entrepreneur by working within small teams of 4-5 students.

Findings

By a confirmatory factor analysis we could confirm three dimensions of "networking" behaviour (building, maintaining, using) ($\chi^2/df=90$; SRMR.95; CFI>.97) (Schermelleh-Engel, 2008, 52). Significant progress of networking behaviour turned out for the experimental group ($\chi^2_1=4.19$; $\chi^2_2=4.39$; $p=.001$; $d=.28$) but not for the control group (which did not get an explicit treatment). Comparable advantages were given for "group potency", "willingness to communicate" and the "use of strong or weak ties". Furthermore, networking explains a significant part of the variance of the learning outcome (measured by achievement, grade, course satisfaction). For assessing teamworking competence IRT measurement was run by using Conquest (Wu et al., 2007). We could confirm our model by acceptable fit values (separation reliability = .983; $\chi^2/2 = 1814.16$; $df=34$, p Theoretical and educational significance of the research Describing and visualizing networking and teamworking competencies is an essential step for fostering these important 21st century skills in a sustainable way. The detailed analyses allow made to measure training methods. By IRT we can map out the item estimates separately from the individuals' ability estimates – and therefore, analysing individual competencies in relation to other variables of teamwork.

SYMPOSIUM

Methodological Perspectives on Researching Learning with ICT

Chairperson: Crina Damsa, University of Oslo, Norway

Organiser: Joerg Zumbach, University of Salzburg, Austria

Maria Beatrice Ligorio, University of Bari, Italy

Crina Damsa, University of Oslo, Norway

Discussant: Charles Crook, LSRI, United Kingdom

Learning with technological support had become a common site in contemporary educational practice. Consequently, research on ICT-supported learning emerged as a prominent field in teaching and learning research. With the width of these developments, research methodology employed for, e.g., investigating the functioning, applicability and efficiency of new approaches varies. Research studies range from strictly controlled experiments with single applications, to qualitative studies of complex electronic learning environments, or case studies of single learners using technology. In this symposium different theoretical and methodological perspectives on ICT research for learning will be presented. The aim is to create the settings for an open academic discussion on the assets of each of these perspectives. The speakers represent the fields of cognitive experimental methodology and of qualitative, ethnographic methodologies, and will present their stances and ideas on this topic. The discussion will focus on commonalities and diverging points between different approaches. As an outcome, we hope to facilitate a deeper understanding of how various research methodologies can serve the investigation of the educational technology in a meaningful manner.

Hybrid minds: researching learning and reasoning in the context of (digital) artefacts

Roger Saljo, Goteborg University, Sweden

Digital technologies produce important changes in the manners in which artefacts are intergrated into human activities. Storing, access and manipulation of information are examples of activities that currently undergo change. We now have the ability to externalize not just information but also to an increasing extent sophisticated cognitive processes. Thus, our future intellectual capacities are neither restricted by our innate abilities, nor bounded by the skin of our bodies; our minds and mindful practices rely on productive "mergers and coalitions" (Clark, 2003, p. 7, *italics in original*) with powerful and increasingly sophisticated external tools that the sociocultural evolution produces. For the study of learning and development this implies that digital technologies are not just resources for learning, they are also increasingly part of a cognitive infrastructure that we have at hand. We constantly oscillate between mind, body and external tools in the flow of our activities, and they give us new access points to knowing (Giddens, 2002). This evolution of technologies challenges the largely Platonic view of learning and development which dominates research. Alternative conceptions of learning and development have to rely on a different unit of analysis that incorporates tool-mediated action as object of research, and they have to accommodate to the fact learning itself is transformed in such circumstances from a reproductive to a more performative practice.

Everyone is willing to accept that physical – or primary (Wartofsky, 1979) – artefacts have changed the manner in which human beings lead their lives and perform many, if not most, activities. Hammers, tongs, saws, spirit levels and a range of increasingly sophisticated instruments have changed the manners in which we build houses, and spades, rakes, lawn movers and excavators have transformed how we lay out a garden. Such tools extend the strength, power and staying power of human performance in dramatic manners, and they transform the very activity they are part of. Lifting heavy objects does not rely on human strength if we have an excavator, and to drive a nail into a piece of wood are much simpler activities with designed artefacts. Our capacity for mastering nature has expanded in symbiosis with such external resources. It is much more difficult to gain widespread acceptance for the idea that there are tools and instruments of the mind that operate in analogous manners; they help us to operate in a world of ideas and discursive activities, and they provide resources for perspectivizing the world and conceptualizing it differently. Access to ideas and concepts such as those of measurement systems, grammar, legal systems and of various sciences help us organize our experiences and communicate with others in increasingly precise manners. We contextualize the world by framing it in discursive categories that suit a particular activity. We do mental digging and excavation by means of such intellectual or psychological tools (Vygotsky, 1978). In addition, most human practices imply combining materiality with intellectual tools; writing is a technology using symbols in combination with physical objects, and calculating is done by means of number systems implemented on artefacts (Cole, 1996). Such material-symbolic artefacts serve as our companions when we reason, remember and reflect. Through history, our practices – cognitive as well as physical – have become increasingly dependent on such material-symbolic artefacts that have emerged in society, and that we learn to use for specific purposes. Hybrid minds and research on learning.

The background of this presentation is an interest in the role of artefacts in human reasoning, learning and social action. The idea of the hybrid mind was introduced in the analysis of the evolution of human cognition presented by Donald (1991; 2001), but this line of thinking is present in the analytical frameworks of many cultural psychologists, anthropologists and other students of the evolution of human resources for thinking and reasoning (Cole & Derry, 2005; Kirlik, 2005; Nelson, 1996; Nickerson, 2005; Ong, 1982). The hybridity of human mindful activity is now so obvious that we tend to view professional competence as very much a manner of skilfully being able to handle instruments such as electronic scalpels (surgeons), advance book-keeping software (accountants) and gps-navigators (in a range of professions such as captains at sea, taxi drivers, emergency vehicle drivers etc.) Digital technologies imply important changes in the manners in which artefacts can be intergrated into human activities. Storing, access and manipulation of information are examples of activities that currently undergo change. We now have the ability to externalize not just information but also to an increasing extent sophisticated cognitive processes. Thus, our future intellectual capacities are neither restricted by our innate abilities, nor bounded by the skin of our bodies; our minds and mindful practices rely on productive "mergers and coalitions" (Clark, 2003, p. 7, italics in original) (Clark, 2003) with powerful and increasingly sophisticated external tools that the sociocultural evolution produces. For the study of learning and development this implies that digital technologies are not just resources for learning, they are also increasingly part of a cognitive infrastructure that we have at hand. We constantly oscillate between mind, body and external tools in the flow of our activities, and they give us new access points to knowing (Giddens, 2002). This evolution of technologies challenges the largely Platonic view of learning and development which dominates research. Alternative conceptions of learning and development have to rely on a different unit of analysis that incorporates tool-mediated action as object of research, and they have to accommodate to the fact learning itself is transformed in such circumstances from a reproductive to a more performative practice.

Basic Experimental Research on Learning with ICT

Roland Bruenken, Saarland University, Germany

Common instructional design theories underlying the development of Information and Communication Technologies (ICT) are often based on assumptions derived from cognitive psychology. Prominent examples are Mayer's Cognitive Theory of Multimedia Learning (Mayer, 2009) and Sweller's Cognitive Load Theory (Sweller, 2010). As technological theories, both aim at supporting instructional design decisions by evidence derived from different forms of empirical research like lab experiments or field experiments of evaluation studies. However, it often remains unclear, whether the underlying assumptions borrowed from basic psychological research are sufficient and used in an adequate way. Illustrated by two series of basic experimental lab studies on combining different cognitive load effects (series one) and on measuring cognitive load (series two) the options and limits of theory-testing psychological research to improve instructional design theories and practice are discussed.

Learning with ICT is one of the major topics of current educational psychology research. Two of the most prominent theoretical models in the field of learning with ICT are the Cognitive Theory of Multimedia Learning (CTML) proposed

by Rich Mayer (e.g. Mayer, 2009) and John Swellers Cognitive Load Theory (CLT) (e.g. Sweller, 2010). While both theories focus on different aspects of information processing, they are more or less compatible with each other. The CTML focuses on aspects of knowledge processing and representation in the human information processing system; CLT focuses on the consumption of (limited) cognitive resources and its relation to efficient learning with ICT. Both theories are characterized by borrowing diverse theoretical assumptions from cognitive psychology and combining them into integrated instructional design models (ID models), like Paivio's dual-coding theory (Paivio, 1986), Bartlett's schema theory (Bartlett, 1932), the three component model of memory from Atkinson and Shiffrin (1968), or Baddeley's working memory model (Baddeley, 1986). These integrated ID models are used to formulate "design principles" (Mayer, 2009) which are proposed to be suitable to guide design decisions of instructional designers as well as to explain differences in learning success while using different variants of ICT. However, when integrating theory pieces from diverse sources of basic psychological research into an integrated model of applied psychology, the question arises whether the whole is more than the sum of its parts. Can the effects found in basic research be replicated also in applied settings or has the increased complexity of the new setting an impact on the basic processes?

To answer this questions more research is asked for which links basic and applied research (e.g. Gerjets, 2010). However, ID models in general are hardly testable in total because of their complexity. Taking them seriously as psychological theories, they should be nevertheless testable at least in their core assumptions. In our view, this demand could be met by experimental research in at least two different ways: (1) by increasing the complexity of the experimental research from one-factorial to multi-factorial designs and (2) by applying research paradigms of basic psychological research in applied psychological research (Brýnken, Seufert & Paas, 2010). The first strategy should be suitable to prove theory based application assumptions like the consideration of multiple design principles in a controlled experimental setting and moreover test the underlying ID model. The second strategy should be suitable to test the basic assumptions of the ID model by testing the "borrowed" ideas in the new, applied field using established methods from basic research.

In the present talk we will show both research strategies by examples from our research group. With respect to (1) increasing the complexity of the experimental design, a series of three experiments will be presented on the simultaneous variation of different design principles and their impact on learning success and cognitive load; with respect to (2) applying research paradigms of basic research, the application of the dual-task paradigm to cognitive load measurement while learning with ICT is presented by three different experiments using different secondary tasks. Results revealed from various experiments of our research group lead to the conclusion that some of the basic assumptions of the ID models can be confirmed by basic experimental research, like the relation of learning efficiency and resources consumption, while other rather applied assumptions of the models like the beneficial effect of the simultaneous consideration of multiple design principles in form of a simple additivity hypothesis have to be thrown into question. With respect to an overall methodological point of view, it can be stated that basic experimental research on learning with ICT is suitable to test the assumptions of ID models on learning with ICT as well as to prove whether findings from basic psychology can be generalized to applied fields of psychological research.

Combining different methodologies in computer supported collaborative learning

Sten Ludvigsen, University of Oslo, Norway

The empirical investigation in computer supported collaborative learning (CSCL) is mostly based on two different approaches, that is a) cognitive science and methodological individualism and b) a sociocultural approach based on methodological collectivism (Wertsch, 1991; Linell 2009). In controlled studies based on methodological individualism we optimize control of variables, and get insight into which specific cognitive processes and performance a CSCL environment will activate for the students. This means that we will be able to describe and explain the differences between the students. We can here specify how different tool features support cognitive performances. By means the socio-culturally oriented studies we can optimize ecological validity. These studies make it possible to explore and understand under which social conditions specific cognitive processes become activated and under which conditions students' collaboration is productive for their understanding of knowledge domain(s).

The cognitive science, with its close relationship with experimental psychology, provides a strong basis for the research within the CSCL field. In experimental psychology, a leading idea is to identify how different variables have an impact on cognitive functions and performance of individuals. In experiments, one tries, based on the idea of falsification, to understand which variables are the most important under the given condition (Popper, 1963). This means that the empirical evidence either supports or challenges models or theories that the research is based on. However given that the theories or models are built up on a high number of experiments, the issue at stake is more about refinement of models, or theories, rather than major changes. This means that the cumulative effects are based on two different aspects; the empirical analysis and the model/theory. This often idealised model or theory is referred to as "the information processing model".

In philosophy of science this model is based on ideas of methodological individualism, implying that the unit of analysis is the individual human mind. This idealised model of human cognition has been essential in projects the last 15 years. Another influential research approach represented in the CSCL is the socio-cultural approach. Since the 1990s what came to be termed as situated or socio-cultural approaches contributed to developing a research program build on different assumptions than the information-processing model. These assumptions are building on the idea that cognitive, social and cultural aspects of the human mind are interdependent and cannot be studied as independent variables. However the situated tradition have long historical roots back to sociocultural and pragmatic perspective developed in the 1920s both in Europe and USA by theorists such as Vygotsky, Mead, and Dewey. It is possible to argue these two research approaches are incommensurable, and that the many attempts to combine or synthesis the two of them have not been successful. Especially since the two approaches are based on different epistemological and ontological assumptions (see Greeno, (2006) for reasonable account for one type of synthesis. We could argue that a theoretical synthesis is not the best solution to this problem. CSCL studies based on the two approaches will make it possible to capture different aspects of students' learning activities, processes and outcomes. This way the two approaches can contribute to a more robust understanding of the phenomena under investigation. Furthermore, the two CSCL research approaches enable empirical studies that optimize two different methodological orientations; a) an orientation towards the individual as unit of analysis and b) an orientation towards the interactional processes as the unit of analysis.

A set of studies can be designed for understanding the context and activities in a broad sense, which means that we optimize the methodological principle of ecological validity. Such studies will cover the social organization, the institutional aspects, the social interaction and sense making around a selected number of tools, and a focus on students' individual and collective learning processes. The students' learning trajectories can be targeted by means of pre- and post-tests, studies of the students' production of objects, and analyses of students' tool use and interaction during their working processes. Such analytic focus can give a robust account of what it's possible to learn in an environment a CSCL, and also seen in relation to the institutional context in which the CSCL environment is used. The most central question in scientific activities is on what grounds we can generalize our findings. It's a long and heated debate about differences in education research about generalizations. In a recent contribution by Ercikan and Roth (2009) a more constructive route is taken. Along these lines, we argue that high-level generalization must of course be based on statistical means. By high level we here talk about claims that involves findings such as "80% of Norwegian students in the Pisa studies have high score on problem solving skills". In most CSCL projects we do not aim for this type of generalization. We aim for what we can call analytic and theoretical generalizations, or what we here label mid-level generalizations. The socio-culturally oriented studies aim to optimize ecological validity. These studies make it possible to explore and understand under which social conditions specific cognitive processes become activated, and under which conditions that students' collaboration is productive for their understanding of the knowledge domain(s). In the controlled studies, where one optimizes control of variables, we can gain insight into which specific cognitive processes and performance will activate for the students. This means that we will be able to describe and explain the differences between the students. We can then further specify how different tool features support cognitive performances. These two approaches imply that the types of generalization we can do are both analytic generalizations and theoretical generalizations, building on the two different methodologies. The analytical

generalizations will be the summary of empirical findings within a set of conducted studies based on both types of approaches. Theoretical generalizations would be the kind of generalizations that can be made within each of the two methodological orientations, and not across, since the generalization here involves the theoretical assumptions in which the studies build on. Both types of generalization are what we can call mid-level generalizations, which means that we aim for generalization based on the following logic; what kind of cognitive processes and activities can occur in relation to which types of tools, and under which types of social conditions.

SYMPOSIUM

Conceptualizing and Measuring Teacher Learning

Chairperson: Maaïke Endedijk, University of Twente, Netherlands

Organiser: Fritz C. Staub, University of Fribourg, Switzerland

Discussant: Frances Rust, University of Pennsylvania, United States

To advance our understanding of the causal chain from teacher preparation or teacher development programs to the achievement of pupils in classrooms we need reliable and valid outcome measures for teacher learning and well grounded conceptualizations for the processes that lead to the development of professional competencies. The aim of this symposium is to bring together research that provides different perspectives and methodological approaches of conceptualizing and measuring teacher learning. In his position paper Vermunt discusses alternatives for conceptualizing and measuring elements of a model of teacher learning (e.g., learning activities, motivation to learn, learning outcomes, and personal and contextual factors) that takes student learning as a point of departure. Based on a model of professional competence and corresponding standardized tests and questionnaires for large-scale research Kunter, Baumert, Kleickmann and Richter investigate the change and stability of knowledge, beliefs and motivational-affective variables during the induction phase of teacher education and search for institutional and individual factors that moderate change trajectories. Kreis and Staub study student teachers' talk with mentor teachers about specific lessons in practica. Based on detailed analyses of such discourse in pre- and post-lesson conferences the goal of this research is to identify discourse moves and characteristics of lesson conferences that foster the learning of student teachers. Rust will address the underlying theoretical and methodological conceptualizations of the presented research and discuss its contribution for the advancement of teacher and pupil learning.

Teacher Learning from the Perspective of Student Learning

Jan Vermunt, Utrecht University, Netherlands

The aim of this paper is to contribute to the development of a model of teacher learning that takes student learning as a point of departure. A firm link between models of teacher and student learning is considered important, because this link can improve our understanding of the "chain of causation" from teacher professional development initiatives to student learning outcomes. The model comprises the following elements: learning activities, regulation of learning, beliefs on learning, motivation to learn, learning outcomes, and personal and contextual factors. I will propose suitable conceptualisations for the domain of teacher learning for all elements of the model. To that end, relevant research literature from a variety of research fields was explored, among which: student learning, teacher learning and professional development, teacher education, and professional and workplace learning. Research on top-down, prescriptive models as well as bottom-up, descriptive models were included. The literature was also explored for measurement instruments that are in line with the conceptualisations considered suitable. For every element of the model, the literature search revealed several possible conceptualisations. I will use recent empirical studies from our research program on 'teacher learning and expertise throughout the professional career' to illustrate and underpin the choices we made for concepts and measurements. The discussion will focus on the current state of the art of the scientific knowledge base of teacher learning from the perspective of student learning.

Aims

The study of teacher learning is a relatively young field. Programs for teacher professional development all claim to foster teacher learning, yet vary widely in their characteristics and theoretical underpinnings, if these underpinnings exist at all. Most models of teacher learning are prescriptive, in the sense that they describe how teachers should learn best. In my view, any attempt to foster teacher learning should be based on solid scientific knowledge about how teachers learn in natural contexts. The aim of this paper is to contribute to the development of a model of teacher learning that incorporates the state-of-the-art scientific knowledge about teacher learning and that takes student learning as a point of departure. A firm link between models of teacher and student learning is considered important, because this link can improve our understanding of the “chain of causation” from teacher professional development initiatives to student learning outcomes.

Methodology

The model is derived from research on student learning. It comprises the following elements: learning activities, regulation of learning, beliefs on learning, motivation to learn, learning outcomes, and personal and contextual factors.

A model of teacher learning

The elements of the model are identical to the elements of models of student learning, but the way these elements are conceptualised is quite different. For example, in the field of student learning ‘learning outcomes’ are often conceptualised as scores on a knowledge test. In the field of teacher learning, knowledge tests are not felt to be a sensible measure of learning outcomes. There is a need for different conceptualisations. The same holds for the other elements of the model.

In this paper, I will propose suitable conceptualisations for all elements of the model. To that end, relevant research literature from a variety of domains was explored: student learning (e.g. Entwistle, 2009), teacher learning and professional development (e.g. Borko, 2004; Feiman-Nemser, 2008; Vermunt, 2011), teacher education (e.g. Grossman, 2005; Korthagen, 2010), and professional and workplace learning (e.g. Eraut, 2004; Tynjälä, 2008). Research on top-down, prescriptive models (e.g. Clarke & Hollingsworth, 2002) as well as bottom-up, descriptive models (e.g. Bakkenes et al, 2010) was included.

The measurement of the components of teacher learning depends, of course, of their conceptualisation. When valuable learning outcomes are not viewed as factual knowledge but as, for example, new teaching practices, instruments have to be used that can measure these practices. Therefore, the literature was also explored for measurement instruments that are in line with the conceptualisations that are considered suitable. Advantages and disadvantages of those instruments will be discussed.

Findings

For every element of the model, the literature search revealed several possible conceptualisations. I will use recent empirical studies from our research program on ‘teacher learning and expertise throughout the professional career’ to illustrate and underpin the choices we made for concepts and measurements. For example, several empirical studies on student teachers’ ‘regulation of learning’ revealed two important dimensions here: active versus passive regulation and prospective versus retrospective regulation of learning. In the domain of learning outcomes, another line of empirical research on experienced teachers’ learning in the context of educational innovation yielded main categories such as: changes in knowledge and beliefs; intentions for new classroom practice; actual changes in teaching practices; and emotional outcomes. Measurement instruments used to tap these components of teacher learning included digital logs, belief questionnaires, standardized teacher learning inventories, learning reports, student perceptions and video recordings of teacher classroom behaviour, and classroom video cases to elicit immediate teacher reactions.

Evidence of relations between components of the model were gathered from these studies as well. Theoretical and educational significance The discussion will focus in the current state of the art of the scientific knowledge base of teacher learning from the perspective of student learning. One advantage of this conceptualisation refers to the “chain of evidence”: student learning leads to learning outcomes, teaching leads to student learning, teacher education leads to student teacher learning, etc. Only one particular kind of learning outcomes that teachers achieve in their learning, namely actual changes in teaching practices, can influence student learning, because only these are part of the context (learning environment) for students’ learning.

The model organizes the scientific knowledge available at this moment. Moreover, it makes it possible to identify directions for further research, especially in the direction of: further study of components of the model and their

interrelations with different populations; the development of well-researched diagnostic measurement instruments for the various elements of teacher learning discussed here; and intervention studies on pedagogical approaches to foster teacher learning.

SYMPOSIUM

Changes in Teachers' Professional Competence during a Practical Induction Phase

Mareike Kunter, Goethe-University, Institute of Psychology, Germany; Jurgen Baumert, Max Planck Institute for Human Development, Germany; Thilo Kleickmann, University of Kiel IPN, Germany; Dirk Richter, Humboldt University Berlin IQB, Germany

In this paper, we introduce a model of the determinants and effects of teachers' professional competence and present the results of a study investigating the development of professional competence during teacher education. Our model assumes that professional competence – i.e., the knowledge, beliefs, motivational and affective variables that teachers need to master the demands of their profession – develops in the interplay between formal and informal learning situations and personal prerequisites that shape the uptake of learning opportunities. In our two-cohort study 556 German teacher candidates enrolled in a teacher induction programme were assessed twice over the course of one year, using standardized tests and questionnaires. As a general trend, small linear gains in knowledge, stability in beliefs, and a curvilinear trend in motivational-affective variables was observed. However, institutional and individual factors such as type of academic programme or prior stress levels moderated the change trajectory, supporting the assumption of differential competence development.

Aims/Theoretical Background

Identifying the personal characteristics of good teachers is considered crucial for improving the quality of educational processes. Some researchers argue that extensive professional knowledge and functional professional beliefs are the result of learning processes within teacher education, and that teacher quality can be best assured by providing high quality learning situations for all candidates (e.g., Darling-Hammond, 2006). Others assume that stable personal characteristics such as general abilities or personality traits play a key role, and that teacher quality can best be assured by selecting persons with the "right" prerequisites (e.g., Yeh, 2009).

"Professional competence" describes knowledge, skills, but also attitudes and motivation that are needed for mastering complex situations (Kane, 1992). Applied to teachers, this includes professional knowledge, professional beliefs, motivation, and self-regulatory skills (Kunter et al., 2007). Empirical studies show that teachers differ substantially in these competence aspects, and that differences in these aspects are reflected in their teaching quality, their students' learning rates, and their professional well-being (e.g., Baumert et al., 2010; Kunter et al., 2008). In this paper, we present a theoretical model that assumes that teachers' professional competence is developed in formal as well as informal learning situations (e.g., in teacher education, but also in the school context). Meanwhile we assume that the existence of learning opportunities alone is not the decisive factor for competence development, but that the uptake of learning opportunities depends also on characteristics of the teachers themselves.

We test this assumption by means of a longitudinal study of German teacher candidates that were investigated during a 2-year induction phase. During this time, candidates are gradually introduced to teaching and are supported by mentor teachers and theoretical seminars. With its gradual transition from theory into practice, the induction phase is assumed to be crucial for developing professional competence. While one may assume that teachers' competence increases substantially during this phase, the first encounter with teaching practice has also been described as a particularly stressful time where professional beliefs and motivation may regress, and is sometimes referred to as practice shock (Veenman, 1984). Following the model of differential uptake of learning opportunities, we were interested in the inter-individual differences in how teacher candidates develop during this intense learning phase.

Methods

Sample and Procedure

The COACTIV-R study is a two-cohort longitudinal study that examines teacher candidates during the induction phase in Germany. The sample for the present analysis included 556 mathematics teacher candidates (65 % women, mean age = 28 years). 430 candidates were in their first year of the programme and 135 in their second year. Corresponding to academic tracking, which is a characteristic of the German schooling system, 43 % were training to be teachers on the academic track, the rest being trained for other tracks.

Candidates worked on tests and questionnaires at the beginning of the school year, and again at the end of the school year. By combining the two-cohort comparison with the repeated measurement, it was possible to draw conclusions relevant to the whole course of the induction phase (see figure 1).

Instruments

Teachers' knowledge was assessed via tests constructed within the project, testing mathematical content knowledge (?time1=.83/?time2=.81) and mathematical pedagogical knowledge (?time1=.76/?time2=.75). Two questionnaire scales measured teachers' beliefs about learning processes, reflecting a constructivist (?time1=.79/?time2=.82) and a transmission orientation (?time1=.78/?time2=.83). As motivational-affective variables, questionnaire scales tapped teachers' enthusiasm for teaching (?time1=.85/?time2=.84), their job satisfaction (?time1=.89/?time2=.91), and their emotional exhaustion (?time1=.77/?time2=.82).

Results

Overall, regarding knowledge, very small linear gains emerged over the course of the two years ($d's < .10$). Regarding beliefs, no significant changes occurred. Regarding motivational-affective variables, we found non-linear trends showing that enthusiasm and job satisfaction decreased towards the end of the first year, and increased again towards the end of the second year, with a reverse trend for emotional exhaustion.

However, investigating possible institutional or individual moderators for change, we found that candidates who trained for the academic track showed significant changes in their knowledge ($d's$ between .20 and .30), while other candidates showed no such gain, indicating that the learning settings in which candidates are trained differ in their potential to foster professional learning. Investigating the role of possible individual moderators, we found that changes in teachers' beliefs occurred in one particular subgroup, namely in teachers who started with high emotional exhaustion. Their transmission orientations increased and constructivist orientations decreased, while teachers with lower exhaustion remained stable. Further individual moderators will be investigated.

Discussion

There is currently a lack of empirical research that examines teachers' learning processes in large scale settings that allow for investigating moderators for change. Our study investigated changes in professional knowledge, beliefs, and motivational-affective competence aspects of young teachers during their induction phase. We found that – differentiating the overall change trends – institutional factors such as the academic programme the teachers were involved in or individual factors such as their stress levels influenced the trajectories of change. Future research on teacher learning should thus take the interaction of different learning settings and personal prerequisites into account.

SYMPOSIUM

Characteristics of Lesson Conferences that Foster Student Teacher Learning

Annelies Kreis, University of Teacher Education Thurgau, Switzerland; Fritz C. Staub, University of Fribourg, Switzerland

School-based practica provide pivotal learning opportunities for student teachers, but empirical studies show that practice often does not correspond to normative models (Hennissen et al., 2008). Content-Focused Coaching (West & Staub, 2003) is an approach that can be used to foster pre-service teacher learning during practica. Based on this model we examined how discourse analytical characteristics of lesson conferences relate to student teacher learning. This study is part of a quasi-experimental intervention study. Empirical data include video recorded pre- and post-lesson conferences of 31 dyads of student teachers and mentors. Lesson conferences were subjected to discourse analyses applying a previously developed coding system (Kreis, in prep.). Codes cover the interactional characteristics as well as discourse activities that are specific for lesson conferences (e.g. invitation to elaborate a lesson plan). In addition, we conducted interviews with student teachers about learning incidences during the recorded lesson conferences. The frequency of reported learning incidences was then related to the aggregated duration of specific discourse activities. Findings indicate the important role of co-constructive and project specific discourse activities for student teacher learning in the context of lesson conferences that are recommended by Content-Focused Coaching.

Aims

School-based practica provide pivotal learning opportunities for student teachers (e.g. Hascher et al., 2004). Normative models calling for reflective practice are prevalent. Empirical studies, however, show that mentors often dominate the interaction and dialogic reflection is found only rarely (e.g., Crasborn & Hennissen, 2010). According to the new approach of Content-Focused Coaching (West & Staub, 2003) student teacher learning is assisted through dialogical post-lesson conferences as well as collaborative pre-lesson planning. In a quasi-experimental intervention study this approach has been shown to lead to significantly more self-reported student teacher learning than the traditional way of assisting student teachers in practica (Kreis & Staub, submitted). The intervention consisted in a substantial professional development for the school-based mentor teachers (120 hours over a period of 15 months) in the experimental group. In this study we analyze lesson conferences regarding relationships between (a) discourse analytical characteristics of lesson conferences and (b) learning gains of student teachers attributed to the respective conferences. Based on research on learning in tutoring (Chi et al., 2001) we expected co-constructive interactions leading to higher learning gains than micro-monological discourse activities. In particular, we expected the occurrence of discourse moves that contribute to a dialogue on lesson plans and to collaborative transformations to be associated with learning gains of student teachers.

Methodology

Data from the quasi-experimental intervention study includes (a) video recorded lesson conferences from 31 dyads of student teachers and their mentors and (b) interviews with 31 student teachers. The mentors of the experimental group (NEG=15) participated in specific professional development, the mentors of the control group (NCG= 16) did not. Both groups consisted of volunteers and did not differ on variables such as teaching experience. The mathematics lessons and the associated lesson conferences were randomly chosen from lessons taught during the last two weeks of a school-based practicum of seven weeks (primary school, grades 1-6). In semi-structured interviews student teachers reported in detail what they had learned from the recorded lesson conference(s). The interviews were transcribed and subject to qualitative content analysis (Kreis, in prep.). The number of reported learning incidences in these interviews is used as an indicator for student teacher learning. Lesson conferences were also transcribed and subjected to a detailed video based and computer-supported discourse analysis applying a coding system developed on the data of a sub-sample of 16 dyads in a previous study (Kreis, in prep.). Units of analysis are sequences of dialogues, which cover one project (e.g. how to give students an assignment). Boundaries between units of analysis are identifiable on the basis of discourse markers and code definitions. 17 Codes capture the function of utterances with respect to the dialogue (e.g. checking understanding, invitation to elaborate the lesson plan, elaborating the lesson plan, reflecting on a past lesson). Codes for sequences are furthermore specified with respect to the initiator of the sequence (mentor or student teacher) and their interactional character (micro-monological in which a project is described by one person alone versus co-constructive in the sense of Chi et al. (2001), if interacting persons mutually discuss and contribute ideas to a project). Interrater reliability on the basis of given units is .8 (Cohen's Kappa). The

duration of the specific discourse activities identified is aggregated per dyad and correlated with the indicator for student teacher learning (Spearman's ρ).

Findings

Significant correlations were found between the number of reported learning incidents (Mode=3, Range=0-8,) and the mean duration of pre-lesson conferences (N=20, M=42', s=25', $r_s=.46$, $p=.020$) and of post-lesson conferences (N=31, M=19', s=11', $r_s=.36$, $p=.024$). There is a significant correlation between reported learning and the overall time of co-constructive interaction for pre-lesson conferences (M=25', s=16', $r_s=.68$, $p=.001$), but not for post-lesson conferences. There are no significant correlations between reported learning and the overall time of micro-monological sequences, neither by student teachers nor by mentor teachers in pre- or post-lesson conferences. At a differentiated level there are significant correlations between teacher learning and eleven specific discourse activities such as e.g. "Invitation by cooperating teachers to elaborate their lesson plan followed by a dialogue" (pre-lesson: $r_s = .64$, $p=.000$), "micro-monological problematization" by cooperating teachers (pre-lesson: $r_s = .52$, $p=.009$) or by student teachers (pre-lesson: $r_s=.56$, $p=.005$), or "co-constructive problematization" initiated by student teachers (pre-lesson: $r_s=.42$, $p=.033$, post-lesson: $r_s=.39$, $p=.015$). There are no significant correlations for the other sub-codes (e.g. „hypothetical optimization of lesson plan“ during post-lesson conferences).

Theoretical and educational significance

Results from our quasi-experimental intervention study have previously shown that mentor teachers who had learned to assist student teachers on the basis of Content-Focused Coaching were more successful in fostering student teacher learning in terms of their reported learning (Kreis & Staub, submitted). A main goal for the mentor teachers in the experimental group (beyond reflecting and elaborating their pedagogical content knowledge) was learning how to foster co-constructive lesson conferences. The analyses presented in this study look in detail at the lesson conferences and search for relationships between co-constructive and project specific discourse activities in lesson conferences and student teacher learning. The research presented draws on conceptualizations and results from previous research in tutoring (e.g., Chi et al., 2001) and extends this work to the domain of mentoring in pre-service teacher education. Such research can help us to better understand the nature of lesson conferences that have the potential to advance teacher learning.

SYMPOSIUM

Understanding and solving word problems: The role of representational models

Chairperson: Erik De Corte, University of Leuven, Belgium

Organiser: Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

Discussant: Kurt Reusser, University of Zurich, Switzerland

Over the past decades, word problems have elicited a lot of research. During the 1980s and 1990s, many studies were set up aimed at constructing and testing theoretical models about the cognitive processes taking place when learners try to understand, represent, and solve word problems as well as about the components that are involved in those processes. Nevertheless, several important questions and challenges for research remain, especially relating to the initial phases of the problem-solving process wherein the solver tries to build an appropriate and functional representation of the problem. The three papers in this symposium represent theoretical and methodological attempts to deepen our insight into these initial representational phases, and their impact on the subsequent phases in the word-problem solving process. They all yield strong support for the complexity of these representational processes, and their crucial role in the whole solution process. The first paper analyses whether the generation of

inferences about the situation, which is typical for (text) comprehension processes, also occurs when the children solve word problems. The second study compares children's understanding and solution of a quantitative problem about fair sharing in a mathematics and a religion class. The third paper describes the conditions under which solvers (can) construct a computationally more efficient alternative mental representation to the initial one. The three papers are discussed by a scholar who developed one of the most influential models about understanding and solving word problems.

Processing of situational information in story problem texts. An analysis from on-line measures

Jose Orrantia, University of Salamanca, Spain; Julio Tarin, University of Valencia, Spain; David Munez, University of Salamanca, Spain; Santiago Vicente, University of Salamanca, Spain

In three experiments, we investigated the extent to which readers process information related to the construction of a situation model when they are confronted with solving word problems. Considering that generation of inferences to match actions with particular goals is part of constructing of the situation model, we constructed "rich story problems", that is, word problems included in the context of a story, in which the characters set goals that are followed by actions to achieve these goals. In Experiments 1 and 2 the story problems were designed so that the character's goal was explicitly (Experiment 1) or implicitly (Experiment 2) related to the activation of a problem schema. In Experiment 3 the problem schema activation was clearly separated from the goal information. In all three experiments, goal information availability was assessed by on-line measures. The results showed that participants processed situational information by keeping track of characters' goals. These results fit nicely with those studies that emphasize the role of situation model construction in word problem solving.

Arithmetic word problem solving can be considered as a complex activity in which solvers create different levels of representation, both mathematical and nonmathematical. The aim of this paper is to analyse the role that nonmathematical representation plays in problem comprehension, representation related to informal comprehension of the situation described in the problem, the so-called situation model, which corresponds to a more qualitative level of representation that specifies the agents, the actions, and the relationship between the events of the problem in everyday contexts.

Although the evolution of the different models of understanding and solving arithmetic word problems can be described as a growing recognition of the importance of the comprehension of the situation described in the problem, the role that this initial nonmathematical representation plays in understanding and solving arithmetic word problems is still put to test nowadays. A specific question that needs to be answered is whether inferences related to the construction of a situation model are generated on line when the word problems are presented in the context of a story, that is, when they are presented in a more enriched and elaborated way by highlighting the situation described by the problem.

The purpose of our research was to demonstrate that readers are, in effect, sensitive to situational information (e.g., causal inferences guided by the goals of a story character, a kind of inferences related to the construction of the situation model). To demonstrate such sensitivity, we designed three experiments in which the situational information was more or less related to the activation of the problem schema. In Experiment 1, the story problems were designed so that the character's explicitly stated goal was closely related to the activation of a problem schema, e.g., the character wants to increase or to decrease a flock of sheep. Experiment 2 was similar to Experiment 1 except that the goal of the character was not explicitly stated; to activate the schema readers would need to infer the character's goal. In these first two experiments, measuring participants' reading times for action statements that were either consistent or inconsistent with the characters' goals assessed goal information availability in participants' working memory. In Experiment 3 the goal information was not linked to any problem schema. In this experiment, the availability of the goal was tested by measuring participants' response times to target words selected from goals that were either completed or failed by the character.

Experiments 1 and 2

Method

Participants

Sixty Spanish psychology undergraduates participated in Experiment 1, and 40 in Experiment 2.

Materials

We created 12 experimental story problems. All problems were constructed on the same model, referring to a single character who performed an action that was either consistent or inconsistent with his or her goal. Whereas in Experiment 1 the character's goal was explicitly stated, in Experiment 2 it was not.

Procedure

Problems were presented on a computer screen one line at a time. Participants controlled the presentation of the problem with a line advance key.

Results

Both in Experiment 1 and in Experiment 2, readers spent more time on the inconsistent target lines than on the consistent target lines, $F(1, 57) = 65.44$, $MSE = 64,117$; $F(1, 22) = 26.46$, $MSE = 45,204$, for Experiment 1, and $F(1, 38) = 23.39$, $MSE = 48,175$; $F(1, 22) = 6.72$, $MSE = 71,358$, for Experiment 2, which indicates that information related to the characters' goals remained available in participants' working memory during the processing of the problem.

Experiment 3

Method

Participants

Fifty-four psychology undergraduates participated in Experiment 3.

Materials

There were 16 experimental story problems. Each problem had two versions: failed goal and completed goal. To determine whether participants maintained the availability of the failed goal information, we recorded, in the context of a lexical decision task, responses to target words that were selected from the goal statement in the story problem.

Procedure

The procedure was the same as for Experiment 1 and 2. The lexical decision task proceeded as follows. After reading a line, a row of asterisks was presented for 500 ms at the center of the screen and was then replaced by the target letter string. Participants had to decide whether the letter string was a word or a non-word by pressing one of two keys ("yes" and "no").

Results

The results showed that failed goal information is more available to readers than completed goal information. This effect was significant by subjects, $F(1, 52) = 12.52$, $MSE = 3,209$; and approached significance by items, $F(1, 30) = 3.4$, $MSE = 6,226$, $p = .07$.

General discussion

Generally, the results showed that participants processed situational information by keeping track of the characters' goals. These results suggest that the generation of goal inferences occurs even when explicit instructions indicate it is not necessary, that is when participants had to solve the story problems. The results of our experiments fit nicely with those studies that emphasize the role of situation model construction in word problem solving. According to these studies, to understand a problem it is important to pay attention not only to specific mathematical information (i.e., the problem schema) but also to the situation and the events described in the text. Although participants were instructed to adopt a problem-solving strategy that, according to some older word problem solving models, does not require the development of a situation model, we emphasize that situational information, particularly information related to goals of characters, remained available in participants' working memory during the processing of the problems. In this way, the construction of the problem model could be facilitated by the provision of situational information, since readers need to engage in some sort of inferential process to attempt to reestablish coherence when they detect an inconsistency (Experiments 1 and 2), and need to hold a goal active when it has not been completed (Experiment 3). One educational implication is that the introduction in the problem texts of relevant goals (which allow the problem solvers to infer the mathematical structure of the problem) may improve their performance.

SYMPOSIUM

Children's understanding and solution of a word problem inside and outside the mathematics class

Tinne Dewolf, KULeuven, Belgium; Wim Van Dooren, K.U. Leuven, Belgium; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

Research shows that primary school pupils tend to exclude realistic considerations when solving mathematical word problems (Verschaffel et al., 2009). Several authors have suggested that this tendency is due to the practice and culture of the mathematics class, but systematic empirical evidence in favour of this claim is scarce (for an exception, see Säljö, 1991). To further examine the influence of the context on pupils' realistic considerations when solving word problems, we confronted 151 pupils (5th and 6th grade) with a quantitative problem in the context of a mathematics

or religion class. Pupils were first asked to solve an assignment during regular teaching hours (mathematics or religion). The quantitative problem, which was about dividing an amount of money fairly, was the same in both groups. Afterwards, pupils had to evaluate several (fictional) answers for this problem. We compared the responses from both groups and found that a) in the mathematics class pupils mainly used precise numerical answers, while in the religion class half of the pupils gave a verbal description of the solution as their answer b) the answers of the pupils in the mathematics class were mostly motivated by calculations, while in the religion class, pupils mostly used non-numerical arguments c) the concept "fairness" was interpreted differently in both conditions d) especially in the mathematics class, pupils expected that there was (only) one correct solution for the problem. These findings provide evidence that the context influences primary school children's solutions of mathematical word problems and their accompanying argumentations.

Introduction

Historically, the inclusion of word problems was mainly intended to develop in students the skills of knowing when and how to apply their mathematics effectively in various kinds of problem situations encountered in everyday life. For a very long time, word problems have played this application function without much reflection and critical concern. But during the last 10-15 years, it has been argued by many scholars from different disciplines that the current practice of word problems in school mathematics does not at all foster in students a genuine disposition towards mathematical modeling. These scholars refer, among others, to research that shows that primary school pupils tend to exclude realistic considerations when representing and solving mathematical word problems (Verschaffel et al., 2009). Several authors have suggested that this tendency is due to the practice and culture of the mathematics class, but empirical evidence in favour of this claim is scarce (for an exception, see Säljö, 1991). In this study we therefore examined the influence of the context on realistic considerations when solving quantitative problems. Our main hypothesis was that pupils would approach a quantitative problem differently when it is presented in a mathematics class as compared to a religion class. Because the problem we used was about dividing an amount of money fairly between two boys, we expected that pupils also would interpret and handle the word "fair" differently in these two contexts.

Method

151 primary school pupils from the 5th and 6th grade, coming from two different schools, received a paper-and-pencil test with the following word problem from Säljö, Riesbeck, and Wyndhamn (2009):

Two boys, Charles and Martin, are going to help Nicholas rake leaves on his plot of land. The plot is 1200 square metres. Charles rakes 700 square metres during four hours and Martin does 500 square metres during two hours. They get 180 crowns/kronor (SEK) for their work. How are the boys going to divide the money so that it is fair? (p. 180) This problem was presented in the context of a religion or mathematics assignment. Seventy-nine pupils completed the assignment in the mathematics class and seventy-two pupils in the religion class. The assignment was offered by the teacher and consisted of two parts. In the first part, the problem from Säljö et al. (2009) was presented together with two other problems. In the religion class these two accompanying problems were typical ethical dilemmas, whereas in the mathematics class they were classical word problems. In the second part of the assignment, pupils were asked to evaluate five fictional answers on the above problem about "fair sharing". Each fictional answer represented a different way of responding to the problem: "dividing the amount of money in half", "a bigger amount for the boy who worked longer", "a bigger amount for the boy who did more square metres", "considering the time and amount of work", and "there is no (single) right solution for the problem". This second part was the same for both groups.

For the first part, pupils' answers on the problem were coded on three characteristics; solution (numerical or non-numerical), response style (calculation or argument), and criteria being implicitly or explicitly used to solve the problem (equality, time used for work, amount of work, efficiency, and other, vague, or no (visible) criterion). In the second part of the assignment, pupils had to grade five fictional answers. We compared the responses of both groups for both parts of the assignment.

Findings

Table 1 presents the results for the first part of the study. First, the answers of the pupils who received the assignment in the mathematics class were more often expressed in a precise numerical form (e.g., Charles gets 120 and Martin gets 60) (86.1%) than those who received it in the religion class (52.8%). In the latter group almost half of the pupils gave another kind of description of their answer: 25% were precise but not calculated numerical (e.g., Charles deserves twice as much as Martin) and 20.8% were non-precise numerical (e.g., Charles deserves a bit more). Second, the answers of the pupils in the mathematics class were mostly motivated by calculations (74.7%), whereas in the religion class giving a non-numerical argument was the most frequent response style (38.9%). Another substantial

number of children (29.2%) of the religion class didn't use any argument or calculation at all, and only wrote down a certain amount of money. Third, in the mathematics class 73.4% of the pupils based their answer on only one criterion, while in the religion class the number of criteria used was more diverse: 38.9% of the pupils didn't use a criterion, 41.7% used one criterion, and 19.5% used more than one criterion. Finally, with respect to the kind of criterion being mostly used, the most striking finding was that only 2.5% of the pupils in the mathematics class found it fair to divide the money equally, whereas in the religion class 18.1% of the pupils applied this criterion in their response.

The analysis of the second part showed that in both groups the fictional answer "there is no (single) right solution for the problem" received the least points. However, in the mathematics class this answer was scored significantly lower (5.2/10) than in the religion class (6.8/10). This suggests that pupils in the religion class more easily accepted that there is no (single) right solution for the problem.

Conclusion and discussion

Our findings show that upper primary school pupils approach and solve quantitative problems differently when the problem is presented in a mathematics class as compared to a religion class. So they yield further evidence to the claim that the context influences pupils' solutions of mathematical word problems and their accompanying argumentations. More specifically, it documents pupils' tendency to reduce the modelling cycle to "doing something with the numbers in the problem" relying on a narrow mathematical interpretation of the problem situation and of the concepts involved in it (Säljö & Wyndham, 1993; Verschaffel et al., 1994, 2000).

SYMPOSIUM

The construction of an alternative mental representation for arithmetic word problems

Catherine Thevenot, University of Geneva, Switzerland

Multiple-step arithmetic problems can be solved by diverse strategies depending on the mental representation constructed by individuals from the situation described in the text of the problem. The initial representation constructed by individuals is based on the sub-goals that are explicitly described in the text of the problem. However, this initial representation is not always the more economic one in terms of cognitive demand during the solving process. In this presentation, we will describe the conditions under which an alternative mental representation to the initial one can be constructed. We will show that the probability of the implementation of an alternative representation depends on its similarity with the representation induced by the text. This result comforts Knoblich's representational change theory initially developed in the domain of insight problems.

Theoretical and empirical background

In verbal arithmetic, multiple-step problems can be solved by different strategies; all of which may lead to the solution, but not all in an optimum way. Let us consider the problem 'How many marbles does Tom have less than John and Paul together? John has 41 marbles, Tom has 31 marbles and Paul has 43 marbles'. The strategy that is most likely to be used by individuals is the one based on the sub-goal explicitly described in the text of the problem. Most adults and children will reach the sub-goal 'John + Paul' and then subtract the quantity of Tom's marbles from the result obtained: $41 + 43 = 84 - 31 = 53$. However, another strategy would be to subtract the quantity of Tom's marbles from the quantity of John's marbles and then, to add the quantity of Paul's marbles to the result obtained: $41 - 31 = 10 + 43 = 53$. In order to solve the problem mentally, this second strategy is obviously more economical than the first one. However, it is not implemented spontaneously by individuals who base their strategy on their initial mental representation of the problem. Such individuals would not engage in the construction of an alternative representation because it is an additional and rather demanding activity.

Nevertheless, we showed that when the solution is extremely difficult to reach from the initial representation (for example when three-digit instead of two-digit numbers are used in the text), an alternative one that leads to the optimum strategy can be constructed by the solvers (Thevenot & Oakhill, 2005).

Aim

In order to precisely account for the conditions under which such alternative representations are constructed by individuals, we have recently adapted the representational change theory proposed by Knoblich and colleagues (1999; 2001) in the domain of insight problem to the domain of arithmetic word problem (Thevenot & Oakhill, 2008). In Knoblich's theory, insight problem solving often lead to impasses because the solver constructs an initial representation of the problem that has a low probability of success. It is only by revising this representation that the solver will overcome the impasse. The probability of such a successful revision depends on two processes, namely constraint relaxation and chunk decomposition. Within the initial representation, some constraints (i.e., what does

and does not count as a solution) are inappropriate and need to be relaxed. It turns out that certain constraints are more likely to be relaxed than others. Indeed, according to the authors, the probability of relaxation of a constraint is inversely proportional to its scope. In other words, it depends on how much a problem representation is affected if the constraint is relaxed: Constraints of narrow scope have a higher probability of being relaxed than constraints of wide scope because the resulting revisions in the problem representation are more circumscribed.

Method and results

Similarly, in a series of two experiments, we studied different types of arithmetic word problems that differ on the scope of the constraint to be relaxed in order to set up a more economic strategy than the one induced by their explicit wording. In our experiments, the number of steps needed to reach the alternative representation was the main variable and was systematically manipulated. In the example taken above, later referred to as P3 problems (i.e., 'How many marbles does Tom have less than John and Paul together? John has 41 marbles, Tom has 31 marbles and Paul has 43 marbles'), the initial representation would take the form "(John + Paul) – Tom". In order to change this representation into the alternative one "(John – Tom) + Paul", the chunk "John + Tom" would have to be broken down. Then, a reorganization into John – Tom + Paul would be necessary and finally, a new chunk ("John – Tom") would have to be created. Therefore, for this specific problem, three steps separate the new and the initial representation. However, it takes only two steps in order to shift from the initial representation of the problem "How many marbles does John have more than Tom and Paul together?" (later referred to as P2 problems) to an alternative one specifying a sub-goal involving the quantities of John and Tom marbles. Indeed, the initial representation "John – (Tom + Paul)" has to be decomposed, which leads to represent the problem as follow: John - Tom - Paul. No reorganization is needed but the new chunk (John – Tom) has to be created.

In the first experiment, we explicitly asked 29 participants to find an alternative strategy in order to solve P2 and P3 problems. More precisely, for both problems, individuals were asked to write down how they would solve them if they were to first find a sub-result that did not involve the number of marbles that Paul has. We showed that it took longer for participants to find this alternative strategy for P3 (134 seconds) than for P2 problems (83 seconds). This result is in accordance with Knoblich's theory because, as already explained above, 3 steps are necessary in order to find the alternative strategy for P2 problems. In the second experiment, we taught 29 adults how to relax the constraint of P2 and P3 problems and asked them to base their subsequent solution strategy on their new representation. We showed that, despite an explicit teaching, it was still demanding for participants to implement systematically the new strategy, especially for P3 problems. Such demand was operationalized by the time that participants took to read the question, only information in the text conveying the relational structure of the problem.

Educational implications

These results indicate that shifting from an initial mental representation to an alternative one that could release memory resources is a difficult cognitive activity. This suggests that individuals have rigid mental representations of situation problems and that children should be taught more systematically that, most of the time, different solution processes can lead to the right answer. This could help people to think more flexibly.

SYMPOSIUM

Factors influencing student achievement in Problem-Based Learning

Chairperson: Sofie Loyens, Erasmus University Rotterdam, Netherlands

Organiser: Sofie Loyens, Erasmus University Rotterdam, Netherlands

Discussant: David Gijbels, University of Antwerp, Belgium

Problem-based learning (PBL) has been successfully implemented in many medical schools all over the world. Many studies have been conducted in which PBL curricula were compared with conventional curricula. These studies demonstrated that students knowledge levels are comparable (Colliver, 2000; Newman, 2003; Dochy, Segers, van den Bossche & Gijbels, 2003; Schmidt, Van der Molen, te Winkel & Wijnen, 2009), but that PBL graduates demonstrated better communication skills, were better at coping with uncertainties and had better collaboration skills (Jones et al., 2002; Schmidt et al., 2006; Hoffman et al., 2006; Cohen-Schotanus et al., 2008; Schlett et al., 2010). However, so far not much is known about why and how distinctive aspects of group learning in PBL positively influence student learning, student motivation and student achievement (Dolmans & Schmidt, 2006). The proposed symposium is aimed at presenting three studies in which factors influencing student achievement in PBL are investigated. In a first study it is investigated how students' situational interest develops during the tutorial group session and how distinctive tutor behaviors influence students' situational interest and achievement. In a second study it is investigated whether tutors

can predict student performance. In a final study it is investigated how constructive, motivational and collaborative activities in the group influence student achievement.

SYMPOSIUM

Problem-based learning and student motivation: The role of interest in learning and achievement

Jerome Rotgans , National Institute of Education, Singapore; Henk Schmidt, Erasmus University Rotterdam, Netherlands

The findings of two studies are reported that shed some light on conditions that influence student motivation in problem-based learning (PBL). Both studies operationalized student motivation by means of situational interest, which is defined as an immediate affective response to a stimulus. The objective of the first study was to investigate how situational interest develops during a one-day PBL event. To that end, five measures of situational interest were administered at critical points in time during the learning event to 69 polytechnic students. Results demonstrate that situational interest significantly increased after the problem stimulus was presented. Subsequently, situational interest gradually and significantly decreased over the day. Testing a path model relating the situational interest measures revealed strong interrelations. Moreover, situational interest was highly predictive of academic achievement. The second study sought to explore whether the tutor characteristics increase students' situational interest in PBL. An analysis of variance (ANOVA) and path analysis were conducted ($N = 498$) to assess potential differences in situational interest based on three tutor characteristics and how well these characteristics predict situational interest. Results revealed that students supported by tutors who scored high on these characteristics reported significantly higher levels of situational interest. The findings suggest that tutors play an influential role in increasing students' situational interest in the PBL classroom. Implications of these findings are discussed.

Aim

Many advocates of problem-based learning (PBL) implicitly assume that this instructional method is highly motivating for students to study. It is expected that specific features of the PBL pedagogy, such as working on meaningful, real-life problems independently in small groups under minimal intervention of a tutor, would promote student motivation and learning. Whether this is the case, however, has not been studied extensively. The objective of this paper is to report two studies that examined whether a PBL environment has a motivating effect on student learning. In both studies, motivation was operationalized by means of students' situational interest, which has been defined as an immediate affective response to certain conditions and/or stimuli in the learning environment that focuses one's attention on the task (Hidi, 1990; Hidi & Renninger, 2006). In study 1 it was investigated how students' situational interest developed over the course of a one-day PBL event. In study 2 it was investigated in how far three distinct tutor characteristics, viz. social congruence, subject-matter expertise, and cognitive congruence (Schmidt & Moust, 1995), influence situational interest in the PBL classroom.

Methodology

Study 1

The sample for Study 1 consisted of 69 participants (61% female) with an average age of 20 years ($SD = 1.18$). All participants were enrolled in a second year PBL economics module at a Polytechnic in Singapore. Unique to this PBL approach is that students work on one problem during the course of one day (Alwis & O'Grady, 2002). A measure of situational interest was devised and validated. In order to determine students' prior knowledge and their academic achievement, a knowledge test was administered twice a day, once in the morning as a pre-test to measure students' prior knowledge and a second time at the end of the day as a post-test to determine what students have learned over the day.

The situational interest measure used in this study was administered for five critical occasions during the day. Potential mean level differences between the situational interest measures were determined by means of a repeated measures ANOVA. Subsequently, the relationships between the five situational interest measures as well as the pre- and post-test were analyzed using path analysis.

Study 2

The sample for Study 2 consisted of 498 participants (52% female) with an average age of 19 years ($SD = 1.62$). The participants were enrolled in various diploma programs at the same polytechnic as in Study 1. To measure the tutor characteristics a rating scale was adapted from Schmidt and Moust (1995), which is used on a regular basis as a program evaluation questionnaire at the polytechnic. Three subscales were administered: (1) social congruence, (2) subject-matter expertise, and (3) cognitive congruence. As a measure for students' situational interest, the same measure was used as in Study 1. Data concerning the three tutor characteristics were extracted from the routine program evaluation. About a month later, the situational interest measure was administered in these classes at five critical occasions during a PBL day (see Study 1). For further analysis, the average value of the five situational interest

measurements was used. In order to determine which of the three tutor characteristics predicted situational interest best, path analysis was carried out.

Findings

The results of Study 1 revealed that situational interest increased significantly after the problem trigger was presented. However, over the course of the day, students' situational interest gradually decreased. In the path analysis, the simplest fitting model was the one in which each measure of situational interest uniquely influenced each subsequent situational interest measure. Moreover, situational interest was a strong predictor of students' academic achievement. In our sample, prior knowledge was not related to situational interest, but it was a significant factor in predicting student achievement at the end of the day.

The results of Study 2 revealed that social congruence and subject-matter expertise were not directly related to situational interest, but were antecedent variables of a tutor's cognitive congruence. Our findings imply that being friendly, socially and emotionally connected with the students as well as having a large body of knowledge about a topic are highly predictive of how cognitively congruent a tutor is. Being cognitively congruent, that is helping students to understand the topic by providing scaffolds and structure to the topic, was a significant factor in predicting students' level of situational interest in the PBL.

Implications

The overall findings of the studies demonstrate the significant influence problems and tutors have on triggering and maintaining students' situational interest in PBL. Study 1 revealed a strong relationship between situational interest and academic achievement. The findings of Study 2 have direct implications for tutor training. If one attempts to increase situational interest by means of controlling for tutor characteristics it is recommended to: (1) increase a tutor's social congruence and (2) a tutor's subject-matter expertise – both resulting in an increased level of cognitive congruence, which eventually has a positive effect on students' situational interest.

SYMPOSIUM

Tutor predictions of students' study success

Lisette Wijnia, Erasmus University Rotterdam, Netherlands; Sofie Loyens, Erasmus University Rotterdam, Netherlands; Nitaasha Koendjie, Erasmus University Rotterdam, Netherlands; Henk Schmidt, Erasmus University Rotterdam, Netherlands

This study examines whether tutors (N =15) from a problem-based learning (PBL) environment were able to predict students' (N = 211) study success in the first year and their entire bachelor program. Tutors were asked to rate each student in his or her tutorial group on the chance that this student would successfully finish the first study year and the entire program. Logistic regression analysis indicated that tutors could successfully predict study success in the first year and completion of the bachelor program. In contrast to earlier studies in PBL, this study indicated that tutors can accurately predict students' study success. The results of this study suggest that tutors' can accurately identify students' at risk of failing or drop out in an early stage of the program. Therefore, tutor judgments of students' performance can be an additional useful source of information to identify students at risk of failing or drop out.

Aim

Drop-out in higher education is a major concern (Georg, 2009). Often successfulness of programs is evaluated based on rates of student success and drop-out. Loyens, Rikers, and Schmidt (2007) demonstrated that students who obtained higher achievement grades and positive tutor ratings of their learning activities were less likely to drop-out. These results demonstrate that teacher ratings of student behavior are negatively correlated with student drop-out, but can teachers also predict study success?

The aim of this study is to investigate the accuracy of tutor predictions in problem-based learning (PBL). Earlier research that examined teacher judgments in PBL was inconclusive. Although Loyens et al. (2007) indicated that students' with positive tutor ratings were less prone to drop-out, two previous studies indicated that tutors cannot

accurately judge students' performance. Kaufman and Hansell (1997) found a significant positive correlation between tutor ratings of students' performance in tutorial meetings and actual performance, explaining 4% of the variance. However, closer examination revealed that only 3 of the 31 tutors in the study could accurately predict student performance. Similar results were found by Whitfield and Xie (2002). Although positive correlations were found between tutor ratings and actual student performance, only a small proportion of the variance in student achievement could be explained.

Methodology

The participants were all first-year tutors (N = 15; 4 male, 11 female) and 211 first-year psychology (57 male, 154 female) students of the 2002-2003 academic year. Students had a mean age of 20.01 (SD = 3.11).

In the first course (i.e., first five weeks) of the academic year tutors were asked to write down the chance that each student of their tutorial group would successfully finish the first study year and the chance each student would successfully complete the entire program. Tutors had no prior knowledge about students' achievement in secondary education. Chance percentages were coded into four categories, ranging from 0-25 to 76-100 percent.

First year study success was coded in two categories: (1) pass (i.e., earned at least 42 study credits) and (0) failed (i.e., less than 42 credits). Study success in the bachelor program was coded into three categories: (0) drop out during bachelor program, (1) not finished the program in three years, and (2) finished.

Findings

Because of the categorical outcome variable, logistic regression analyses were performed. The model with tutor ratings as the predictor variable was significant, $\chi^2(3, N = 211) = 39.57, p(N = 211) = 29.12, p$

Table 1- Logistic regression first year study success

Implications

This study aimed to investigate whether tutors are able to predict students' study success. In contrast to the earlier studies conducted in PBL (Kaufman & Hansell, 1997; Whitfield & Xie, 2002), this study shows tutors can predict first year success and success in the bachelor program. This finding is important because it enables educators to identify and help students who are at risk of failing or drop-out in an earlier stage of their program.

In this study we did not examine on what information tutors based their expectations. Knowing on which information tutors based their decisions, could give more insight in how tutors make judgments about future study success. As mentioned, the tutors did not have access to relevant prior information about students' performance in secondary education. They did observe students participating in group discussions and students' roles as chair or scribe of a tutorial meeting. It is likely that tutors mostly based their expectations on observed learning activities in group meetings, since they had no further information about the students' learning activities and history.

In conclusion, the results of this study show tutors can accurately predict students' short and long term study success. Therefore, tutor judgments can act as an additional useful source of information to identify students at risk of failing. By doing so student drop-out can be diminished.

SYMPOSIUM

The relationship between students' small group activities, time spent on self-study and achievement

Rachelle Kamp, Maastricht University, Netherlands; Diana Dolmans, Maastricht University, Netherlands;

Henk van Berkel, Maastricht University, Netherlands; Henk Schmidt, Erasmus University Rotterdam, Netherlands

Within Problem-based learning it remains unclear which specific student activities are crucial for good learning achievements. Therefore, this study investigated the relationship between the contributions students make to the problem-based tutorial group processes as observed by their peers, self-study time and achievement. To that end, the Maastricht-Peer Activity Rating Scale (M-PARS) was administered to students participating in PBL tutorial groups. With this rating scale students had to rate the constructive, collaborative and motivational activities of their peers within

the tutorial group. In addition, time spent on self-study was measured with a self-estimation method and achievement was measured with a unit test and a group assignment. A causal model of these variables was developed, in which the three types of activities were assumed to affect self-study time, which would subsequently affect test and group assignment scores. A Structural Equation Modeling analysis indicated acceptable model fit. Especially apparent were the causal relations between a student's constructive activities and his/her unit test score and between a student's collaborative activities and the group assignment score. Surprisingly, time spent on self-study was not affected by the students' contributions, nor did it have an effect on the unit test score. The results suggest that there are indeed causal relations between a student's contributions to the tutorial group process, as perceived by their peers, and achievement. These findings suggest that it is important to monitor and evaluate the contributions of students in tutorial groups.

Aim

The quality of the discussion within a problem-based learning (PBL) tutorial group seems to play a crucial role in the success of PBL (Savery & Duffy). Gijssels and Schmidt (1989) found that tutorial groups that are perceived as well functioning by the students within the group, spent more time on self-study and subsequently achieved better. A shortcoming of this model is that it treats group functioning as a single variable and therefore does not differentiate between types of students' contributions. Other research has studied the different processes that take place within tutorial groups, but the relationship between these different processes, self-study time and achievement has not been investigated. It remains unclear which specific student activities are crucial for good learning achievements (Hak & Maguire, 2000). Another shortcoming is that measurements of PBL group functioning are often based on students' self-evaluations, while the validity and reliability of self-evaluation are not optimal (e.g. Eva, 2001). Therefore, this study investigated the relationship between the contributions students make to the tutorial group process as observed by their peers, self-study time and achievement. Three different types of student contributions were evaluated by peer group members, viz. constructive, collaborative and motivational contributions, which are thought to be conducive to effective learning in small groups (Slavin, Hurley & Chamberlain, 2003). The central research question is: 'Do students who perform better in tutorial groups (i.e. display more constructive, collaborative and motivational activities according to their peers) also spend more time on self-study and subsequently achieve better' (see Figure 1).

Methodology

Participants were 650, divided into 65 tutorial groups, first- and second-year students attending the medical curriculum (PBL) at Maastricht University during the academic year 2009-2010. Students met each other twice a week for a two-hour session over a period of six (first year students) to 10 (second year students) weeks.

Students' activities were measured with the earlier validated 14-item Maastricht-Peer Activity Rating Scale (M-PARS) (Kamp, Dolmans, Van Berkel & Schmidt, 2010), consisting of three subscales: constructive (i.e. This student asked critical questions), collaborative (i.e. This student felt responsible for the group) and, motivational activities (i.e. This student participated well). With this scale students evaluated the performance of their peers in the tutorial group by responding on a 5-point Likert-scale (1 = strongly disagree – 5 = strongly agree).

Student achievement was measured with a group assignment and a test at the end of the unit.

Self-study time was measured at the end of the course, before the unit test, with a self-estimation method.

The causal relations between student activities, self-study time and achievement, were investigated with a structural equation modeling analysis on the model in Figure 1 (AMOS Version 17.0). Good model fit was assessed by the following criteria: CMIN/DFp-value, RMSEA \leq .05, and NFI $>$.95 (Garson, 2009).

Findings

The initial model (Figure 1) generated a poor fit. Based on the modification indices and theoretical insights the causal model in Figure 2 was developed, which demonstrated good model fit: chi-square [5df] = 5.167, $p = 0.396$, RMSEA = 0.008 and NFI = 0.997. Figure 2 illustrates a significant causal relation between a student's constructive activities and his/her unit test score, between a student's collaborative activities and his/her group assignment score and between a student's group assignment score and his/her unit test score. Unexpectedly, the effect of the tutorial group activities on achievement was not mediated by self-study time.

Insert Figure 2 here

Significance

The significance of this study is that it further specifies the relationship between group functioning in PBL and achievement. The findings indicate that students who, according to their peers, display more constructive activities achieve better on the unit test than their peers who make less constructive contributions. In addition, the results indicate that students who are perceived as more committed to the group and promote collaboration within the

group, achieve better on the group assignment than students who are perceived as less committed. The absence of the mediating effect of self-study time could be explained by the argument of Plant, Ericsson, Hill, and Asberg (2005), that learning achievements are not so much influenced by the amount of time students spend on self-study, but by the manner in which they spend it.

The findings also suggest that in order to improve achievement in PBL curricula, students' tutorial contributions should be evaluated and monitored. For this purpose the M-PARS could be used as a feedback instrument. Based on their scores, students receive feedback on the quality of their behavior within the tutorial group, which might lead to improved behavior and subsequently, better achievement. Further research is needed to investigate this hypothesis.

SYMPOSIUM

Motivational perspectives on study behaviors and learning outcomes in Higher Education.

Chairperson: Richard Walker, University of Sydney, Australia

Organiser: Luke K. Fryer, Kyushu Sangyo University, Japan

Discussant: Kirsti Lonka, University of Helsinki, Finland

Student Learning Theory (SLT) research has often failed to include current motivational theorizing within model development. Contemporary motivational theories may provide opportunities for further conceptual and practical development. This symposium addresses the role of current motivational theories within Higher Education learning research. The symposium consists of three quantitative, empirical papers centered upon two current, broad motivational fields—Achievement Goals and Self Determination Theory (SDT)—and their relationship with student's study behaviors and learning outcomes. Paper-1 tests the suitability of the Achievement Goal Questionnaire (AGQ) (Elliot & McGregor, 2001) framework for adult learners. Following validation of the AGQ, relationships between goal adoption and learning-related outcomes are assessed. Paper-2 takes a primarily participant-orientated analytical approach to the question of study behaviours' relationship with motivation; results logically follow from prior theory but also raise new questions. Paper-3 tests the effect of student' reasons "to study" and "not study" on their approaches and achievement outcomes by employing SEM panel analysis. Results suggest both "reasons" have an effect on approaches but only high-quality goals affect achievement outcomes.

Motivations have a clear relationship with both study behaviours and outcomes such as achievement and course dropout. Amotivations had a direct effect on students' adoption of maladaptive study behaviours, raising questions about this hitherto under-researched aspect of SDT and its implications for learning in tertiary education. These papers suggest that a range of motivations play important roles in Higher Education. Further research, employing current motivational theories and modern analytic methods may lead to stronger models of tertiary learning.

SYMPOSIUM

Achievement goals in adult learners: Evidence from distance education.

John Richardson, The Open University, United Kingdom; Richard Remedios, University of Durham, United Kingdom

There is evidence that learners may adopt different kinds of achievement goal: mastery-approach, mastery-avoidance, performance-approach and performance-avoidance. In higher education, this evidence has mainly come from young people who have recently gone straight from high school to college. In this study, the Achievement Goal Questionnaire was administered to adult learners taking courses by distance education. Usable data were obtained from 195 men and 586 women between the ages of 19 and 87. The results confirmed the reliability and construct validity of the Questionnaire in this distinctive population. As in previous studies of younger students, mastery-approach goals were unrelated to attainment, performance-approach goals facilitated attainment, and performance-avoidance goals tended to impair attainment. In addition, mastery-avoidance goals impaired students' attainment and also increased the likelihood that they would drop out of their course altogether. The achievement-goal framework is as appropriate for understanding the influences on attainment on adult learners as it is in younger students. There is also evidence that students who adopt mastery goals are more likely to hold reconstructive conceptions of learning and are more likely to adopt a deep approach to their studies. Future research needs to explore these links between students' achievement goals and their approaches to learning.

Aims. Dweck and Elliott (1983) suggested that achievement motivation involved two broad kinds of goal: learning goals (seeking to increase one's competence, understanding, or mastery) and performance goals (seeking favourable judgments or avoiding negative judgments of one's competence from others). Both kinds of goal could promote mastery-oriented behaviour. However, if confidence in one's ability was low, performance goals increased helpless behaviour and lowered motivation. Ames and Archer (1988) offered a similar account but referred to learning goals as "mastery goals". Students who adopt mastery goals are more likely to hold reconstructive conceptions of learning (Sachs, 2001) and are more likely to adopt a deep approach to studying (Grant & Dweck, 2003). Elliot and Harackiewicz (1996) divided performance goals according to whether they were oriented towards the attainment of success or the avoidance of failure. Elliot and McGregor (2001) noted that this distinction could be applied to mastery goals, too. They developed an Achievement Goal Questionnaire (AGQ) measuring mastery-approach goals ("I want to learn as much as possible from this class"), mastery-avoidance goals ("I worry that I may not learn all that I possibly could in this class"), performance-approach goals ("It is important for me to do better than other students"), and performance-avoidance goals ("I just want to avoid doing poorly in this class"). They found that students who adopted mastery-approach goals were more likely to adopt deep processing in their learning, whereas students who adopted performance-avoidance goals were more likely to adopt surface processing. Performance-approach goals appeared to facilitate academic attainment, performance-avoidance goals appeared to impair attainment, but neither mastery-approach nor mastery-avoidance goals were significantly related to attainment. Subsequent research has provided extensive confirmation of this framework. However, a major limitation of the research is that it was carried out with samples consisting predominantly of young people who had recently gone straight from secondary school to college. The present study was carried out to evaluate Elliot and McGregor's (2001) framework in adult learners using a large sample of students who were taking courses by distance learning. Our interest was in the component structure of the AGQ in this population and in whether their scores predicted their subsequent attainment in a similar manner to previous studies.

Methodology

A sample of 1,140 students was drawn from students about to embark on three courses with the Open University in 2005. They were supplemented by three additional items. Two were "On the whole, I expect this course to be very interesting" and "On the whole, I expect this course to be very enjoyable", and the participants responded on the same response scale. The final item asked participants to say whether they were studying to understand the material or to obtain a good grade by checking one of seven boxes, where the extreme categories were labelled "primarily understanding" (coded 1) and "primarily grades" (coded 7). The questionnaire was distributed in a postal survey that was mailed at the beginning of September 2005, and a reminder was mailed 2 weeks later. The survey was closed 6 weeks after the original mailing when the courses had just started so that the students' responses would not be influenced by their experience of their courses.

Findings.

Completed questionnaires were returned by 781 (or 68.5%) of the participants, consisting of 195 men and 586 women varying in age from 19 to 87 years. A principal components analysis of their AGQ responses yielded four components that corresponded to the Mastery Approach, Mastery Avoidance, Performance Approach and Performance Avoidance scales. For each of the four scale scores Cronbach's (1951) coefficient alpha was 0.69 or higher. The correlation coefficients among the four scale scores were all positive and statistically significant, which is consistent with the idea that students can pursue different kinds of achievement goal at the same time. The students obtained very high

scores on Mastery Approach, high scores on Mastery Avoidance and Performance Avoidance, but low scores on Performance Approach. The majority of students expected their course to be both interesting and enjoyable, but they were evenly divided between intrinsic and extrinsic motives for studying. The students' scale scores were compared with (a) whether they completed their course, (b) whether those who completed their course passed, and (c) the marks (on a percentage scale) awarded for assignments and an examination to the students who passed their course. Scores on Mastery Avoidance were negatively related to course completion, but none of the scale scores significantly predicted passing versus failing in students who had completed the relevant course. There was no relationship between scores on Mastery Approach and marks. Students who obtained higher scores on Mastery Avoidance achieved significantly lower marks; students who obtained higher scores on Performance Approach obtained significantly higher marks; and students who obtained higher scores on Performance Avoidance obtained significantly lower marks.

Theoretical and educational significance.

Our results are entirely consistent with those of previous research in showing that the different kinds of achievement goal are related to students' academic attainment in different ways: mastery-approach goals are unrelated to attainment; performance-approach goals tend to facilitate attainment; and performance-avoidance goals tend to impair attainment. The findings are further evidence of the robustness of the goal-outcome relationships, at least for mastery-approach, performance-approach and performance-avoidance goal constructs. In addition, the adoption of mastery-avoidance goals not only tends to impair attainment but also makes it more likely that students will drop out of their course. From a theoretical point of view, this provides additional evidence for Elliot and McGregor's (2001) position that mastery-avoidance goals operate in many achievement settings and have consequences for subsequent attainment. From a practical point of view, these results suggest that the AGQ could provide a simple but useful diagnostic tool to identify students at risk of dropping out of their studies. More generally, the present study demonstrates that the achievement-goal framework is as appropriate for understanding influences on attainment in adult learners as it is in younger students. Future research needs to explore the relationship between students' achievement goals, their conceptions of learning and their approaches to studying.

SYMPOSIUM

Relating academic motivation and processing strategies with students in higher education.

Gert Vanthournout, University of Antwerp, Belgium; Sven De Maeyer, Antwerp University, Belgium; David Gijbels, University of Antwerp, Belgium; Vincent Donche, University of Antwerp, Belgium; Peter Van Petegem, University of Antwerp, Belgium

The present study aims at exploring the theoretically proposed relation between motivation and learning strategies, using contemporary and complex models of learning and motivation, namely the learning pattern-model and self-determination theory. To gain a nuanced and in-depth understanding of this relation the combination of a variable-oriented and a person-oriented perspective in data-analysis was used. Three research questions were addressed: (RQ1) What profiles can be identified, based on students' processing strategies? (RQ2) Do motivational dimensions predict the use of processing strategies? (RQ3) Do motivational dimensions predict profile membership? 408 students in the first year of a professional bachelor programme participated in the study. Students' motivation and learning strategies were assessed using the Learning and Motivation-questionnaire. To identify profiles, a hierarchical cluster analysis, using Ward's method, was used. A multivariate regression analysis was carried out to answer the second research question. To answer the third research question, a multinomial regression analysis was conducted. Results of these analyses on the one hand confirm the relationship between motivation and processing strategies, but on the other hand caution that this relation is not as straightforward as the theoretical models propose. No evidence for one-on-one relations between motivational dimensions and specific strategies were found. A clear relation between high quality motivational regulation and deep processing strategies or profiles could be established. However, the picture becomes less clear-cut at the other end of the continuum. High scores on surface strategies or membership of weaker profiles were not predicted by low quality or quantity of motivation.

Aims

Previous research-models in the approaches to learning tradition hypothesize a direct link between motivational aspects and students' learning strategy use (e.g. Entwistle, 1988). However, most models incorporate traditional and general motivational dimensions. Moreover some models theoretically assume an almost irrevocable relation between certain specific types of motivation and the use of specific strategies (e.g Biggs, 2003). Advances in research and theorizing on learning and motivation, however, suggest that reality is more complex (Baeten et al., 2009; Cano & Berben, 2007). The present study aims at exploring the relationship between motivation and processing strategies, using contemporary and complex models in learning and motivation. To investigate students' motivation, self-determination theory (Deci & Ryan, 2002) was used. This model distinguishes between five types of motivational

regulation: lack of motivation, external regulation, introjected regulation, identified regulation and intrinsic regulation. To map students' processing strategies, Vermunt's learning pattern model (Vermunt & Vermetten, 2004) was used, encompassing five processing strategies: relating and structuring, critical processing, analysing, memorising and concrete processing.

The following research questions were addressed: .

- (RQ1) What profiles/clusters can be identified, based on students' processing strategies? (person-oriented approach) .
- (RQ2) Do motivational dimensions predict the use of processing strategies? (variable-oriented approach) .
- (RQ3) Do motivational dimensions predict profile membership? (combined approach)

Based on previous research and theoretical models we expect high quality motivation (intrinsic or identified regulation) to predict the use of deep strategies (relating and structuring, critical processing, concrete processing) and membership of strong learning profiles. Similarly we hypothesize low quality (introjected or external regulation) or quantity of motivation (lack of motivation) to be related to the use of surface strategies (memorising, analysing) or weaker profiles.

Methodology

Participants were 408 first year students enrolled in a professional bachelor programme. Students were questioned on their motivation and processing strategies using the Learning and Motivation questionnaire (Donche & Van Petegem, 2008). This instrument combines adapted scales from Vermunt's Inventory of Learning Styles (Vermunt, 1998) with adapted and selected items and scales from the Academic Self-Regulation Scale (Ryan & Conell, 1989) and the Academic Motivation Scale (Vallerand et al., 1997). A combination of a variable-oriented and a person-oriented perspective in data-analysis was carried out because both perspectives provide complementary information (Goldblatt & Fortunato, 1996). To identify profiles, a hierarchical cluster-analysis was carried out on the processing strategies, using Ward's method. Statistical and theoretical criteria were taken into account to determine the most suitable number of clusters. To explore the relationship between motivational dimensions and processing strategies a multivariate regression analysis was used, with the regulations as predictors and the processing strategies as dependents. To investigate the relationship between these profiles and motivational dimensions, a multinomial regression analysis was conducted with the motivational dimensions as predictors and the profiles as dependents.

Findings

Results In the cluster analyses, a six cluster solution was deemed most appropriate. The resulting clusters were labeled as follows: 1. Deep-flexible learners (n=92; 23%): Students in this cluster combine high scores on relating, concrete and critical processing with average scores on analysing and below average scores on memorising. 2. Moderate deep learners (n=72; 18%): Students with this profile have moderate scores on relating, concrete and critical processing as well as below average scores on both analysing and memorising. 3. Stepwise learners (n=63; 15%): Students in this cluster have a combination of high scores on analysing and memorising and moderate scores on relating, concrete processing and critical thinking. 4. Memorizers (n=140; 34%): Students with this profile score below average on most processing strategies except for memorising. 5. Passive learners (n=41; 10%): Students in this cluster have low scores on all processing strategies. Results of the multivariate regression analysis indicate that all predictors except external regulation and lack of motivation are significant predictors of the full model, explaining about 20% of the variance. Introjected regulation predicts the use of analysing and memorising strategies, while identified regulation is linked to the use of all processing strategies. Finally, Intrinsic regulation significantly predicts the use of critical processing and relating as processing strategies. The multinomial regression analysis was conducted with the deep-flexible learners as reference group. The model is significant at the .001 level. All motivational dimensions except external regulation and lack of motivation prove to be significant predictors of cluster membership. Scores on introjected, identified and intrinsic regulation differentiate between the deep flexible learners and the passive learners. Students with lower scores on these regulations have a higher chance of being members of the passive learners profile. Identified and intrinsic regulation also distinguish between the deep-flexible learners and the memorizers. Students who perceive courses as being relevant or are personally interested, have a higher chance of belonging to the deep-flexible profile. Intrinsic motivation is the sole significant predictor for distinguishing between the deep-flexible learners and the stepwise learners. Deep-flexible learners are more interested in the courses. Finally, none of the motivational dimensions significantly predicts cluster membership when comparing the deep-flexible with the moderate deep profile.

Theoretical and educational significance

Results from our analyses on the one hand confirm the link between motivation and the use of processing strategies as proposed by theoretical models in the SAL-tradition. On the other hand, they also caution that this relation might not be as straightforward as these models envisage. For instance, there doesn't seem to be an unequivocal relationship between specific motivational drives and accompanying processing strategies. Moreover, although there seem to be a clear link between high quality of motivation and deep learning strategies or strong learning profiles, the relation becomes less clear-cut at the other end of the continuum. For instance, students in the memorizers or passive learners profile have a lower score on high quality motivational dimensions, compared to the deep-flexible learners, but this is not accompanied by higher scores on low quality or quantity motivational regulations. For research and theory, these results contribute to a more in-depth and nuanced understanding of what appears to be a complex relationship between learning and motivation. They also warn practitioners not to draw conclusions on students' strategy use based solely on motivational indicators.

SYMPOSIUM

The longitudinal effect of reasons to study and not study on approaches to learning and achievement.

Luke K. Fryer, Kyushu Sangyo University, Japan; Richard Walker, University of Sydney, Australia; Paul Ginns, University of Sydney, Australia; Raymond Debus, University of Sydney, Australia

This research tested a longitudinal structural model assessing the effect of students' reasons "to study" and "not to study" on their approaches to learning and achievement. Students' Instrumental goals and Amotivation for learning were hypothesized to have a direct effect on students' self-reports of study behavior. Effort-belief amotivations were found to have a direct medium effect on Surface Approaches and Distal-internal goals had a direct medium effect on Deep Approaches and achievement. Effort-beliefs are important sources of maladaptive study behaviours and therefore a practical topic for instructors concerned with helping students pursue adaptive study strategies. Conversely, the adoption of internal goals by students was positively associated with both adaptive study strategies and achievement. This would suggest that aiding students in developing instrumental goals, beyond external sources of instrumentality such as graduation and future employment, might be beneficial for student learning in university.

The importance of a student's approaches to learning, including Deep (DA) and Surface (SA) approaches, has been widely recognized within the higher education literature. Reflecting the original Student Learning Theory (SLT) research (Marton & Säljö, 1976), questions regarding the inducement of DA and prevention of SA have generally focused on correlational research examining the relationship between the learning environment and students' approaches (e.g. Ramsden & Entwistle, 1981). Relatively fewer studies have explored other intra-individual factors related to students' approaches, although some researchers have begun to explore individual and motivational correlates (e.g. Chamorro-Premuzic & Furnham, 2009; Prat-Sala & Redford, 2010). The present study tests a structural model including both perceptions of the learning environment, and emerging motivational constructs, as they relate to approaches to learning and academic achievement.

Aims

To date, relatively little SLT research has employed a Structural Equation Modeling (SEM) approach. SEM with longitudinal rather than cross-sectional data enables causal models to be tested, and is therefore an essential step toward developing a SLT model with practical implications for higher education stakeholders concerned with quality assurance.

Student perceptions of Good Teaching tend to be moderately correlated with DA (positively) and SA (negatively) to learning (Wilson, Lizzio, & Ramsden, 1997). This core SLT construct thus provides a "benchmark" to judge the relative importance of novel constructs.

Two areas of motivational research that may be of practical importance in higher education are Instrumental motivation and Amotivation. Both types of motivation are relatively new components of Self Determination Theory (SDT). Amotivation refers to a lack of motivation. Considerable research during the past two decades has led to the development of the Academic Amotivation Inventory (AAI) (Legault, Green-Demers, & Pelletier, 2006). The AAI measures amotivation within four motivational frameworks: Task-Value, Effort Beliefs, Ability Beliefs and Task Characteristics.

Instrumental motivation is a mixture of task-value, extrinsic motivation and future-time perspective. Higher education, with its strong connection and close proximity to work-life, is a context within which instrumental motivation is both ubiquitous and varied. Depending on the students, their development, and their study context, they may be motivated by different instrumental motivations. Research has shown that it is not the quantity of motivation but the quality that is important for learning outcomes (Vansteenkiste, Lens, & Deci, 2006). Therefore, to assess a range of

instrumental reasons for studying in Higher Education, Simons, Dewitte, & Lens' (2004) 2 (Proximal/Distal) x 2 (Internal/External) goal framework was employed for scale development during prior piloting. To test the relative causal efficacy of Instrumental goals and Amotivation on student approaches, Trigwell & Ashwin's (2006) version of the Approaches to Study Inventory, measuring DA and SA constructs, was employed.

Methodology

At Time 1, perceptions of Good Teaching, Instrumental motivations for studying and Amotivations for not studying were measured. At Time 2 (seven months later), students' approaches were measured, and student achievement data for the entire year, in the form of annualized GPA, were obtained from the university with students' written consent. All surveys were piloted the year prior to research and found to be valid measures of their respective constructs. The sample was 70% male, proportional to enrolment. The final matched sample was $n = 1173$. An example item and the scale reliability for the finalized scales are listed in Table 1.

Table 1. Scale items, reliability and example item.

The hypothesized model tested both direct and indirect relations between constructs measured at Time 1 and Time 2.

Findings

Figure 1 presents the final longitudinal model: beginning of semester one, to the end of semester two. The presented model fits the data acceptably: CFI = .93, TLI = .92, RMSEA = .05. Only nine of the tested paths were significant ($p > .05$)—represented by solid lines in Figure 1.

Figure 1. Longitudinal SEM at three time points: Motivation, Approaches, and Achievement.

Theoretical and educational significance

The longitudinal effect of students' Effort-beliefs and Distal-internal goals are of particular significance for practice. Despite the temporal distance (seven months), Effort-beliefs have a consistent medium effect on students' less adaptive approaches. Instructors seeking to improve their students' study behaviours would be well advised to discuss time management and explicitly portray the time demands of the course in a comprehensible and achievable manner. As hypothesized, high quality internal goals had the strongest impact on adaptive study behaviours. This suggests that helping students develop clear internal goals, beyond grade and career would benefit not only their approaches but also directly improve their learning outcomes.

Several unexpected results emerged in the present study. Firstly, perceptions of Good Teaching were positively correlated with both approaches. In addition, SA and DA were positively correlated ($r = .38$). Both of these results suggest that the learning environment in Japanese universities may be inconsistent with what is generally found in many western Universities, indicating a need for further examination of this under-researched higher education setting.

SYMPOSIUM

Strategy flexibility: Analyzing its related structures and processes

Chairperson: Joke Torbeyns, K.U.Leuven & GROUP T - Leuven University College, Belgium

Organiser: Joke Torbeyns, K.U.Leuven & GROUP T - Leuven University College, Belgium

Discussant: Ineke Imbo, Department Experimental Psychology, Belgium

During the last decades, the efficient and flexible or adaptive use of various strategies on mathematical tasks has become an important topic for researchers in the domain of cognitive and educational psychology (e.g., Baroody & Dowker, 2003; Kilpatrick et al., 2001; Shrager & Siegler, 1998; Verschaffel et al., 2007). This symposium brings together three empirical contributions focusing on children's and adults' strategy flexibility on mathematical tasks and its related structures and processes. The three studies start from a common definition of what it means to select strategies flexibly/adaptively, but use an interesting variation in methodologies to study this topic. In the first contribution, meta-analytic techniques are used to analyze the relations between people's conceptual and procedural mathematical knowledge. In the second contribution, a micro-genetic study is presented in which the role of feedback on children's adaptive strategy use is tested. In the third and final study, the authors show the impact of previous strategy selection on the choice process. Taken together, the different contributions do not only increase our understanding of the structures and processes that are related to the flexible use of different strategies on mathematical tasks, but also provide building blocks for cultivating the acquisition of adaptive expertise in mathematics classrooms.

SYMPOSIUM

Strategy flexibility matters for student achievement: How flexibility relates to other outcomes

Kelley Durkin, Vanderbilt University, United States; Bethany Rittle-Johnson, Vanderbilt University, United States; Jon Star, Harvard University, United States

Strategy flexibility is an important component of student learning in mathematics but has only recently been rigorously examined by researchers. Consequently, the relationships between strategy flexibility and other constructs, such as conceptual and procedural knowledge or general mathematics achievement, remain poorly understood. The current paper used meta-analytic techniques to find mean effect sizes for the relationships between strategy flexibility and these other constructs. Using data from eight studies that measured strategy flexibility, conceptual knowledge, procedural knowledge and general mathematics achievement, we found moderate to strong relationships between flexibility and each of the other constructs. These results provide empirical support for the idea that strategy flexibility is an important construct that is related to, but distinct from, other constructs. Also, based on these results, test makers may want to consider adding measures of students' strategy flexibility to standardized measures of mathematics achievement to give teachers and parents a more complete understanding of students' mathematics abilities.

While conceptual and procedural knowledge have been the focus of much discussion for years in mathematics education, flexibility in problem solving has only recently been examined and measured more rigorously (Star, 2005). This increased attention on strategy flexibility suggests the need to investigate how flexibility may relate to other constructs, including conceptual and procedural knowledge and general measures of mathematics achievement. The current paper provides empirical support for the idea that strategy flexibility is important and is related to, but distinct from, other constructs related to students' mathematical abilities. Flexibility is acknowledged as an important component of student learning in mathematics, and people who develop strategy flexibility are more likely to use or adapt existing procedures when facing unfamiliar problems and to have a greater understanding of domain concepts (e.g., Blöte, Van der Burg, & Klein, 2001).

While the importance of flexibility is increasingly acknowledged by researchers, flexibility is not frequently assessed as an instructional outcome in schools (Star, 2005). More specifically, standardized tests in the United States often include sections on concepts, procedures, and problem solving, but they do not include measures of flexibility. However, in recent years, researchers have begun to develop assessments of strategy flexibility and to consider how this outcome is or is not related to conceptual and procedural knowledge (Star, 2005; Verschaffel, Luwel, Torbeyns, & Van Dooren, 2007). There are some differences in how researchers define flexibility (e.g., Verschaffel et al., 2007). We use a common definition, which is that flexibility involves knowing multiple strategies and their relative efficiencies and adapting strategy choice to specific problem features (e.g., Blöte et al., 2001; Rittle-Johnson & Star, 2007). We separated the construct of strategy flexibility into flexibility knowledge and flexible use of procedures (e.g., Rittle-Johnson & Star, 2007). Flexibility knowledge is defined as knowing multiple strategies and the relative efficiency of the procedures. Flexible use of strategies is defined as students picking the most efficient procedure depending on problem features. It is important to examine both flexibility knowledge and flexible use because students can sometimes identify a more appropriate strategy for solving a problem before they actually choose to use it (e.g., Blöte et al., 2001).

To examine the relationship between flexibility and other measures, we searched for studies that measured strategy flexibility, conceptual knowledge, and procedural knowledge, and included standardized test data. This resulted in the inclusion of eight studies that focused on flexibility in the domains of equation solving and computational estimation with students in Grades 5 – 8 in the United States (e.g., Rittle-Johnson & Star, 2007; Star & Rittle-Johnson, 2009). Each study used a pretest-intervention-posttest design, and all of the interventions involved learning conditions meant to promote flexibility, such as having students compare multiple solution methods. In the included studies, the conceptual knowledge measures assessed the ability to recognize and explain key domain concepts (Hiebert & Wearne, 1996).

Procedural knowledge was defined as the ability to execute action sequences to solve problems on both familiar and novel problem types (Hiebert & Wearne, 1996). Different mathematics standardized tests were used in different studies depending on what was used at the participating schools. We examined correlations between measures at posttest. Because these were correlations between continuous variables, we used Fischer's Z to transform correlations to effect sizes (Lipsey & Wilson, 2001). The mean effect size for each type of correlation (e.g., the correlation between flexibility knowledge and flexible use) was calculated using meta-analytic techniques and then transformed using the inverse Fischer's Z transform.

The mean effect sizes for each correlation are shown in Table 1. Our analysis yielded three main results. First, as expected, flexibility knowledge and flexible use measures were strongly related to each other, although they were not perfectly correlated with one another ($r = .635$). We interpret this finding to indicate that it is important to measure flexible use and flexibility knowledge separately; measures of knowledge and measures of use appear to be tapping somewhat different aspects of flexibility. Second, we found that conceptual and procedural knowledge had moderately strong relationships to both flexibility measures (r 's from .541 to .627), indicating that conceptual and procedural knowledge are related to, but distinct from, flexibility. Finally, the standardized test measures were significantly correlated with other outcome measures, especially flexibility knowledge ($r = .535$).

Overall, these results suggest that it is important to measure students' flexibility, both in terms of knowledge of multiple strategies and ability to flexibly choose efficient strategies. In addition, test makers may want to consider adding measures of students' strategy flexibility to standardized measures of mathematics achievement to give teachers and parents a more complete understanding of students' mathematics abilities.

SYMPOSIUM

Practice without feedback can increase the adaptivity of strategy choices: A microgenetic study

Michael Schneider, ETH Zurich, Switzerland; Daniela Nussbaumer, Verhaltenswissenschaften, Switzerland

The ability to choose problem solving strategies flexibly and adaptively is an important part of mathematical competence. However, it is unclear how simple forms of problem solving practice affect this ability. On the one hand, as demonstrated by the Einstellung effect and the Stroop effect, practice leads to automatized routines which can decrease the adaptivity of strategy choices. On the other hand, practice helps problem solvers to associate problem types with effective solution strategies what can increase the adaptivity of strategy choices. It is unknown which of those two mechanisms has a stronger effect on adaptivity. In a microgenetic design with 48 trials of a mathematical problem solving task, we found that the adaptivity of strategy choices increased linearly during practice without feedback in a group of ninth-graders. Instructional support to stimulate insight sped up this process in a second experimental group. Adapting strategy choices to problem types led to shorter solution paths, higher solution rates, and higher speed. The results are interpreted in terms of cognitive models of strategy choices and their educational implications. They demonstrate how procedural practice and feedback to foster learning with understanding together shape the development of adaptive strategy choices.

Theoretical background Strategies are step-by-step procedures for solving a problem. From among available strategies adaptive problem solvers choose the strategy which allows them to solve the problem most efficiently, particularly in terms of high accuracy and high speed. The adaptivity of strategy choices has been recognized as an important outcome of competence development, as a central component of expertise, and as a favorable educational outcome (Star & Rittle-Johnson, 2008). In the current study we investigated the effect of simple problem solving practice without feedback on adaptivity. Two opposing influences of practice on adaptivity have been proposed in the literature. On the one hand, practice leads to automatized problem solving routines that can decrease the adaptivity of a problem solvers behavior. These phenomena are discussed, for example, in the literatures on the costs of expertise, on the Einstellung effect, and on the Stroop effect (Bilalic, McLeod, & Gobet, 2008). On the other hand, over the course of practice a problem solver can gather information about which strategy is most efficient for solving which problem type. This mechanism can increase the adaptivity of strategy choices. It has been described most comprehensively in Robert S. Siegler's models of strategy choices and development (e.g., Shrager & Siegler, 1998).

According to the models, during practice individuals acquire information about each strategy's effectiveness, in terms of accuracy and speed, for solving the encountered problem types. This information subsequently helps learners to choose the strategies that maximize the efficiency of the problem solution. These two opposing mechanisms might co-exist but it is currently unknown which of them is stronger. Therefore, it is also not known whether practice without feedback ultimately increases the flexibility of strategy choices, decreases it or leaves it unchanged. The aim of our study is to investigate this question.

Method

The sample consisted of 77 ninth-graders. Each student solved 48 trials of a mathematical problem solving task, i.e., solving two equations with two unknowns. This task can be solved by three alternative strategies: the equating strategy, the substitution strategy, and the addition strategy. Depending on the structure of the presented equations, one of the three strategies is most efficient because it requires the smallest number of mathematical operations to derive the solution. We constructed three types of problems. For equating problems the equating strategy is more efficient than the other two strategies. For addition problems the addition strategy is most efficient; and on substitution problems the substitution strategy is most efficient. In the following, we label strategy choices following

this pattern as adaptive. The problems were presented one by one in 16 blocks of three trials. Each block comprised, in a random order, one addition problem, one substitution problem, and one equating problem. The problems were presented on a computer screen, had to be copied to a booklet, and solved in written form. The solutions had to be entered into the computer which recorded accuracy and speed. Two raters (agreement: 99% of trials) categorized each written solution path as (a) addition strategy, (b) equating strategy, (c) substitution strategy, or (d) other. We made sure that all students knew the three solution strategies. They did not receive any instruction with respect to making adaptive strategy choices. Each student was randomly assigned to one of two treatment groups. The no-feedback group ($n = 39$) practiced problem solving without any instructional support. The feedback group ($n = 38$) solved the same problems and indicated after each trial by clicking one of three buttons which of the alternative strategies they had used. The computer told them if they had chosen the most efficient strategy, which saved them unnecessary work, or if they had chosen a less efficient strategy, which created unnecessary work.

Results

Compared to all the other trials, trials with adaptive strategy choices had higher mean solution rates (68 vs. 53 %, $p = .000$), lower mean solution times (126 vs. 171 sec, $p = .000$), and a smaller number of lines in the written solution paths (4.4 vs. 6.0 lines, $p = .000$). So matching strategies to problem types is adaptive behavior. Adaptivity increased in both treatment groups, as we confirmed by regression analyses ($p = .000$ for both groups) and as is displayed in Figure 1.

Discussion

Our results provide strong evidence for the hypothesis that practice has a positive net effect on the adaptivity of strategy choices. Adaptivity increased in both treatment groups but the increases were stronger and quicker in the feedback group. The strong positive net effect of practice without feedback on the adaptivity of strategy choices is remarkable because the students were in a complex situation and received minimal information. The students solved equation problems while simultaneously learning how to increase adaptivity. They were not instructed to focus on strategy use, efficiency or strategy choices. They also did not know ahead of time that there would be three different problem types, each corresponding to one strategy. Still the students increased their adaptivity, what provides evidence for the associative learning mechanisms outlined in Siegler's model of strategy choices. The students learned to associate problem types with those strategies that led to the lowest solution times, shortest solution paths, and highest solution rates. From an educational perspective, the results emphasize the importance of feedback in problem solving practice. The feedback group learned more quickly than the no-feedback group. However, the results also show clearly that problem solving without immediate feedback, as it is common in homework assignments, does not hurt students' flexibility but further increases it. Future studies need to test the generalizability of our results to students in different age groups and on different achievement levels.

SYMPOSIUM

The perseveration effect: Individuals' tendency to reuse the preceding strategy

Viki Schillemans, Katholieke Universiteit Leuven, Belgium; Koen Luwel, Katholieke Universiteit Leuven, Belgium; Patrick Onghena, K.U.Leuven, Belgium; Lieven Verschaffel, K.U.Leuven, Belgium

Adaptivity is an important feature of strategy use. Among other things, this implies that one can switch smoothly between strategies when appropriate. However, using a numerosity judgement task, Schillemans, Luwel, Bult  , Onghena, and Verschaffel (2009) recently demonstrated that participants are not always adaptive; they often persevere on the last applied strategy. In this study, we replicated this result with the same task but with a different paradigm. Adult participants had to determine the number of coloured blocks presented in 5x10 grids using one of two strategies: an addition strategy (whereby participants add the coloured blocks) or a subtraction strategy (whereby they subtract the number of empty cells from the total grid size). The different numerosities were presented in three different presentation orders: ascending, random, and descending. In the ascending order, participants started with solving low-numerosity items (which are known to be solved with the addition strategy) that gradually increased to high-numerosity items (which are known to be solved with the subtraction strategy). In the descending order, participants started with solving high-numerosity items that gradually decreased to low-numerosity items. We hypothesized that participants' change point (i.e., the numerosity on which they switch from one strategy to the other) would differ for the three presentation orders, and, more specifically, that it would be largest in the ascending order and smallest in the descending order. The results confirmed this hypothesis. As such, this study provides further evidence for the previously observed perseveration effect. The educational implications of this result will be discussed.

In the last 25 years, numerous studies have shown that individuals exhibit a remarkable variability in their strategies for accomplishing cognitive tasks. Strategy diversity is advantageous since it offers the potential to adapt to problem

characteristics, but also to changing situational demands, and to subject features (e.g., Verschaffel, Luwel, Torbeyns, & Van Dooren, 2009). This strategic variability implies that one always has to choose a strategy from his/her strategic repertoire for each problem at hand. It can be assumed that the better one can adapt one's strategy to the demands of the task and situation and to one's own abilities, the better the resulting performance in a specific task will be. Being adaptive, however, requires that one can switch smoothly between strategies when appropriate. This involves, among other things, that one is able to disengage from the last activated strategy and select and execute another strategy that is more adaptive. However, it has recently been shown that participants persevere on the last applied strategy. Schillemans, Bulté, Luwel, Onghena, and Verschaffel (2009) used a numerosity judgement task to demonstrate that participants are more inclined to use the strategy that they had been using on the preceding trials, at least for certain numerosities.

The goal of the task was to determine the number of coloured blocks in 5x10 grids. To do so, participants can use two strategies, namely the addition strategy (whereby they add the coloured blocks) and the subtraction strategy (whereby they subtract the number of empty cells from the total grid size) (e.g., Verschaffel, De Corte, Lamote, D'Herdt, 1998). Schillemans et al. demonstrated that participants choose more often for the addition strategy after a series of addition items (i.e., items with small numerosities that strongly elicit the addition strategy) and more often for the subtraction strategy after a series of subtraction items (i.e., items with large numerosities that strongly elicit the subtraction strategy), but only on midrange numerosities that are not strongly associated with either strategy. Likewise, using a two-digit mental addition task that can be solved with two strategies (i.e., partial-decomposition and full-decompositions), Lemaire and Lecacheur (2010) also demonstrated that participants were more inclined to repeat the previous strategy than to switch to the other strategy.

The purpose of this study was to replicate these findings with the same numerosity judgment task as Schillemans et al. (2009) but with a different paradigm. We looked for the perseveration effect in terms of participants' change point, that is, the numerosity on which they switch from one strategy to the other. It has previously been demonstrated (e.g., Luwel, Lemaire, & Verschaffel, 2005) that when the numerosities are presented randomly, participants use the addition strategy for numerosities below that change point and the subtraction strategy for numerosities above it. However, some unexpected strategy choices were observed around the change point (i.e., the subtraction strategy being used in the numerosity range below the change point and the addition strategy above it). A closer inspection revealed that these were almost always replications of the previous strategy.

For the present study, wherein we manipulated the presentation order, we hypothesized that this change point would depend on the order in which the numerosities are presented to the participants: in an ascending, a random, or descending order. In the ascending order, participants started with solving low-numerosity items (e.g., 16, 18), which are known to be solved with the addition strategy and we gradually increased the items to high-numerosity items (e.g., 36, 38), which are known to be solved with the subtraction strategy. In the descending order, the items were presented in the opposite presentation order compared to the ascending order: Participants started with solving high-numerosity items and we gradually decreased the items to low-numerosity items. In the random order, the different numerosities were presented randomly. We hypothesized that participants' change point would differ for the three presentation orders, and, more specifically, that it would be largest in the ascending order and smallest in the descending order.

Method

Fifty-seven university students (mean age = 18.72 years) were individually tested with the above-mentioned numerosity judgement task. They were instructed to judge coloured blocks in 5x10 grids in three presentation orders, namely an ascending, a random and a descending order. The numerosities 16-38 were used as the test items. So, an example of an ascending order was 16-18-19-22-24-26-27-28-29-31-34-35-37. An example of a descending order was 38-36-33-32-30-28-27-26-25-23-21-20-17. The three orders were presented twice (in a counterbalanced order) and were separated from each other by a lexical decision task to prevent for influences from one sequence to the next one.

Results

The main result of this study was a significant difference in participants' individual change points. In line with our hypothesis, the average change points for the ascending, random and descending orders were, respectively Ms: 27.88, 26.67, and 25.90, $F(2, 100) = 4.71$, $p = .01$

Discussion

The results of this study provided additional evidence for the existence of a perseveration effect in strategy selection; that is, participants are more inclined to repeat the previously used strategy, at least for items that are not too

strongly associated with a particular strategy. The question remains whether this behaviour can be called adaptive or not. At first sight, just repeating the previous strategy does not seem to be adaptive but rather an expression of stereotyped behaviour. But, if the items on which the perseveration effect occurs are indeed strategy-neutral, it can be cognitively advantageous to repeat the previously used strategy because this reduces cognitive load without leading to decline in performance. Therefore, now that the existence of the perseveration effect has been shown for different tasks and with different paradigms, an important issue for further research is testing whether the perseveration effect only occurs on items for which both strategies are equally applicable or also for items for which one of the strategies is clearly more suitable. From a (mathematics) educational perspective, a better understanding of the perseveration effect may lead, for instance, to adaptations in the sequencing of exercises in textbooks and test.

SYMPOSIUM

Gender differences in interest and achievement in science classrooms

Chairperson: Manuela Paechter, Karl-Franzens-University Graz, Austria

Organiser: Bernhard Ertl, Universität der Bundeswehr München, Germany

Manuela Paechter, Karl-Franzens-University Graz, Austria

Discussant: Jim Ridgway, University of Durham, United Kingdom

Across the domains of mathematics and science, there are significant gender differences in achievement, interest, and motivation for male and female students. For example, in most of the countries which took part in the PISA studies, girls were less likely than males to choose science courses, showed less interest and motivation, and put less priority on doing well in science. In some countries, girls also achieved less, especially in physics. The contributions of this symposium aim to explain reasons for such gender differences and to give didactic solutions or good-practice examples.

According to the study of Ding, differences between girls' and boys' achievements may be explained by differences in processing information, e.g. graphical representations in physics. Girls processed representations with a focus on explaining a problem while boys focused on finding a solution. Ding also shows that female students achieved less in gender-mixed groups.

These results can be explained by the study of Ertl: In his survey, girls expressed less interest and self-confidence in science and mathematics classrooms than boys. The results of the study can also be seen as recommendations of how to design instruction from students' point of view.

The study of Paechter and Jones takes up these recommendations. They investigate an instructional design which supports female and male middle and high school students' interest by introducing hands-on experiences in science education. Results show that female students' interest was related to the linking of science content to opportunities for hands-on and social interaction.

SYMPOSIUM

Equal-status interaction and gender experiences in computer supported STEM classrooms

Bernhard Ertl, Universität der Bundeswehr München, Germany

Researchers and practitioners aim at providing equal-status interactions in the classroom to allow all students to make beneficial learning experiences. Yet, in STEM (sciences, technology, engineering, and mathematics) classes there are often status inequalities with respect to gender, which is associated with the phenomenon that girls show less self-confidence and interest.

This paper investigates prerequisites for equal status interaction in computer supported STEM classrooms in the context of gender. It provides results from a quantitative study and a qualitative study. The quantitative study investigates females' and males' structure and self-confidence (according to Rheinberg, Vollmeyer, & Burns, 2001) with respect to STEM and the qualitative part analyses how students perceive gender and status inequalities.

Results of the quantitative study show no differences between boys and girls for the dimensions of fear of failure, chance for success, and challenge but that boys score significantly higher for the dimension of interest and self-confidence. The qualitative part presents deeper insights how gender and status inequalities are perceived by girls and boys.

Providing equal-status interaction in computer supported STEM classrooms

Heterogeneity in classrooms can be seen as a chance and as an obstacle for learning. As chance, it provides motivation for knowledge sharing and mutual learning; as obstacle heterogeneity often enables more knowledgeable pupils to benefit more in such scenarios. One reason for this are status inequalities that allow higher status pupils a more active part in learning while pupils with a lower status have a more passive spectator role. To avoid this, teachers should aim at providing equal-status interaction in the classroom (see Cohen & Lotan, 1995).

Status inequalities may result from different sources, e.g. ethnicity, socio-economic-status, or gender. For computer supported STEM classrooms, perceived status inequalities coming from gender stereotypes can be an important issue. They can result in differences in self-confidence, interest and motivation and thereby support the development of self-fulfilling prophecies that have a negative effect on girls' achievements (see Cohen & Lotan, 1995).

Research Questions

The aim of this study is to investigate gender related for status inequalities in STEM:

Research question 1: What are the differences of girls and boys regarding their motivational structure and self-confidence in STEM?

Research question 2: How are gender inequalities perceived in computer supported STEM classrooms?

Method

For answering these research questions, the paper will present the results of two empirical studies. Study 1 was a questionnaire survey of 91 upper secondary students, 49 females and 42 males, enrolled in a computer science course; study 2 comprised of 14 qualitative interviews with 8 girls and 6 boys of this course. Both studies were part of a bigger study project and therefore only the parts relevant for this paper were reported.

Quantitative study

The quantitative study was done by a questionnaire which comprised of scales for self-confidence and actual motivations (adapted from Rheinberg et al., 2001).

The self-confidence scale comprised of 7 items surveying a student's self-confidence in performing computer science tasks. The internal consistence of the scale was good (Cronbach's $\alpha > .75$).

The questionnaire for actual motivations comprised of four sub-scales: challenge (4 items, Cronbach's $\alpha > .56$), interest (5 items, Cronbach's $\alpha > .72$), chance for success (4 items, Cronbach's $\alpha > .95$), and fear of failure (5 items, Cronbach's $\alpha > .76$).

Qualitative study

The qualitative study aimed at looking beyond the gender differences to get insights about how pupils perceive gender interaction in the computer supported STEM classroom. The study was carried out by 7 small focus groups, each with two participants. Students in the focus groups followed a semi-structured interview protocol concerning topics e.g. how pupils estimated the class climate and if they perceive differences between females and males in class. The interviews were recorded, transcribed and analyzed according to grounded theory.

Results

Research question 1

Results of the questionnaires show that there are some sub-scales without differences and some with significant differences between males and females (see values in table 1). There was no significant difference for the dimensions of chance for success ($F(89,1) = 0$; n.s.), fear of failure ($F(89,1) = 0$; n.s.), and challenge ($F(89,1) = 1.41$; n.s.) even if females felt slightly more challenge than boys. Yet, females and males differ significantly with respect to interest ($F(89,1) = 7.04$; $p = .07$) and self-confidence ($F(89,1) = 4.08$; $p = .04$). Table 1: Results of the quantitative study (Min = 1; Max = 10).

Research Question 2

Results of the qualitative study support the quantitative results. In particular, boys attribute girls as less capable compared to themselves. Girls are often attributing boys more knowledge or giftedness, however they sometimes realize that boys are often acting "the big shot" which means that they just pretend to have experience. Yet, in several cases females stated that they avoid to make contributions during lessons because they are afraid of receiving negative comments from males.

Discussion

Results of the qualitative and quantitative study show an ambiguous image on gender in the computer supported STEM classroom: On the one hand regarding outcome expectancies females estimate themselves the same level of chance for success and fear of failure like boys. This is an important prerequisite for equal-status interaction. Besides, females estimate the tasks a little bit more challenging than boys (not significant). On the other hand, girls show

significantly less interest and less self-confidence. Particularly the latter is an important finding because this can inhibit equal status interaction. A reason for this may be found in the qualitative study: During lessons, girls perceive boys to be more capable in the subject. This may lead to the lower self-confidence of girls in this subject. In contrast, fear of failure and chance for success are more outcome-oriented than subject oriented. As the test outcomes are comparable between boys and girls, it seems reasonable that the estimations of outcomes are also comparable. This leads us to the hypothesis, that gender differences in computer supported STEM classrooms belong more to attributions than that they are grounded by outcomes. However, as these estimated differences are an obstacle for equal-status interaction, there is the educational goal to find appropriate support methods.

Consequences

Based on these findings, one should focus support on interests and self-confidence, e.g. by task selection or by facilitating appropriate attributions. This could be accompanied by designing a beneficial classroom collaboration, e.g. by scripting gender interaction in computer supported STEM classrooms.

SYMPOSIUM

Promoting female and male students' interest in science by hands-on experiences

Manuela Paechter, Karl-Franzens-University Graz, Austria; Gail Jones, North Carolina State University, United States

An instructional program on the study of viruses, related mathematical and science concepts, and the use of nanotechnology tools was designed. To widen appeal to female and to male students science content was connected to applications, opportunities for hands-on experiences and social interactions with researchers were provided.

The instructional program was evaluated by the following research questions: Do female and male students differ in their interest toward the instructional program prior to the instruction? Does the instructional program lead to a change in interest and are any such changes different between the genders?

Four middle school and four high school classes took part in the empirical testing and completed the instructional program. The results show no differences in initial interest for middle school students but a lower level of interest for female high school students in comparison to male students. Both, in middle and in high school, female and male students showed a positive shift in interest towards the learning contents. Female high school students showed an even higher shift in their interest than male students.

The results suggest various measures to widen appeal of science education for female students. Linking science content to application, providing opportunities for social interactions, and hands-on experiences proved to be interesting for both, male and female students in this investigation.

Introduction and aims of the research

Across the domains of mathematics and science there are significant gender differences in course grades, interests, and career selection for males and females. For example, in most of the countries which took part in the TIMS or the PISA studies girls are less likely to choose science in their courses or for a career and they show less interest in science (e.g., Mullis, Martin, Fierros, Goldberg, & Stemler, 2002). One reason for such gender differences lies in the lower interest of girls in sciences and mathematics (e.g., Hoffmann, Häussler, & Lehrke, 1998; Tracey, Robbins, & Hofsess, 2005).

A possibility to design instruction in such a fashion that it appeals to girls and boys is to offer different learning opportunities. In the reported study an instructional program for middle and high school focusing on viruses and scaling concepts was designed. The instructional program incorporated sophisticated nanotechnology tools to conduct the investigations of viruses. It attempted to stimulate students' interest and curiosity by providing hands-on experiences with the nanotechnology tools, by connecting the science content to applications, and by providing interactions with numerous scientists. The instruction about viruses and scaling effects intentionally made connections to a variety of applications and everyday situations.

It was investigated how the instructional program is able to arouse students' interest in its most central learning content, the use of the technology and the technological aspects of the program. Three research questions were investigated:

1. Prior to the instruction, do female and male students differ in their interest toward the technology?
2. Does the instructional program lead to a change in interest and are any such changes different between the genders?
3. Are certain elements of the instructional program more interesting for female or for male students?

Methodology

Four high school biology classes (38 female, 40 male) and four middle-school science classes (38 female, 28 male), all in North Carolina (USA), completed the instructional program.

Prior to the instruction (pre-test) and one week after the instruction (post-test), students completed an attitudes questionnaire that assessed their interests related to the technology introduced in the instructional program. Immediately after the students completed the instructional program, they wrote an article about their experiences. The stories were analyzed for the length of stories and the number of words written about the different elements of the instructional program

Findings

Results of the middle school sample:

Differences on the pre-test between female and male students on attitudes related to the technology of the instructional program were investigated using a Mann-Whitney non-parametric test. The analysis yielded no significant differences between female and male students' attitudes. To investigate whether the instructional program had led to a change in the students' attitudes, Wilcoxon rank test were carried out separately for female and male students. Results showed a more positive attitude towards the technology of the instructional program for both, female and male students (where necessary alpha-adjustments were carried out). Responses to the attitudes questionnaire were also analyzed to determine if females and males expressed differing levels of change in their attitudes towards the instructional program. A difference score was computed (value on the post-test minus value on the pre-test). Only a statistical tendency was found (p

Data on students' impressions of the various elements of the instruction were taken from the stories they wrote at the conclusion of the instruction. Mann-Whitney comparison showed that females wrote longer stories about their experiences than did males. However, they did not write longer or shorter parts about the different elements of the instruction.

Results of the high school sample:

Differences on the pre-test for interest were investigated using a Mann-Whitney test. Results showed a lower level of interest for females. Wilcoxon rank tests showed significant positive changes in interest after instruction for both, females and male students. Again, responses to the attitude questionnaire were analyzed to determine if females and males expressed differing levels of change in their attitudes (Mann-Whitney test). Females improved significantly more than males, indicating a more positive shift in the level of interest than males. High school females showed a statistical tendency to write longer stories about their week-long experience (Mann-Whitney test). Female students showed a statistical tendency to write more about the interviews with scientists than did male students.

Theoretical and educational significance

The results parallel findings of studies on gender differences in science subjects (Häussler & Hoffmann, 2002): Younger students (middle school) had similar attitudes whereas in the high school sample a shift in the attitudes could be observed. Here, female students expressed less interest than males. It also seems that gender differences are not restricted only to specific subjects but include the use of specific technologies. Two aspects ascertain the success of the instructional program: Firstly, the program led to a higher interest in using the technology, and secondly, the program was appealing to female students. Indeed, students in middle and in high school showed more positive attitudes after their instructional experience. Female high school students showed a higher shift in their interest than male students. The results suggest various measures to widen appeal of science education for female students. Linking science content to application, providing opportunities for social interactions, and hands-on experiences proved to be interesting for the female high school students in this investigation. It seems, however, that not only one specific measure but rather a diversity of instructional experiences was important to raise girls' interest in science instruction.

SYMPOSIUM

Gender Difference in Graphical Representations during Collaborative Problem-Solving in Physics

Ning Ding, Hanze University of Applied Science, Netherlands; Egbert Harskamp, GION, University of Groningen, Netherlands; Bernhard Ertl, Universität der Bundeswehr München, Germany

The aim of this study was to explore the gender difference in terms of the way that students represent their knowledge when solving a physics problem collaboratively. This empirical study was based on a pre- and posttest design. Twenty-five dyads of Chinese tenth graders participated. The analyses included students' pre- and posttest scores, and their graphical representations on the communication log-sheets. A gender difference in graphic representations in problem-solving was found.

In high school physics education, students are expected to represent their understanding in a scientific pictorial manner. Problem information needs to be accurately and pictorially reflected, while problem components need to be interrelated and categorized into an abstract representation (Kellogg, 1995, pp.167). But in practice, it is frequently found that students tend to miss the important features of the problem or stick to a superficial interpretation of problem information.

The current study focuses on high school students' graphical representations in collaborative physics problem solving, examining whether there is a gender difference and whether it is related to students' learning achievement.

The research question is: Is there a gender difference in graphical representations in collaborative physics problem-solving?

We distinguished three levels of graphical representation: Interpretation, Qualitative Reasoning, and Developing the Solution Strategy (Table I).

Methods:

The study was conducted in a high school in Shanghai, China. Fifty tenth-graders (26 females and 24 males), aged 16, participated in the study. Students were randomly paired: 12 mixed-gender dyads, 7 female-female dyads, and 7 male-male dyads.

We used a randomized group design with a pre- and a posttest. Each test was 50-minute long and consisted of five problems about Newtonian mechanics (see Figure 1). Every graphical representation shown students' communication on the log-sheets was the basic unit of analysis on the aforementioned three levels. Figure 2 is one of the students' communication log sheets based on the pulley problem.

Results:

The ANOVA test with "gender" as the independent factor and "pretest" as the dependent variable showed that there was no significant gender difference, ($F(1, 48) = .00, p = .95$). The ANCOVA test with the pretest as covariate showed students' learning achievement in the pre- and posttest (Table II). A pair-wise comparison with Bonferroni adjustment indicated that females in the single-gender dyads did significantly better than females in mixed-gender dyads ($F(1,23) = 9.63, p = .02$). Besides, within the mixed-gender dyads, male students scored significantly higher than their female partners ($F(1,21) = 12.08, p = .02$).

We classified students' graphical messages into three modes: interpretation, qualitative reasoning and developing the solution strategy. Table III summarizes the sums of students' graphical representations from eight Newtonian problems.

Overall, male students generated significantly more graphical representations than female students ($F(1,48) = 12.01, p = .00$). Females' graphical representations were much more at the interpretations level than males' ($F(1,48) = 5.21, p = .03$), while males' had more representations concerning developing the solution strategy than females ($F(1,48) = 23.47, p = .00$). Figure 3 shows the sum of three levels graphical representations for both female and male students throughout eight physics problems.

Table IV shows the correlations controlling for students' pretest scores. A positive correlation between the sum of students' graphical representations and their learning achievement was found, $r = .49$, p (one-tailed) $= .00$. Among the three levels of graphical representations, only the third level, developing a solution strategy, was found to be significantly correlated with students' learning achievement, $r = .52$, p (one-tailed) $= .00$.

Figure 4 illustrates the relationship between the amount of three levels graphical representations and students' learning achievement. It is evident that male students produced significantly more representations as developing a solution strategy (level 3) than female students did, and the amount of level 3 representations was positively correlated with their learning achievement.

Conclusion and Discussion

Our study suggested that female and male students did have differences in representing knowledge graphically. Female students generated much more graphical representations to interpret the problem information while males used the graphical representations to map the relationship of problem components and develop their solution strategy. Females' tendency in this regard shouldn't be downplayed in instructions. This finding sheds light on the future research focus such as computer-supported collaborative learning, structured collaborative learning with clear-cut labor division, etc.

SYMPOSIUM

Teacher goals: theory development and future research

Chairperson: Marold Wosnitza, RWTHUniversity Aachen, Germany

Organiser: Marold Wosnitza, RWTHUniversity Aachen, Germany

Caroline Mansfield, Murdoch Universityity, Australia

Discussant: Helen Watt, Monash University, Australia

Teacher motivation has become an increasingly important field of research (Richardson & Watt, 2010) and researchers have utilized theories regarding student motivation to inform research about how and why teachers are motivated to teach. Consequently a range of theoretical approaches have been used to investigate teacher motivation, one of which is goal theory. Research on teacher goals, however, is in its infancy and is currently very narrow despite the fact that research in other fields has shown individuals' goals as significant for learning and working. The aim of this symposium is to contribute to the under researched field of teacher goals by presenting studies grounded in different theoretical perspectives that used different methodologies and focused on different career stages of teachers. Hagger & Malmberg focus on the ideographic goals and concerns, future time extension, and wellbeing of pre-service teachers. Mansfield, et al. present a conceptual framework for understanding goals for teaching. The framework is grounded in a goal content approach and is informed by data collected from graduating teachers, early career teachers, and experienced teachers. Butler focuses on a further development of her achievement goal approach, which she extends to incorporate relational goals; she will present data from three different studies with student teachers, practicing teachers, and teacher-class pairs. This symposium will provide evidence for the significance of using goals to inform teacher motivation research and will shed light on the contribution of conceptualizations of teachers' goal structures to better understanding teacher motivation before and during the profession.

SYMPOSIUM

Pre-service teachers' ideographic goals and concerns, future time extension, and well-being.

Hazel Hager, University of Oxford, United Kingdom; Lars-Erik Malmberg, University of Oxford, United Kingdom

Human goal processes are conceptualised in an action-theoretic model of motivation. In line with discourse on self-directed teachers we, within this model posited teachers' teaching related goals, future time extension, concerns, and well-being. Doing so, we expand previous studies focusing only on teachers concerns, or on their goals and concerns. Eighty-eight pre-service teachers reported ideographic professionally-related goals and concerns, future time extension of the goals, and well-being (self-esteem and depression). Thirteen goal and fifteen concern categories were identified, broadly reflecting the literature on teachers' transition into the profession. When the goals were ordered in a perceived future time-sequence these did not reflect discrete developmental stages of teachers. Goals were related to concerns in six content domains demonstrating the utility of investigating both. Analyses of relationships between goals and concerns, and well-being revealed interesting patterns, suggesting one the one hand that goals and

concerns, at a general level reflect objects in mind that teachers both hope to realize and, simultaneously are worried not to realize. On the other hand, not all goals were deemed "good" and all concerns "bad".

In the 21st Century teachers face several challenges, which demand flexibility, adaptability, self-regulatory skills, problem solving, and interpersonal skills, within a changing context. In order to understand pre-service teachers' thoughts in relation to such a challenging context, their goal-processes are important to unveil.

Earlier models of teacher development focussed on how teachers expressed different concerns at different stages of their professional career, while recent models have focussed on both goals and concerns. In order to broaden our understanding of pre-service teachers' thoughts about their development, we propose a heuristic action-theoretical model (Brandtstädter, 1998) of motivation (Kuhl & Goeshke, 1994). Human actions are regarded goal-orientated. A history of successful goal pursuits promotes motivation for further goal-setting and a sense of well-being, while a history of failures undermines further goal setting and thwarts well-being.

The first major attempt to conceptualise teacher concerns was carried out by Fuller and Bown (1975), who proposed that teachers first focus on the self, then on teaching tasks and situations, then on students and finally on the impact they have on learners. Although the stage model has intuitive appeal, the number and order of stages, and their contents have been called into question (Watzke, 2007). Moreover, the "concern-only" model has been described as being a one-sided (Conway & Clark, 2003), suggesting that aspirations and goals should be incorporated. We expanded previous studies of teachers' goals and concerns, by including a measure of their future-orientated thinking, and measures of well-being.

Research questions and aims

- (1) What are the contents of pre-service teachers' professional goals and concerns?
- (2) Within which future time perspective do pre-service teachers expect to realize their goals?
- (3) How are goals, future time extension and concerns associated with well-being?

Methodology

As part of a larger study (see Malmberg & Hagger, 2009) 88 pre-service teachers (69.4% females, Mage = 25.9 years), within one Post Graduate Certificate of Education (PGCE) course, filled in an adapted version of the "hopes and fears" questionnaire (e.g., Salmela-Aro et al., 2007). Respondents were asked to report up to five professionally related goals and five concerns. For each goal they were asked to indicate the time point at which they thought they could realize it. Participants also filled in two measures of well-being, the Rosenberg (1965) self-esteem and the General Health Questionnaire for measuring depression (Goldberg, 1982).

In total 266 goals, 242 future extensions and 174 concerns were categorized separately into 13 categories which were common for both hopes and concerns (presented in order of expected realization: relations with pupils, teaching strategies, PGCE-course, self, planning and organisation, differentiation, behaviour management, subject/curriculum knowledge, teacher engagement, teacher impact, student engagement, relations with colleagues and community, career), and two additional categories for concerns only (health and external restrictions), giving 15 concern categories in total. Future time extension was coded into the number of months from the present they thought they would be able to realise the goal. Co-judge agreement was 87% for goals, 87% for concerns, and 93.8% for future time extension.

Findings

The most frequent goal categories, expressed as proportion of the pre-service teacher groups reporting one or more of each content category: teaching strategies (22.7%), self (30.7%), planning and organisation (29.5%), behaviour management (27.3%), teacher impact (29.5%), student engagement (28.4%), and career (25.0%). The most frequent concerns were about behaviour management (31.8%) and career (21.6%).

Next we inspected within which timeframe future goals were expected to be realized. The first five goals (see above) were located approximately within the next term (within the next four months ahead in time). The next batch of goals was located in the third and final term (between five and eight months ahead). The following three goals were roughly located within the first year of teaching. Career related goals were located in the second year of teaching. Overall, it was noticeable that the variability of the future time extension of the goals (i.e., the SD), was larger the further into the future the goal was projected.

The number of concerns was associated with an elevated level of depression ($r = .20$). Goals and concerns within the same content category were associated in the categories of relations with students, self, behaviour management, teacher impact, student engagement and career, indicating that teacher can strive toward realizing a certain goal, and at the same time being worried they might not be successful.

A higher self-esteem was associated with fewer goals about behaviour management ($r = -.18$) and with more career goals ($r = .20$). A higher level of depression was related to more goals about relations with students ($r = .19$) and planning and organisation ($r = .21$). A higher self-esteem was associated with fewer concerns about teaching strategies ($r = -.23$) and differentiation ($r = -.22$). A higher level of depression was related to more concerns about the self ($r = .31$), and student engagement ($r = .19$), but fewer concerns about planning and organisation ($r = -.23$). Theoretical and educational significance of the research

When asking pre-service teachers about their professionally related goals and concerns, the contents reflect both the self (themselves, their health and their career progression), teaching tasks (skills and techniques), students (relationships with students, colleagues and community) and impact. When asked about the anticipated timing (future time extension) of the goals pre-service teachers are definitely on a steep, and in the beginning quite well-defined (i.e., narrow variation in timing between pre-service teachers) learning trajectory as two thirds of the goals are located within the second and third terms within the one year teacher education program, with the remaining goals situated up to the middle of the second year of teaching. The order and the timing of the goals reflected cultural prototypes and grand narratives of teacher development. Goals were related to concerns in six content domains reflecting underlying human promoting and undermining processes (anticipating goal realization but at the same time being concerned that it might not be realized), but also in the relationships between well-being and goals and depression and concerns. Overall, the inclusion of goals and future time extension as conceptual entities alongside concerns provides a theoretically broader basis for future research on teacher development than using a model restricted to teachers' concerns only.

SYMPOSIUM

Goals for teaching: A goal content approach to understanding teacher motivation.

Caroline Mansfield, Murdoch University, Australia; Marold Wosnitza, RWTH University Aachen, Germany;
Susan Beltman, Curtin University, Australia

Teacher motivation is an important field of research, especially in countries where issues such as teacher retention and quality have become prominent concerns. This paper presents a conceptual framework for understanding the stage appropriate goals for teaching of graduating teacher education students. Participants were 218 graduating teacher education students who nominated their goals for their future teaching careers. Goals were analysed through a collaborative, iterative, inductive-deductive process, generated from both empirical data and grounded in established literature (Ford & Nichols, 1987). Through this process the framework for understanding goals for teaching was developed. Results show that both within-person and person-environment consequences inform goals for teaching and that graduating teachers pursue multiple goals. The goals for teaching framework is proposed as a useful tool which can be further developed to reflect the content of teachers' goals at particular career stages and thus provide further insights into teacher motivation.

Many factors motivate individuals to pursue a teaching career and teacher motivation has been investigated from a variety of perspectives. Achievement goals have been used to explain teacher and student goals and have yielded important findings about teacher motivation and its association with instructional practices, interest in teaching and burnout. Even so, the focus on specific pre-determined goals can be limiting and may reduce opportunities to understand teacher motivation more broadly, in the context not only of the work of the classroom, but of broader life goals. The field of teacher motivation is yet to benefit from understanding the content of teachers' multiple goals and how these may influence motivation, well-being and career decisions.

Aims

The aim of this paper is to extend the current teacher motivation literature in two unique ways. First, it presents a study examining the content of goals for teaching reported by graduating teachers, thus offering some insight into both reasons for choosing teaching as a career and the motivating factors for future professional work. Second, as there is no current consensus in the literature as to how to conceptualize teacher goals from a content perspective, a conceptual framework for understanding goal content is presented. The framework is generated from empirical data and grounded in a goal content approach (Ford & Nichols, 1987).

Methodology

The participants were 218 graduating student teachers from two universities in Australia, qualified to teach in primary ($n=128$), secondary ($n=66$) or early childhood ($n=24$) settings. Participants completed a survey at the end of their teacher education program which included the open ended questions "Considering your future career as a teacher what are your three major goals? Please list these in order of importance. Why are these goals important to you?" A total of 598 responses were obtained.

Data analysis

To analyse the responses, a coding system that reflected the broad goals articulated by graduating teachers was developed. Using a combination of inductive and deductive processes to examine the data, the comprehensive Ford and Nichols' (1987) Taxonomy of Human Goals provided the most appropriate system for identifying and categorising goals emerging from the data. This Taxonomy was contextualised to reflect 'stage appropriate' goals for graduating teachers. All responses were analysed iteratively using a collaborative process involving three researchers. Inter-judge agreement was 86%. Where disagreements occurred, responses were re-examined and coded by agreement.

Findings

Graduating teachers have multiple content goals that inform their future teaching. These goals include self-focused goals (affective goals: wellbeing, happiness; cognitive goals: understanding, positive self-evaluations, intellectual creativity) and socially focused goals (social relationship goals: resource acquisition, superiority, belongingness, resource provision, equity, altruism; and task goals: instrumental goals, career aspirations, mastery). Consistent with their stage of professional development, graduating teachers are focused on obtaining employment, continuing to develop and learn, and be the best teacher they can be.

Overall, the sub-category mentioned most was instrumental goals such as gaining employment ($n=83$; 13.9% of responses), followed by cognitive understanding goals ($n=73$; 12.2% of responses), resource provision ($n=66$; 11% of responses) and positive self-evaluation ($n=65$; 10.9% of responses). With 33 nominations (5.5% of responses) altruism, which is newly included in this taxonomy, is only in the mid-range of nominations. The least nominated sub-category was superiority ($n=8$; 1.3% of responses). It would appear that in this sample, participants were aiming to attain employment where they would continue to gain knowledge as learners and professionals, and provide effective learning experiences for their students.

The broader dimensions and categories were compared for significant differences in frequency of nominations. Consistent with their aim of being effective teachers for their students, the distribution of nominations of goals showed that the graduating teachers nominated significantly more person-environment consequences than within person consequences ($\chi^2=4.876$, $df=1$, $p=.027$). With regard to the dimension of within person consequences, cognitive goals like understanding, positive self-evaluations and intellectual creativity were significantly more nominated than affective goals that focus on well-being and happiness ($\chi^2=19.059$, $df=1$, $p=.000$). With regard to the dimension of person-environment consequences, there was no significant difference between nominations of social relationship goals and task goals ($\chi^2=.442$, $df=1$, $p=.506$), although the category of task goals did have the most nominations.

Theoretical and educational significance of the research

The Goals for Teaching Framework was developed through collaborative, iterative, inductive-deductive processes generated both from the empirical data and from established literature. Use of an open-ended question (rather than a pre-determined set of goals) to elicit responses means the data represent graduating teachers' spontaneously articulated goals for teaching. As such, the framework has the advantage of accurately reflecting anticipated within-person and person-environment desires of graduating teachers while being grounded in a broader, comprehensive taxonomy of human goals. Conceptualising goals this way enables teacher motivation research to look beyond motivation as a solely cognitive process, and to consider the affective and behavioural dimensions of motivation in the teaching context.

The Goals for Teaching Framework represents a starting point from which goals for teaching at various stages of teaching career can be better understood. Furthermore, as beginning teachers experience the 'real world' of teaching, that 'reality' may trigger other goals not yet illustrated in the framework. Given the dynamic nature of goals and the influence of context on goal pursuit, variations of goals emerging during particular professional life stages can be expected. Currently the goals for teaching of early and mid-career teachers are being analysed and preliminary results show differences in the goals of these three groups. These findings will also be presented at the conference as understanding the content of teachers' goals for the profession, their goal patterns and how goals develop over time may provide useful insights to further contribute to the field.

SYMPOSIUM

Extension of a new achievement goals approach to teacher motivation.

Stuart Karabenick, University of Michigan, United States

There has been surprisingly little research on teachers' motivation for teaching, in part due to the paucity of compelling theoretical frameworks. I have proposed (e.g., Butler, 2007) that achievement goal theory (Ames, 1992; Nicholls, 1989) can be fruitfully applied to the study of teacher motivation because the school is an achievement arena not only for students, but also for teachers who presumably strive to feel successful in their work, but differ in the ways they define success, and thus in their personal achievement goals for teaching. The main aim is to extend my framework by examining the proposal that strivings to create close and caring relationships with students constitute a fifth, relational goal for teaching, which has distinct implications both for teachers' own coping strategies and for their teaching practices. I shall present results from three new studies conducted with 150 student teachers (Study 1), 550 practicing teachers (Study 2), and 74 teacher-class pairs (Study 3). Results converged with my earlier work in confirming that teacher goals matter because they are coherently and differentially associated with more or less adaptive patterns of coping and teaching. They also significantly extended this work by showing that teachers' relational orientation was most conducive to good teaching as reported not only by teachers, but also by their students.

Results from several research programs have confirmed teacher self-reports of their mastery, ability-approach, ability-avoidance, and work avoidance goal orientations (GO's) for teaching (Butler, 2007; Butler & Shibaz, 2008; Retelsdorf, Butler, Streblow, & Schiefele, 2009) were associated with distinct patterns of coping, wellbeing, and teaching. In keeping with research on students' achievement goals, mastery goals for teaching predicted adaptive and avoidance goals predicted maladaptive processes and outcomes; ability-approach strivings to demonstrate superior teaching predicted neither positive nor negative outcomes. Extrapolating from theories of student motivation can be faulted, however, for failing to consider how motivations for teaching and for learning are not only similar, but also differ. Perhaps most important, some consider caring, whereby teachers are oriented to create and maintain close and authentic relationships with students, as the heart of the teacher role and of good teaching (e.g., Noddings, 1986; Rogers & Webb, 1991).

Aims

The main aim of this presentation will be to extend my achievement goal framework to examine the proposal that strivings to achieve close relationships with students constitute a fifth class of relational goals for teaching that has distinct implications both for teachers' own coping strategies and for their teaching practices.

Methodology

Participants included 149 student teachers (Study 1), 550 practicing teachers (Study 2), and 74 teacher-class pairs (Study 3: 74 middle school teachers and 1800 pupils in one randomly selected class per teacher) in Israel. Participants in Study 1 responded to an expanded measure of goal orientations that included items assessing strivings to achieve authentic and caring relationships with students and to an inventory assessing help seeking strategies and preferences. Teachers in Study 2 responded to the expanded measure of goal orientations at the beginning of the year and to measures of instructional practices (mastery-oriented, performance-oriented, promoting mutual respect among students and prioritizing social relations over subject matter) at the end of the year. In Study 3, teachers responded to the GO measure at the beginning of the year. At the end of the year, pupils in one randomly selected class reported on the teacher's instructional practices. Studies thus used different informants (student teachers, teachers, paired samples of teachers and their pupils) and designs (cross-sectional and longitudinal), which required and enabled different data analytic strategies (EFA, CFA, hierarchical regressions, SEM, HLM).

Findings

First, results (EFA) from Studies 1 and 2 confirmed the proposed 5-factor structure for both student and practicing teachers; CFA conducted on half the randomly split sample of Study 2 showed good fit. Relational strivings loaded on a distinct factor, and formed a reliable scale that was moderately, rather than highly correlated with the other "positive" (mastery) GO for teaching. Second, results from all three studies confirmed that the three "approach" GO's for teaching had distinct correlates. Regarding coping strategies, regression analyses of the data from Study 1 confirmed that mastery (but not relational) orientation predicted student teachers' preferences for seeking adaptive help, relational (but not mastery) orientation predicted preferences for seeking emotional support, and ability-approach orientation predicted help-avoidance. Mastery and relational GO's were both negatively associated with burnout at the end of the year, but the former emerged as a more significant protective factor (Study 2). Regarding teaching, a series of SEM models of associations between teacher GO's and teacher reports of instructional practices completed several months later (Study 2) all showed good fit ($NFI > .94$, $CFI = 1$, $RMSEA$

Theoretical and educational significance

The studies provided further evidence that goal orientations for teaching do indeed matter for both the quality of teachers' own coping and engagement and the degree to which they create more or less positive and effective

environments for learning. Perhaps most important, they confirmed the central role of relational strivings to create and maintain close and caring relationships with students in orienting teachers to teach in ways that not only consider and promote students' wellbeing and social relationships, but also emphasize personal progress and learning for understanding. I shall discuss theoretical implications of the present framework for conceptualizing and studying teacher motivation and applied implications for creating training and school environments that can foster positive motivation and engagement for both teaching and learning. I shall also address the ways in which current climates of accountability might undermine both relational and mastery motivations for teaching.

SYMPOSIUM

Deepening our understanding of the deep approach to learning

Chairperson: Anna Parpala, University of Helsinki, Finland

Organiser: Anna Parpala, University of Helsinki, Finland

Discussant: Noel Entwistle, The University of Edinburgh, United Kingdom

University students' deep approaches to learning have been seen as more desirable than the surface approach among the academics because of its relationship with higher level learning outcomes. However, recent studies suggest that the relation between the deep approach and better learning outcomes is not so straightforward. The deep approach to learning refers to different things in different disciplines, because of the way understanding is developed in each discipline. Thus, the processes involved in the deep approach need to be refined within each discipline. This symposium aims to deepen our understanding of the variation in the deep approach to learning by exploring university students' understanding in different disciplines and in different learning environments using qualitative methods. The aim is to clarify the differences in the way students' understanding develops and how students' deeper understanding is related to learning outcomes. The first paper of this symposium provides us with a broader look of the concept deep learning in different disciplines and the two subsequent papers focus on the deep approach in specific learning environments and its relation to students' learning outcomes. The symposium aims to provide important information on what is regarded as deep learning in different disciplines and how deep learning can be promoted in these learning environments.

SYMPOSIUM

Analysing deep learning and understanding: getting the meanings clear first

Erik Jan van Rossum, Twente University, Netherlands; Rebecca Hamer, Platform Science and Technology, Netherlands

In our recent book *The Meaning of Learning and Knowing* we have come to the conclusion that our six stage developmental model of learning and teaching conceptions describes a set of six world views, each characterised by its own unique set of meanings for words such as understanding, knowing, (deep or surface) learning, etc. The six world views, and as such the six languages that students and teachers speak when talking about learning and good teaching, can be grouped in two sets of three languages. Levels one through three focus on reproduction of knowledge and although each higher level increases in complexity of thinking about concepts, in these three ways of knowing understanding is perceived to mean different levels of reproduction. The second set of three languages focuses on learning and knowledge in a more constructive way, and understanding takes on a deeper and more complex meaning. Taking this into account, we propose that there are three types of surface learning and surface type understanding, and at least three different conceptions of deep learning and more complex understanding. To what extent these languages, and thus the different types of understanding, are linked to specific disciplines is as yet unclear. For one thing, often the disciplinary way of knowing is unclear to students, as it is mediated by the way of knowing of the teacher: teachers and their usual teaching practice often fail to provide students with a clear view of the disciplinary way of knowing.

In our recent book *'The Meaning of Learning and Knowing'* we have come to the conclusion that our six stage developmental model of learning and teaching conceptions describes a set of six world views, each characterised by its own unique set of meanings for words such as understanding, knowing, (deep or surface) learning, etc. The six world views, and as such the six languages that students and teachers speak when talking about learning and good teaching, can be grouped in two sets of three languages. We have come to prefer to explain our model in terms of different languages people speak and the resulting types of communication versus miscommunication. However in the international research community many other terms are used to refer to the same phenomenon, such as ways of knowing, orders of consciousness, belief structures, personal epistemologies or ways of meaning making. In the paper we will illustrate the similarities between all these different theoretical approaches.

The six languages we have uncovered all differ not only with regard to the definition of what to know, but in particular they differ in views on how to know. The first three languages focus on reproduction of knowledge. The first language is characterised by an atomistic view on knowing, all knowledge is seen as equally important. Knowledge has no structure. In the second language some things are deemed more fundamental than others, there are main points and "stuff you don't really need to remember for the test." Knowledge now has structure, often based on chronology. In the next language this initial selection skill is perfected and expanded to learning only that which probably will prove to be useful in practical assignments or a future career. Speakers of this language are often sceptical about expert knowledge. Experts often disagree and so it seems natural that everybody is entitled to a personal opinion and all opinions are worthy of respect (multiplist thinking, Perry, 1970). Although each higher level increases in complexity of thinking about knowledge and knowing, in these three ways of knowing understanding is perceived to mean different levels of reproduction. The second set of three languages focuses on learning and knowledge in a more constructive way, and understanding takes on a deeper and more complex meaning. Level-four language is characterised by a focus on deep learning as a technical skill, e.g. looking for relationships between concepts or course content, reconstructing argumentations or lines of thought that may lead to constructing new knowledge (self authoring, Kegan, 1994), and becoming expert in a disciplinary way of thinking.

This language often sounds procedural, analytical and systemic (Belenky et al., 1997; Kegan, 1994). However in becoming an expert, the practitioner cannot as yet examine the (limitations of) the system itself: in the words of Kegan, the speaker is still embedded in the system which itself is still "subject" and not yet "object". The large change that occurs when people learn to speak level-5 language is that they realise that "every way of knowing is a way of not knowing" (Kegan, 1994) and so systems and disciplines are open to analysis as incomplete knowledge structures. Each system or discipline is only a particular, in some way flawed perspective on reality. By changing perspectives, the world changes before the eyes of the beholder (self transforming, Kegan, 1994). If carried too far, this relativist language can evolve into cynicism about the value of all systems and theories. The tone of voice in language-6 is recognisable because speakers of this tongue reject the purely analytical perspective, they feel they need to "think the world together" (Palmer, 1998) to embrace the paradox that knowledge can come from thinking, but also from not-thinking, from turning your mind off (Baxter Magolda, 2001). Where language-5 speakers are skilled in shifting perspectives as a form of deep learning, language-6 speakers are in search of the person behind the perspectives: "...getting to know what it means to be a human being with a soul" (Baxter Magolda, 2001).

Deep learning here takes on the meaning of seeking and developing wisdom in the sense that one realises that there is no perfect solution and one must settle for one that "does the most good while doing the least harm" (Kitchener and Brenner, 1990). Taking this into account, we propose that there are three types of surface learning and surface type understanding, and at least three different conceptions of deep learning and more complex understanding. To what extent these languages, and thus the different types of understanding, are linked to specific disciplines is as yet unclear. For one thing, often the disciplinary way of knowing is unclear to students, as it is mediated by the way of knowing of the teacher: teachers and their usual teaching practice often fail to provide students with a clear view of the disciplinary way of knowing.

SYMPOSIUM

Research on students' approaches to learning and self-evaluations of their learning outcomes

Henna Ryttonen, Faculty of Behavioural Sciences, Finland; Viivi Virtanen, 00014 University of Helsinki, Finland;
Anna Parpala, University of Helsinki, Finland; Sari Lindblom-Ylänne, University of Helsinki, Finland

The studies concerning the relationship between students' approaches to learning and their study success have had contradictory results. The aim of this study is to qualitatively examine what kind of approaches to learning high and low achievers in the Faculty of Biological and Environmental Sciences have and what is the relationship with self-evaluations of their learning outcomes and how they achieve in their studies. The participants of the study were 10 students participating in two bioscience courses. Students' learning outcomes were measured by course grades and the participants were interviewed by semi-structured interviews. The results of the present study indicate that students' achievement tells very little about the quality of student learning. Students who applied a deep approach to learning but are not organised did have trouble achieving the courses. In addition, students applying a surface approach achieved also highly. The assessment in the courses should be more closely examined. Furthermore, student counselling should emphasise students' study skills, such as time management and self-regulation skills, as a part of the programme.

Introduction

The studies concerning relationship between students' approaches to learning and study success have had contradictory results. Some studies have shown a positive relation between deep approach to learning and better

learning outcomes (e.g. Amirali, Huon & Kevin, 2004; Román, Cuestas & Fenollar, 2008). However, Diseth (2003, 2007) has found a connection only with strategic approach and study success. In addition, Lizzio, Wilson & Simmons (2002), for example, found a positive relationship between a surface approach to learning and academic achievement. Assessment seems to have a significant impact on how students engage in learning (Reid, Duvall & Evans, 2007). Furthermore, in the recent studies, the relationship between students' approaches to learning and academic achievement has mostly been explored quantitatively. Qualitative research has been scarce.

Aim of the study

This study explores low and high achievers approaches to learning and self-reported learning outcomes in two courses. The aim is to qualitatively examine the differences between the low and high achievers approaches to learning and their experience of the learning outcomes in the two courses.

Method

Ten students participated voluntarily in the present study. Students were divided into two groups based on their achievement in the examination, namely high achievers and low achievers. The high achievers (n=6) scored highly on the course exam (4 or 5) and low achievers (n=4) failed the test or just passed it (0 or 1) on a scale from 0 to 5. Thus, the average students (2&3) were excluded from the study. The study was conducted in two different bioscience courses: Biomolecules and Gene techniques. The students were distributed in terms of which course they were taking and their way of achieving in the course. The distribution can be seen in the Table 1. The interviews concerning students' approaches to learning were semi-structured and concentrated on what meanings students gave to their learning in the particular course. In addition, students were asked to describe what they had learned in this particular course. The students were also asked about their overall experience about the course, what goals did they have concerning the course, how did they study in the course and did they accomplish their goals. The intention of the analysis was to see how students described their way of learning and studying in a particular course. First the data were coded to fragments which described students learning approaches. Secondly specific themes were comprised to describe individual students and at the same time broad themes were conducted which separated for example deep learning and reproducing learning from each other. Finally, each student profile was conducted according to the categories.

Results

The four student profiles based on students' approaches to learning and their self reported learning outcomes were conducted as follows.

A Deep learning: This profile describes students who had interest in the subject matter and used deep processes in their learning such as developing own summary structures of the knowledge and linking learning matter to his or her prior knowledge. These students felt that the exam was easy and that they have learned and understood the subject matter.

B Deep unorganized: This category describes students who have motivation to (really) understand deeply the content matter and they use deep learning processes. The difference between the previous profile A is that it takes very long time to study and they just do not have enough time to understand. Learning outcomes were experienced to be weak due to poor organising skills.

C Understanding through surface processing: Students representing this profile aimed to understand the subject matter, but they use surface strategies in studying such as reproducing knowledge as many times as it takes to understand. They also felt that they have learned and understood well.

D Surface learning: This category describes students who had little interest in the course, whose aim was to pass the course and they used learning processes such as memorizing and reproducing knowledge. These students also feel that the learning was not very good. High achievers in both courses represented deep learning and understanding through surface processing. In addition, in Gene Technology course, there were also high achievers who applied surface approach to learning in the course. Furthermore, in both courses the low achievers were students who applied deep approach to learning but did not organise their studies well and thus represented the profile B. The distribution of the students according to the categories and their achievement is shown in the Table 2.

Discussion

The preliminary results show that students whose aim to understand but do not organise their studies have troubles achieving well in these bioscience courses. This supports the result of the previous study, which showed a positive relation between organised studying and study success in the Faculty of Biology and Environmental Sciences (Rytkäinen, Parpala, Lindblom-Ylännä, Virtanen & Postareff, submitted). Interestingly, according to Parpala, Lindblom-Ylännä, Komulainen, Litmanen & Hirsto (2010) Unorganised students applying a deep approach is the largest student group in the Faculty of Biosciences. Furthermore, in Gene Techni course, it seems that reproducing learning and

memorising can also result to higher grades. This implies that assessment method used in this course encourages students' rote learning instead of deep learning processes. Results of the present study suggest that students' grades do not necessarily tell anything about the qualitative learning outcomes. Thus, the assessment of the courses should be more closely examined. Furthermore, the results of the present study suggest that students who apply deep approaches to learning but are unorganised should be assisted with their study skills. Student counselling should emphasise students' study skills, such as time management and self-regulation skills, as a part of the programme.

SYMPOSIUM

The enactment of metalearning capacity

Sophie Ward, Durham University, United Kingdom; Roy Connolly, University of Sunderland, United Kingdom;
Jan H.F. Meyer, Durham University, School of Education, United Kingdom

This study investigates understanding of learning amongst a cohort of ten students entering higher education by engaging them, via drama-based activities, with the process of their own learning (metalearning). It combines Meyer's (2004) Reflections on Learning Inventory (RoLI) and Performance Based Research (PBR). In previous studies, the RoLI has demonstrated the capacity to raise students' awareness of the self as learner. PBR casts students as researchers into their own learning, enabling them to create their own knowledge from their experiences. Students entering a BA Honours Drama Programme were invited to: complete the RoLI; 'brainstorm' their conceptions of learning stimulated by the RoLI profiles; produce short monologues about a breakthrough in their learning; work in groups to convert the monologues into dramas; enact their dramas; write 1,500 word reflective essays about what they had learnt about their own learning strategies during the above activities. The triangulation of methods (RoLI; enactment; reflective essay) yielded consistent findings in terms of how the students positioned themselves as learners, for example as 'passive' or 'proactive learners', and the validity of the findings was confirmed in the students' first formative assignment in drama. The enactment provided a dynamic perspective for developing metalearning that was personal and meaningful for the students: it stimulated students to confront their fears about learning in a supportive environment; gave tutors insight into the needs of particular students, and enabled tutors to offer early intervention to support students' learning.

Aims: This study investigates understanding of learning amongst a cohort of students entering higher education by engaging them via drama-based activities with the process of their own learning (metalearning). The aim is to discover how the development of students' understanding of their own learning might aid them in developing learning strategies suited to the demands of undergraduate study, and to help develop study support mechanisms that will enhance the experience of these students for the duration of their time at university.

Methodology:

The present study combines Meyer's (2004) Reflections on Learning Inventory (RoLI) and Performance Based Research, and thus builds upon, and extends, the methodology of research into metalearning (see for example, Meyer, Ward & Latreille, 2009; Ward & Meyer, 2010). a) Reflections on Learning Inventory (RoLI) The RoLI is an instrument used in metalearning research that generates an explicit and graphic colour-coded personal learning profile. The domain of the RoLI 'operationalizes motivations, intentions, conceptions and processes of learning that traverse an accumulative (surface)-transformative (deep) emphasis' (Lucas & Meyer, 2004: 460). In previous studies, the RoLI has demonstrated the capacity to reveal key features of students' approaches to learning and to raise students' awareness of the self as learner by highlighting both un-interrogated assumptions about what constitutes 'learning' and unconscious habits of 'learning'. It thus provides a basis for increasing students' understanding of how their learning strategies resonate with those considered to be effective in higher education. b) Performance Based Research (PBR) employs drama as 'a way of creating and fostering understanding' about everyday life (Pelias, 2008: 185-6). Using PBR, knowledge is represented through 'action, enactment or performance' (Leavey, 2009: 168). The present study made use of PBR to deploy students as researchers into their own learning, thereby enabling the students to 'create their own knowledge from their own experiences' (Llapputtong & Rumbold, 2008: 18) and to bring into focus ideas that may otherwise have been difficult to explore. The present study was conducted with ten students shortly after they entered a BA Honours Drama Programme.

The research method employed did not require knowledge of drama, and it is posited that the methodology could be replicated with students in other disciplines.

1) The students were presented with propositions about learning taken from the university's undergraduate handbook, and were invited to interrogate the dynamic between their beliefs about learning and the model of learning presented in the handbook.

- 2) The students were asked to think about their learning experiences prior to entering university, and to complete the RoLI with these experiences in mind.
- 3) The students were split into groups and 'brainstormed' their conceptions of learning, stimulated by the RoLI profile, and gave a poster presentation about these conceptions.
- 4) The students were asked to write and recite a short monologue about a breakthrough in their learning.
- 5) In groups, the students began the process of taking on roles and acting out incidents from the monologues; telling new stories or sharing ideas that the monologues provoked.
- 6) The students then enacted their dramas.
- 7) The students were then asked to write 1500 word reflective essays about what they had learnt about their own learning strategies during the above activities. Data analysis: The metalearning materials (RoLI profiles; enactments; reflective essays) were analysed qualitatively, using criteria devised by Meyer, Ward & Latreille (2009). The categorisation of the data produced a range of themes and tendencies that were analysed for evidence of potentially effective or ineffective learning engagement in the context of HE, using Meyer's (1991) concept of 'study orchestration'.

Findings:

The triangulation of methods (RoLI; enactment; reflective essay) yielded consistent findings in terms of how the students positioned themselves as learners. For example, students who displayed evidence of reproductive/passive learning engagement in their RoLI profiles enacted dramas in which they were 'rescued' from ignorance by teachers, and wrote about being frightened and confused by learning, while the students who displayed evidence of deep learning engagement in their RoLI profiles enacted dramas in which they took control of a learning experience, and wrote about feeling empowered by conquering their fears. The validity of the findings was confirmed by the relative performance of the reproductive/passive students and the 'deep learners' in their first piece of assessed work in drama.

Theoretical and educational significance:

The enactment provided a dynamic perspective for developing metalearning that was personal and meaningful for the students: it stimulated students to confront their fears about learning in a supportive environment; gave tutors insight into the needs of particular students, and enabled tutors to offer early intervention to support students' learning. This present study contributes to the literature on, and discussion about, how to:

Encourage students to reflect upon their learning strategies.

Enhance students' experience of entering higher education.

Enhance dialogue about learning between teachers and students.

Improve study support strategies.

SYMPOSIUM

Typical and atypical development of numerical skills

Chairperson: Evelyn Kroesbergen, University of Utrecht, Netherlands

Organiser: Evelyn Kroesbergen, University of Utrecht, Netherlands

Sylke Toll, Utrecht University, Netherlands

Discussant: Johannes E.H. Van Luit, Langeveld Institute, Netherlands

Mathematical learning difficulties have their origin at an early age. However, research on the significant causes and predictors of these difficulties is largely lacking. In this symposium, three papers will be presented that each add a significant contribution to fill this gap. Three large-scale studies were conducted in Finland, Belgium and the Netherlands. The first paper shows, based on a longitudinal study, which early math skills are especially relevant to predict math development. The second paper also describes the role of spelling in children with mathematical learning difficulties. This paper further describes relations with visuomotor skills. The third paper shows that both nonverbal and verbal numerical representation skills are important predictors for later math development. In addition, the results show the important role of verbal and visuo-spatial working memory in the development of early numerical skills. Together, the results of the three papers give important clues for early identification – and possible remediation – of mathematical learning difficulties.

SYMPOSIUM

Mathematical development in kindergarten and first grade: the stability of weak performance

Pirjo Aunio, University of Helsinki, Finland; Riika Mononen, University of Jyväskylä, Finland; Tuire Koponen, Niilo Mäki Institute, Finland

This paper reports a longitudinal study on children's mathematical skills in kindergarten and grade one. The aim of the study was to find out how stable the weak performance is during kindergarten and first grade years. In addition the predictive power of different mathematical skills in this transition phase was studied. The preliminary analysis was done with data from kindergarten and the main analysis will include data on first grade performance (December 2010). There were five performance clusters (based on scores on scale for basic arithmetic) found. The performance clusters were quite stable during the two kindergarten measurements. The preliminary Hierarchical multiple regression analysis revealed that from the eight Early Numeracy Test subscales (time 1) two were significant predictors for the Total Performance (time 2), namely the skills to solve simple math problems and to recite number word sequence. From the Scale for Kindergarten Math Skills (1 time) the best predictors for the Total Performance (time 2) were the skills connecting number symbol with correct number of items, the understanding the concepts of comparison, and the skills to recite the number word sequence forward, and backward. Our preliminary results demonstrate that early math skills have several developmentally relevant skills, which should be regarded in screening for low performance and in designing for interventions. The results also show that it is important to find the weak children in the beginning of the non-formal teaching kindergarten year. They need additional support to be able catch up their normal achieving peers.

Introduction

This paper reports a longitudinal study on children's mathematical skills in kindergarten and grade one. A number of longitudinal studies have been published recently on mathematical development in the transition phase from kindergarten (non-formal teaching) to primary school (formal teaching) among normally developing children. These studies have targeted cognitive antecedents (Aubrey & Godfrey, 2003; Aunola, Leskinen, Lerkkanen & Nurmi, 2004; DeSmedt, Janssen, Browens, Verschaffel, Boets & Ghesquière, 2009; Fayol, Barrouillet & Marinthe, 1998; Passolunghi, Mammarella & Altoè, 2008), family socio-economical status and gender (Aunola et al., 2004), motivational factors related to learning mathematics and teacher's teaching goals (Aunola, Leskinen & Nurmi, 2006), and parents' beliefs and parenting style (Aunola & Nurmi, 2004; Huntsinger, Jose, Larson, Krieg & Shaligram, 2000; Natale, Aunola & Nurmi, 2009) as predictors of mathematical performance and development. However we still lack knowledge of how relevant different mathematical skills are for the development. In addition less attention has been focused on stability of weak performance in the transition from kindergarten to first grade, from informal to formal mathematics instruction. Both of these issues have relevance in screening and intervention wise.

Aims

The aim of the study was to find out how stable the weak performance is during kindergarten and first grade years. We wanted to know if the same children were weak in the beginning of the kindergarten and first grade. In addition we investigated the predictive power of different mathematical skills in this transition phase.

Methodology

Participants. The participants were 169 children (84 girls), aged six years four months. All of the children participated to regular kindergarten instruction in one northern city of Finland.

Methods of data collection. There were two measurement times in kindergarten (one in December and one in April) and one will be in first grade (December 2010). In the data collection three scales were used. Individually used Early Numeracy Test (ENT by Van Luit et al., 2006) takes a developmental perspective on children's early numeracy, and

aims at tapping eight aspects of numerical knowledge, including the concepts of comparison, classification, one-to-one correspondence, seriation, the use of number words, structured counting, resultative counting, and the general understanding of numbers. Basic arithmetic skills were assessed using items from the Mathematics school test (Makeko by Ikäheimo, Putkonen, & Voutilainen, 2002), which is a group test and takes a maximum of 45 minutes to complete. In addition we designed an individual Scale for Kindergarten Math Skills, (SKMS by Authors 2009) to measure number sequence skills and relational skills (concepts of direction, order and comparison). The main idea of SKMS is to supplement ENT and Makeko-K, by measuring core skills in different way or context, or adding some less studied concepts. Children's skills have been measured twice in kindergarten (Makeko-kindergarten and SKMS or ENT) and will be measured once in grade one (Makeko – first grade) December 2010.

Procedure.

A group of kindergarten teachers volunteered to collaborate with the researchers. The educators were trained in one day training to use the instruments. After which they measured the mathematical skills of the children in their own teaching group. The answer sheets were returned to the researcher by mail to be keyed and analyzed.

The preliminary analysis was done with two kindergarten measurements. The presentation in the symposium will be based on measurements done in kindergarten and grade one. For the analysis we had two databases: one including children whose skills were measured twice in kindergarten with Makeko-K and ENT (N= 78, girls n = 38) aged 6 years 4 months (M in months 76.23, SD 3.35) in time of the first measurement, and the other including children whose skills were measured with Makeko-K and SKMS (N=91, girls n= 46) aged 6 years 4 months (M in months 76.13, SD 3.58) in time of the first measurement.

Findings

In the preliminary Cluster analysis there were five performance clusters (based on scores on Makeko-K) found in both data sets. The performance clusters were quite stable during the two kindergarten measurements. The more profound analysis will be done including the third measurement on first grade and with ISAO approach (Bergman & El Khouri, 1999). The preliminary Hierarchical multiple regression analysis revealed that from the eight ENT subscales (time 1) two were significant predictors for the Total Performance (time 2) (Makeko-k + ENT), namely the skills to solve simple math problems ($b = .28$, p

Theoretical and Educational Significance

In comparison to existent research literature the add value of our study is that we have measured early mathematical skills including a variety of subskills, including basic enumeration skills and skills directly related to that (e.g., recite number word sequence, number symbol and number of items connection) and the children's abilities to use and understand concepts related to mathematical problem solving. Our preliminary results demonstrate that early math skills include several developmentally relevant skills, which should be regarded in screening for low performance and in interventions. Our results confirms the results that it is possible to find the weak children in non-formal teaching kindergarten year and that without any intervention their learning is more troublesome than in their normally achieving peers. In addition, our data provides possibilities to discuss about the practical value of using individual and group-based screening methods.

SYMPOSIUM

The profile of children with isolated and non-isolated mathematical problems

Stefanie Pieters, Ghent University, Belgium; Annemie Desoete, Ghent University, Belgium; Ruth Vanderswalmen, University College Arteveldehogeschool, Belgium; Herbert Roeyers, Ghent University, Belgium; Hilde Van Waelvelde, Ghent University, Belgium

The aim of this study was to investigate reading, motor coordination, visual perception and visual-motor integration in children with mathematical and/or spelling problems. Fifty seven children with isolated mathematical problems, 150 children with isolated spelling problems, 113 children with mathematical + spelling problems and 76 age-matched control children without mathematical and spelling problems participated. All 396 children were at least of average intelligence and were assessed with standardized tests for reading, motor coordination, visual perception and visual-motor integration. ANCOVA's showed that children with co-morbid mathematical + spelling problems obtained significantly lower scores than children with mathematical problems and control children on all measured domains. Furthermore, they performed significantly worse in comparison with children with a spelling problem on all measured domains except for visual-motor integration. Children with spelling problems have significantly lower reading capacities in comparison with children with mathematical problems but not for visual perception, motor coordination and visual-motor integration. Spelling does matter in mathematical problems as the co-morbidity implies significantly more problems on all measured domains. Children with mathematical and/or spelling problems are often at risk for additional reading, motor coordination, visual-perceptual and visual-motor integration problems and these problems

may interfere with other scholastic skills. Our data underline the need for the application of carefully selected tests in the diagnostic assessment of children with learning problems in order to develop a STI(mulation), CO(mpensation), R(emediation) and DI(spensation) advice based upon the specific needs of each child.

Aims

Recently, researchers found that the co-morbidity of mathematical learning disabilities with spelling disabilities may have a stronger biological foundation than the co-morbidity with reading disabilities (Landerl & Moll, 2010). Therefore, in this paper we brought mathematical and spelling problems together. Measuring reading is not only important in spelling, but also in mathematical skills. However, research in this domain is rather scarce. Motor coordination, visual perception and visual-motor integration are needed to complete for example a jigsaw puzzle, or to recognize a triangle, a square, a cube... They all are believed to play an important role in scholastic skills (such as mathematics, reading, spelling...), but the association is not fully understood (Cirino et al., 2007; Geary, 2004; Kulp, 1999; Mazzocco & Myers, 2003). Therefore, the aim of this study was to investigate reading, motor coordination, visual perception and visual-motor integration in children with mathematical and/or spelling problems. A better understanding of conditions under which developmental disorders (for example the different learning disabilities and developmental coordination disorder) co-occur is necessary to specify profiles of risk and protective factors useful for diagnosis and assessment.

Methodology

Subjects. Fifty seven children with a score \leq percentile 10 on the KRT-R (procedural calculation) or the TTR (fact retrieval) (mathematical problems), 150 children with a score \leq percentile 10 on the PI dictation (spelling problems), 113 children with a score \leq percentile 10 on the KRT-R or the TTR and on the PI dictation (mathematical + spelling problems) and 76 age-matched control children without mathematical or spelling problems (a score \geq percentile 25 on the KRT-R, the TTR and the PI dictation) participated in this study. All 396 children were at least of average intelligence and were between 6.8 and 12.5 years old ($M=8.9$ years; $SD=0.9$ years). Control children were age matched but differed on intelligence ($F(3,392)=16.8$, p) from other groups. Therefore, IQ will be taken as a covariate in the analyses of variances described below.

Instruments. In order to estimate the intellectual capacities, all children were assessed with the short version of WISC-III (Similarities, Picture Arrangement, Block Design and Vocabulary; Wechsler et al., 2002). For other inclusion criteria, all children were also assessed with Dutch standardized tests for spelling (PI-dictation, Geelhoed & Reitsma, 2000), number fact retrieval (Arithmetic Number Facts Test [TTR], De Vos, 1992) and procedural calculation (Courtrai's Arithmetic Test Revised [KRT-R], Baudonck, et al., 2006). Next, children were tested for reading (One Minute Test (Brus & Voeten, 1999) and Klepel (van den Bos et al., 1994), motor coordination (Movement Assessment Battery for Children -2nd Edition (Henderson & Sugden, 2007) and Beery VMI subtest motor coordination), visual perception (Beery VMI subtest visual perception) and visual-motor integration (Beery VMI copy task) (Beery et al., 2004). Children were assessed by specially trained investigators, on three different moments.

Findings

Analyses of covariances comparing the four groups (mathematical problems, spelling problems, mathematical + spelling problems and a control group) revealed that children with mathematical + spelling problems obtained significantly poorer scores on all domains (reading, visual perception, motor coordination and visual-motor integration) in comparison with the control group and the group of children with mathematical problems. Furthermore, they scored significantly lower on measures of reading, visual perception and motor coordination (both VMI motor coordination and M-ABC 2) in comparison with the group of children with spelling problems. No significant differences were found between those two groups on visual-motor integration. Moreover, children with spelling problems obtained significantly poorer scores than control children for reading, visual-motor integration and motor coordination (both VMI motor coordination and M-ABC 2), but not for visual perception. They had significantly lower scores on reading in comparison with the children with mathematical problems, but not for visual perception, motor coordination skills (both VMI motor coordination and M-ABC 2) and visual-motor integration. Finally, children with mathematical problems performed significantly worse than control children for reading, visual-motor integration and motor coordination (both VMI motor coordination and M-ABC 2) but not for visual perception.

Theoretical and educational significance Spelling does matter in mathematical problems as the co-morbidity implies significantly more problems on all measured domains. These findings underscore that having a co-morbid mathematical + spelling problem is significantly worse in comparison with having an isolated mathematical problem on all measured domains and in comparison with having an isolated spelling problem on all measures except for visual-motor integration. Not mathematical problems or spelling problems are associated with visual-perceptual problems, it is the co-morbidity of both that makes children underachieve in this domain. These findings are thus in

accordance with the cognitive subtype hypothesis of the different co-morbidity models (Pennington, 2006; Rhee et al., 2005; Wilcutt et al., 2005). Finally, children with mathematical and/or spelling problems are often at risk for additional reading, motor coordination, visual-perceptual and visual-motor integration problems. Therefore, the results of this study might also have diagnostic and educational implications. The findings underscore the need for the application of a wide range of carefully selected measures in the diagnostic process and the assessment of the individual child. Individual assessment always aims to develop a STICORDI-advice. STICORDI refers to STimulation, COmpensation, ReMediation and DIspensation. This advice can be adapted based upon the specific needs of children with co-morbid reading, motor coordination or visual-perceptual problems, with regard to their strengths and weaknesses. Examples of such an advice could be a larger font, adjusting the margin of the page, using squared paper to aid in the spatial placement of numbers, replacing complex figures by text, a good position on an adapted chair (for example a Tripp Trapp) or the use of ergonomic pencils.

SYMPOSIUM

The development of early numerical skills in Kindergarten

Meijke Kolkman, Utrecht University, Netherlands; Evelyn Kroesbergen, University of Utrecht, Netherlands;

Paul Leseman, Utrecht University, Netherlands

The development of accurate numerical representations is important for math learning. However, little is known neither about the nature of the developmental changes in basic numerical comprehension nor about the causes of inter-individual differences therein. Therefore, the aim of the present study was to examine the co-development of verbal and visuo-spatial working memory, executive functions, and early verbal and nonverbal numerical representation skills. In this study longitudinal data is presented in which the reciprocal relations between cognitive skills and numerical abilities are examined. A sample of 267 Dutch Kindergartners was tested four times in a two-year period. Numerical tasks were administered to assess non-verbal quantity representations, verbal counting skills and mapping skills. Cognitive abilities were assessed using tasks assumed to measure verbal and visual working memory skills, shifting skills and inhibition. Preliminary hierarchical regression analysis showed that both nonverbal and verbal numerical representation skills, and mapping skills, predict substantial variance in math performance. A direct effect of working memory on math performance, however, remains. These results demonstrate that domain-general cognitive abilities, in particular verbal and visuo-spatial working memory, influence math development at least partly through involvement in the development of domain specific numerical skills.

Introduction

Nonverbal representation of magnitudes emerges already very early in life and is regarded the fundament of math development many years later. Increasing experience in early childhood with verbal numerical skills such as counting and with symbols such as digits for written notation, gives rise to further development of early math competence. The integration (or 'mapping') of verbal and symbolic knowledge with the nonverbal magnitude representation system results in more complex and increasingly accurate cognitive representations of number (e.g. Dehaene, 2001; Mundy & Gilmore, 2009; Krajewski & Schneider, 2009). This novel competence is strongly related to math achievement, as several studies have shown (e.g. Laski & Siegler, 2007). Although the importance of accurate representations of numerical magnitudes has been convincingly demonstrated, still little is known neither about the nature of the developmental changes in basic numerical comprehension nor about the causes of inter-individual differences therein. Several studies have found positive relations between working memory, executive functioning and (early) math performance (e.g., Geary, 2010; Locuniak & Jordan, 2008) but the evidence is still inconclusive. It is not clear, for instance, whether domain-general cognitive functions contribute separately to math development, in addition to the effect of basic domain-specific numerical representation skills, or contribute mainly via a constructive role in basic numerical development, in particular regarding the integration of verbal and nonverbal number representations.

Aims

Therefore, the present study was designed to examine the co-development of verbal and visuo-spatial working memory, executive functions, and early verbal and nonverbal numerical representation skills, and to test reciprocal effects and mediation.

Methodology

The sample of 267 four-year-old Dutch children (124 boys; mean age = 51.60 months; SD = 3.52 at first measurement) was tested four times in a two-year period. The first measurement took place when children entered kindergarten and the last measurement is planned halfway the first grade when the children are approximately six years old. To measure working memory and executive functions, different neuropsychological and cognitive tests of executive functions were used. For the assessment of visual and verbal working memory, we adapted several tasks from the Automated Working Memory Assessment Battery (Alloway, 2007). We used 'Odd One Out' and 'Dot Matrix' to

measure visual working memory skills. 'Word Recall Forward' and 'Word Recall Backward' were used to measure verbal working memory skills. An adjusted version of the 'Flanker task' (Eriksen & Schultz, 1979, as cited in Stins, Van Baal, Polderman, Verhulst, & Boomsma, 2004) was used to measure inhibition and the 'Dimensional Changing Card Sorting' (Zelazo, 2006) task was used to assess shifting. To measure early math skills, different tasks were used for the measurement of non-verbal, verbal and symbolic numerical skills and mapping skills. For the assessment of non-verbal skills, we used a non-symbolic comparison and number line estimation task (adapted from Laski & Siegler, 2007). Verbal and symbolic skills were measured using a counting task and a number identification task. Mapping skills were assessed by symbolic comparison and number line estimation tasks. Math achievement will be measured in first grade, after about a half year of math instruction.

Findings

Growth modeling techniques will be applied to test the developmental relations between the general cognitive skills and the emerging math abilities of the children. However, preliminary hierarchical regression analysis, based on part of the data, show that visual and verbal working memory skills predict substantial variance in a modality specific way in verbal and symbolic numerical representation skills ($R^2 = .13 - .25$); mapping skill is partly predicted by both verbal ($R^2 = .09$) and visual ($R^2 = .15$) working memory skills. Inhibition and shifting do not predict additional variance in numerical representation. Both nonverbal and verbal numerical representation skills, and mapping skills, predict substantial variance in math performance. A direct effect of working memory on math performance, however, remains, although a substantial part of the relationship between working memory and math can be regarded as mediated by numerical representation skills.

Theoretical and educational significance

To conclude, the present study provides tentative evidence that domain-general cognitive abilities, in particular verbal and visuo-spatial working memory, influence math development at least partly through involvement in the development of domain specific numerical skills. A possible explanation, to be addressed in future research, is that basic numerical representation skills rely on the simultaneous and successive processing of multiple sources of information, presented in both the verbal and visual modality, requiring temporary storage and control. Nevertheless, the results of this study contribute to the field of math development in providing knowledge about the early determinants of math development. These understandings will help to identify problems in number skills at an early age and can be used to develop appropriate math programs for normal developing kindergartners or young children experiencing math problems.

SYMPOSIUM

Learning science through participation in its epistemic / symbolic language practices

Chairperson: Russell Tytler, Deakin University, Australia

Organiser: Russell Tytler, Deakin University, Australia

Discussant: Larry Yore, University of Victoria, Canada

This symposium focuses on exploring the development of student understanding and application of the discursive tools of science in order to reason in this subject, as the basis for classroom practices that parallel the knowledge production practices of scientists. We explore how this account of the disciplinary literacies of science can be enabled through effective pedagogies. The papers draw on research from Australia and Sweden that have overlapping agendas and theoretical perspectives including pragmatism (Peirce 1931-58; Dewey 1938/1997), social semiotics (Kress et al. 2001) and socio cultural perspectives on language and learning (Lemke 1990, 2004). The papers will examine the role of language / multimodal representations in generating knowledge claims in science classrooms, the classroom epistemologies that support learning, and what it is to assess knowledge from this perspective. A large body of research in the conceptual change tradition has identified trenchant problems in conceptual learning in science, spawning a long-standing and ongoing program of searching for pedagogies to address this. By redefining the problem in terms of language and representation, we aim to offer a way forward for supporting student engagement and learning in science.

SYMPOSIUM

A representation-intensive pedagogy for school science

Russell Tytler, Deakin University, Australia; Peter Hubber, Deakin University, Australia

This paper will describe the theoretical underpinnings and the key features of a representation-intensive pedagogy developed in a major Australian project, and its relationship to the epistemic practices of science. The pedagogy is

grounded in socio cultural and pragmatist perspectives on learning and cognition that see knowledge as grounded in multi modal representations that are discursively generated, negotiated and coordinated in science classrooms. From this perspective, the learning challenges identified by research in the conceptual change tradition are seen as inherently representational in nature, and the pedagogy centres on students generating representations in response to structured challenges. The paper will use evidence from a range of units designed and implemented by the researchers working in partnership with a small group of teachers, to interrogate the key aspects of the pedagogy and the way it supports learning. The role of representations in supporting learning will be explored in terms of the way they afford and productively constrain knowledge generation, in ways that mirror the knowledge building practices of science. Examples of student artefacts and reasoning will be presented to demonstrate significant learning outcomes.

Aims

There is now a growing consensus that learning science at school entails students learning the literacies of a specific discourse community, one that uses a range of subject-specific and general representational tools to construct and justify evidence-based claims about the natural world (Kress et al. 2001; Lemke, 2004; Moje, 2007). Researchers in classroom studies where students were guided to construct their own representations of scientific ideas (Carolan, Prain & Waldrup, 2008; Greeno & Hall, 1997) have noted the importance of teacher and student negotiation of representational meaning and of students having opportunities to explore, elaborate, re-represent and coordinate representations to interpret science phenomena. There is growing evidence (Hubber, Tytler & Haslam 2010; Hubber 2010) that this can lead to increased student engagement and improved learning outcomes.

This paper will report on aspects of an Australian project that worked with teachers to develop and validate a pedagogy based on student generation and negotiation of representations. It will address the research questions: 1) What are the key features of a pedagogy based on student generation of multi-modal science representations, reflecting the knowledge building practices of science? 2) How does such a pedagogy support student reasoning in science, and 3) What evidence is there that this approach leads to improved conceptual learning? **Methodology**

The research team worked with four experienced primary and secondary teachers to collaboratively develop a series of teaching sequences on science topics that the conceptual change literature has shown to present learning difficulties. The sequences focused explicitly on student generation and negotiation of representations related to key concepts. In working with the teachers over two years, we developed a set of pedagogical principles based on our experience and on theoretical ideas described above.

The teachers' practices, student-teacher interactions, and student activity and discussion were monitored using classroom video capture. Key lessons were coded using an emergent scheme generated using Studiocode software, to make apparent the patterns of pedagogical moves and to explore the key features that could be considered fundamental to a representation-intensive pedagogy. Teaching and learning sequences were selectively transcribed and subjected to ethnographic analysis to identify the extent to which and in what ways the pedagogical principles were exemplified, and for evidence of the ways in which the focus on representations supported reasoning and learning about key science ideas. Students were interviewed about their learning, and teachers about their perceptions of the effectiveness of aspects of the sequence. Student workbooks were collected to provide a continuous record of representational work.

Pre- and post- test data were analysed to look for evidence of improved understanding, flexibility in the generation of representations, and the capacity to transfer ideas to a wider range of phenomena.

Findings

The pedagogy has the following key principles:

1. The sequencing of representational challenges involving students generating representations to actively explore and make claims about phenomena, involving a) identifying appropriate representations underpinning key concepts; b) establishing a representational need and c) working towards alignment of student generated and canonical representations.
2. Explicit discussion of representations, including a) their selective purpose, b) group agreement on generative representations, c) form and function and d) the adequacy of representations.
3. Meaningful learning through representational/ perceptual mapping between objects and representations
4. Ongoing and summative assessment focusing on the adequacy, and coordination of representations.

Moreover, analysis of the patterns of conceptual clarification and orientation, representational challenge, clarification and negotiation of representations, and explanation/resolution showed similar pathways for lessons but differences depending on year level, place of the lesson in the sequence, and topic.

Analysis of the teacher – student exchanges and of student artefacts produced in these sequences demonstrated a strong alignment of the pedagogy with inquiry principles, and evidence of significant reasoning and learning. The analysis of reasoning is linked to the use of representations as epistemic tools in science knowledge – building, and draws on Peirce's (1953) triadic model of meaning making, and notions of affordances (Norman 1999) to identify the way representations selectively focus attention on aspects of the problem space.

Significance

There is increasing acceptance of the view that learning involves a process of induction into specific discipline-based discursive practices, and is mediated by representations as the epistemic tools of science. This research represents a serious attempt to translate these theoretical insights into a practical classroom pedagogy that can effectively frame learning in science. Such a program has both practical significance for teacher practice and teacher education, and theoretical significance in bringing science classrooms and science practice into closer alignment. A re-interpretation of conceptual problems in learning science in terms of representational issues, and a program to translate this into a pedagogy, shows promise of making inroads into the problems in learning science well established in the conceptual change literature.

SYMPOSIUM

Using pragmatism in making semiotic resources meaningful in the science classroom

Per-Olof Wickman, Stockholm University, Sweden; Annie-Maj Johansson, Stockholm University, Sweden;

In this paper we demonstrate a heuristic based on semiotic and pragmatist educational research results that can be used to support teachers in scaffolding students' learning and agency in the science subjects. Studies on how the use of representations can aid science teaching and learning are supplemented with a study on how the progression of learning could be understood as oriented by ends-in-view (proximate purposes), which the teacher can make continuous with the ultimate purposes of an educational sequence in joint action with the students. The example comes from a Year 5 school class studying friction. The events in the classroom were filmed and transcribed and analysed by using Practical Epistemology Analysis. The study shows how the students and the teacher mainly use semiotic resources on the basis of the more proximate purposes rather than from more ultimate purposes and that there is no continuity created between the language of science and the language that students use during the lesson. We demonstrate how the two kinds of organising purposes can be used to scaffold the lesson better.

Aim and significance

In this paper we discuss how educational research in semiotics and on the use of representations in the science classroom can be supported by some notions developed within pragmatically oriented science education research.

The aim is to demonstrate a heuristic based on research results that can be used to support teachers in scaffolding students' learning and agency in the science subjects. Common to semiotic and pragmatist research is a socio-cultural stance approaching knowledge not as ready made, but as continuously developing in interactions between people, artefacts and semiotic resources (e.g., Chaiklin & Lave 1996; Sfard 1998). The unit of analysis is action and activities, rather than mental entities, and hence important aspects of learning can be studied as visible processes in communication and interaction as mediated by different semiotic resources and artefacts. In science education Lemke's (1990) book *Talking Science* represented a seminal reformulation of the learning processes in these terms. Other pioneering studies in science education are the social semiotic studies by Kress and co-workers (e.g., Ogborn et al 1996; Kress et al 2001), studies of mediation within the group of Säljö (e.g., Säljö & Bergqvist 1997) as well as Roth's (1998) research on learning communities.

In this study we supplement these studies with the pragmatist notion about how the progression of learning could be understood as oriented by ends-in-view, which the teacher can make continuous with the ultimate purposes of an educational sequence in joint action with the students (Wickman & Ligozat, 2011; Johansson & Wickman, in press). The concept of ends-in-view originates from John Dewey's (1938/1997) thinking about progression (growth in Dewey's terminology) as creating continuity between the prior experiences of students, the current situation and the new kinds of practices that students are introduced to. Because the ultimate purposes belong to the new kinds of practices that are not yet familiar to the students, Dewey discusses how situations can be found that have purposes, i.e. more proximate goals that make sense to students. Dewey called such purposes ends-in-view. However, as a teacher it is not enough to give students such ends-in-view. The teacher in joint action with the students has to make the activity with those familiar ends-in-view continuous with the ultimate goals of the lessons using the artefacts and semiotic resources available. The ultimate purposes make sense to the teacher, but the teacher has to translate them and make the students understand how the activity with ends-in-view also deals with the ultimate purposes. The praxis of using ends-in-view is commonplace in teaching, although they are rarely examined by educational researchers. How they can be made continuous with the ultimate purposes are far from clear (Wickman & Ligozat, 2011).

Methodology, and findings

In this paper we use an example from a Year 5 school class studying science (Johansson & Wickman, in press). The ultimate learning purpose for the lessons studied is about how friction facilitates or impedes motion. It is introduced by the teacher through more proximate purposes. We have studied two such proximate purposes used by the teacher: 1) why cars have tyres, and 2) that a vehicle can continue to travel indefinitely if there is no resistance at all. The events in the classroom were filmed and transcribed. As a method for analysis practical epistemology analysis (PEA) is used, which is based on the ideas of John Dewey but also on the late Ludwig Wittgenstein's investigations into language and action (Wickman, 2004; Wickman & Östman, 2002).

The study shows how both the students and the teacher mainly use semiotic resources on the basis of the more proximate purposes rather than from more ultimate scientific learning purposes and that there is no continuity created between the language of science and the language that students use during the lesson. We demonstrate how these two kinds of organising purposes can be used by teachers as an heuristic to better to help students to use friction as an overarching semiotic resource in dealing with and communicating within the proximate activities (why cars have tyres and how a vehicle can continue to travel indefinitely if there is no resistance at all). We also extend our results to how these organising purposes can be related to an Australian study on using representations as semiotic resources in the science classroom (Hubber, Tytler & Haslam, 2010), and so show how they can be applied more generally.

SYMPOSIUM

Assessment from a representational perspective

Vaughan Prain, La Trobe University, Australia; Bruce Waldrup, Monash University, Australia

This paper focuses on the effects of a representation-intensive pedagogy for formative and summative student assessment in junior secondary science learning. We report on two case studies of teachers working with students on middle school science topics, noting changes to teacher and student assessment processes and practices. Analysed classroom practices and student examination scripts indicated that this sustained focus on a sequence of student negotiation of representational challenges and refinement resulted in (a) different emphases in formative assessment practices from normal routines, and (b) students integrating more representations in their responses to test questions, writing longer and more comprehensive explanations, and scoring higher in achievement tasks than students normally obtained in these scripts. We consider the implications of these findings for current accounts of effective formative and summative assessment practices in science learning.

SYMPOSIUM

Classroom scaffolding: conceptualisations and applications

Chairperson: Dolly van Eerde, Utrecht University, Netherlands

Organiser: Dolly van Eerde, Utrecht University, Netherlands

Discussant: Peter David Renshaw, The University of Queensland, Australia

Abstract

Scaffolding is often used in educational studies as a concept for analysing and promoting support provided in classrooms. Some scholars stay close to the metaphor's origin in dyadic adult-child interaction as introduced by Wood, Bruner and Ross (1976) and determine scaffolding in the classroom by focusing on how teachers adapt their support contingently to students' level of understanding. The first presentation (Van de Pol, Volman and Elbers) shows that this is an appropriate way of analysing scaffolding in naturalistic classroom settings. However, different applications show the need for different conceptualisations. In the second presentation Smit and Van Eerde extend the original definition of scaffolding so as to use it for design-based whole-classroom studies that deliberately promote particular scaffolding strategies. Mercer and Warwick broaden the original definition of scaffolding by including the use of an artefact, the interactive whiteboard, as a scaffolding tool in whole-classroom settings. This symposium brings together three studies that redefine and demarcate scaffolding according to specific educational needs and research goals. The discussant will position these contributions within the broad field of scaffolding conceptualisations. The scientific significance lies in substantiating the concept of scaffolding, by thinking through useful interpretations for particular purposes. The studies presented will also provide insight into how teachers can promote productive classroom interaction in order to support learning.

SYMPOSIUM

Measuring Teacher Scaffolding in Classroom Situations: A Contingency Perspective

Abstract

Scaffolding, providing tailored or contingent support aimed at enhancing learning, is a dynamic process that takes place in interaction. This makes scaffolding difficult to measure. No generally accepted measurement framework is available to study teacher scaffolding in naturalistic classroom situations. Therefore this study sought to develop a valid and reliable measurement framework that can be used to measure classroom scaffolding from a contingency perspective. In order to take into account the interactional nature of scaffolding, both student and teacher turns and their relations were considered. Teacher turns were coded with regard to the degree of control they exert. Student turns were coded with regard to their accuracy and mode. Each three-part-sequence of a teacher turn – student turn – teacher turn was considered contingent if it followed one of two rules provided by Wood, Wood, and Middleton (1978): if a learner fails, increase control or cognitive complexity; if a student succeeds, decrease control or cognitive complexity. A body of interaction data collected in Social Studies lessons (7th/8th grade) was used in this study. The instrument appeared valid, in that it enabled measurement of variability in the degree of teacher control and contingency. Moreover, degree of contingency as measured with the instrument appeared to be positively correlated to students' demonstrated understanding. Both interrater and intrarater reliability analyses were performed and showed a substantial reliability.

Summary

The metaphor of scaffolding (Wood, Bruner, & Ross, 1976) provides us with a valuable means to describe contingent or tailored teacher support with the aim of transferring responsibility to the learner. Scaffolding in the classroom has been studied to a great extent since its introduction, mainly in an observational and qualitative manner. Due to its interactional nature, it is difficult to measure scaffolding systematically. No generally accepted measurement instrument that takes into account this interactional nature exists in the classroom-scaffolding literature (Van de Pol, Volman, & Beishuizen, 2010). A solid instrument, however, is needed to be able to study for example the effectiveness of scaffolding; such studies have been rare until now. Therefore, the aim of this study is to develop such an instrument to examine scaffolding in classroom interaction.

Wood et al. (1976) described scaffolding as taking over task parts to enable students to perform a task that they could otherwise not have performed. Later, scaffolding was measured by focusing on contingency, one of the key features of scaffolding (Wood, Wood, & Middleton, 1978). They introduced the contingent shift principle to measure scaffolding in one-to-one interactions on highly structured tasks. This principle consisted of two rules: if a learner fails, increase control; if he/she succeeds, decrease control. Because scaffolding describes a dynamic process, its measurement needs such an interactional approach; both the support of the teacher and the student responses need to be taken into consideration. Few scaffolding researchers take into consideration this interactional nature in their measurements, especially not in naturalistic classroom settings (an exception is Nathan & Kim, 2009). In this study, the contingency framework of Wood et al. (1976; 1978) is adopted to explore its suitability for measuring classroom scaffolding. Additionally to the original framework of Wood et al. (1978), students' response mode is measured; the degree to which students make their understanding clear (i.e., claimed or demonstrated understanding, Sacks, 1992). Only students' demonstrations will give teachers enough information to act contingently upon. Teachers' contingency will be determined according to the accuracy of students' demonstrated understandings only to obtain a more precise measurement of contingency.

The question that will be answered here is: How can scaffolding in teacher-student interactions in naturalistic classroom settings be measured in a valid and reliable way while taking into consideration its interactional nature?

Methods

Twenty-two fragments from a larger study on scaffolding containing teacher – small-group interactions in 7th/8th grade Social Studies lessons were used for this study. First, all teacher turns were coded with regard to the degree of control, ranging from no control (level 0; teacher not present) to high control (level 5; providing an explanation). Second, student turns were coded with regard to accuracy and mode. Accuracy was coded into not-understanding, partially understanding or understanding. Additionally and different from the Wood et al.'s (1978) methodology, each student turn was also coded with regard to mode: claimed understanding ("I get it!") or demonstrated understanding (giving elaborated answers). Only demonstrations provide the teacher with information to give contingent support and therefore teacher's use of claims without asking for demonstrations was seen as non-contingent.

Once all turns are coded, contingency can be determined by applying the contingent shift principle:

1. When a learner fails, increase control

2. When a learner succeeds, decrease control

A rule about partially correct answers was added (because no such rule was provided by Wood et al., 1978); the level of control needs to stay the same or be increased. These rules were applied to each three-part-sequence consisting of a teacher turn, the next student turn, and the subsequent teacher turn. The percentage contingent sequences determined contingency per interaction.

Indicators of construct validity were variability that could be determined with the instrument in the main variables (degree of control and contingency) and the correlation between contingency and students' success.

Results

To illustrate the instrument, we provide a short example here with a contingent sequence. Teacher control increased because the student's understanding was low.

Teacher: What does prosperity mean? (low level of control; 1)

Student: It's about products (low understanding; demonstration)

Teacher: Just think of well-being (higher level of control; 4)

Note that the goal of scaffolding is not to increase or decrease control per se, but to act contingently upon the needs of the students. With this measurement instrument, variability in the main variables was detected which supports the construct validity of the instrument: for teacher control ($M=2.17$, $SD=1.6$), and for contingency ($M=63\%$, $SD=31\%$). To further explore the construct validity, we investigated the correlation between teachers' contingency and students' demonstrated understanding which appeared to be positive and significant ($r(22)=.57$, $p=.01$). Twenty percent of the data was coded by two coders to establish the interrater reliability. With Cohen's Kappa's of .78 for teacher control, .89 for student accuracy, and .78 for mode, the interrater reliability was found to be substantial. The intrarater reliability was performed by the first author by coding 30% of the data two times with one month time in between. With Cohen's Kappa's of .75 for teacher control, .78 for student accuracy, and .80 for mode, the intrarater reliability was substantial.

In conclusion, the presented measurement instrument appeared suitable to analyse scaffolding from a contingency perspective in teacher-student interactions. classroom interactions. The instrument appeared valid and enabled measurement of variability in a reliable way. This measurement instrument might be used in future research on for example classroom scaffolding's effectiveness, which could be beneficial for practice.

SYMPOSIUM

Scaffolding language in a multilingual mathematics classroom

Jantien Smit, Utrecht University, Netherlands; Dolly van Eerde, Utrecht University, Netherlands

Abstract

Dealing with ethnic and linguistic diversity is one of the major challenges in today's education (Gibbons, 2009). Multilingual pupils experience difficulty learning the subject-specific register needed to participate in, say, mathematics education. As a result, their achievement scores are lagging behind those of their native peers. In response to this problem, Gibbons (2009) advocates a content-based language-focused programme across the whole curriculum: teachers need to be prepared to teach content effectively while supporting pupils' development of the academic registers needed for learning throughout the curriculum. In line with Gibbons' approach, we employ the concept of scaffolding to study and promote a primary mathematics teacher's strategies that support language development along a continuum from most spoken-like to most written-like, subject-specific language.

Summary

Theoretical framework

The metaphor of scaffolding was first introduced by Wood, Bruner and Ross (1976) to describe the adults' role in children's problem-solving activities. In most classroom studies the concept is related to one-to-one classroom interaction and regarded as the temporary support provided within the zone of proximal development (ZPD). Some researchers seem to be in favour of applying the idea of ZPD also to group situations. Nyikos and Hashimoto (1997) point at the strengths of what they call 'group zone' by referring to its thought collective and social mediation. Mercer's (2007) concepts of 'interthinking' and 'intermental development zone' both capture a comparable richness of thinking together in whole-classroom interaction.

In analogy, it is argued that scaffolding can be a powerful teaching strategy in whole-classroom interaction (Gibbons, 2009). Such wider application of the concept implies concessions to its original key characteristics such as contingency and handover to independence. As the teacher in whole-classroom interaction is working with multiple ZPD's (Myhill & Warren, 2005), there are multiple levels of understanding involved. Diagnosing, which is a prerequisite for contingency, then seems a difficult task. Handover to independence will inevitably not take place for all pupils at the same time. Moreover, in well-planned instruction, the contingency feature of scaffolding can be called into question. Gibbons (2009), for example, sees the need to distinguish between designed scaffolding (all activities consciously selected and designed to scaffold learning) and interactional scaffolding (unplanned, i.e. contingent support which is spontaneously provided in ongoing classroom talk). Hence, broadening the scaffolding concept to teaching in whole-classroom settings requires rethinking it. The aim of our research is to gain more insight into how scaffolding in whole-classroom situations can be conceptualised.

As a basis for such reconceptualisation we use empirical data from a classroom study focussing on the following research question: How can teachers in multilingual classrooms scaffold in whole-class situations pupils' development of the language required for mathematical learning?

Methods

This study can be characterised as dual design research (Gravemeijer & Van Eerde, 2009), as it studies and promotes both the teacher's and the pupils' learning processes, and experimental lessons had to be specifically designed in order to answer the research question. To design these lessons, we used Gibbons' (2009) teaching and learning cycle in which a particular text genre needed at school – here: description of a line graph – is introduced, modelled and practiced. This cycle constitutes an approach of scaffolding how to speak and write in a subject-specific genre. We presumed that the teacher would demonstrate an increasing frequency and variability in performing interactional scaffolding strategies as a result of the designed scaffolding strategies embedded in the lesson plans and discussions between the teacher and the researchers in between experimental lessons.

Six experimental lessons were carried out by an experienced teacher at a suburban primary school in the Netherlands (22 pupils aged 11-12). Data collection included: video recordings, pupils' pre- and post-tests, their writing tasks, observational data, and pre- and post-interviews with the teacher. Based on the scaffolding strategies suggested by Gibbons and our observations throughout the teaching experiment, an analytical framework for analysing scaffolding was developed. Teacher-class interaction was coded with this framework to detect changes in performed scaffolding strategies. Furthermore, we conducted case studies as to analyse changes in pupils' use of written and spoken language.

Results

The analysis first of all resulted in a conceptual framework for whole-classroom scaffolding, consisting of sixteen scaffolding strategies grouped in three main categories: 'language promoting questions', 'gestures' and 'responding to spoken and written language' (e.g., 'pay explicitly attention to subject-specific words'). In answer to the research question we conclude that there is a broad repertoire of whole-classroom scaffolding strategies from which a teacher can choose. Regarding the teacher's development, the analysis gave insight into the growing frequency and variety of scaffolding strategies throughout the experiment. A threefold increase of performed scaffolding strategies was observed and the teacher's scaffolding repertoire did indeed substantially expand over time. Comparison of pupils' pre- and post-tests and analysis of the case studies of pupils' learning indicated that pupils developed the more subject-specific language needed for participating in mathematical discourse. The results of our research can contribute to the design of professional development on how teachers can perform scaffolding in multilingual mathematics classrooms.

It is hard, perhaps impossible, to attribute pupils' longer-term learning processes in whole-class situations to particular instances of scaffolding. Hence, reconceptualising scaffolding for whole-classroom situations implies explaining pupils' learning processes as the cumulative effect of performed scaffolding strategies over time.

SYMPOSIUM

Using the interactive whiteboard to scaffold pupils' learning of science in collaborative activities

Paul Warwick, University of Cambridge, United Kingdom; Neil Mercer, University of Cambridge, United Kingdom

Abstract

Interactive whiteboards (IWBs) are usually used by teachers for whole-class teaching. This paper is based upon a project in which pupils were allowed to use the IWB when working together on science-related activities (designed by the teacher). Using an analysis of video and other data from lessons in UK Year 4 and Year 5 primary classrooms (pupils aged 8-10 years), it focuses in particular on the 'vicarious presence' of the teacher evident in the group interactions at the board. We address the following questions: How does the teacher use the IWB to organise and support children's learning activity? In what other ways does the teacher structure children's activity without actually becoming involved in it? How useful is the concept of 'scaffolding' for interpreting the vicarious influence of the teacher and its effects on children's activity in the context of collaborative interaction at the IWB?

Summary

Our research investigated the potential of the IWB as a resource for assisting collective thinking and learning in the study of science. Focusing on children's collaborative use of the IWB during science curriculum activities, the overarching exploratory research question was 'How do children use the IWB when working together on science-related activities?'. We focused on exploring the distinctive role of the IWB for supporting and contextualising productive dialogue and other forms of interaction amongst students in collaborative science activities in the primary classroom, and on examining how students use the IWB to share relevant ideas and create new joint understanding in science activities.

Twelve teachers and their classes in Year 4 and Year 5 primary classrooms (pupils aged 8-10 years) in England participated in the research. Teachers received some initial professional development, which focused on the organization of collaborative learning and the role of talk in learning, and the use of the IWB for designing science-related collaborative activities. The teachers then developed a series of science activities on the IWB, which allowed their children to consider options, plan their actions and make joint decisions. These activities were designed to exploit features of IWBs that could be expected to help support pupil's collaborative activity, such as the easy and flexible reference to relevant information, easy annotation of pictures and texts, the facility for moving quickly between different images and writing drafts, and the combined presentation of images, text and sound. For each teacher, three lessons based on these activities were video-recorded and the recordings were transcribed. Teachers were also interviewed about their teaching plans and their consequences for the children's activities.

Our observations revealed that the teacher remotely mediated the activity of the pupils at the board in two specific and interlinked ways. Firstly, the vicarious presence of the teacher seems to be 'in the minds of pupils', enabling them to appropriate and use introduced rules and procedures, in this case in relation to group talk. Secondly, it is evident in the ways in which the constructed task environment on the IWB guides and mediates the pupils' actions, enabling them to connect with, interpret and act upon the teacher intentions for the task. Here, the teacher's vicarious presence is 'in' the technology.

We suggest that the concept of 'scaffolding' is useful for understanding how the teacher mediates the group activity, through prior guidance and the design of IWB-based activities – even though (a) this scaffolding is achieved without the teacher being physically present; and (b) we are concerned with the learning activity of a group, not an individual child. As originally defined by Wood, Bruner & Ross (1976), scaffolding is help which provides contingent support for pupils' cognitive and meta-cognitive activity by reducing the 'degrees of freedom' of a task but without supplanting the

child's active performance. Moreover, the contingent nature of scaffolding support means that, if it is successful, the child (or in our case, the group) eventually achieves a new level of independent competence. In our previous work (particularly Warwick, Mercer, Kershner & Kleine Staarman, 2010) we have considered the links between the use of specific IWB affordances and teacher scaffolding of tasks – these suggested links are outlined in the table :

Table 1: Linking teacher use of IWB affordances and scaffolding strategies

We consider this that conceptualisation is potentially important in articulating the ways in which the teacher's vicarious presence links not just with cognitive and meta-cognitive scaffolding intentions, but also with the intention to engage and excite the pupils in their own learning. Our contribution to this symposium takes up this perspective and explores it in more detail.

SYMPOSIUM

Teaching and learning in social science and history

Chairperson: Ola Hallden, Stockholm University, Sweden

Organiser: Cecilia Lundholm, Stockholm University, Sweden

Discussant: Peter Davies, University of Birmingham, United Kingdom

15 years ago, Carretero and Voss presented an edited volume entitled *Cognitive and Instructional Processes in History and the Social Sciences* (1994). The volume was an important contribution and a starting point for further enquiry into the field of teaching and learning in the social sciences and history. During these 15 years, however, the interest for researching teaching and learning in natural science and mathematics seems greater than ever, and we still lack clear evidence of growing interest, recognition and empirical studies for and in other domains.

In this symposia we acknowledge the theme of the conference in addressing students' understanding of society as global and changing, where concepts such as racism and nation need to be put into focus. Researchers from Europe and the US will report results of their findings. The studies focus on; i) teachers' understanding of racism, and their sense-making in terms of repeatedly shifting from structural and institutional interpretations to interpretations that focused on individual deficits (US), ii) Swedish teacher students studying political science and their understanding of the concept of 'nation' in terms of theoretical and ideological contextualisation and the role of personal values, and, iii) findings on students' conceptual understanding in history, where the role of emotions in the learning process is of particular significance and interest from both a teaching and learning point of view.

This symposia is an important step in gathering researchers in the field, and furthering our understanding of teaching and learning in the social sciences domains and history.

SYMPOSIUM

Contextualizing in political science: university students reasoning about the concept of nation

Linda Murstedt, Stockholms universitet, Sweden; Jonas von Reybekiel Trostek, Stockholm University, Sweden

This study focuses on exploring students' learning processes in the discipline of political science by scrutinizing how they understand a given task; an examination of theories about 'nation'. The empirical data consists of written exam papers from 22 students produced within the framework of a first year university course in political science. Previous research on conceptual change has mostly focused on students' (or children's) understanding of concepts in natural science. This study will contribute with knowledge in the area of conceptual change in the social sciences in general and in political science in particular. It is assumed that students may apprehend theories in the discipline of political science as addressing questions of an ideological character. It is therefore likely that students deal with at least two contexts – an ideological and a theoretical – when handling the theories. Our preliminary results confirm this assumption by showing that some students interpret the theories mainly in an ideological context while other mainly reason about them within a theoretical context. A third group of students oscillate between the two contexts. Finally, students in a fourth group do not differentiate between the two contexts, but rather compound these into one

coherent context of interpretation. The results point toward that students solve different kinds of problems depending on how they contextualize the theories. Hence, the study draws attention to significant aspects of knowledge in the political science discipline – the ideological – and elucidates how ideological foundations, like norms and values, relate to the conceptual change process.

Aim

This study focuses on exploring students' learning processes in the discipline of political science. This is done through scrutinizing how they understand a given task; an exam paper. It is assumed that students may apprehend theories in the discipline of political science as addressing questions of an ideological character. The study therefore aims at exploring how the students contextualize the task.

More specifically we explore:

- I. If students contextualize a given task as theoretical and/or ideological, and if so, in what way?
- II. What kind of problems are students solving when reasoning about required theories in a task?
- III. If students/ norms and values are of significance when solving problems, and if so, in what way?

Methodology

The data consists of written material in form of 22 student exam paper, produced within the framework of a first year university course in political science. According to the instructions in the exam paper, the students were assigned to "problematize and analyze how nation, ideas of Swedishness, of communion and identity are constructed" in Swedish newspaper articles covering the Nobel Prize Award Ceremony. Furthermore, the students were instructed to use Billig's theory (1995) on 'banal nationalism' and Brune's theory (2004) on 'story types' as benchmarks in the analysis.

A crucial methodological assumption is that the students may deal with theories within different conceptual contexts of interpretation (Caravita & Hallden, 1994). Therefore it is reasonable to make a distinction between the task introduced and the problem, i.e. the interpretation of the task given (Hallden, 1988; Hallden et al, 2008). As a result, the analysis focuses on what the students are doing in their exam papers, i.e. what kind of problems they are solving (cf. Hallden et al, 2007). Since the aim is to investigate how the students deal with two specific contexts – the theoretical and the ideological – the analysis focuses in particular on students' problems within these contexts of interpretation.

Findings and conclusions

The findings point to four different ways of contextualizing the task. Some students mainly interpret the theories within an ideological context while other mainly reason about them within a theoretical context. A third group of students oscillate between the two contexts. Students in a fourth group do not differentiate between the two contexts, but rather compound these into one coherent context of interpretation.

In terms of problems, the results indicate that students solve different kinds of problems depending on how they contextualize the theories. Problems within a theoretical context of interpretation seem to concern the link between theoretical concepts and the empirical material that was included in the instruction for the exam paper. On the contrary, problems within an ideological context seem to presuppose a personal world view as a starting-point for valuing the theories. Within a compounded context of interpretation, theoretical reasoning seems to solve ideological problems and arguing for certain values seems to be a way of dealing with a theoretical problem.

Theoretical and educational significance

As the study focuses on students' learning in higher education and as the participants are teacher students the results have an educational significance in a double sense; partly with regard to teaching at university level and partly to increase knowledge on future teachers' understanding of the political science discipline. A greater understanding of this aspect contributes to the possibility of improving the teacher education.

Regarding research on students' conceptual change the study contributes with increased knowledge concerning how values and norms relate to the conceptual change process (cf. Lundholm, 2005; Sinatra & Pintrich, 2003). In the study it is assumed that students may apprehend theories in political science discipline, like Billig/s (1995) on 'banal nationalism' and Brune's (2004) on 'story types', as addressing questions of an ideological character. The study explores how these norms and values become aspects of the conceptual change process and aims at elucidating these relations.

The findings of this study make it reasonable to question the traditional description of the conceptual change process as abandoning and replacement of concepts in a linear fashion (cf. Posner et al 1982). Here, instead some students

show that they are capable of differentiating and oscillating between different contexts of interpretation (Caravita & Hallden 1994).

SYMPOSIUM

The importance of intuitive knowledge in teachers' sense-making of race, racism and racial justice

Thomas Philip, UCLA, United States

Through a framework that synthesizes theories of ideology and intuitive knowledge and through the examination of in-depth interviews with teachers, this paper explores the importance of ideological intuitive knowledge in teachers' sense-making of issues of race and racism within their larger historical, social, political and economic context. It explores how intuitive knowledge has been undertheorized, glossed over and often conflated under the category of beliefs, resulting in limited understandings of how teachers make sense of racial equity and justice. This study contributes to the literature on teacher preparation and development and also contributes more generally to how students make sense of issues of equity and justice in the social sciences.

Aims

Through a framework that synthesizes theories of ideology and intuitive knowledge and through the examination of in-depth interviews with teachers, this paper explores the importance of ideological intuitive knowledge in teachers' sense-making of issues of race and racism within their larger historical, social, political and economic context. It explores how intuitive knowledge has been undertheorized, glossed over and often conflated under the category of beliefs, resulting in limited understandings of how teachers make sense of racial equity and justice.

Educational significance

The equity implications for how teachers understand the nature and purpose of their work, particularly when there are stark differences between teachers' and students' racial, ethnic, class and immigration backgrounds has been well documented (Hollins & Guzman, 2005; Sleeter 2008). This study contributes to the literature on teacher preparation and development, particularly for teachers from dominant backgrounds who teach historically marginalized students. It also contributes more generally to how students make sense of issues of equity and justice in the social sciences.

Theoretical framework and significance

In this paper, I argue that a theory of "ideology in pieces," which builds on diSessa's (1993) theory of "knowledge in pieces" and Stuart Hall's (1996) theory of ideology, offers new possibilities in understanding the intersections between teacher learning and issues of race, racism and racial justice through a focus on ideological intuitive knowledge. By synthesizing these traditionally disparate fields, "ideology in pieces" contributes to the "cognitive, sociocognitive, sociocultural and systems-oriented perspectives" (Fishman & Davis, 2006) that the learning sciences offer in studying questions that cut across teacher learning and social processes and structures. Working toward this synthesis, I have three primary objectives in this paper. First, I introduce the key characteristics of an "ideology in pieces" framework. Second, acknowledging that it is not possible to survey the entire literature on teachers' racialized beliefs and sense-making, I focus on four approaches to this issue, outlining the contributions they have made to the field, and highlighting their limitations that arise from an inattention to intuitive knowledge. These approaches are:

- a) A learning sciences approach to teacher knowledge and teacher identity (e.g., Enyedy, Goldberg & Welsh, 2005)
- b) Perspectives on teacher identity outside of the learning sciences (e.g., Phillion & Connelly, 2004)
- c) Perspectives that emphasize relatively fixed beliefs (e.g., McFalls & Cobb-Roberts, 2002)
- d) Approaches that emphasize critical theories of race (e.g., Picower, 2009).

Third, I examine interview data with a teacher to demonstrate how an “ideology in pieces” perspective might analyze and interpret such data differently from the other approaches discussed in the paper.

Methods and data sources

The data examined in this paper include in-depth, open-ended interviews with teachers in the United States. Extending empirical analyses in conceptual change (diSessa, 1993; diSessa & Sherin, 1998; Wagner, 2006) and the study of ideology (Bonilla-Silva, 2003), the transcripts were analyzed line by line particularly for existential, propositional and value assumptions (Fairclough, 2003), and for shifts in teachers’ interpretations and explanations of disparities from structural and institutional emphases to emphases on individual choices and behaviors.

Results

Shifting salience, as defined in this paper, is the phenomenon in which one’s interpretation of a context shifts to another interpretation with distinct ideological meaning without apparent notice or unease. Shifting salience was evident in the data examined here as teachers’ sense-making shifted repeatedly from structural and institutional interpretations to interpretations that focused on individual deficits. This phenomenon is examined in light of ideological intuitive knowledge and the framework of “ideology in pieces.” The importance of shifting salience in understanding teachers’ racialized reasoning as well as the limitations of other approaches in explaining this crucial phenomenon is explored through a discussion of the data.

SYMPOSIUM

Conceptual change in history: responses to a concept related to present and historical situations

Carla Van Boxtel, University of Amsterdam, Netherlands; Albert Logtenberg, University of Amsterdam, Netherlands

In History students come across many concepts they know from everyday life, but have a different meaning when applied to a historical situation. In order to understand the past, students need to build a different representation for the different –historical- situation.

Building upon research on conceptual change in the domain of science, this process study aims at gaining more insight into students' reactions when they come across these concepts. To what extent and how do students apply their present and historical representations to the past situation and differentiate between past and present meanings? Participants of the study are 12 students from a larger sample of 33 who read a text about the situation in a factory in Manchester in the nineteenth century. Participants were instructed to underline text elements that are striking, (un)familiar or (un)clear to them. At each underlined text element they were asked to verbalize why they underlined it and to (further) explain their thoughts. Protocol analysis of the episodes on factory work shows that many students respond emotionally, mostly with indignation or amazement. After expressing their emotion and using present meanings, some students use their historical knowledge of factory work, differentiate between the present and historical situation and try to contextualize the situation and events described in the text.

The study contributes to conceptual change theory and shows that in history the conflict students experience often goes together with emotions. These emotions, however, not necessarily obstruct differentiation between present and historical meanings and contextualization.

Theoretical framework

The discipline of history uses many general concepts students come across in everyday life or other subjects, such as trade, democracy, war and Christianity. These concepts have received little attention in research on the learning of history, although they are important tools to contextualize, one of the key components of historical thinking and reasoning (van Drie & van Boxtel, 2008). For example, students can only understand the act of a pope in the late Middle Ages when they know that the Church in that period differed from the Church nowadays and when they have an idea of the organization, role and characteristics of the mediaeval Church.

From research within the domain of science, we know that terms that are used within the discipline and overlap with terms used in everyday life, give rise to particular problems (e.g. Carravita & Hallden, 1994). From a conceptual change perspective it is emphasized that students must experience that their conceptions are not adequate in explaining certain phenomena.

To what extent are these insights applicable to how students deal with concepts used in history, but also in everyday life? There seems no need for a profound revision or transformation of the everyday ideas, since students' present meanings are mostly functional and not problematic when confronted with present phenomena. Trade in the Middle Ages, however, differs from trade in our present society. Conceptual change in this case means that in order to understand past phenomena, students need to build a qualitatively different representation for the different – historical- situation and learn to differentiate between present meanings and meanings used in a specific historical context.

Constructing a historical representation and making a distinction between the present and historical situation are, however, not unproblematic. From studies in the domain of history we know that students are inclined to apply to the past situation what they know from the present (e.g. Limon, 2002; Hartmann & Hasselhorn, 2008). Students often experience the past as strange and react with indignation or amazement, especially when they read or hear about people who suffered oppression, bad economic circumstances or a lack of freedom. This emotional engagement may obstruct the construction of a historical representation and differentiation between past and present meanings, which are important to contextualize situations, events and acts of people in the past.

Research question

The question we address in this paper is: How do students respond when they read about a historical phenomenon that is described with a term that has a different meaning in the present?

Method

We conducted a process study to answer our question. The data we used are a sample from transcripts of the thought processes of 33 secondary school students (15/16 years) engaged in reading an introductory text about the Industrial Revolution. The text contains vivid descriptions of 19th century Manchester and describes conditions of women and children working in a factory. Students were asked to read the text and underline text elements that are striking, (un)familiar or (un)clear to them. At each underlined text element participants were asked to verbalize why they underlined it and to explain their thoughts. We transcribed protocols of all students and divided the data into episodes. An episode is defined as the utterances of the student after a text segment is underlined. We selected the episodes in which students underlined sentences with information about the factory and factory work(ers), since factory and factory work(ers) are also concepts they come across in daily life. Twelve students (4 boys and 8 girls)

underlined text fragments about the factory and factory workers and verbalized their thoughts. We analysed a total of 15 episodes. First, episodes were coded on the appearance of prior knowledge (knowledge deficit, knowledge conflict, association or no prior knowledge). Second, we coded each episode on appearance of affect (no affect, interest, indignation, astonishment, empathy or boredom). Third, episodes were coded on the appearance of historical reasoning (no historical reasoning, contextualization, comparing, causal reasoning, argumentation). Inter-rater reliability was acceptable (Cohen's kappa reached from .65 to .90).

Results

Our analysis shows that most students respond emotionally, mostly with indignation or amazement. Part of the students only responds emotionally and doesn't verbalize any prior knowledge nor tries to contextualize. After expressing their emotion and verbalizing present meanings and ideas, some students verbalize their historical knowledge of factory work in the nineteenth century, differentiate between the present and historical situation and try to contextualize the historical situation and events described in the text. Some students seem to lack the historical knowledge to adequately contextualize but still attempt to contextualize. Sometimes their questions show that students try to get their prior knowledge more explicit or are aware of a knowledge gap.

Theoretical and educational significance

This study contributes to the idea that conceptual change is not always a matter of changing or transforming preconceptions, but may also consist of building multiple representations and knowing when to apply which representation. It also shows that in history, the conflict that students experience is expressed by showing emotions such as amazement or indignation. Identification of similarities and differences between past and present, contextualization and development of the awareness that terms change meaning over time and across societies may be important ingredients of an instructional strategy that helps students overcome problems that may arise when students come across concepts in history they know from everyday life. Further research is needed to investigate the effectiveness of such a strategy.

SYMPOSIUM

Errors and their role for the development of negative knowledge

Chairperson: Christian Harteis, Universitat Paderborn, Germany

Organiser: Christian Harteis, Universitat Paderborn, Germany

Discussant: Hans Gruber, University of Regensburg, Germany

This session aims at providing theoretical concepts and empirical evidence for conditions which support learning from errors and the development of negative knowledge. The contributions from three different domains comprise empirical studies investigating different aspects of learning from errors. They analyze environmental and personal influences on how individuals utilize errors for the development of negative knowledge – also in relation to other knowledge stocks. The contributors emphasize erroneous events as well as almost-mistakes, and they investigate reflective processes of knowledge creation. By discussing almost-mistakes as well as errors and considering several kinds of knowledge for the development of individual competencies, this symposium applies a wider perspective than usual research on learning from errors.

SYMPOSIUM

Towards a theory of Negative Knowledge: Almost-mistakes as amplification-motor for remembering

Fritz Oser, Universitat Freiburg, Switzerland; Albert Dueggeli, PH (FHNW), Switzerland; Catherine Naepflin, University of Fribourg, Switzerland

In past, theoretical research on the phenomenon and function of Negative Knowledge has advanced substantially. Educational psychologists as well as educational philosophers, researchers in the field of pedagogical content knowledge and practitioners in education made attempts to circumscribe and operationalize this construct. Most of these oeuvres do however not address how NK is retrieved and actualized in a new, similar situation, even though actualization seems to be a key issue related to the concept. To date, the reconstruction of NK can only be understood by using special situational elements like the fear of committing the same mistake again and/or the hunch of suffering from consequences of similar mistakes. In this article we explore the phenomenological possibilities on NK and introduce the concept of almost-mistakes (nearby-mistake or near-miss) and its nonlinear relationship to NK as a new important dimension. We carried out a qualitative small pilot-study in which we asked subjects to remember what kind of almost-mistakes they experienced, what they learned from them and how they felt about them. We used a semi-standardized questionnaire to interview children, adolescents and adults. In the health sector, any mistake can have fatal consequences. For nursing staff and doctors it's not easy to talk about their mistake, even if it is "only" a near-miss. If a platform gives them the possibility to discuss their concerns while remaining anonymous, this might help them the reluctance to discuss these negative experiences.

Negative knowledge (NK) refers to memories related to events, things, procedures or strategies that are experienced as false, as inadequate or even as ineffective, the linked consequences and memories such as feeling ashamed, and being blamed or exposed in ones own intimacy.

Therefore we think NK have the functions

- a) to create a useful alert against committing the same mistake again (protection),
- b) to distinguish between contrasts (bad and good),
- c) to find orientation between opposite characteristics (high versus low),
- d) to produce certainty in addressing a problem following a particular procedure.

Schumacher (2007) names a kind of pedagogical functions whereas Bauer (2008) sees the function in the sense of pragmatics, such as helping to prevent from damaging engines in a factory etc. In this presentation we ask how almost mistakes (AM, mistakes that happen near-by) help to remembering real mistakes and its negative consequences. AM produce the same activity but with protected agitation and projected consequences. If the norm to which the mistake relates is important (personally and/or publicly) the remembering is strong; if not we adapt ourselves without further consequences.

To become mentally aware of a mistake in the past helps to avoid its repetition in the future. It is related to the ability of traveling back mentally and use personal memory to prevent the same mistake or error again from happening (see Wheeler et al., 1997). Tulwing (2000) calls this "autonoetic" remembering. The application of these remembering lead to our notion of NK on the one hand, whereas the difference to AM lies in the fact, that NK is only active if the new situation recalls the mistaken one and thus protects us from a new similar case.

There is a kind of ambiguity: on the one hand the AM seem not to be important but on the other no one does forget. Peoples told an AM is like an alarm clock to show that you're not attentive enough. The dimension of sharing the experience with others shows that elderly persons keep the AM for themselves arguing that sharing wouldn't help and cannot be shared. For younger persons sharing has a different meaning. It is just telling.

In the medical field it is very important to discuss AM-situations. Aspden speaks about a protected reporting system (CIRS-System) which is used by clinics to promote a collection of AM helping others to prevent them and to break the taboo.

Hence, towards our definition of NK, AM are an actualization of NK that we become aware of risks, consequences and pains of something negative that happened once before, but now, in a new near-by situation, we think, belief, fear that it happens again, finally it doesn't.

Studies

In a first study we gained insights about peoples reactions to AM (in general N=15, between 9 and 85 years old and specific profession N=3 between 38 and 52 years old). Each person was asked 14 questions. First they had to describe one or two "AM-situations" with its real and imagined consequences they suffered (emotionally and materially), the way they cope with the situation, the intensity of remembering it (NK) and the difference between a real mistake and a AM. Finally, questions on sharing this experience with someone, effects and functions of the AM for the future closed the interview process. We analyzed the answers in a co judgment and found, that children mostly described situations in school, teenagers mentioned AM-situations on a moral level like friendship risks and that it is important to keep a promise. Adults told their experience with AM in the job or leisure activities. The imagined consequences

were probably greater than would have been possible in a real situation. In the medical field very profound responsibilities and reactions were found. It seems that subjects connect a deep commitment with the wish not to fail, but to do the best for each patient. The higher the stakes the deeper the experience and the less the re-actualized NK becomes.

In a second study (Hofer, 2009) we analyzed the error culture through near-miss in firms (N=455). The super-ordinate target of this study is to analyze how the (1) personality traits, (2) self-efficacy, (3) achievement motivation, (4) professional self-esteem, and (5) personal handling of errors –are correlated with the firm-error-culture. It seems that females in a professional setting react less sensitive to a full mistake culture than males. For males the relationship between self-efficacy belief and mistake culture ($r = .41^{**}$) or between professional self-esteem and mistake culture is a highly positive one ($r = .36^{**}$).

In a third study different situations (moral, conventional and social) were presented in a questionnaire to four-member-families (Ntotal=399, Nkids=147, Nmothers=135, Nfathers=117). It showed that they discussed a lot about conventional and social mistakes, but not about moral ones. That is self-evident.

Discussion

AM are drivers for the reanimation and amplification of NK. The question of how we re-actualize the NK in a similar situation is accompanied by the question of how strong we are touched by the AM. The more NK someone has collected without being taped in, as more positive knowledge is possible. AM are always related to real mistakes, and the experience of an AM needs as a precondition the NK in relation to a real mistake.

As seen in the previous paragraphs AM are effective means for extending NK, but also for generating it in a tense situation in order to prevent the same mistake from happening again.

There are a couple conclusions to be drawn from our presentation. First, AM refer always to a prior event in which the adverse incident was either realized or experienced advocatorily by seeing others doing the same errors. Therefore we argue that AM actualize and deepen the respective NK. – Second, in daily life we often cannot speak about very serious AM; whereas in professional settings, within a reporting system, very serious situations are presented, reflected and used to protect us from doing such things again. Third, the emotional reaction to AM can be even stronger than the reaction of real adverse mistake events, because the feelings are double bounded, namely positive and negative.

SYMPOSIUM

Development of positive and negative knowledge in a professional community

Els Boshuizen, Open University, Netherlands

The term 'negative knowledge' is rather new in educational research. Earlier it was used in legal and in the logical-mathematical contexts where it depicts knowledge about errors and failure, about things not to do. Gartmeier, Bauer, Gruber and Heid (2008) applied this concept in the educational domain and position it in the higher levels of expertise development.

A requirement for learning from errors in professional communities is a 'learning culture', which requires that its members seek feedback, face errors, and are committed to improve their knowledge and working procedures. This means that both the process and the outcomes have to be shared with colleagues, which makes it relevant to the community and to the profession as a whole.

The present paper approaches learning of negative knowledge from the perspective of the professional community by analysing a case of knowledge development in a community, extending over several decades, i.e., knowledge development about Lyme's disease.

Negative knowledge developed in this community mainly regarded the sensitivity and specificity of the patient findings and diagnostic tests used. To move further more knowledge was needed about the underlying immune processes and how these affect the course of the disease and the test outcomes. It is suggested that in this case negative knowledge is not the most important knowledge developed in the learning process of the community from failure and error.

The term 'negative knowledge' is rather new in educational research. In the literature, it has a legal and logical-mathematical background rather than a cognitive-epistemological one. In the legal context a concept exists called

'negative know-how' – knowledge about failures and mistakes; under the US Uniform Trade Secrets Act this negative know-how can be considered a commodity and the property of a business (Graves, 2006). In the logical-mathematical context negative knowledge is depicted as a negative evaluation of two propositions, e.g., This cake is made with paraffin AND this cake is tasty IS FALSE. Together with its counterpart, positive knowledge which is defined by the positive evaluation of the combination of two propositions (e.g., This cake is made with butter AND this cake is tasty IS TRUE) it belongs to the same knowledge base (Booth & Paris, 1998). This might be a fair assumption for artificial knowledge bases, but research from personality psychology has shown that positive and negative knowledge about self can also be compartmentalised in two sub systems that have hardly any relation. Gartmeier, Bauer, Gruber and Heid (2008) hypothesised that negative knowledge is learned from errors, an opinion closely related to the legal meaning. Furthermore they conclude that "The concept of negative knowledge augments existing theories of professional knowledge by emphasizing knowing about what to avoid as part of experts' effective actions. During routine actions, negative knowledge enhances professionals' certainty of how to proceed and increases the efficacy through the avoidance of impasses and suboptimal problem-solving strategies. Quality and depth of reflective processes after actions are related to the development of negative knowledge." (p. 2). In all domains where the concept is used it is a part of a dichotomy.

Learning from errors is often approached from the perspective that this requires a 'learning culture' in a company, a culture that requires its members to seek feedback, face errors made, and the commitment to improve one's own knowledge and the working procedures in terms of when to do what and when not, that is, of positive and negative knowledge. This means that both the process and the outcomes have to be shared with colleagues, which makes it relevant to the community and to the profession as a whole.

These conclusions generate some new questions: 1) Gartmeier et al (2008) describe negative knowledge as an end product of the learning process; what kind or pre-existing knowledge is required for that goal and what kind of errors is required for building negative knowledge? and 2) is negative knowledge an end-product or is it 'just' a step in further knowledge building?

Method

To answer this question I will analyse a historical case in which individual doctors and the medical profession as a whole in the Northern hemisphere struggled with a new disease. I approach this from the perspective of the profession, not of the individual doctor. It regards Lyme disease (borreliosis) that had been very rare and only partially described until in 1975 a small epidemic broke out in the village of Lyme (Connecticut). In the period following clinical errors, failures and improvements were reported on the one hand, while biomedical research was reported focussing the features of the micro-organism involved, the associated immunological reactions, and diagnostic strategies. Historical documents, especially diagnosis and treatment protocols were analysed (e.g., , to investigate the sequence of triggering events.

Results and conclusions

Negative knowledge that was developed in this field mainly regarded the sensitivity and specificity of the patient findings and diagnostic tests used. The associated misconceptions in part of the medical community has led to many errors and failures. At the positive site of the same coin is the emerging knowledge how these test qualities can be improved in the able hands of laboratories and specialists especially devoted to Lyme's disease. Evidence-based guidelines for diagnosis and treatment protocols have been developed; yet there is debate about the correctness of these protocols as two conflicting theories about the disease dynamics and expression lead to different evaluation of the results of the underlying studies.

The case does not yield an answer to the question what kind of knowledge is needed to develop negative knowledge. It is suggested that in this field negative, dichotomous knowledge is not the most important knowledge developed in the learning process of the community from failure and error. More important was the recognition of the reasons for these failures that had to be resolved that formed the key to solutions. The community has moved a step toward fewer failures and better knowledge of reasons for these failures; a new learning cycle has started influenced by specialised Lyme specialists, patients, and the health insurances who have different concerns, which will add new dimensions to the knowledge generation process.

SYMPOSIUM

Learning from errors through computer-supported guided reflection

Johannes Bauer, TU Munchen, Germany; Stefan Ufer, University of Munich, Germany

Recent research on learning from errors has shown the importance of a learning-oriented 'error culture' in the classroom, involving teachers' ways of dealing with students' errors and the corresponding classroom atmosphere they establish for making errors. Theory claims that causes of errors need to be reflected and appropriate conclusions for future tasks must be drawn. Whereas many existing studies focus on describing error-culture in the classroom, less is known about how and under what conditions reflections on students' errors lead to changes in knowledge, and how this helps to improve performance in similar tasks. Moreover, we need a more thorough understanding of how students can be supported in learning from errors.

We aim at investigating the effect of guided reflection on errors in 6th-grade students' learning. As content area we use fraction addition and subtraction tasks. We conduct a randomized field-experiment, in which students' learning is embedded in a computer-supported learning environment. The one-factorial design involves three treatment conditions that offer increasing guidance in students' reflection on errors through providing computer-generated feedback and prompts that invite the students to reflect on their errors, when they occur.

We are collecting qualitative data concerning students' reflection as well as quantitative achievement data from pre- and post-tests. With regard to our hypotheses, we expect to find that increasing guidance enhances the quality of reflection and students' performance in solving fraction addition and subtraction tasks.

Aims

In our study, we aim at investigating the effect of guided reflection on errors in 6th-grade students' learning. As content area we use fraction addition and subtraction tasks. The issue of learning from errors is receiving increasing attention in educational research (Gartmeier et al., 2008; Harteis et al., 2008). Theory claims that errors in the classroom provide a fruitful source for learning if causes of errors are reflected and appropriate conclusions for future actions are drawn (Keith & Frese, 2008; Oser & Spychiger, 2005). There are few studies, however, that directly investigate the actual potential of learning from errors for students' competence development and how students can be supported in learning from their errors (Grosse & Renkl, 2007). In our study, we contribute to this line of inquiry by addressing research questions whether providing students with feedback and guidance in the reflection of errors (a) enhances the quality of reflection on errors and (b) has an impact on their achievement in subsequent similar tasks.

Methodology

To answer our research questions, we are conducting a randomized field-experiment in a middle track secondary school class (6th grade). Students' learning is embedded in a computer-supported learning environment on fractions. The design of the fraction addition and subtraction tasks is based on a long tradition of research from mathematics education on typical student errors in fraction addition and subtraction (e.g. Tatsuoaka, 1984; Brown & Quinn, 2006). The one-factorial study-design involves three treatment conditions that offer increasing guidance in the reflection on errors through computer-generated feedback and prompts. Using the prompts, students are asked to think about why an error occurred, what general rule underlies the error, and how they can avoid it next time. In all treatments the students are asked to solve fraction addition and subtraction problems of varying complexity and to document their solution steps in the computer-based learning environment. Treatment condition 1 provides a specific feedback pointing at the operational step containing the first error. However, while being asked to reflect on the error, students do not receive any guidance. Condition 2 provides specific guidance on the reflection process through electronic prompts. Here, the students receive only the general feedback if an error occurred and they have to figure out the wrong operational step by themselves. Finally, condition 3 combines specific feedback and guided reflection. Data collection involves pre- and post-tests on achievement in fraction addition and subtraction tasks that vary in complexity and degree of required transfer. Furthermore, we collect qualitative data concerning the quality of reflection through the answers the students give to the electronic prompts.

Expected Findings

As data collection is in progress, the findings are not available yet. We hypothesize that there is an advantage of the combination of specific feedback and guided reflection for the quality of reflection and students achievement in the post-test, over the two other conditions. The underlying assumption is, firstly, that the specific feedback reduces cognitive load that is required when searching for the error in the general feedback condition (Grobe & Renkl, 2007). Therefore, cognitive resources are available for the reflection process in the specific feedback conditions. Secondly, the guidance through prompts should enhance the quality of students' reflection process. We assume that the students require this assistance because the cognitive strategies needed for reflection are not easy to apply and perhaps even unknown to the students.

Theoretical and educational significance of the research

Recent research on learning from errors has made a case for a learning-oriented 'error culture' in the classroom, involving teachers' ways of dealing with students' errors and the corresponding classroom atmosphere (Harteis et al., 2008). Whereas many existing studies focus on describing error-culture in the classroom, less is known about how students' can be supported in learning from errors (Oser & Spychiger, 2005). Our study aims at gaining a more thorough understanding of how and under what conditions reflections on students' own errors lead to changes in knowledge and how this helps to improve performance in similar tasks.

SYMPOSIUM

Understanding achievement and participation in STEM subjects

Chairperson: Terezinha Nunes, University of Oxford, United Kingdom

Organiser: Peter Bryant, Oxford University, United Kingdom

Beno Csapo, University of Szeged, Hungary

Discussant: Elsbeth Stern, ETH Zurich Institute for Behavioral Sciences, Switzerland

It is a matter of concern for many technologically advanced countries that participation in STEM (Science, Technology, Engineering and Mathematics) subjects is declining. Longitudinal studies are particularly suited for the investigation of possible reasons for this decline. In this symposium, studies in three different countries (Australia, Hungary and the UK) consider three types of factors that affect participation and achievement in STEM subjects: cognitive, affective and socio-economic status. A variety of analyses is used, which show the power of longitudinal research and provide an opportunity for methodological discussions. The main results from these papers indicate that: (a) the relationship between cognitive factors related to achievement in science and mathematics remains constant over time; (b) a model that investigated whether mathematical reasoning can be seen as a mediator of SES effects in the prediction of mathematical achievement provides a better fit to this prediction than an alternative one, in which the predictors are treated as independent; (c) the up-take of science in secondary school is related to previous enjoyment and interest in science.

These results point to actions at primary school level that could lead to better achievement and participation in STEM subjects. These should include greater attention to promoting reasoning skills in mathematics and science in order to raise achievement and to increase participation of under-represented SES groups and supporting students' perception of these subjects as relevant and enjoyable.

SYMPOSIUM

How Mathematical Reasoning mediates the Relationship Between SES and Mathematical Achievement

Peter Bryant, Oxford University, United Kingdom; Terezinha Nunes, University of Oxford, United Kingdom;
Rossana Barros, Department of Education, University of Oxford, Peru

Socio-economic status (SES) predicts mathematical achievement, but the mediators of this relationship are not yet understood. We analyzed whether two factors, knowledge of arithmetic and mathematical reasoning, can be mediators of this relationship. If SES effects are mediated by these factors, then schools could intervene to attenuate SES effects on achievement.

In a longitudinal study of children (N=3,458) born in the UK in 1991-2, knowledge of arithmetic and mathematical reasoning were measured at age 8. SES was assessed by mothers' and of fathers' occupation and mother's education. The outcome measures of mathematical achievement were state mathematical tests given to students at approximately 11 (Key Stage 2 – KS2) and 14 years (Key Stage 3 – KS3).

In multiple regressions, knowledge of arithmetic, mathematical reasoning and SES made significant and independent contributions to predicting KS2 and KS3 mathematics; mathematical reasoning was the strongest predictor. Structural equation models established a strong indirect pathway from SES via mathematical reasoning to both measures of mathematical achievement (KS2 & 3). SES had a powerful effect on children's mathematical reasoning, which in turn strongly affected their mathematical achievement.

SES effects can be better understood through the mediators that intervene between family background and educational achievement. This has major consequences for how schools can proactively address SES differences and aim to attain equity in education.

Objectives

Socio-economic status (SES) predicts mathematical achievement well. This paper analyzes mediators of this relationship. Two cognitive factors were considered: knowledge of arithmetic and mathematical reasoning. If SES effects are mediated by these factors, then schools could intervene to attenuate SES effects on achievement.

Framework

Researchers (e.g. Ginsburg & Russell, 1981; Lee & Bryk, 1989; Reyes & Stanic, 1988; Sacker, Schoon, & Bartley, 2002; Tate, 1997) recognize that SES differences can be mediated by home activities that create cultural capital as well as by choices in school curriculum, among other things. This study analyzes whether mathematical knowledge developed in the first school years mediates the relationship between SES and mathematics achievement later on, at the end of primary and in secondary school. Two sorts of knowledge are considered: knowledge of arithmetic, which can be reinforced at home through drill and practice, and mathematical reasoning, which can be encouraged at home through discussions of mathematical ideas in context. If these factors mediate the relation between SES and mathematical achievement, the relation between SES and achievement should be attenuated when the mediators are taken into account. Longitudinal studies are crucial in testing this hypothesis.

Method

In a longitudinal study of children (N=3,458) born in the UK in 1991-2, knowledge of arithmetic and mathematical reasoning were measured at age 8. SES was assessed by a factor, composed of mothers' and of fathers' occupation and mother's highest qualification. At the school level, a composite SES score was used, based on the SES of children attending the same school. The outcome measures of mathematical achievement were state mathematical tests given to students at approximately 11 (Key Stage 2 – KS2) and 14 years (Key Stage 3 – KS3).

Results

In multiple regressions, knowledge of arithmetic, mathematical reasoning and SES did make significant and independent contributions to the prediction of KS2 and KS3 mathematics. The b coefficients for SES when the analyses were run before entering mathematics reasoning into the equation were .467 for the analysis with KS 2 Maths as the outcome variable and .418 for the analysis with KS 3 Maths as the outcome variable. When mathematics reasoning was added to the equation, the b values for SES were reduced to about one half in each analysis; they were .159 for KS2 and .245 for KS3. These were much lower than the b coefficients for the relation between reasoning and mathematical achievement (.62 at KS2 and .71 at KS3). Entering knowledge of arithmetic did not affect the relationship between SES and achievement as much. Therefore, mathematical reasoning, but not arithmetic, could mediate the relationship between SES and achievement in mathematics.

This idea was supported by structural equation models, which established a strong indirect pathway from SES via mathematical reasoning to both measures of mathematical achievement (KS2 & 3). SES had a powerful effect on children's mathematical reasoning, which in turn strongly affected their mathematical achievement. The coefficient for SES in this mediational model remains significant but goes down to .13 for KS2 and .23 for KS3. The model in which mathematical reasoning was entered as a mediator of attainment explained more variance in KS2 (53%) than a model in which reasoning was not a mediator (42%); the same was true about KS3 attainment, where the linear model explained 52% of the variance and the mediator model explained 59%.

Multi-level analyses were used to take into account the schools' social composition (through the mean SES for the school) and the individual SES, in order to investigate how SES affects mathematical reasoning. This analysis was possible because there were over 2,200 children in 86 schools, with a range of 6 to 65 children in the same school. The analysis showed that SES had an effect at the individual and school level; the interaction between these levels was not significant.

Conclusions and significance

SES effects can be better understood through the mediators that intervene between family background and educational achievement. The mediator effect of mathematical reasoning between SES and mathematical attainment observed here should be very stimulating for educators. They suggest that the negative effects of coming from less privileged homes can be offset by an approach to education that offers teaching which improves children's mathematical reasoning. Therefore, this study has major consequences for the way schools can proactively address SES differences and aim to attain equity in education.

SYMPOSIUM

Using Longitudinal Data to Investigate Influences on the Uptake of Science Studies

John Ainley, Australian Council for Educational Research, Australia; Mary Ainley, University of Melbourne, Australia

Many developed economies have experienced a decline in participation in science, technology, engineering and mathematics (STEM) studies over the past two decades. One of the responses proposed in relation to this decline in STEM participation has been to make school science studies more attractive. We argue that longitudinal data are essential for understanding the relationship between interest in, and enjoyment of, science studies at school and subsequent uptake of specialist science-based studies. This paper makes use of multivariate analysis (principally structural equation modelling) of data based on a follow through of the PISA 2006 sample in Australia. As a result of analysing these longitudinal data from 2006 to 2009 we conclude that taking up specialist science-related studies in the final year of secondary school is associated with higher levels of science achievement and stronger interest in science. Science education that is perceived by students to be personally important and enjoyable will be associated with stronger interest in science and a greater likelihood of taking up science-related studies. The paper also shows that different patterns of influence apply to biology, physics and chemistry and that an appreciation of these differences is important in understanding science participation.

Objectives

As observed by the Global Science Forum, many developed economies have experienced a decline in participation in science, technology, engineering and mathematics (STEM) studies over the past two decades (OECD, 2006). One of the responses proposed in relation to this decline in STEM participation has been to make school science studies more attractive. This paper makes use of multivariate analysis (principally structural equation modelling) of longitudinal data to investigate the relationship between interest in, and enjoyment of, science studies in middle secondary school and subsequent uptake of specialist science studies in the final year of school. The data are based on a follow through of the nationally representative PISA 2006 (OECD, 2007) sample in Australia.

Perspective

A number of previous research studies have indicated the influence of generic interests on school subject choice (Elsworth, Harvey-Beavis, Ainley, & Fabris, 1999). In this paper we focus specifically on interest in science and, adopting Ajzen's (2001) theory of planned behaviour, we see intentions to study science as a mediating influence on the uptake of science-related studies. Our argument is that interests in science influence the uptake of science-related studies mainly through their influence on intentions. Science achievement operates both indirectly through intentions and directly on the uptake of science studies. Our investigations of PISA 2006 data have shown the centrality of enjoyment of science for interest in science and intended future participation in science-related activities (Ainley & Ainley, accepted).

Data

The sample of 15-year-old students for PISA 2006 in Australia consisted of 14,000 students from 356 schools (Thomson & De Bortoli, 2007). Those students completed an extensive assessment of science literacy as well as a questionnaire that provided measures of interest in science, enjoyment of science, current and future planned science activities, future-oriented motivation to learn science as well as family and social background (OECD, 2009). The interest measures included general interest in science (measured through response to a series of statements recorded on a Likert scale) as well as more situated measures based on expressed interest in 31 science topics through questions embedded in the achievement test.

These students then formed the basis for a cohort of the Longitudinal Studies of Australian Youth. They were contacted each year using computer-assisted telephone interview (CATI) and provided information about their educational (including the subjects that they studied), employment and social activities. Our analyses are based on the 8,400 respondents to the 2008, interviews and the 7,300 respondents who continued into 2009, as these are the years in which students would have taken up the study of specialist science disciplines or not. Our analyses compensate for the effects of sample attrition by the use of post-stratification weights.

Analysis

Our analyses are part of the "event occurrence" stream of longitudinal data analysis (Singer & Willett, 2003) and we use structural equation modelling to examine the ways in which interest (and its antecedent of enjoyment) operates in conjunction with achievement to predict the uptake of specialist science studies in senior secondary school. Our previous analyses have examined the structure of science interests and factors that shape planned science participation. This paper extends those investigations to focus on actual uptake of science studies. In these analyses we focus on three dichotomous outcome measures of uptake of science representing studying biology (20% of the full cohort), chemistry (13% of the full cohort) and physics (12% of the full cohort) respectively (using logistic regression methods).

Educational and scientific importance

As a result of analysing these longitudinal data from 2006 to 2009 we conclude that taking up science-related studies in the final year of secondary school is associated with higher levels of science achievement and stronger interest in science. Science education that is perceived by students to be personally important and enjoyable will be associated with stronger interest in science and a greater likelihood of taking up science-related studies. The paper also shows that different patterns of influence apply to biology, physics and chemistry and that an appreciation of these differences is important in understanding participation in specialist science studies. It is important to know the strength of the relationships of the uptake of specialist science studies with interest and achievement in science as well as the factors that shape interest such as personal valuing of science. Longitudinal data are essential for understanding these relationships.

SYMPOSIUM

The Impact of Inductive Reasoning on Educational Achievements

Beno Csapo, University of Szeged, Hungary; Gyongyver Molnar, University of Szeged, Hungary

Previous research identified the roles inductive reasoning plays in acquiring and applying knowledge. The present analysis (1) estimates how well the developmental level of inductive reasoning predicts the later achievements at other areas of cognition; (2) compares the impact at several ages; and (3) examines if the observed relationships are based on internal processes or external factors. Data were collected in the framework of the Hungarian Educational Longitudinal Program (HELP). Representative samples (nth and a 10th grader sample and a problem solving test administered a year later the correlations were .47 and .52., while with a test of the application of science knowledge administered at the same second measurement point the correlations were .44 and .45. English reading test administered two years after the inductive reasoning test correlated with it at .46 and .48. The comparable correlations of the middle and oldest sample were almost identical, indicating that the relationships are not age dependent. When the correlations were controlled for mothers' education, partial correlations were only slightly lower. These observations suggest that the relationships may be attributed in a major part to internal cognitive mechanisms.

Theoretical framework

Previous research described the development of inductive reasoning (e.g. Csapo, 1997) and showed the role it plays in learning, in organization and in application of knowledge. It has also been shown that inductive reasoning is modifiable by systematic training, especially in young children (e.g. Klauer & Phye, 2008). Improving inductive reasoning may transfer to other areas of cognition and improves learning at distant areas like language development (Marx & Keller, 2010) and second language acquisition (Csapô & Nikolov, 2009; Marx, 2009). Most previous research studied the development and impact of inductive reasoning by cross-sectional data-collection, while longitudinal research offers the possibility of analyzing the predictive value of assessing inductive reasoning. Aims

The present analysis aims at (1) estimating how well the developmental level of inductive reasoning predicts the success at other areas of cognition in the following years. Using data from a multi-cohort longitudinal program, (2) we compare the impact at several ages. Furthermore, (3) we analyze if the observed relationships between inductive reasoning and other areas of achievements are based on internal cognitive processes or can be attributed to external factors.

Methods

This analysis utilizes the data of the Hungarian Educational Longitudinal Program (HELP) which was launched in 2003 in three cohorts. Representative samples of students entering grade 1, 5 and 9 were selected from the school populations of Hungary. The initial sizes of the samples were 5286, 3881 and 3131 respectively. Students' achievements at a variety of curricular and general cognitive domains were assessed at the end of the school years by paper-and-pencil tests; furthermore, questionnaires were administered to collect data about students' affective characteristics and social backgrounds. In this analysis, the results of an inductive reasoning test (composed of number series, number analogy and word analogy tasks), a problem solving test, a test for application of science knowledge, and reading in English as a second language will be used.

Analysis and results

Several correlation coefficients were computed for analyzing the relationship between inductive reasoning and later cognitive achievements. An inductive reasoning test was administered to the youngest sample at the end of grade 4, and a mathematics test at grade 6. The correlation between them was .56 ($n=3306$). When the relationship was controlled for mothers' highest qualification, the partial correlation still remained high, .5.

For the middle and oldest sample, the same test results are available. An inductive reasoning test was administered to them when they were at the 6th and 10th grade. A problem solving test administered a year later, at grade 7 and grade 11 correlated with its result at .47 ($n=3059$) and .52 ($n=1794$). After controlling for mothers' education, the remaining partial correlations were .44 and .49.

A test of the application of science knowledge was also administered to these samples at this second measurement point, the correlations were .44 ($n=3066$) and .45 ($n=1832$), while the partial correlations were .40 and .45 respectively. We have data from a third measurement point for these samples as well. A part of the entire sample (those studying English as a second language) solved English reading test at grade 8 and 12. The correlation between inductive reasoning and English reading was .46 ($n=1708$) and .48 ($n=866$), while the partial correlations were .41 and .45. (Due to large sample sizes each correlation coefficient is significant at least at $p=0.0001$.)

As for age differences, the comparable correlations of the middle and oldest sample were almost identical, indicating that the relationships do not depend on the age at the observed age range. Comparing the correlation coefficients with the corresponding partial correlations, only minor differences can be seen. These observations suggest that the relationship may be attributed in a major part to internal cognitive mechanisms.

Educational and scientific importance

The results of the analyses of the longitudinal data suggest a strong link between inductive reasoning and the subsequent educational achievements. In this way, assessment of inductive reasoning may offer an early indicator of later learning success. Inductive reasoning can be relatively easily measured, and on the bases of the results of this project, more suitable instruments can be devised. As the longitudinal data collection with the youngest sample continues, and a large number of further cognitive and background data are available, more sophisticated models can be developed for understanding the role inductive reasoning plays in school learning.

SYMPOSIUM

K 19 02 September 2011 09:00 - 10:00 Room Building 1 Matrix Lecture Theatre

Advancing research on shared regulation in collaboration: Juxtaposing empirical approaches

Chairperson: Sanna Jarvela, University of Oulu, Finland

Organiser: Sanna Jarvela, University of Oulu, Finland

Allyson Hadwin, University of Victoria, Canada

Discussant: Nancy Perry, University of British Columbia, Canada

Socially-shared regulation of learning refers to processes by which group members regulate their collective activity. Successful individuals regulate their motivational, cognitive, and metacognitive engagement (Winne & Hadwin, 1998). Similarly, successful groups share in regulating group processes. Implicit notions of socially shared regulation are often embedded in collaborative learning research (e.g. Barron, 2000; Janssen, Erkens & Kirschner, 2010). However, there is a paucity of empirical research systematically examining how students collectively share in the regulation of learning toward a collective outcome (Hadwin, Järvelä & Miller, 2011). Recent empirical research has shown that it has been especially challenging to empirically distinguish between shared regulation and shared knowledge construction. This may be because of dominance of discourse and observation data of inter-individual dialogue and transactions between group members and lack of methods and analytical techniques for examining solo and collaborative performance outcomes associated with interactional processes. The aim of this symposium is to advance our understanding about shared regulation by contrasting the findings from shared metacognition, socially-shared regulation and communicative perspectives.

SYMPOSIUM

Socially-shared metacognition: Convergence and co-construction CSCL planning

Allyson Hadwin, University of Victoria, Canada; Mariel Miller, University of Victoria, Canada; Philip Winne, Simon Fraser University, Canada

The purpose of this cross case comparison was to examine shared regulation of task perceptions and goals in three consecutive collaborative tasks. Specifically we compared groups with strong versus weak collaborative task performance in terms of three indicators of shared regulation: (a) co-constructed planning statements (task perceptions and goal statements), (b) convergence of group members' individual planning statements (task understanding and goal statements), and (c) metacognitive calibration between the goal efficacy and goal

performance ratings of both individuals and groups. We hypothesize that groups who achieved collaborative success would demonstrate: (a) The convergence in their individual task perceptions and goals by the end of the task, (b) co-construct accurate and complete task perceptions and high quality goals, (c) demonstrate efficacy for achieving both individual and co-constructed goals, and (c) self-report high attainment of individual and co-constructed goals.

Ideal collaboration is coordinated and interdependent work during which learners strive to achieve a shared goal or solve a shared problem (Roschelle & Teasley, 1995). In contrast to cooperative work where labor is divided among group members, collaboration involves dynamic, mutually interdependent interaction toward a joint outcome or goal (Dillenbourg, 1999). A collaborative team leverages each members' unique and distributed knowledge and expertise to achieve something that could not be achieved by the individuals alone (Johnson & Johnson, 1989).

Success in collaboration depends on: (a) strategies and self-regulatory skills individuals contribute to the group, (b) support members provide to one another that facilitates individuals' self-regulatory competence (co-regulation), and (c) shared or collective regulation of learning involving metacommunicative awareness and successful coordination of strategies (Barron, 2003). From this perspective, collaborative work fuses individuals' distributed metacognitive work with shared and coordinated metacognitive work of the group. Full collaboration implies meta-awareness of the coordinated whole. Successful groups unite their individual metacognitive information and regulatory actions to negotiate consensus about task perceptions, goals, knowledge about group processes, evaluations of collective progress and outcomes, and regulatory decisions.

We posit that successful collaboration emerges when teams collectively regulate learning (SSRL) across four phases outlined by Winne & Hadwin (1998): (a) task perceptions, (b) goal setting/planning, (c) task enactment, and (d) evaluation/adaptation. This study focuses shared regulation in planning phases (task perceptions and goal setting/planning). Much like individual regulation, this shared regulatory process is metacognitive in nature. Shared regulation involves continually planning, monitoring, evaluating and updating within and across phases of regulation. In order to achieve collaborative potential, group members must align individual task perceptions and co-construct a shared understanding of what they are being asked to accomplish. Without shared task perceptions, group members are more likely to work at cross purposes and less likely to achieve interdependence. Similarly, developing consensus about task goals is essential for collaboration. Goals are the translation of task perceptions into standards that guide collaborative work. Without these shared standards, it is challenging for groups to achieve consensus about plans and strategies, as well as accurately predict, monitor and evaluate their collective progress.

The purpose of this cross case comparison was to examine shared regulation of task perceptions and goals in three consecutive collaborative tasks. Specifically we compared groups with strong versus weak collaborative task performance in terms of three indicators of shared regulation: (a) co-constructed planning statements (task perceptions and goal statements), (b) convergence of group members' individual planning statements (task understanding and goal statements), and (c) metacognitive calibration between the goal efficacy and goal performance ratings of both individuals and groups.

Participants included 120 undergraduate students enrolled in a first year elective course at the University of Victoria (ED-D 101). Students worked in 30 collaborative teams of 3 or 4 over a 13-week semester on three collaborative tasks. Collaborative tasks were constructed to be challenging and require multiple student perspectives. The Moodle learning management system (Dougiamos, 2001) was used for individual and collaborative synchronous and asynchronous planning and task work. Tools included a text based chat, collaborative forum tool, and an editable wiki space, and a planning-reflection activity. Moodle captured records of the timing of nature of individual contributions to the shared wikispace, forum, and chat.

Data was examined for evidence of (a) individual group members' perceptions of task requirements and task goals completed prior to collaboration, (b) groups co-constructed perceptions of the task and task goals, (c) groups' collaborative engagement and reflection on the task evidenced in the wiki workspace, forum, and chat, and (d) individual group members' reflections on goal achievement. .

We hypothesize that groups who achieved collaborative success would demonstrate: (a) The convergence in their individual task perceptions and goals by the end of the task, (b) co-construct accurate and complete task perceptions and high quality goals, (c) demonstrate efficacy for achieving both individual and co-constructed goals, and (c) self-report high attainment of individual and co-constructed goals. Upon completion of a shared tasks, if group members maintain different task perceptions, hold dramatically different task goals, or have disparate perceptions of the degree to which task goals were achieved, it suggests the group did not achieve shared metacognition and should be

characteristic of poor collaborative task performance because group members were monitoring and evaluating performance against different standards than other members of the group.

SYMPOSIUM

Emerging shared regulation in collaboration:

Sanna Jarvela, University of Oulu, Finland; Hanna Jarvenoja, University of Oulu, Finland; Jonna Malmberg, University of Oulu, Finland; Allyson Hadwin, University of Victoria, Canada

The aim of this study was to investigate socially shared regulation of learning in the context of collaborative groups. Our hypothesis is that successful collaboration emerges when teams collectively regulate learning. Following our earlier conceptual and empirical work on social aspect of motivation and regulation of learning (Hadwin & Järvelä, 2011; Järvenoja & Järvelä, 2009; Järvelä, Volet & Järvenoja, 2010) we aim to answer : How individual students in collaborative groups construct shared regulation and how successful groups are in their sharing regulation? We present an empirical study where 18 graduate students worked in collaborative teams of 3 to 4 over an 8-week period. The nStudy (Winne et al., 2008) software was used for collaborative planning and work, as well as face-to-face and online collaboration between team members. Data included: (a) individual and collaborative statements about collaborative challenges, (b) collaborative statements of contextual and future regulation strategies and (c) collaborative learning performance and (d) collaborative chat discussions. The results indicated three kinds of "regulation over time profiles": strong, progressive and weak shared regulation and emerging shared regulation was linked to the collaborative learning results. The three groups also differed in terms of activated shared regulation strategies so that the strong shared regulation group showed more deep level strategies than routine level regulation strategies.

Introduction

Socially-shared regulation of learning refers to processes by which group members regulate their collective activity. Successful individuals regulate their motivational, cognitive, and metacognitive engagement (Winne & Hadwin, 1998). Similarly, successful groups share in regulating group processes. Implicit notions of socially shared regulation are often embedded in collaborative learning research (e.g. Barron, 2000). However, there is a paucity of empirical research systematically examining how students collectively share in the regulation of learning toward a collective outcome. How shared and individual regulations interact in the process is also unknown. Following our earlier conceptual and empirical work on social aspect of motivation and regulation of learning (Hadwin & Järvelä, 2011; Järvenoja & Järvelä, 2009; Järvelä, Volet & Järvenoja, 2010) we aim to answer : How individual students in collaborative groups construct shared regulation and how successful groups are in their sharing regulation? From our perspective (Hadwin, Järvelä & Miller, 2010) empirical research should recognize the following perspectives if it is about regulated learning: (a) regulated learning is intentional, goal directed and metacognitive, (b) learners regulate motivation, behavior, and/or cognition and it is always embedded in social context and influences, (c) research should target challenge episodes since they invite strategic regulation of learning.

Aims

The aim of this study was to investigate socially shared regulation of learning in the context of collaborative groups. Our hypothesis is that successful collaboration emerges when teams collectively regulate learning. The research questions are:

- a) What are the individual and shared statements of challenges experienced in collaborative group work?
- b) How do students collectively regulate the contextual challenges and their future challenges?
- c) What are the collaborative learning results compared to the emerging shared regulation among the different groups?

Methods

Participants and context

Participants included 18 graduate students in a Learning and Educational Technology Masters Program (mean age = 43, SD = 6,3; 17 females and 1 male). The students participated in a six weeks course titled Cognitive, Motivational and Emotional Bases in Learning for Understanding. Students participated in three learning cycles each consisting of: (a) one day face to face meeting (b) one week virtual solo studying period, and (c) one week virtual collaborative task period. Course materials and workspaces for solo and collaborative work were accessed through nStudy (Winne, Hadwin, & Beaudoin, 2010).

Data Collection

Data for this study included

- (a) individual and collaborative statements of challenges for the collaborative task,

(b) collaborative strategies the students used for regulating the contextual tasks and future tasks,
(c) collaborative task performance and
(d) collaborative chat discussions. The students filled in the solo and collaborative planning notes in nStudy in the beginning of each solo or collaborative learning phase.

Solo and collaborative notes consisted of two parts:

(a) Reflection on last collaborative session, and
(b) Planning for this collaborative session. In this paper we focus specifically on the following questions on challenges: What was the main challenge you encountered achieving your goal last week? and What was the main challenge your group encountered during this collaborative task? and on regulation strategies: What did you (as a group) do to address that challenge?, What could you (as a group) do differently or better next time? Collaborative Task Performance was scored on a 5 point scale based loosely on Bigg's Solo Taxonomy.

Results

Based on the collaborative planning note responses we created "regulation over time group profiles" which consist of 1) groups' challenges and 2) their statements of situated regulation strategies and 3) their reported future regulation strategies. All together, seven different strategies were coded from the data: Performing (Pe), Planning (PI), Cognitive processing (C), Asking for external help (H), Task and environmental structuring (T), Motivation (M) and No strategies expressed (O).

The cross case analysis among the six groups resulted three kinds of collaborative regulation profiles which were labeled; strong shared regulation (group 1), progressing shared regulation (group 3, 5 and 6) and weak shared regulation (groups 2 and 4). Each of these characterizations will be described in details in the presentation.

When the groups' performance on the collaborative tasks was compared to their emerging shared regulation it was seen that the group which showed strong shared regulation succeeded in collaboration task. Also progressive shared regulation among the three groups contributed to strong or improving collaborative learning results. Instead, weak shared regulation resulted weak or improving collaborative learning results.

Conclusions

The aim of this study was to investigate socially shared regulation of learning in the context of collaborative groups. Our hypothesis was that successful collaboration emerges when teams collectively regulate learning. The results confirmed our hypothesis since three kinds of "regulation over time profiles" were found and emerging shared regulation was linked to the collaborative learning results. The three groups also differed in terms of activated shared regulation strategies so that the strong shared regulation group showed more deep level strategies than routine level regulation strategies.

With this data set we are unable to elaborate the progress of group and individual regulations skills, but we will continue the analyses with the other data. However, we assume that group challenges provide an opportunity for developing both group and individual self-regulation skills. Opportunities for sharing regulation will be a chance to develop individual self-regulation skills (e.g. weak study skills) because the skills will be compensated by the group competence. We could assume that shared regulation is a kind of "test bed" for individual self-regulation and an opportunity to train collaborative learning skills. The kind of shared regulation emerges in groups' seem to contribute to the success in collaborative learning.

SYMPOSIUM

Regulation of Team Activities and its Effects on Learning

Bert Slof, +31 (0)503636611, Netherlands;Jeroen Janssen, Utrecht University, Netherlands;Paul A. Kirschner, Open Universiteit, Netherlands;Gijsbert Erkens, Utrecht University, Netherlands

This contribution examines regulation of collaborative learning from a communicative perspective. During collaboration, group members must explicate their knowledge and ideas. This implies that they must coordinate their collaboration process. Three different coordination activities are distinguished: (1) focusing (maintaining common focus during discussions), (2) checking (making sure group members have shared understanding), and (3) argumentation (convincing others using arguments and explanations). To examine whether coordination activities contribute to team and individual learning, 102 secondary education students collaborated in 34 teams in a computer-supported collaborative learning environment. Analyses of the groups' discussions, their performance on the group task, and students' performance on a knowledge post-test revealed that focusing negatively affected team performance and checking positively affected team performance. No effect of coordination on individual learning was found however.

Introduction

Collaboratively carrying out a learning task is often regarded as an effective method for group and individual learning. The premise is that through a dynamic process of eliciting one's own knowledge, discussing this with peers, and establishing and refining the group's shared understanding, students acquire new knowledge and skills and process them more deeply (Hmelo-Silver, Duncan, & Chinn, 2007). Meaningful discussions are, however, difficult to achieve when teams do not properly regulate their activities (Barron, 2003). Collaborative learning situations require that team members coordinate their collaboration process by carrying out specific coordination activities. Three important coordination activities are; (1) focusing, (2) checking, and (3) argumentation (Erkens & Janssen, 2008). Team members must make their own knowledge and ideas explicit to other team members. When made explicit, learners must maintain a shared topic of discourse (i.e., achieve a common focus) and repair that focus if they notice divergence. Team members also must maintain the coherence and consistency of their shared understanding by checking (Van der Linden, Erkens, Schmidt, & Renshaw, 2000). Furthermore, they must reach agreement about relevant concepts, principles and procedures. Through argumentation they try to convince others by elaborating on their own point of view and by explaining, justifying and accounting for them (Andriessen, Baker, & Suthers, 2003). This contribution examines whether the aforementioned coordination activities contribute to team and individual learning during computer-supported collaborative learning (CSCL).

Method

Participants

Participants were students from 6 classes in three secondary schools in the Netherlands. The sample consisted of 102 students (61 male, 41 female, mean age = 15.7 years; SD = .56, Min = 14, Max = 17). The students were randomly assigned to 34 learning teams (i.e., triads).

Learning-environment and Learning-task

Working in a CSCL-environment called Virtual Collaborative Research Institute, the teams had to solve a business-economics problem. Team members communicated through a chat-tool.

Procedure

All 34 teams spent four, 45-minute lessons solving the problem during which learners worked on separate computers. All actions and decisions in the environment were logged.

Measurements

Team learning

To measure team learning, a 28 item assessment form was developed. Items were coded as; 0, 1 or 2, whereby a '2' was coded when the answer given was of high quality and '0' when it was of low quality. Items addressed criteria such as the suitability of team decisions, correctness of the use of business-economics concepts, and the quality of the formulated advice. Reliability of this measurement was .84.

Individual learning

Recall and understanding of the knowledge domain was measured with a multiple-choice pre-test (20 items, $\alpha = .46$) and post-test (20 items, $\alpha = .48$).

Coordination

Each chat message was coded for the type of dialogue act used (see Table 1). A dialogue act was regarded as a communicative action which is elicited for a specific purpose representing a specific function in the dialogue (Erkens & Janssen, 2008). Coding was based on the occurrence of characteristic words or phrases indicating the communicative function of an utterance. This was done automatically using 1,250 'if-then' decision rules that uses pattern matching to find typical words or phrases. When compared to hand-coding, a Cohen's Kappa of .75 was found.

Table 1: Overview of coordination activities.

Results

Multiple regression analysis was used to examine the impact of coordination on team learning. Results showed that focusing negatively affected the score obtained by the groups ($b = -.92$, $p = .04$), whereas checking positively affected team learning ($b = 1.18$, $p = .03$). No effect of argumentation on team learning was found. In addition, the impact of coordination on student performance on the post-test was examined using multilevel analysis. No significant effects of focusing, checking and argumentation were found.

Discussion

The results provide insight into the effects of regulation of team activities on team and individual learning. More research is, however, needed to explain why no effect of regulation on individual learning was found. An explanation

may come from cognitive load theory, which posits that regulative activities increase the cognitive demands placed on students, thus preventing them from learning (F. Kirschner, Paas & Kirschner, 2009). Interestingly, a negative effect of focusing on team learning was found. Possibly, when groups must devote much time and energy to maintaining shared focus, this may distract from discussing the domain concepts or appropriate strategies.

SYMPOSIUM

Engagement in learning History. Argumentation, questioning and controversial topics.

Chairperson: Jannet van Drie, University of Amsterdam, Netherlands

Organiser: Albert Logtenberg, University of Amsterdam, Netherlands

Discussant: Matthias Nuckles, University of Freiburg, Germany

This symposium brings together three recent empirical studies that investigate how different students reason historically. Empirically based research in historical reasoning, a key activity in history learning (Van Drie & Van Boxtel, 2009), is a growing field of research. This research is aimed at a better understanding of cognitive and affective activities that foster and stimulate historical reasoning. Examples of engaging students in History are student inquiry, historical narratives, controversial topics and topics that connect to student present-day experiences. The first paper reports about student interest and engagement triggered by discussing a controversial issue in the history of Israel and by composing a group of 12th grade (aged 17/18) students (N=49) with different ethnic backgrounds. Differences in identity (Middle-eastern/Western) fostered and influenced historical argumentation. The second study deals with 33 students (aged 15/16) reading a historical introductory text that triggers interest and student questions. In order to study students' questioning different types of student perplexity in terms of prior knowledge, affect and historical reasoning is described. The final study investigated the role of popular historical narratives in shaping undergraduate students' historical consciousness. The study describes student interest in History of pre-service history teachers and their ability in formulating historical questions. Different models of historical thinking are compared and used for analysing progress in historical reasoning in student learning journals. The discussant will reflect on the different empirical approaches in research in history education and the relationship between student engagement in History and historical reasoning processes as asking historical questions and argumentation.

SYMPOSIUM

Identity, interaction and historical distinction of students discussing a charged historical issue

Tsafrir Goldberg, University of Haifa, Israel; Baruch Schwarz, Hebrew University, Israel

Forty nine Israeli students of two Jewish ethnic groups (23 Mizrahi, 26 Ashkenazi) completed a multiple source historical learning task about Israel's "Melting Pot" policy. Following it participants conducted self led small group discussions in ethnically mixed and homogenous groups. Prior to and following the learning students wrote short essays presenting their opinion about the policy's goals and outcomes. Students' level of argumentative writing, group discussion style and historical consciousness in discussions were analyzed. Findings reveal influence of group composition over improvement of argumentative writing – with ethnically mixed discussion groups presenting a significantly higher frequency of improvement. In discussions students frequently used historical distinctions reflecting an elaboration of agent and action complexity. Distinctions such as the differentiation between intended goals and unintended outcomes, while reflecting more nuanced understanding, were many times used as part of identity oriented apologetics. Non conflictual discussion style appears to have had a significant positive correlation to expressions of historical consciousness such as historical distinction and to the final level of argumentative writing. These phenomena were more pronounced in the ethnically mixed discussion groups. The above results were interpreted as reflecting a possible intersection of contact theory and situated learning theory. Acquisition of disciplinary practice tools such as agency based distinctions apparently occurred in directions which serve identity needs aroused by encounter. However, findings seem to contradict some of argumentative theories' assumptions about the role of conflict and disagreement in fostering argumentation

Introduction

Growing attention is given to diversity and multiculturalism in curriculum planning, teacher education and research. However, it is not accompanied by ample research into the ways social identity and intergroup contact influence actual learning (Epstein, 1998). The learning activity which our study explores centers on a historical controversy whose relevance to students' diverse social identities makes it a charged issue. As such it is meant to promote interest, inquiry and argumentation (Barton & Levstik, 2004). Contact theory assumes heightened group loyalty accompanying intergroup encounter may impair reasoning (Fiske, 2002). Collective memory may function in a similar way to delimiting students' processing of historical information (Reference removed for review). However,

participation in the disciplinary practices of a professional community may help acquiring its impartial tools and norms (Lave & Wenger, 1991). These influences have been studied at the level of the individual. However, since diversity of identity or opinion is experienced through encounter, this study seeks to explore the effects of a discussion group's ethnic composition on learning. Aims The purpose of this study was to explore the influence of the ethnic and attitudinal composition of a discussion group on written outcomes in the learning of a charged identity relevant historical issue.

Research question

What are the effects of the ethnic identity on discussion dynamics, historical consciousness and argumentation? Method Participants Participants were 49 12th grade students. 26 of the participants were Ashkenazi (descendants of Jews from Western countries) and 23 were Mizrahi (descendants of Jews from Muslim or Asian countries). Students participated in discussion groups, which were ethnically mixed or homogeneous (comprising 33 and 16 students respectively).

Procedure

Following an historical argumentative study of conflicting sources about the melting pot policy, students engaged in self administered discussions assessing the policy's impact. Discussions were audio taped by participants. Prior to the learning intervention and following the discussion students wrote individual compositions on the topic (Reference removed for review)

Analysis

Group discussion style Each turn in discussion was coded on a continuum between agreement and rejection. Categories started with agreement, followed by development, challenge, response to challenge, opposition and rejection. Historical distinction Propositions which expressed distinction of complexity within an event or process were coded in relation to Shemilt's (2000) hierarchy of narrative construction. These include distinctions of intentionality (between ends and means and between ends and outcomes) distinctions of perspective (between the perspectives of different groups, between short and long term or between present and past perspectives) Written outcome variables Students' level of argumentative writing was assessed on a 5 point scale (unwarranted, absolutist-one sided, multiplist- two sided, arbitrary-decided, evaluativist), based on Deana Kuhn's (1993, 2001) classification of arguments and epistemological stances. Results Effects of ethnic composition of discussion groups on written argumentation

The frequency of argumentative writing improvement in the mixed groups was twice as high as in the ethnically homogeneous groups. A chi square test proved the differences in frequency of change to be significant $\chi^2=29.01$, p Ethnic composition of groups and Group discussion style Mixed groups presented a somewhat higher frequency of agreement oriented group discussion style. Historical argumentation in discussion and writing Historical distinction. In all 65 % of the students used some kind of historical distinction. The most frequently used, by 39% of the students ($N=19$) was the distinction between historical agents' goals and their actions' outcomes. Following that was the distinction used by 31% of the discussants ($N=15$) between ends and the means taken to realize them. The more historically elaborate distinctions were used by less than quarter of the discussants (between perspectives of different groups (13%), between short and long term (26%) or between present and past perspectives (16%)). Some influence of identity can be seen in the fact that the (apologetic) 'goals – results' distinction was used twice as much by the Ashkenazi students compared to their Mizrahi peers. Group discussion style and historical consciousness In the whole sample historical distinction was positively related to developments ($r=.37$ $p=.014$) and negatively related to challenges ($r=-.43$, p Group discussion style and argumentative writing In the mixed groups agreement discussion style was positively related to the level of argumentative writing in final composition ($r=.40$, $p=.028$).

Discussion

Our findings align to some degree with current theory and research findings, while diverting from them to a certain extent. Contact theory led us to assume inter-group encounter will arouse in-group loyalty and intergroup conflict in mixed groups and lead to mastering better arguments to maintain in-group image. Apparently, more elaborate historical practices and arguments indeed appeared, many times in directions possibly reflecting identity needs. However, quite surprisingly, it was agreement oriented group discussion style that promoted both historical distinction and higher level of argumentative writing. It seems that historical distinction, which indicates an ability to perceive historical complexity was used not in intergroup confrontation but in the context of mutual development of knowledge. However, it may also indicate evasion of conflict limiting the potential of critical discussion to promote argumentation.

SYMPOSIUM

The onset of students' questioning in History

Albert Logtenberg, University of Amsterdam, Netherlands; Carla Van Boxtel, University of Amsterdam, Netherlands; Gonny Schellings, University of Amsterdam, Netherlands; Bernadette Van Hout-Wolters, University of Amsterdam, Netherlands

This study aims at deeper insight into processes underlying student questions in History. A process study is carried out to investigate the characteristics of the onset of questions when students read a historical introductory text. Thirty-three secondary school students are instructed to read the text and underline striking text segments. At the point of underlining, students verbalize their thoughts and may spontaneously ask questions. In our protocol analysis, we focus on the role of prior knowledge, the role of affect and on students' domain-specific reasoning. Verbalizing prior knowledge with associations is done most frequently. It appears that in half of the 251 utterances, when reading has stopped, students verbalize affective thoughts and show historical reasoning. Characteristics of the onset of questioning appear to come together in profiles of perplexity. We describe four profiles that occur most. Questions were mostly asked in cases in which students express a knowledge deficit without verbalizing any affect and without historical reasoning. In some of the cases questions were connected to affective reactions or to the attempt to reason historically (e.g., contextualizing, explaining or comparing). Implications of the role of affect and domain-specific reasoning in the onset of questions for research and practice are discussed

Introduction

In order to design an instructional method that uses students' questions to develop their historical thinking adequately, it is important to have more knowledge of the origin of student questions. Van der Meij (1994) describes a componential model of questioning. Three stages characterize the process of questioning: (1) the onset of questioning (perplexity), (2) the development of a question (asking) and (3) the search for and processing of an answer (answering). In our study we focus on the stage of perplexity in the domain of history. What types of perplexity (cognitive or affective) do students experience when reading a text about a historical topic and does this perplexity spontaneously generate historical questions? Perplexity can be triggered internally and externally. Students may experience that the presented information contradicts their prior knowledge (internal cue) or students experience curiosity triggered by the text (external cue). Students, when confronted with historical content, especially controversial issues, tend to judge historical agents and situations from a present-oriented perspective or use stereotypes to describe and explain historical actions or events (Hartmann & Hasselhorn, 2008). Students experience difficulties in seeing persons, events and developments in the past in their own historical context (Barton & Levstik, 2004). Students may be perplexed when they experience disequilibrium between the information that is given about the past and what they know from their experience and present-day standards. This perplexity may also be characterized by emotions, such as interest or indignation. In a previous study (Reference removed for review) we found that only a small part of the questions contained presuppositions that may be the result of taking a present-oriented perspective and reflect emotions such as indignation or empathy. Part of the students was able to ask higher order questions about the historical context, processes of change and continuity and causes and consequences, which can be considered important components of historical reasoning (Reference removed for review). So, besides cognitive processes, emotions and historical reasoning may underlie the perplexity students experience when reading a text about history. In this study we want to investigate whether students are able to formulate questions when they are confronted with this state of perplexity that can be characterized by cognitive, affective and historical reasoning characteristics.

Research questions:

- 1) What type of perplexity do students experience while reading a historical introductory text?
- 2) What type of questions do students spontaneously ask?

Method and Analysis

Participants 33 students in higher secondary education (15 years, 10 boys, 23 girls) are recruited from 6 different classes from 3 different schools aiming for maximum variation (N=174). Students are selected in order to compose an equally divided sample concerning the variables prior knowledge and school subject interest. Prior knowledge was measured with a paper-and-pencil test.¹ (N= 174; 8 items; $\alpha = .74$). Interest in History was measured with a questionnaire (N=174; 32 items; $\alpha = .92$). 33 students from different schools were selected from groups of low interest/prior knowledge, medium interest/prior knowledge and high interest/prior knowledge.

Task and procedure

The historical introductory text (770 words) about the Industrial Revolution contains narrative and problematising characteristics that trigger both situational interest (engagement and emotions) and different types of historical questions. Participants are asked to read the text and underline text elements that are striking, (un)familiar or (un)clear to them. At each underlined text element participants were asked to verbalize why they underlined it and explain their thoughts.

Analysis

The protocols are divided in episodes that consist of the underlined text, and student reasoning. We developed a coding scheme in order to label each episode on 1) prior knowledge (knowledge deficit, contradiction with prior knowledge or association), 2) affect (indignation, interest, empathy, astonishment, boredom) 3) historical reasoning (no historical reasoning, historical reasoning) and 4) type of spontaneous questions (descriptive, comparative, explanative and evaluative questions). For each category interrater reliability was calculated in terms of Cohen's kappa. ($\kappa > .60$ for each category).

Results

251 episodes were generated by 33 students and a total of 129 questions were spontaneously formulated. Table 1 describes the coding outcomes; Table 1: Frequencies and percentages of categories prior knowledge, affect and historical reasoning.

Prior knowledge is an important dimension in the characterization of students' perplexity. We found that students often (74.1%) stopped reading when text fragments triggered prior knowledge. In 57 (22.7%) cases students verbalized a knowledge deficit. However, students did hardly express a knowledge conflict (21%), whereas such conflicts are considered important sources of student questions (Graesser & McMahan, 1993). In regard to affective dimensions of perplexity, we can conclude that in explaining their perplexity, students quite often verbalized affect (51%) in terms of indignation (23%), astonishment (11%) and interest (10%). 48% of the episodes contained historical reasoning, mainly contextualization (32%). Out of these descriptions, 4 profiles of perplexity were most prominent. Association combined with historical reasoning with affect or no affect are combinations that occur most. Questions are especially asked when students experience a need for more information (and thus a knowledge deficit). This need for information is sometimes grounded in the attempt to contextualize, which is an aspect of historical reasoning. Although indignation and astonishment occur in a third of all episodes, these emotions gave not much rise to the asking of questions.

Knowledge of the onset of a question can provide us with more information in determining the quality of a question asked by students.

SYMPOSIUM

Fostering undergraduate history teacher students' skills in asking reflective historical questions

Nicola Brauch, University of Freiburg, Germany, Germany

This study aims to assess the stage and progress in pre-service history teachers' ability in asking reflective historical questions during a course in medieval history. Nineteen pre-service history teacher students (undergraduates) were

six times instructed to write weekly prompted learning journals referring to six scientific historical research narratives. A coding scheme precisising three levels of asking historical questions by types of historical reasoning was generated to assess levels and changes in the quality of asking historical questions. Results underline the assumption to reach more detailed approach in assessing competencies of historical asking by defining the levels according to types.

Moreover the prompted learning journal method was proofed as a tool in assessing competencies of historical reasoning and to some extent in bringing forward students achievement in asking scientific historical questions. What kind of similarities can be identified between the two author's narratives and how can these be explained? Time, argumentation, interpretation

Results

85 learning journals have been written, students created in total 182 questions (highest mean learning journal 2: 2.53). Most questions were generated in the second learning journal (N=48), fewest in the third and fifth one (N=31 each). The mean amount of questions is between 1 and 2. The results show increasing levels of standard deviations and variances in the learning journals concerning levels of historical questions. As preliminary results (data analysis in progress) can be argued the prompted learning journal as a reliable tool for individual achievement analysis. Furthermore students' achievement mirrors a correlation between the complexity of the given research narrative and the level of asking historical questions in the learning journals dealing with those text. Eleven students (58 %) show a progression in the quality of their historical asking, four (21 %) remain on the level represented in the first learning journal, and four (21%) students' questions quality degrade. This results can be seen by using the detailed levels coding scheme, while weak advancement and degradation could not been documented by using the classified levels coding scheme.

SYMPOSIUM

Analyzing important components of self-regulated learning

Chairperson: Franziska Perels, Saarland University, Germany

Organiser: Franziska Perels, Saarland University, Germany

Bracha Kramarski, Bar-Ilan University, Israel

Discussant: Roger Azevedo, McGill University, Canada

Self-regulated learning is important for life-long learning and academic achievement. Therefore, it is important to analyse the different components of self-regulation to find possibilities to assess and support self-regulated learning in different learning contexts. In this symposium, we present three approaches, which focus on different aspects of academic self-regulation in the context of different target groups. The symposium starts with a methodological contribution by Whitebread et al. (UK) who present the results of an international study. In this project they developed and validated an observational instrument to identify and measure self-regulated learning in young children (age 3-6). After that Olay et al. (Germany) present a study in Primary school. In their study they try to predict first graders' school achievement in mathematics by their self-regulated learning. We close the symposium with a study conducted by Bellhäuser (Germany) who developed and evaluated a web-based training to foster self-regulated learning among prospective students. The presented studies will be discussed regarding their theoretical and educational significance (Azevedo, USA).

SYMPOSIUM

Predicting first graders' school achievement in mathematics by their self-regulated learning

Nadja Olyai, Frankfurt University, Germany; Barbara Otto, Institut of Psychology, Germany; Gerhard Buettner, University of Frankfurt, Germany; Kristin Krajewski, Giessen University, Germany

This study examined, whether self-regulated learning (SRL) is a significant predictor of first grade students' achievement in mathematics. Particularly, it was of further interest, whether first graders' SRL could even account for math achievement beyond students' cognitive abilities. Based on a process model of SRL, data of 674 students were collected. Cognitive abilities were assessed by the CFT Scale 1. Moreover, two measures for students' mathematics achievement were assessed: (1) Students solved an objective mathematics test (MBK); and (2) Mathematics teachers graded their students' mathematic achievement. Accordingly, SRL was assessed by two measures: (1) students filled in a questionnaire; (2) teachers rated their students' self-regulated learning behavior. Firstly, regression analyses were conducted using both SRL measures separately as predictors in order to predict math achievement. These analyses revealed that teachers ratings of SRL but not students' self-report could indeed predict both measures of math achievement. Regarding the second research question, blockwise analyses of regression were conducted including cognitive abilities (first block) as control variable and the teachers' rating of SRL (second block) as predictors. The results confirm that teachers' ratings of SRL significantly accounts for the prediction of both measures of math achievement beyond students' cognitive abilities. These results suggest that SRL indeed significantly contributes to students' math achievement already at the beginning of their school career. However, students' self-report measure did not work as predictor. These findings lead to several theoretical and practical conclusions which will be discussed at the end of the presentation.

Objectives

Individual differences in cognitive abilities are a very good predictor for academic achievement (e.g. Walberg, 1984). The prognostic validity of cognitive variables is so strong that some researchers even doubt that other psychological constructs could have any additional contribution to the variance of school performance (cp. Gagné & St.Péère, 2002). However, several studies show that for instance motivation also has an impact (e.g. Kreidler, Zigler, Kagan, Olsen, Weissler & Kreidler, 1995; Schicke & Fagan, 1994; Spinath, Spinath, Harlaar & Plomin, 2006). In line with these findings, Helmke and Schrader (2001) assume that not only cognitive abilities determine academic achievement but also students' motivation, volition, and metacognition. All of these three constructs are considered in most of the well-known process-models of self-regulated learning (SRL) (e.g. Schmitz & Wiese, 2006; Zimmerman, 2000). Even though a large number of recent studies on SRL show that high self-regulation is accompanied by high academic performance (Hidi & Ainley, 2008; Pintrich & Zusho, 2002; Ruban, McCoach, McGuire & Reis, 2003; Zimmerman & Bandura, 1994), most of these studies are purely correlative. Due to the potential combined variance of self-regulation with other variables (e.g. cognitive variables) these correlation studies might overrate the exclusive influence of SRL on academic achievement. Thus, regression analyses including SRL as one potential predictor should help to explain the variance of school performance data. If self-regulatory competencies truly are crucial, then they should show a substantial contribution in the prediction of the academic performance even beyond cognitive abilities. A recent study of Otto, Kistner, Perels & Býttner (submitted) revealed that this is indeed the case for secondary school students. However, no empirical study exists so far, which examines whether this is also true for students at the beginning of their school career. Thus, this empirical study addressed the research question whether or not SRL significantly contributes to the prediction of first grade students' math achievement even beyond their cognitive abilities.

Theory

The present study is based on a process model of SRL, which is basically consistent with the theoretical assumptions of Schmitz and Wiese (2006). According to Zimmerman (2000) the learning process is divided into three consecutive phases: The pre-action phase, the action phase, and the post-action phase.

The learning process begins with the pre-action phase which refers to the preparation of the learning. The given assignment and the particular conditions in the learning environment initiate the beginning of the SRL processes by evoking certain motivational and emotional tendencies within the learner. If the learner is not intrinsically motivated or shows low self-efficacy he needs to apply self-motivating strategies. Under these affective-motivational conditions the student has to set goals for his learning. Moreover, the learner will have to plan the application of learning strategies as well as the time he will invest for finishing the task.

Afterwards, the learner starts with learning (action phase). In order to complete his assignment he will apply different learning strategies. Moreover, he has to apply volitional strategies in order to avoid internal or external distraction and maintain concentration, effort, and motivation while performing academic tasks (Corno, 2001). In case the learner deviates from his planned learning behavior it is beneficial if he self-monitors his actual behavior. Finally, a learning outcome results.

In the post-action phase the student has to compare his actual final result with his prior set goal (ideal result). Hereby, he also has to evaluate whether the final result can be interpreted as success or failure. Furthermore, he will also reflect how he approached the given task. As a consequence of comparing, evaluating, and reflecting, certain emotions (e.g. satisfaction) will arise depending on whether the task was successfully solved or failed. These subsequent emotions and evaluations have an impact on future learning, as they can lead to modifications in planning strategies and time or in setting goals.

Methods

In order to answer the research questions data of 674 German first grade students were collected. Cognitive abilities were assessed by the CFT Scale 1 (Cattell, Weip & Osterland, 1997). Moreover, two measures for students' mathematics achievement were assessed: (1) Students solved an objective mathematics test (MBK, Krajewski, in press); and (2) Mathematics teachers graded their students' mathematic achievement. Accordingly, SRL was assessed by two measures: (1) students filled in a questionnaire concerning their self-regulated learning behavior (25 items; $\alpha=.86$); (2) mathematics teachers rated their students' self-regulated learning behavior (13 items, $\alpha=.91$).

Results

Firstly, regression analyses were conducted using both SRL measures separately as predictors in order to predict math achievement. These analyses revealed that teachers ratings of SRL could indeed predict math achievement with regard to the objective test MBK ($R^3=.12$; $\beta=.347$; $T=9.50$; p

Regarding the second research question, blockwise analyses of regression were conducted including cognitive abilities (first block) as control variable and the teachers' rating of SRL (second block) as predictors. The results confirm that teachers' ratings of SRL significantly accounts for the prediction of both measures of math achievement beyond students' cognitive abilities. With regard to the objective math test MBK cognitive abilities accounted for 28% of the variance in the criterion, which could be significantly enhanced up to 33% by including SRL as second predictor. The same is true for the variance of the second criterion math grade: Cognitive abilities accounted for 18% of the variance whereas the additional inclusion of SRL significantly increased the prediction up to 21%.

These results suggest that SRL indeed significantly contributes to students' math achievement already at the beginning of students' school career. However, students' self-report measure did not work as predictor. These findings lead to several theoretical and practical conclusions which will be discussed at the end of the presentation.

SYMPOSIUM

Fostering Self-Regulated Learning Online

Henrik Bellhauser, Technical University of Darmstadt, Germany; Thomas Loesch, Technical University of Darmstadt, Germany; Bernhard Schmitz, Technical University of Darmstadt, Germany

Trainings on self-regulated learning (SRL) have been shown to be effective both in improving self-regulation skills and in objective measures of performance (Benz, 2010). However, human trainers can only reach few people at the same time. Web-based trainings (WBT) could improve efficiency as they can be distributed to unlimited numbers of participants. Furthermore, users are more flexible in time and space when trained in a WBT, enhancing opportunities to participate.

Aiming at prospective students in a mathematics e-learning course we developed a WBT based on the process model of learning (Schmitz & Wiese, 2006). 170 participants were tested in a randomized control evaluation study. The experimental group had access to the WBT that consisted of three online lessons, each including presentations, exercises and group discussions. In both pre and post test a test of mathematical knowledge, a test of knowledge about learning strategies and self-regulation questionnaires were applied. Objective data was collected by recording log-files from users' online behavior.

Results showed that students highly appreciated the WBT and reported significant changes in subjective measures of SRL. Furthermore, participant of the experimental group significantly improved their knowledge about learning strategies and invested significantly more time on learning than the control group.

Theoretical Framework

Self-regulated learning (SRL) is defined as students' self-generated thoughts, feelings and actions that are systematically oriented toward the attainment of their learning goals (Zimmerman & Schunk, 2001). SRL competencies are regarded as crucial especially for students as academic learning oftentimes craves more self-determination than learning in school does.

Many studies report positive effects of SRL interventions on learning outcomes (e.g., Kramarski & Mizrachi, 2006, Azevedo & Cromley, 2004). However, most SRL trainings are effective yet not efficient as trainings in presence can only reach a certain number of participants at a time.

An alternative to human trainers could be to involve computers as instance of delivery. But as Benz (2010) could show in a meta-analysis, scaffoldings provided by computer were less successful than human trainers in improving learning outcomes. In this comparison though, the instance of delivery (human vs. computer) is confounded with the type of support (process support via scaffoldings during learning vs. strategy support via trainings before learning). So far, there is a lack of web-based trainings (WBTs) that try to equip learners with SRL strategies.

Thus, the aim of this study is to develop a WBT on SRL and to evaluate its effect on SRL competencies and objective learning outcomes.

Methods

170 prospective students (130 male, 40 female) with a mean age of 20.11 (SD = 2.23) participated in the evaluation study. They were enrolled in an e-learning course at a Technical University in Germany in which they prepared themselves for mathematically oriented fields of study (computer science, civil engineering, mechanical engineering or mathematics). The e-learning course (built with the learning management system Moodle) covered mathematical knowledge from all school grades and provided learners with definitions, arguments, examples, assignments and visualizations. Duration of both the course and the study was four weeks in which all participants had the freedom to decide for themselves what to learn, when to learn and how to learn.

The study design was a pre-post test evaluation with participants randomly assigned to one of two study groups: The experimental group attended a web-based training on self-regulated learning while the control group was not supported in their learning process.

The three lessons of the WBT were constructed with Moodle and were free to be attended each within a two-day time frame with intervals of one week between two lessons. The content of the lessons was based on the process model of self-regulated learning (Schmitz & Wiese, 2006). The first lesson ("Before Learning") focused on the preactional phase and included the topics goal setting and time management. Lesson 2 ("During Learning") dealt with the actional phase and included the topics volition, cognitive learning strategies and metacognitive learning strategies. The third lesson ("After Learning") highlighted the postactional phase and included the topics attribution and reflection. Each lesson applied presentations, tests, exercises and group discussions in an online forum. Mean time necessary to attend one lesson was 90 min.

In both pre and post test a test of mathematical knowledge and a test of knowledge about learning strategies were applied. Furthermore, self-regulation questionnaires were applied, including scales from the Motivated Strategies for Learning Questionnaire (MSLQ; Pintrich, Smith, Garcia, & McKeachie, 1993) and the Volitional Components Questionnaire II (VCQII; Kuhl & Fuhrmann, 1998). Additionally, an evaluation form was used and objective behavioral data (log files from the Moodle mathematics course) were recorded.

Results

Results of the evaluation form showed that participants highly appreciated the WBT (e.g., mean consent to the item "It was worth investing the time for the lessons" was $M = 4.67$ (SD = 1.14) on a 6-point Likert-scale). A repeated measures ANOVA on the test of mathematical knowledge did not show significant interaction effects between groups and time, but the majority of questionnaires showed significant improvements from pre to post test of the experimental group compared to the control group, for example: Metacognitive Strategies: $F(1, 168) = 16.251$, $p = 0.008$ and Positive Self-Motivation: $F(1, 168) = 18.890$, $p = 0.010$. Furthermore, the test of knowledge about learning strategies showed a significant increase of knowledge in the experimental group but not in the control group: $F(1, 168) = 107.089$, $p = 0.000$. In the behavioral data a one way ANOVA showed that participants from the experimental group spent more days per week on learning mathematics: $F(1, 166) = 4.418$, $p = 0.037$, $d = 0.322$.

Theoretical and educational significance

The results of this study show that SRL competencies can be trained by means of a web-based training and that such a training can influence not only subjective but also objective measures of learning behavior. As WBTs are more flexible in time and space than trainings in presence, students can access these competencies more easily. Additionally, WBTs are more efficient because once they are constructed they can be administered to an unlimited number of students

without further effort. In the future we plan to develop an adaptive version of the WBT that diagnoses users' SRL competencies and only administers content that optimally fits the individual needs.

SYMPOSIUM

Identifying and measuring self-regulation in young children: the development and validation of the CHILD

David Whitebread, University of Cambridge, United Kingdom; Deborah Pino Pasternak, University of Cambridge, United Kingdom; Donna Bryce, University of Cambridge, United Kingdom; Laura Vuillier, University of Cambridge, United Kingdom; Gerhard Buettner, University of Frankfurt, Germany; Franziska Perels, Saarland University, Germany; Zemira Mevarech, Bar-ilan University, Israel; Adina Shamir, Bar-Ilan University Tel Aviv, Israel; Tamar Levi Reich, Bar-Ilan University Tel Aviv, Israel; Josephin Simchen, University of Frankfurt, Germany

The established orthodoxy within metacognition research has been that metacognitive skills emerge around the age of 8 to 10 years. However, this position has been challenged by recent research at both the methodological and theoretical levels. While experimental and self-report methods have been shown to under-estimate the abilities of younger children, recent evidence from observational studies has established that emergent cognitive, emotional, motivational and social aspects of self-regulation can be identified in the performance and behaviour of young children. This paper reports the development and validation of the CHILD observational instrument, which has been developed for use by teachers and includes items relating to significant self-regulation developments in the 3-6 age range. Exploratory factor analysis, based on a sample of 274 children in the 3-6 age range from different studies in the UK, has revealed a two factor structure with items relating to cognitive, emotional and motivational self-regulation loading on Factor 1, termed Individual Self-Regulation, and items relating to Social Self-Regulation loading on Factor 2. Both factors show high levels of internal consistency. Evidence is presented from the various studies within the UK, which measured the children's self-regulatory skills directly by analysis of their performance on a train track construction task, of the external validity of the instrument. Further validation of the instrument is also reported, based on a sample of 120 children in Germany and Israel. This international evidence consists of a confirmatory factor analysis examining the two-factor model, together with further evidence from the train track task.

This paper focuses on the use of observational methodologies in the investigation of metacognition and self-regulation in young children. While there are significant methodological challenges in this kind of approach, recent research using observational techniques has successfully questioned the established orthodoxy within the literature that metacognitive skills emerge around the age of 8 to 10 years (Stipek et al, 1995; Perry, 1998; Boekaerts, 1999, Whitebread et al, 2005, 2007). As a consequence, it is increasingly recognised that research relying on self-report or verbally-based experimental methodologies may significantly underestimate the metacognitive and self-regulated performance of young children (Van Hout Wolters, 2000; Whitebread et al, 2005), and that there are clear advantages in the use of observational methods (Winne and Perry, 2000; Whitebread et al, 2009). Recent evidence from a range of studies has established that emergent cognitive, emotional, motivational and social aspects of self-regulation can be identified in the performance and behaviour of young children (Bronson, 2000; Rothbart, Posner & Kieras, 2006; Whitebread et al, 2005, 2007, 2009).

This paper reports the development and validation of the CHILD (Children's Independent Learning Development) observational instrument, which has been developed for use by teachers and includes items relating to significant self-regulation developments in the 3-6 age range. It is argued that the development of a valid observational instrument which could be reliably used by teachers of children in this age range would be highly beneficial. This claim is based on the now extensive evidence of the significance of developments in cognitive and other aspects of self-regulation for learning (Wang, Haertel & Walberg, 1990; Veenman & Spaans, 2005) and of the effectiveness of a wide range of interventions designed to encourage them (Hattie, Biggs & Purdie, 1996; Swanson et al, 1999; Dignath, Buettner & Langfeldt, 2008). A number of observational instruments have been developed in related areas (Ponitz et al., 2008; Rothbart, Ahadi, Hershey & Fisher, 2001; Gioia, Isquith, Guy & Kenworthy, 2000), but none which cover the various aspects of self-regulation comprehensively and which are designed to be used by teachers in the assessment of typically developing children in the younger age range.

The CHILD instrument was originally developed within the C.Ind.Le (Cambridgeshire Independent Learning) project, and was derived from an original list of 35 statements extracted from the existing literature. As part of this project, 32 teachers made three assessments, at 3-4 month intervals, of approximately 200 children in the 3-5 age range. The details of the procedures whereby this data was used to refine the original list of statements down to a 22-item instrument covering cognitive, emotional, motivational and social aspects of self-regulation have been previously reported (Whitebread et al, 2009). The final 22 statements were identified as those which discriminated most between high and low self-regulated children, which showed the clearest progression between the first and third assessments, and which were perceived as the most significant and easily observable by the teachers in relation to the

children in their class. The 22 item scale achieved a high level of internal consistency (Cronbach alpha = .97) and, in tests of reliability, very high levels of agreement were achieved, between teachers. The use of this scale in a number of subsequent studies also demonstrated clear external validity, with scores significantly correlating with direct measures of metacognitive and self-regulatory skills, inhibition and theory of mind (Perels, Merget-Kullmann, Wende, Schmitz & Buchbinder, 2009; Demetriou, 2009).

Subsequent use of CHILD in a range of studies, within which metacognitive and self-regulatory abilities have also been measured directly, however, has led to further psychometric analysis, refinement and validation of the instrument. This paper reports these further analyses, based on a total sample of 274 children in the slightly extended age-range of 3-6 years in the UK, across 4 studies, and a sample of 120 children in the 5-6 age range in studies in Germany and Israel.

Exploratory factor analysis of data from the UK sample has revealed a two factor structure with 16 items relating to cognitive, emotional and motivational self-regulation loading on Factor 1, termed Individual Self-Regulation, and 5 items relating to Social Self-Regulation loading on Factor 2. Both factors show high levels of internal consistency (Cronbach alpha = .97 for Factor 1 and .89 for Factor 2), and significant levels of test-retest reliability and external and predictive validity. In three of the studies within the UK, for example, the children's self-regulatory skills were also measured directly by analysis of their performance on a train track construction task. Correlation and regression analysis showed strong relationships between these measures and the CHILD factors. In one of the UK studies scores on both factors have also been shown to be significantly related to a range of other direct measures of metacognitive skill and executive functioning (working memory and inhibitory control).

Further validation of the instrument is also reported, based on a sample of 120 children from Germany and Israel. Paralleling one of the UK studies, these children were assessed by their teachers using the CHILD instrument, and were also observed while they completed the train track construction task. This international evidence was used as the basis of a confirmatory factor analysis examining the two-factor model. The relationships between the CHILD factor scores and the direct measures of metacognitive skill from the train track task were once again analysed, and provided clear evidence of the instrument's external validity.

This new data and analysis has resulted in the construction of a revised CHILD instrument, consisting of 21 items, and providing two measures of self-regulation: Individual Self-Regulation relating to cognitive, emotional and motivational aspects (Factor 1) and Social Self-Regulation (Factor 2). The potential of this new instrument as a research tool, and as a diagnostic instrument within educational contexts, is clearly supported by the growing evidence of its external and predictive validity.

SYMPOSIUM

Evaluating and comprehending conflicting information on scientific issues

Chairperson: Joerg Wittwer, University of Goettingen, Germany

Organiser: Joerg Wittwer, University of Goettingen, Germany

Discussant: Panayiota Kendeou, Neapolis University Pafos, Cyprus

When dealing with scientific issues in both formal and informal learning settings, we usually read a multitude of information. This information often directly conflicts with each other and, thus, requires careful evaluation. Such an evaluation can be roughly described as being the result of the interplay between reader-related and information-related characteristics. To understand how such characteristics specifically operate in evaluating conflicting and science-related information, the work presented in this symposium puts emphasis on those reader-related and information-related characteristics that can be assumed to be crucially important for evaluating conflicting and science-related information. On the part of the reader-related characteristics, we focus, for example, on epistemological beliefs and need for cognition. On the part of the information-related characteristics, we focus, for example, on the plausibility and the source of information. The goals of the symposium are threefold. From a methodological perspective, the goal of the symposium is to present various methods for studying evaluation processes. From a theoretical perspective, the goal of the symposium is to deepen our understanding about mechanisms operating in processing information from multiple sources. From an educational perspective, the goal of the symposium is to inform how learning from conflicting information on scientific issues might be improved.

Multiple-documents comprehension strategies, trustworthiness, sourcing and argumentation in essays.

SYMPOSIUM

Comprehension of Text and Graphics, Discourse processing

Oistein Anmarkrud, Department of Educational Research, Norway; Ivar Braten, University of Oslo, Norway; Helge Stromso, University of Oslo, Norway

This study examined how strategic processing of multiple contradictory documents on a social-scientific issue was related to the evaluation of document trustworthiness, as well as to the source citations included in essays. Fifty-one undergraduates thought aloud while reading six different documents about potential relationships between cell phone use and health risks. After having read the documents, participants ranked their trustworthiness and wrote essays where they judged the health risks of cell phone use on the basis of the documents. The think-alouds were coded into episodes of strategic processing, and explicit and implicit references to the six source documents were identified in the essays. Students' overall level of strategic processing while reading the documents was positively related to the total number of source citations included in the essays, the number of explicit source citations, and the number of source citations linking source to content. Positive relations between strategic processing and source citations in the essays were also found for subcategories of multiple-documents comprehension strategies, in particular, intertextual linking strategies and evaluation strategies. Results also showed that the more students engaged in evaluation strategies during reading, the more trustworthy they considered a popular science document presenting a balanced view on the issue and the less trustworthy they considered a textbook excerpt and a document presenting alarming, yet undocumented, information. Further analyses will be performed to investigate the role of source citations in students' argumentation in the essays.

Aims

We examined how strategic processing of multiple contradictory documents on a social-scientific issue was related to the evaluation of document trustworthiness, as well as to source citations and argumentation in essays. Active, deeper-level, and flexible strategic processing seems to be a hallmark of expert reading (Alexander, 2006). Research on strategic text processing has mainly studied individuals trying to comprehend single texts or documents. Essentially, comprehending multiple documents differs from comprehending single documents because it requires that readers build "documents models" by keeping sources apart (i.e., noting and remembering "who says what") and, at the same time, integrating information from textual materials expressing diverse and even contradictory viewpoints (Britt et al., 1999).

Drawing on work on the reading of multiple documents (e.g., Strömsö et al., 2003; Wineburg, 1991), Afflerbach and Cho (2009) developed a taxonomy of strategies involved in the reading of multiple documents, consisting of three categories: 1) identifying and learning important information, for example, comparing and contrasting the document being read with related documents and connecting information from current document with previous document contents; 2) monitoring, for example, detecting a comprehension problem with a particular document and trying to solve the detected problem by searching for clarifying information in other available documents and perceiving that multiple documents related to the same topic can provide diverse views about the topic; and 3) evaluating, for example, perceiving and distinguishing the characteristics of different documents (e.g., document types, authors) and evaluating documents' trustworthiness based on these features. Thus far, very little is known about how such strategic processing of multiple documents may be related to the building of documents models encompassing both source information and integrated understandings.

Methodology

Fifty-one undergraduates read the following six documents presenting different views on cell phones and health risks while thinking aloud: 1) a science textbook excerpt explaining the functioning of cell phones and electromagnetic radiation, 2) a document from the National Radiation Protection Authority (NRPA) stating that research has not documented a link between cell phones and cancer, 3) a popular science article presenting a review article written by a brain surgeon who argued that there is solid evidence for the link between cell phone use and brain tumours, 4) a debate article in a health care magazine written by an engineer who took issue with the brain surgeon's view, 5) a document from a power critical magazine claiming that proven links between the use of cell phones and cancer are concealed from the public by the telecom industry and dishonest politicians, and 6) a newspaper article about a musician diagnosed with brain tumour. Source information (author, publisher, document type, and date) was given for each document.

The documents were read in a Google-like environment for the purpose of advising a friend who experienced discomfort using her cell phone. After reading and thinking aloud, participants ranked the trustworthiness of each document and wrote essays where they judged the potential health risks of cell phone use.

Verbalizations were coded as episodes of strategic processing and categorized according to the taxonomy of Afflerbach and Cho (2009). In addition, we created an overarching category of episodes involving the linking of

different documents, which was called intertextual linking strategies. The essays were coded for explicit and implicit references to the six source documents, as well as for argumentation integrating the different views on cell phones and health risks, as opposed to taking a strong, one-sided stance on the issue.

Results

Results showed that the more students engaged in evaluation strategies during reading, the more trustworthy they considered the document from the NRPA which presented a balanced view on the issue ($r_s = .32$, p $r_s = -.41$, p $r_s = -.36$, p

Moreover, students' overall level of strategic processing while reading the documents was positively related to the total number of source citations included in the essays ($r_s = .29$, p $r_s = .31$, p $r_s = .30$, p $r_s = .33$, p $r_s = .32$, p

Finally, students' overall level of strategic processing while reading the documents was positively related to their use of arguments integrating the different views on cell phones and health risks in the essays ($r_s = .37$, p $r_s = .35$, p

Theoretical and educational implications

First, the findings suggest that multiple-documents comprehension strategies may be associated with more trust in balanced information sources and less trust in sources judged to be biased. Interestingly, strategic processing may also be related to less trust in the textbook, that is, with a reduction in the "blind trust" that students often have in this particular information source (Paxton, 2002). Second, strategic processing was found to be related to students' remembering and distinguishing between different information sources as evidenced by their essays. Third, the positive relation between strategic processing and integrated arguments in essays indicates that such processing may also be linked to the construction of a representation combining contradictory viewpoints. Theoretically, this set of findings is consistent with the view that multiple-documents comprehension strategies may facilitate the building of documents models in the sense of Britt et al. (1999). Practically, they suggest that students should be taught such strategies to promote their multiple-documents literacy.

SYMPOSIUM

The role of plausibility and coherence in evaluating competing explanations on scientific issues

Natalie Wahl, Educational Institute at the Georg-August-University of Göttingen, Germany; Joerg Wittwer, University of Göttingen, Germany

In daily life, laypersons often encounter information about controversial scientific issues on the internet. An important characteristic of such controversial scientific issues is that there are competing explanations for a scientific phenomenon. Thus, laypersons need to evaluate the quality of the explanations to understand which explanation best explains the scientific phenomenon. Although theories in the philosophy of science postulate criteria for evaluating the quality of explanations, empirical investigations of the psychology reality of these criteria in a layperson's evaluation are rare. Similarly, it is not clear how characteristics of the internet come into play when evaluating explanations. For example, explanations on the internet are often not presented in a coherent fashion. Against this background, we conducted a study in which we manipulated the plausibility and the coherence of competing explanations for scientific phenomena. A total of $N = 240$ university students were asked to critically read the explanations and to evaluate their quality. The plausibility significantly affected the evaluation of explanations in that plausible explanations were preferred over implausible explanations. The coherence affected only the evaluation of implausible explanations in that implausible explanations that were coherent were preferred over implausible explanations that were not coherent. The results suggest that laypersons tend to routinely check explanations for implausible information. However, when evaluating implausible explanations, their evaluation seems to be contaminated by factors that are not related to the content.

Aims

In daily life, laypersons often encounter information about controversial scientific issues on the internet. A characteristic of such controversial scientific issues is that competing explanations for a scientific phenomenon exist. Thus, laypersons need to evaluate the quality of explanations to understand which explanation best explains the scientific phenomenon.

Theories in the philosophy of science postulate different criteria, such as logical consistency, for evaluating the quality of explanations. However, whether these criteria are used by laypersons as a basis to evaluate explanations has not been the object of much research. Similarly, the criteria formulated in the philosophy of science are assumed to be context-free. Thus, the context in which an explanation is given is expected not to affect explanation evaluation. However, when evaluating explanations on the internet, characteristics of the internet are likely to influence the

evaluation process. For example, information about a scientific issue is often not complete and provided on a single website. Instead, laypersons have to collect information from different websites to arrive at a coherent understanding about a scientific issue. Accordingly, the coherence of information provided on the internet might influence explanation evaluation. For example, research has shown that information is evaluated differently depending on the degree to which information is presented coherently.

Against this background, we examined the role of plausibility and coherence in explanation evaluation. We made the following predictions:

- (1) Laypersons assign a higher quality to plausible explanations than to implausible explanations.
- (2a) Laypersons assign a higher quality to plausible explanations that are coherent than to plausible explanations that are not coherent.
- (2b) Laypersons assign a higher quality to implausible explanations that are not coherent than to implausible explanations that are coherent.

Methodology

A total of $N = 240$ university students participated in the experiment. Their mean age was $M = 21.90$ years ($SD = 3.30$). Of all university students, 71% were female and 29% were male.

We used two independent variables. The first independent variable was difference in plausibility between explanations. The second independent variable was difference in coherence between explanations. Plausibility was manipulated by varying whether the explanations were logically consistent (i.e., plausible) or logically inconsistent (i.e., implausible). Coherence was manipulated by varying whether the explanations were presented as stemming from one website (i.e., coherent) or stemming from several websites (i.e., incoherent). The manipulation resulted in six experimental conditions in which the two explanations differed in their plausibility and/or in their coherence. The dependent variable was the difference between the quality scores that participants assigned to the two explanations. If the difference score was greater than zero, the perceived quality of the explanation expected to be preferred (e.g., plausible explanation) was higher than the perceived quality of the explanation expected not to be preferred (e.g., implausible explanation). If the difference score was smaller than zero, the perceived quality was lower.

The experimental procedure was as follows: First, the participants reported their prior knowledge about the scientific phenomena under study. Second, they read a description of the scientific phenomenon to be explained. Third, they read two competing explanations for the scientific phenomenon. Fourth, they evaluated the quality of the two explanations on a 5-point-scale ranging from good to bad. Fifth, their need for cognition was measured by a questionnaire. In total, participants read explanations for the following scientific phenomena: biological aging, ball lightning, and dinosaur extinction.

Results

First, we tested the plausibility hypothesis that participants would prefer plausible explanations over implausible explanations. We calculated an ANCOVA with the difference in plausibility and coherence as independent variables, prior knowledge and need for cognition as covariates, and the difference scores as dependent variable. The results showed a significant main effect for the difference in plausibility between the two explanations, $F(1, 167) = 5.23$, $p < .05$, $\eta^2 = .03$. As expected, plausible explanations were assigned a higher quality than implausible explanations.

Second, we tested the coherence hypothesis that plausible explanations would be assigned a higher quality and implausible explanations would be assigned a lower quality when they were coherent. We computed two planned contrasts comparing explanations that differed in their plausibility and in their coherence against explanations that differed in their plausibility but not in their coherence. The first contrast with plausible and coherent explanations vs. implausible and not coherent explanations as reference condition was not significant, $F(1, 167) = 0.00$, ns, $\eta^2 = .00$. Hence, coherence made plausible explanations not significantly better. The second contrast with implausible and coherent explanations vs. plausible and not coherent explanations as reference condition was significant, $F(1, 167) = 3.82$, $p = .05$, $\eta^2 = .03$. Contrary to expectation, coherence made implausible explanations not worse but better.

Theoretical and educational implications

The experiment demonstrated the psychological reality of a preference for plausibility in processing competing explanations. Participants evaluated the quality of plausible explanations as higher than the quality of implausible explanations. Hence, even though participants possessed little knowledge about the scientific phenomena, they were able to detect the logical inconsistencies in the implausible explanations. However, albeit significant, the effects of plausibility on perceived quality were rather small. This suggests that participants did not have a strong preference for plausible explanations. It might be assumed that, due to their low knowledge, it was difficult for the participants to

identify all logical inconsistencies in the explanations. The results also showed that coherence operated differently in evaluating explanations depending on their plausibility. First, coherence did not make plausible explanations better. Obviously, the plausibility of the explanations mainly guided the evaluation process and, thus, devaluated coherence as an explanatory virtue. Second, coherence made implausible explanations better. This result indicates that, in evaluating implausible explanations, laypersons were erroneously influenced by a superficial characteristic of explanations like their coherence. From an educational perspective, the findings suggest that laypersons need to be supported in critically evaluating explanations. From a theoretical perspective, the findings suggest that models of multiple-documents comprehension might take into account explanations as a specific type of texts influencing the evaluation process.

SYMPOSIUM

Author attributes and adaptivity of epistemological beliefs as predictors of source evaluation

Torsten Porsch, WWU Munster, Germany; Rainer Bromme, Universitat Muenster, Germany

Scientific information in online environments is often conflicting and fragmentary. Laypersons have to take attributes of authors and their own beliefs about nature of knowledge into account in order to evaluate the sources of conflicting information. The purpose of our studies is to consider attributes of author (expertise and trustworthiness) and student's adaptivity of epistemological beliefs when dealing with conflicting information in online environments. In the first study, 118 high school students read an online information text about plans for a tidal power plant. Afterwards, an online blog entry contradicts with the information in the text and demands a different version of the power plant. Author's attributes are varied experimentally. Students had to make a decision for one version of the tidal power plant or abstain from a decision and look for further information. Results show that a less trustworthy expert causes students to abstain from a decision and look for further information. A moderate qualified but trustworthy layperson with less expertise induces students to decide for one of the tidal power plant versions. Additionally the adaptivity of epistemological beliefs mediates the impact of author attributes on student's decision or abstaining from a decision. The study indicates effects on online participation and extends the scope on author attributes with regard to change in epistemological beliefs.

Aims

Social and political participation in modern societies entails making decisions about themes which we – as laypersons with regard to most of these issues – cannot understand in detail ("socio-scientific issues"; e.g., energy politics), instead we have to rely on experts. Modern societies offer a great variety of such experts, and access to expert knowledge has become easy, particularly, via the Internet (Bromme, Kienhues, & Porsch, 2010). Experts often disagree and provide conflicting information. Especially dealing with science information requires strong abilities to evaluate sources (Rouet, Britt, & Perfetti 1997; Stadler & Bromme, 2007). The capabilities of evaluating sources are an essential element of "digital literacy" (Coiro et al. 2008; Goldman et al. 2010; Rouet 2006; Wiley et al. 2009), but it is still not exactly known what these capabilities consist of and how they relate to other student variables. Individual parameters such as the awareness of context and situation as well as features of the sources are crucial, and there is a great need for empirical research on these variables (e.g. Baram-Tsabari et al. 2009; Porsch, Bromme, & Pollmeier, 2010; Porsch & Bromme, accepted). Attributes of authors (e.g., expertise or trustworthiness) in online environments are multidimensional and often inconsistent and incomplete. Authors can be experts in a domain but biased in reasons for providing information (e.g., by money givers). Trustworthy authors are not always experts. We ask for the influence of author's attributes on students' decisions or abstaining from a decision to look for further information. In addition to attributes of authors, reader's epistemological beliefs play an important role in source evaluation and we also include this variable. We focus on readers' adaptivity of epistemological beliefs. Whitmire (2004), Bråten, and Strömsö (2010), Mason and Boldrin (2008), Hofer (2004), and Stadler and Bromme (2008) report about the relationship between epistemological beliefs and how people search the Web and deal with conflicting information. Within these research accounts it has been assumed that someone who conceives knowledge as being static and as a collection of clear but separated facts, evaluates sources less elaborated than a person holding more dynamic beliefs about knowledge (i.e., conceiving knowledge as dynamic, interrelated, and constructed). We bear on this research, but we focus on the adaptivity of epistemological beliefs. There are topics and circumstances where a static view on knowledge is more appropriate than a dynamic one (Bromme, Kienhues, & Stahl, 2009; Hammer & Elby, 2002). In preceding studies we have found (Kienhues, Bromme, & Stahl, 2008) that some students change their epistemological beliefs on single topics when they are confronted with information highlighting controversies and conflicts. We assume that this change in epistemological beliefs (here called "adaptivity of epistemological beliefs") mediate the impact of author's attributes on students' willingness to make a decision or to look for further information and thereby to abstain from a decision. In some cases, it is crucial to choose the one most appropriate and trustworthy source (Iding et al. 2009; Metzger & Flanagin 2008). But, there are also cases in which it is reasonable to abstain from a decision and look for further information.

Methodology

In a first study, 118 (99 female) high school students were randomly recruited during an open day at the university. Mean age was $M = 17.9$ ($SD = 0.82$). Students read online an information text about a city planning a tidal power plant. Functions and mechanisms of the tides and the tidal power plant were explained in the text, figures illustrated the text. Afterwards, students read an online blog entry exemplifying that the tidal power plant should be build in a more expensive version caused of scientific findings about the change of the tides in the long run. Students were assigned by a random generator to two subsamples receiving one of two different descriptions of the author's attributes. One subsample ($n = 55$) received a description depicting the author as an expert on this topic but as less trustworthy. The second subsample ($n = 63$) received a description depicting the author as a moderate qualified layperson with less expertise but as very trustworthy. As a dependent variable, students had to decide for which version of the tidal power plant they would vote or if they would abstain from a decision and look for further information. Students' adaptivity of epistemological beliefs about the topic was determined by administering an epistemological questionnaire (CAEB; Stahl & Bromme, 2007) before and after reading the texts. In a second study, we used the same materials, but conducted the experiment with a bigger sample. Furthermore we added three further versions of the description of the author's attributes (author is an expert and trustworthy; author is neither an expert nor trustworthy; no information about the author).

Results

The results of the first study show that a less trustworthy expert causes students to abstain from a decision and look for further information. The moderate qualified but trustworthy layperson with less expertise induces students to decide for one of the tidal power plant versions ($\chi^2 = 7.31$; $df = 2$; p Theoretical and educational implications). The results indicate that online participation (e.g., in blogs) is influenced by author's attributes. Laypersons are encouraged to share their decisions by – sometimes amateurish – comments of other laypersons. In contrast a less trustworthy but expert authors make student laypersons to act with reserve and look for further information. Furthermore the studies extend the scope on effects of author's attributes with adaptivity of epistemological beliefs. Next to a direct impact of author's attributes, adaptivity of epistemological beliefs mediates the influence on students' decision or abstaining from a decision.

SYMPOSIUM

Bridging the Different Worlds of Teachers and Students in the Same Learning Environment

Chairperson: Karen Konings, Maastricht University, Netherlands

Organiser: Karen Konings, Maastricht University, Netherlands

Tina Seidel, Technische Universitat Munchen, Germany

Discussant: Christine Pauli, University of Zurich, Switzerland

People involved in education all have their own perspectives: Teachers and educational designers (as developers and providers of a learning), and students as "consumers" of these environments. Although it is mostly common practice that teachers/designers predominantly operate from their own "world", we argue that it would be beneficial to enhance the integration of student perspectives. Human factors engineering and human-computer interaction studies stress the importance of including users of any system in its design phase. The Combination-Of-Perspectives (COOP) model of Konings et al. (2005) proposes feedback loops between students and teachers/designers and between teachers and designers. This symposium is aimed to focus on decreasing the discrepancies in perceptions between students and teachers on education. In the first presentation, a study will be presented investigating existing differences between teachers' and students' perceptions on a learning environment. Using latent class analyses, profiles are defined of students and teachers being at risk experiencing adverse discrepancies in perceptions. After specifying the problem during the first presentation, the second and third presentation will provide different possible ways to reduce these discrepancies. Jan Zottmann and colleagues will present a study on improving teachers' ability to become immersed in multiple perspectives. Finally, Eleni Kyza and colleague will present a study on participatory designing an innovative web-based learning environment, including teachers, researchers, and designers in the design phase, and incorporating students' input. Challenges and realities of including students in the design process will be discussed.

SYMPOSIUM

Students' and Teachers' Perceptions of Education: Differences in Perspectives

Karen Konings, Maastricht University, Netherlands; Tina Seidel, Technische Universitat Munchen, Germany; Saskia Brand-Gruwel, Open University, Netherlands; Jeroen Van Merriënboer, Maastricht University, Netherlands

Teachers and students have their own perspectives on education. Congruent perspectives contribute to facilitating teaching-learning processes and help to achieve optimal learning outcomes. This study investigates both teachers' and students' perceptions on a learning environment in Dutch secondary education. It is aimed to define which students are at risk experiencing adverse discrepancies to their teachers' perceptions. Additionally, teacher profiles are defined on their discrepancies to students' perceptions. All tenth graders (N = 994) of four schools and their teachers (N = 136) filled out the Inventory of Perceived Study Environment Extended. In addition, students filled out the Inventory Learning Styles (ILS-SE) and teachers completed the Approaches to Teaching Inventory (ATI). By using Latent Class Analyses profiles in difference scores were defined. Profiles were characterized by analyzing differences on the ILS-SE and ATI. Teachers' perceptions were mostly more positive than students' perceptions. LCA profiles showed a 'distal' student profile which was at highest risk and experienced most motivational problems. Also, for the 'intermediate' student profile the discrepancy between perceptions was related to negative learning-related characteristics. Analyzing teacher profiles, 'idealistic' teachers were at risk to cause destructive friction. This study stresses the importance of improving congruence between perceptions. Future research has to focus on effective interventions. Improving teachers' immersion in the students' perspective or including students in the instructional design process to better account for their perceptions might be beneficial.

Aims

Teachers and students have different perceptions of the same learning environment. Teachers tend to perceive it more favorable than their students do (Fraser & O'Brien, 1985). A good fit between students' competences and interests, and the design of the learning environment influences effectiveness of learning and commitment to study (Neuenschwander, 2008). Some friction between students' learning strategies and teacher's teaching strategies can have a positive effect by stimulating students to develop more mature learning strategies (i.e., constructive friction). But friction can also cause a decrease in learning and thinking skills when discrepancies are too large (i.e., destructive friction; Vermunt & Verloop, 1999). In today education, there has to be mutual adaptation of teachers' and students' responsibilities and tasks. This requires more collaboration between teachers and students, which stresses the importance of congruence between their perspectives on education. The problem with existing studies on differences between students' and teachers' perceptions is that it is difficult how to improve instruction on global information about differences in perceptions. Therefore, the main goal of the current study is to investigate the existence of meaningful student profiles with respect to their difference in perceptions compared to their teachers. At the same time, it is aimed to determine profiles for teachers. Comparing these subgroups with respect to learning-related characteristics (for students) and approaches to teaching (for teachers) enables to define which students and teachers are at highest risk to experience large discrepancies that might cause destructive friction.

Methodology

Participants were 994 tenth grade students and 136 teachers from four schools for secondary education. Students filled out two questionnaires: The Inventory of Perceived Study Environment Extended (IPSEE) and the Inventory of Learning Styles for Secondary Education (ILS-SE). The IPSEE (Könings et al., 2008) includes eight scales: Fascinating contents, productive learning, integration, student autonomy, interaction, differentiation, clarity of goals, and personalization. The ILS-SE (Picarelli et al., 2006) measures students' learning-related characteristics and consists of 16 scales about processing strategies, regulation strategies, motivational orientations, conceptions of learning, and affective processing strategies. Teachers filled out two questionnaires: (1) a parallel version of the IPSEE (teacher version), measuring perceptions with respect to the learning environment, and (2) Approaches to Teaching Inventory (Prosser & Trigwell, 1993), measuring teaching approaches: Information-transmission/teacher-focused and conceptual-change/student-focused. For each student, difference scores were computed between perception scores and the mean teachers' score on the corresponding scale (called 'student differences'). Additionally, difference scores were computed between the teacher's perception scores and the mean of student scores (called 'teacher differences'). Using Latent Class Analysis (LCA) we defined profiles with respect to both student differences and teacher differences.

Results

Student Differences. The LCA solution with three latent classes fits the data best. These three student profiles vary in the degree to which student perceptions differ from teacher perceptions. All students predominantly perceived the learning environment less positive than teachers did. Students in the 'closest match profile' showed smallest differences between students' and teachers' perceptions. Difference scores in the 'intermediate profile' were larger than in the closest match profile, but smaller than in the third profile, called 'distal profile'. ANOVA's on differences with respect to student characteristics (ILS-SE) yielded a number of significant differences so that results with $d \geq .40$ are summarized. Closest match students reported more use of self-regulation strategies than intermediate students. They were more vocation-oriented, more intrinsically motivated, and less ambivalent motivated than all

other students. They conceived learning more as construction and use of knowledge than others. Finally, closest match students experienced less motivation/concentration problems than distal students. Teacher Differences. LCA yielded a two class solution. Teachers in the 'idealistic profile' perceived the learning environment as much more powerful than their students. Teachers in the 'adaptive profile' had smaller discrepancies with students' perceptions and, additionally, they showed mixed differences across scales. Teachers with idealistic profile had lower scores on information transmission ($d = .53$) and higher scores on conceptual change ($d = .69$) than teachers with adaptive profile.

Discussion

This study aimed at identifying students and teachers who are at risk for experiencing large discrepancies in their perspectives on education. LCA enabled us to define student' and teacher' profiles that provide a comparative picture of the situation. It showed that the distal student profile is at highest risk and experience most motivational problems. Substantial differences were found between student characteristics of closest match students and distal/intermediate students, but not between distal and intermediate students. This implicates that, also, for the largest group of students (i.e., intermediates; 59 %) the discrepancy related to negative learning-related characteristics. From the teachers' perspective it is shown that idealistic teachers are at risk to be too progressive and to cause destructive friction, especially for distal and intermediate students. Otherwise, adaptive teachers may cause destructive congruence (i.e., too little challenge) for closest match students. This study stresses the importance of improving congruence between perspectives of students and teachers, since the majority of the students experience substantial discrepancies. Teachers' immersion in the students' perspective and adaptation of instruction may prevent losing them during educational innovations. Another possibility would be to include students in the instructional design process (i.e., participatory design) to be able to better account for students' perspectives. Future research has to focus on finding effective interventions to decrease discrepancies.

SYMPOSIUM

Enhancing Computer-Supported Case-Based Learning for Pre-Service Teachers - A Matter of Perspective?

Jan Zottmann, University of Munich, Germany; Annika Goeze, University of Tuebingen, Germany; Frank Fischer, Universitat Munchen, Germany; Josef Schrader, University of Tuebingen, Germany

The ability to understand and analyse classroom situations can be seen as a central aspect of the professional competency of teachers. While case-based learning is considered to have great potential for the promotion of the analytical competency of teachers, attempts to investigate the effects of corresponding instructional support have been scarce. Hence, an empirical study was conducted to investigate the effects of instructional support in the form of hyperlinks to conceptual knowledge and multiple perspectives in a computer-supported case-based learning environment based on the principles of the Cognitive Flexibility Theory. 97 prospective foreign-language teachers participated in this field study with a 2x2-factorial design. The study was realised as a four-day university course with individual and collaborative phases of case-based learning. Individual learning outcomes reveal that specific components of analytical competency could be fostered by the different treatments: participants who were supported with hyperlinks to conceptual knowledge (i.e., pedagogical models and theories of learning and instruction) drew on conceptual knowledge more often in the post-test case analyses, while participants supported with hyperlinks to multiple perspectives (i.e., authentic comments of the teachers and learners from the cases) adopted teacher and learner perspectives more often at the end of the course. Process analyses show that particularly the hyperlinks to multiple perspectives affected the small group discussions of the cases as they helped case-based learners to adopt the relevant perspectives. These results underline the importance of adequate instructional support for effective case-based learning in teacher education.

Aims

The professional competency of teachers is strongly connected to their competency of being able to understand and analyse classroom situations (Goeze & Hartz, 2008). Analytical competency can be structured into (1) the ability to portray pedagogical situations in a differentiated way, (2) the ability to become immersed in multiple perspectives (especially those of teachers and learners, see Oser & Baeriswyl, 2000), and (3) the ability to apply conceptual knowledge to case information in order to better understand the situation at hand. Case-based learning is considered to have great potential for promoting analytical skills in teacher education (Lundeberg, 1999) and is also expected to enable learners to broaden their viewpoint beyond their own perspectives (Fitzgerald et al., 2009). Recent empirical studies, however, have demonstrated that learners do not get the most out of case-based learning without additional instructions (e.g., Moreno & Valdez, 2007). Cognitive Flexibility Theory (CFT) can be drawn upon as a basis for instructional support that seeks to further flexible knowledge application in different real situations, increase awareness of one's own perspective, and allow for the construction of connections to alternative perspectives (Spiro, Collins, Thota, & Feltovich, 2003). Against this backdrop, the study presented here aimed to answer the following research question: how do hyperlinks to conceptual knowledge, hyperlinks to multiple perspectives, and a combination of both facilitate the analytical competency among pre-service teachers in a computer-supported case-based learning environment? Moreover, collaborative learning processes were investigated to find out if instructions like these may help counteract known deficits of case-based learning, i.e. learners tending to get sidetracked instead of analyzing the case in a goal-oriented way, and insufficient immersion of case-based learners (Zottmann et al., in press). We hypothesised for learning process and outcomes that the availability of conceptual knowledge would have a positive effect on the application of conceptual knowledge, and the availability of multiple perspectives a positive effect on immersion.

Methodology

A total of 97 prospective foreign language teachers participated in this field study with a 2x2-factorial design, the factors being "conceptual knowledge" and "multiple perspectives". The case-material for the study was recorded in regular English lessons for intermediate learners. Authentic case sequences of up to 15 minutes were implemented in a computer-supported learning environment that was developed for this study based on the ideas of the CFT. The study was realised as a four-day university course for prospective foreign language teachers. On day one, the participants were introduced to case-based learning within the scope of a lecture, before control variables and demographic data were assessed. Subsequently, learners wrote a pre-test case analysis without instructional support. For the following four training cases on days two and three, the experimental conditions were realised: the factor "conceptual knowledge" was varied by providing / not providing hyperlinks to pedagogical models and theories of learning and instruction (Cognitive Apprenticeship being of them, for instance), while the factor "multiple perspectives" was varied by providing / not providing hyperlinks to authentic comments made by the teacher and learners from the video. These comments were generated from interviews conducted a few weeks after the course. For quantifying the dependent variable analytical competency, a complex coding scheme for the measurement of analytical competency was developed that incorporated its aforementioned three components. Regardless of the condition, learners analysed each training case individually (40 min.) and in groups of three (65 min.). The small group interactions were recorded on video to investigate the learning processes. On day four, learners had to write a post-test case analysis individually, without instructional support.

Results and Conclusions

Individual learning outcomes show that learners drew on conceptual knowledge more often in their post-test case analyses when hyperlinks to conceptual knowledge were available to them throughout the course, $F(1;92)=9.97$; $ph2=.10$. Learners supported with hyperlinks to multiple perspectives adopted teacher and learner perspectives more often in the post-test than participants who did not have this support, $F(1;92)=6.04$; $ph2=.06$. With respect to the learning processes observed in the small groups, the hyperlinks to multiple perspectives led to an increase of immersion, $F(1;92)=4.90$; $ph2=.05$. With respect to sidetracking, however, a significant interaction between the two factors was found, $F(1;92)=4.43$; $ph2=.05$. Learners in the combined condition made fewer case-related statements than learners in any other experimental condition. In summary, results of this study provide evidence that additional instructional support in the shape of hyperlinks to conceptual knowledge and multiple perspectives embedded in a computer-supported environment can enhance the effectiveness of case-based learning by fostering specific components of analytical competency - a competency that is crucial for teachers' professional performance.

Participatory Design for Effective Web-based Learning Environments

Eleni Kyza, Cyprus University of Technology, Cyprus; Iolie Nicolaidou, Cyprus University of Technology, Greece

Participatory design is widely used in studies of human-computer interaction and less so in cognitive and educational studies. The premise upon which it is based is simple: for a design to address the users' needs, users should be part of the design process. This premise is beginning to be acknowledged in relation to teachers but is still in nascent form when it comes to students, who are the end users of the instructional materials. In this paper, we present data from a longitudinal design-based research study, during which teachers, researchers, designers, and science content experts participated in a two-year effort to design an innovative web-based learning environment. Teacher data were collected from design planning meetings, classroom enactment planning sessions, and teacher interviews. Students' input was gathered through tasks, classroom observations, pre- and post- tests and motivation measuring instruments, and interviews. The data were analyzed using qualitative and quantitative methods. Results indicate that the teachers' perspective on the design strongly influenced the design and the enacted experience while students' feedback served as a guiding structure for the redesign of the learning environment. The implications of the teachers' and students' participation in the design process is discussed with particular emphasis on a critical, reflective analysis of open questions that pertain to the involvement of these two key categories of actors in the design process.

Aims

Modern societies call for radical changes in how people learn, moving away from industrial models of teaching and learning and embracing constructivist ideas. Many educational systems are at the center of heated discussions about what needs to change and how, with researchers actively being involved in reform- and research-based instructional design. These efforts have led to success stories, usually at the level of a teacher or a school but have also documented many problems. Failed innovations, lethal mutations, lack of scalability, loss of student interest are all challenges which have been documented in the literature. Teachers' uptake of reform-based innovations has been a recent focus in the reform literature, as teachers are seen as a decisive factor in the successful implementation of an innovation, resulting to calls to include teachers in the design of educational materials. However, the role of the student has been traditionally largely ignored: even though students' perceptions are often measured as part of evaluation studies not much attention has been given to students' role as a key stakeholder during the design process. In this proposal, we describe a design-based research program and present data about the role of the teacher and of the students in participatory design. Qualitative and quantitative data, collected over a period of two years, provide empirical validation of the effectiveness of the participatory design processes but also provide the opportunity to problematize the construct of participatory design.

Methodology

To examine the role of teachers and students in participatory design we collected various data, following the design-based research methodology, during which development and research take place through continuous cycles of design, enactment, analysis, and redesign (Brown, 1992). A team consisting of two university researchers and three practicing teachers participated in a two year-long design of a web-based environment to support secondary students' inquiry-based learning. The role of the teacher was examined by analyzing data from design sessions, lesson planning sessions, and teacher interviews throughout the design process. Twelve students participated in the pilot enactment and 21 students participated in the second enactment of the learning environment. Students' input was solicited through an analysis of usability testing, students' interactions with the instructional materials, formative assessment of students' learning processes, pre-post achievement tests, and two motivation surveys. The FAM motivation instrument (Vollmeyer & Rheinberg, 2003) addressed challenge, interest, probability of success, and anxiety factors. The FKS motivation instrument (Rheinberg, Vollmeyer & Engeser, 2003) measured flow, defined as a working state in which a person is fully absorbed in a task.

Findings

The teachers' role Findings indicate that the effectiveness of the teachers' participation in the design process depended on the role the teacher held during enactments: during the pre-enactment design phase all three teachers engaged in conversations about content and pedagogy, which could not have been possible if only one teacher was included in the design team. The ability of the non-enacting teachers to provide input about the design during the enactment phase was constrained because of the lack of first-hand experience of what was happening in the class. The enacting teacher's participation in the design process led to increased feelings of ownership of the materials. These results suggest that it is important to involve more than one teacher in the participatory design process but that their capacity to meaningfully inform iterative design will be mediated by the opportunities they have to experience the interactions during enactment.

The students' role

The examination of the students' learning processes, learning products, and the teacher's feedback from classroom enactments guided the revision of the learning environment. This analysis was necessary, despite statistically significant learning gains during the pilot enactment for both conceptual understanding and assessing the credibility of data. The qualitative analysis indicated that students had difficulties focusing on methodological issues of the studies they evaluated. Building on the results of the pilot study, the design team emphasized methodological issues to better support students. A paired samples t-test indicated significantly better results in post-tests in conceptual understanding, $t(17) = -2.60$, $p = .019$, $d = .61$ and credibility skills, $t(17) = -5.97$, $p = .001$, $d = 1.40$. Results from the analysis of students' motivation using the FAM and FKS questionnaire during the pilot enactment showed statistically significant results for the "probability of success" factor, $z(12) = -2.09$, $p = .04$. Significance Involving teachers in the design process and soliciting students' input led to a successful learning environment, as measured by the results of the pre-post tests on conceptual understanding, credibility skills, and motivation. An open question is the extent to which we could increase student involvement in the design process. This approach was not adopted due to logistics. Even though it appears that the effectiveness of the designed learning environment was not compromised we believe that future studies should explore the potential of ongoing student feedback in improving designs and enactment experiences. The teacher's self-reports about increased motivation to engage in the curriculum and the teacher's sense of ownership are encouraging, in light of the challenges reported in the literature regarding the sustainability of reform-based efforts. These results also raise concerns about existing curriculum development frameworks and suggest a need to revisit policy frameworks on scaling up innovations.

SYMPOSIUM

The eye in the web: Investigating web search with eye tracking with cued retrospective reports

Chairperson: Halszka Maria Jarodzka, Open University of the Netherlands, Netherlands

Organiser: Halszka Maria Jarodzka, Open University of the Netherlands, Netherlands

Discussant: LADISLAO SALMERON, UNIVERSITY OF VALENCIA, Spain

The WWW has become an important source for retrieving novel information. Hence, it is increasingly used for educational purposes, although, students search information often in a superficial manner (Stadtler & Bromme, 2007). The aim of this symposium is to get a better understanding of processes involved in web search to state recommendations for educational scenarios.

The task of searching information on the WWW is composed of overt actions that can be investigated by logging data, like mouse clicks (Kammerer & Gerjets; Argelagôs, Jarodzka & Pifarré; both this symposium). More important, however, this task is composed of covert processes of perceptual and cognitive nature. Perceptual processes, i.e.,

information on where a person paid attention to, for how long, and in which order, can be investigated by eye tracking. This method captures processes that are difficult to express verbally due to their fast speed, high automatization, or visual representation in working memory (Ericsson & Simon, 1993). On the other hand, this method does not provide information on why a person paid attention to an area, i.e., on cognitive processes. Thus, to interpret eye tracking data, it should be combined with a method that captures cognitive processes, like cued retrospective reporting.

The presentations in this symposium address the advantages of methodological triangulation to investigate WWW search in evaluating found information depending on expertise (Brand-Gruwel, Van Meeuwen & Van Gog) or on search list design and epistemic beliefs (Kammerer & Gerjets) and as a methodological comparison to single data sources (Argelagôs, Jarodzka, & Pifarré).

Effects of search interface and epistemic beliefs on source evaluations during medical Web search

Yvonne Kammerer, Knowledge Media Research Center, Germany; Peter Gerjets, University of Tuebingen, Germany

This study examined the impact of the interface design of search engines as well as of Internet-specific epistemic beliefs on laypersons' source evaluations during Web search for a complex medical issue. Participants either received search results provided in a Google-like list interface with search results presented in a rank-ordered list or in a grid interface with search results presented in a 3x3 matrix, thus possessing no clear ranking order of the search results. Furthermore, participants' epistemic beliefs about the Web as a knowledge source were assessed. To examine participants' source evaluations, search results were presented either in an optimal order with the most trustworthy search result being on top of the list or in the upper left corner of the grid, respectively, or in a reversed suboptimal order with the most trustworthy search result being at the bottom of the list or in the bottom right corner of the grid, respectively. Results revealed that in the suboptimal order university students using the grid interface fixated significantly shorter on search results of low trustworthiness and selected significantly more search results of high trustworthiness than students using the list interface. Furthermore, grid interface users verbally reflected more on the quality of search results and less on their ranking-position than list interface users. Additionally, with regard to Internet-specific epistemic beliefs eye-tracking data and verbal reports revealed that the naïve belief that the Web is a reliable source of certain and correct knowledge was related to less source evaluations on SERPs and on Webpages.

The WWW has become a major source for laypersons to search for medical and health information. However, as anyone can publish virtually anything on the WWW, the trustworthiness of Web information varies considerably, with many medical Websites containing misleading or even false information. Despite this fact, previous research has shown that during Web search for medical issues laypersons often do not spontaneously engage in source evaluations to verify the reliability and trustworthiness of information (e.g., Stadtler & Bromme, 2007). Furthermore, when using search engines, searchers usually direct most attention to the search results in the top of the search engine results page (SERP) and also predominantly select these first few results (e.g., Pan et al., 2007). In the present study we examined two potential reasons for these findings: the interface design of SERPs and searchers' epistemic beliefs. Standard SERPs might not provide sufficient affordances for searchers to engage in own evaluations, as search results are presented in a rank-ordered list (cf. Google) which suggests to start reading at the top of the list and simply to follow its order. Therefore, we compared a Google-like list interface to a grid interface that presented search results in a 3x3 matrix.

We hypothesized that the grid interface which provided no clear ranking order would increase the awareness of the selection process, and thereby would stimulate users to evaluate search results, for instance in terms of trustworthiness. Furthermore, searchers' epistemic awareness of the varying trustworthiness of Web-based information might be an important precondition for realizing the necessity of source evaluations during Web search. Searchers with naïve epistemic beliefs about the Web as a knowledge source might see no need to critically evaluate the trustworthiness of Web-based information (e.g., Bråten, Strömsö, & Samuelstuen, 2005). Thus, we administered participants the "certainty and source of knowledge" scale (8 items; Cronbach's alpha = .84) of the Internet-Specific Epistemological Questionnaire (ISEQ, Bråten et al., 2005).

High scores represented the view that the Web provides certain and correct knowledge. Low scores indicated doubts that the Web is a reliable source of certain and correct knowledge. We hypothesized that naïve beliefs in certainty and source of Web-based knowledge would relate to less source evaluations. To investigate the extent to which participants evaluated the trustworthiness of search results, search results were presented either in an optimal order with the most trustworthy search result being on top of the list or in the upper left corner of the grid, respectively, or in a reversed suboptimal order with the most trustworthy search result being at the bottom of the list or in the bottom right corner of the grid, respectively. Search result trustworthiness was determined in a pilot study where 24

students rank-ordered the search results according to their trustworthiness. In the experiment 80 university students (63 female, mean age: 24.04) were randomly assigned to one of four conditions with trustworthiness order (optimal vs. suboptimal) and search results interface (list vs. grid) varied as between-subjects factors.

Participants' task was to seek information on the WWW about two competing therapies for Bechterew's disease in order to give informed advice to a fictitious friend. For this purpose, participants were presented with two SERPs, each containing nine search results linked to nine Webpages. Participants' eye movements and mouse clicks were registered during task performance which was limited to eight minutes. In addition, cued retrospective verbal protocols were obtained by presenting participants with their gaze recordings and asking them to report what they were thinking during SERP inspection. As indicators of evaluation processes on SERPs we measured the total dwell time on search results and the selection frequency of search results as a function of their trustworthiness, as well as verbal utterances concerning the quality, trustworthiness, type of source, and position of the search results. Furthermore, on the Webpages total dwell times on Webpage logos as well as on source information were assessed. Results of ANCOVAs revealed that when the top search results were of low trustworthiness (suboptimal order) students using the grid interface fixated significantly shorter on the five least trustworthy search results ($p = .06$) than list interface users, whereas there were no differences regarding the more sophisticated criteria trustworthiness and type of source.

Additionally, eye-tracking data and verbal reports revealed that the naïve belief that the Web is a reliable source of certain and correct knowledge was related to shorter dwell times both on search results ($p = .09$). Furthermore, in the suboptimal order condition the respective belief was related to shorter dwell times on the Webpage logos ($p = .09$). To conclude, across different types of processing data the study provides indications that both the interface design of SERPs and Internet-specific epistemic beliefs influence source evaluations during Web search on a complex medical issue. From a practical point of view, these findings may inform the development of concrete interventions, such as design guidelines for search interfaces or trainings addressing the varying trustworthiness of information on the Web.

SYMPOSIUM

Measuring processes in web search: logfiles, eye-movements and cued retrospective reports compared

Esther Argelagos, University of Lleida, Spain; Halszka Maria Jarodzka, Open University of the Netherlands, Netherlands; Manoli Pifarre Turmo, University of Lleida, Spain

Students often use the WWW for searching information to accomplish school assignments. To design instruction to foster student's web searching skills insight in the involved cognitive processes is needed. This study compares Logfiles (LOG), Eye-movements (EYE), and Cued Retrospective Reports based on eye movements records (CRR) to evaluate how different kind of data help to gain insight in the involved cognitive processes. Fifteen participants searched the WWW for information on the planet Mars. LOG and EYE were collected during and CRR data after tasks performance. Results revealed that LOG provided information on the overt actions (web-pages visited, search terms used, answers performed, etc.) and that analysing these actions can give insight in the main cognitive processes involved in web searching. However, when scoring participants regulation activities the coding was more interpretative. EYE-data which combines loggings and eye-movements showed a more fine grained insight in the cognitive processes. Not only could be seen on which web-page participants looked at, but also where they looked at. For instance if they were reading or scanning the page. Also the allocation of attentional processes could be analysed. It showed for instance that students spent much attention on reading the assignment. Results of the CRR in with the other two data-types were included revealed that especially on the regulation of the process more fine grained information could be obtained. It can be concluded that to gain insight in cognitive processes the methods are complementary, but they also provide different kinds of information.

Solving information-based problems on the WWW involve complex cognitive activities. The model by Brand-Gruwel, Wopereis, & Vermetten (2005) makes a distinction between five involved processes: defining the information problem, searching for information, scanning information, processing information in depth and organizing and presenting information. These processes are divided in sub-processes, as for instance generating search terms, or sourcing. Furthermore, emphasize is put on regulation processes during solving information-based problems. To

measure the involved processes different methods can be used. In this study three methods will be compared: Logfiles only (LOG), Eye-movements in combination with logfiles (EYE), and Cued Retrospective Reports based on eye movements records in combination with logfiles (CRR). LOG are digital recordings of the changes over time on the screen. LOG provide information on overt actions made on the screen during the task, i.e.: web-pages visited, search terms used, results selected in a search engine results page (SERP), answers provided in the web-based activity by each participant, etc. EYE can provide overt actions but also provide unique information concerning what is visually attended to, in what order, and for how long. CRR is a method to capture verbalizations of thought processes after task performance cued by a replay of one owns eye-movements (Van Gog, Paas, Van Merriënboer, & Witte, 2005). The methods are complementary, but also provide different kind of data. The questions answered in this research are: 'In what way can cognitive processes involved in web searching be described using different kind of methods?' and 'What are the differences and similarities between these methods?'

Method

Fifteen participants (5 men, 10 women; age $M=33.47$, $SD=4.47$) accomplished a web-based activity (WebQuest) composed of two tasks in 45 minutes, where they had to search for information about the planet Mars. During task performances, logfiles were captured, and eye-movements were tracked. Afterwards, participants reported on their thoughts during both task performances for five minutes each while reviewing their overt actions and eye-movements.

To gain insight in the cognitive processes involved in web searching when analysing the different data types, a coding scheme based on Brand-Gruwel, Wopereis, and Vermetten (2005) was developed. The scheme gives an overview of the involved main processes ('Defining problem', 'Web searching', 'Scanning and processing', 'Organizing and presenting information'), sub-processes, and regulation (e.g., orientation, monitoring-steering, testing). The scheme was used to analyse all three data types. Furthermore, to analyse the EYE data also areas of interest (AOI) were defined to get grip on the allocation of attentional processes. The preliminary results described below are based on 5 participants. During the presentation all results will be available.

Results and conclusions

The information provided by LOG was an average of 67.57 actions per task. 14% of these actions were coded as regulation (in an interpretative way). Considering the four main processes, LOG could provide the actions' frequencies: 17%, 27%, 45%, 11%, respectively; and the time spent on each process: 16%, 24%, 47%, 13%. EYE provided an average of 76.57 actions per task. Furthermore, this method gave qualitatively more information, as EYE revealed more different sub-processes than LOG. For instance, the code 'Select result in SERP' from LOG could be differentiated into two categories in EYE: 'Select by reading title-description' and 'Select by reading url'. This kind of fine graining happened on average of 7.86 times per task. Furthermore, EYE could revealed that the 15% of the actions were considered as regulation (in an interpretative way), and also the actions' frequencies performed in each process (22%, 24%, 42%, 12%), and the time spent in each one (20%, 24%, 46%, 11%). Moreover, EYE could provide additional information about the 'Defining problem' and 'Organizing and presenting information' processes, by analyzing the allocation of participants' attention on the assignment web-page in one task. Therefore, the assignment web-page was divided into the following AOIs: 'header and navigation', 'problem statement', 'response field'. In terms of mean time to first fixation, participants looked first at 'problem statement' (1.47 seconds), then at 'response field' (44.40 seconds), and last at 'header and navigation' (1:35.34 minutes). In terms of total fixation duration, participants looked the longest on 'response field' (5:04.50 minutes), shorter on 'problem statement' (2:04.00 minutes), and the shortest on 'header and navigation' (6 seconds). Thus, the added value of EYE compared to LOG was information about attentional processes. CRR, delivered even more quantity (mean 78.29 actions per task) and quality of information in terms of cognitive processes, considered behind certain actions. For example, the code 'Scanning' provided by EYE, could be differentiated into two categories in CRR: 'Scanning' and 'Elaborating on the content while scanning'. This kind of fine graining happened on average of 1.29 times per task. The total amount of cognitive processes was the 43% and the 31% of the actions were coded as regulation (e.g.: 'I need information about Mars!' was coded by Orientation; 'I couldn't find it!' as Monitoring-Steering). Furthermore, CRR could provide the actions' frequencies performed in each main process: 22%, 25%, 42%, 11%, but could not provide the time spent in each process, because utterances' duration were not related with actions or process' duration performed. The added value of CRR in respect to EYE was the more grained information about cognitive processes and regulation. In sum, all three methods provided similar action frequencies performed in each process. LOG and EYE provided similarly the time spent for each process and the percentage of regulation. CRR, however, did not reveal the time spent. Most important is the added value that each method can provide to LOG only, particularly EYE (with attentional processes) and CRR (with cognitive processes and regulation). Already these initial results showed that each method provides different kinds of information and that these may be used complementarily.

SYMPOSIUM

Evaluation of information while searching on the Internet: Differences between experts and novices

Saskia Brand-Gruwel, Open University, Netherlands; Ludo van Meeuwen, Open Universiteit Nederland, Netherlands; Tamara Van Gog, Erasmus University Rotterdam, Netherlands

Searching for information using Internet means that one has to evaluate and select appropriate information or solving a task. However, evaluating and selecting sources and information is not always done based on clear criteria, but on intuition. To gain more insight in the criteria domain experts and novices use when evaluating information, in the study presented in this paper twenty psychology students and 17 psychology university teachers searched for information about a psychology topic on the Internet while their eye movements were tracked. These eye movements were used for the method of cued retrospective reporting. Results revealed that experts use more criteria to question the reliability of information and Websites. Furthermore, a correlation was found between the used evaluation criteria and the quality of the selected information.

Presently using the Internet for searching information of any kind is an activity almost everyone does. Especially in education students frequently use the World Wide Web (WWW) for selecting information to accomplish assignments such as writing an essay or preparing a presentation. The evaluation of sources and information found on the WWW is an important skill, because the amount of information is enormous and there are no gatekeepers that filter information on the web (Brand-Gruwel et al., 2005).

Research reveals that when evaluating Web-based information instead of looking for the author or organization behind the site superficial criteria are used, such as the presence of pictures on a website (Walraven et al., 2008). But research also shows that prior knowledge concerning the subject matter can influence the use of criteria when evaluating information (Britt & Aglinskas, 2002). However, methods used in research about the use of criteria when evaluation information found on the Internet are often retrospective recall and thinking aloud. These methods give some insight, but in this study we will go a step further by using cued retrospective reportings with eye-tracking as the cue. Thereby, we aim at gaining more detailed insight in criteria domain novices and domain experts use. Furthermore, a central goal is to determine whether the use of more sophisticated evaluation criteria leads to the selection of higher-quality information. Method Twenty psychology students act as domain novices (age $M=20.2$, $SD=4.07$) and 17 university teachers in psychology (age $M=39.5$, $SD=12.33$) as domain experts. They worked on a task for 10 minutes, while their eye movements were recorded. Then, they reported their thoughts while reviewing their own eye movements on half speed (20 minutes). This method is called Cued Retrospective Report. Two tasks were developed (topic1: reliability of human memory, topic2: altruism) to ensure that results (i.e., the evaluation criteria participants mention) are not related to the subject matter of the task. Tasks were of equal complexity according to the complexity level of Mosenthal (1998). For each task a Google-like search engine results page (SERP) with 17 links (i.e., hits) was composed (including a mix of different types of Websites). Participants selected and ranked five sites.

To score the quality of the participants selection each site (in the SERP) got a value (10-point scale) based on different evaluation criteria. Two raters independently scored all sites (correlation was $r=.99$, p). The coding scheme from Brand-Gruwel et al. (2005) was adapted to score the criteria participants use. The main classification is an evaluation of a hit in a SERP, of a site, or of information. Within this classification three levels of exactness in participants' evaluations are distinguished: 1) superficial evaluations (Hmm, no, not this one!); 2) an evaluation on a global level of usability, and reliability (I don't think this information is very useful); 3) specific evaluations based on a certain criterion. Results and conclusions The criteria are categorized by the evaluation of the usefulness and reliability of the hits in the SERP, the sites, and the information found on a site.

Concerning the evaluation of hits in a SERP all participants judged the hits on usefulness for solving the problem. A significant difference between experts and novices was found on the criterion 'usage of language' ($p=.03$). In contrast to novices, experts did not judge on the language in terms of that it is written in a popular or scientific way. When evaluating the reliability of the SERP, the reputation, the kind of source, and the familiarity is questioned more than once by the novices and the experts. Only on the use of the criterion 'familiarity' a significant difference with regard to domain expertise was found ($p=.045$) (in favour of the experts). Furthermore, a difference on the criterion 'position in the SERP' was found ($p=.022$). The novices used this criterion more often than the experts.

Concerning evaluating information a difference was found on the kind of information ($p=.012$). The novices more often gave their judgment on the fact, that, for instance, the information was found in a blog or forum. When evaluating a site in particular the reliability was judged. Experts used the following criteria more often than novices: reputation of the organization behind the site ($p=.05$); kind of source ($p=.05$), familiarity ($p=.028$). Furthermore, the novices judged the appearance of the site (colours, pictures, lay-out) more often than experts ($p=.021$). Furthermore, results revealed that the novices evaluated sites more in a superficial way ($p=.007$). It means that the novices used more utterances like 'no not this site'. No criteria were mentioned. To determine the relation between the use of criteria and task performance (selection of sites) correlations were calculated (Pearson). Results revealed a correlation of .35 ($p=.016$) between the quality of the selection and the amount of evaluations concerning the reliability of a site. The more participants evaluated the reliability of sites, the higher was the score on the quality of the selected sites. Furthermore, a negative correlation ($r=-.61$, $p=.000$) was found between the quality of the selected sites and how often information was judged in a superficial way. More superficial evaluations lead to the selection of lower-quality sites. To conclude, as expected domain experts used more criteria to evaluate the reliability of information and sites, and they also selected sites of a higher quality than the novices. So, more prior domain knowledge and the use of sophisticated evaluating criteria helps to find information of a higher quality. This result does have its implication for the design of education in order to help students to become critical web searchers.

SYMPOSIUM

Quality and development in all-day schools in Europe and in afterschool programs in USA

Chairperson: Marianne Schuepbach, University of Bern, Switzerland

Organiser: Marianne Schuepbach, University of Bern, Switzerland

Discussant: Hans Guenther Rossbach, University of Bamberg, Germany

Traditionally Germany, Austria and Switzerland differ from most (European) countries and the USA with regard to their length of a school day and their curricular and extracurricular activities in the afternoon. In answer to a societal change and the unfavourable results of the PISA studies the establishment of all-day schools is now starting. These all-day schools suggest positive effects on the development of the students not only on the level of academic achievement, but also with regard to their social and emotional development. USA afterschool programs, specifically intervention programs for children at risk, have been known for a long time. In the last years there has been an increasing interest in afterschool programs with high quality that can provide youths with a safe and supportive adult-supervised environment and offer them activities and experiences that promote academic, personal, social, and recreational development. As little empirical research exists regarding the effectiveness of all-day-schooling in Europe and the quality in afterschool programs in USA. The aim of this symposium is to bring together current studies addressing these research deficits conducted in Switzerland, Germany, and in the USA. Schuepbach presents data comparing the effects of all-day-schooling with the traditional schooling on the development of Swiss children. The German paper from Gogolin et al. focuses on the question of whether all-day schools make a difference to immigrant minority children's integration and success. Finally Vandell and Pierce present results from the Study of Promising After-School Programs and look into the quality of afterschool programs in USA.

SYMPOSIUM

Quality and effectiveness of all-day schools for primary school age children in Switzerland

Marianne Schuepbach, University of Bern, Switzerland

The research project EduCare presented in this paper takes place in 11 cantons of the German-speaking part of Switzerland. This longitudinal study addresses questions relating the quality of different settings of education and care to their effects on children's cognitive and socio-emotional development in the first years of school (age 6-9). As a conceptual framework of these study we developed a model on quality and effectiveness of school curricular and

extracurricular activities based on Radisch et al. (2008) developed and applied in the StEG-Study, Helmke (2004) and Pekrun and Helmke (1991). The hypotheses will be tested using a longitudinal survey with a quasi-experimental design using one test group (students attend all-day schools) and one control group (students attend schools with core times) (N=43 classes; N= 295 students). In our paper we are going to focus on the following questions: How do students in all-day schools develop compared to the control group (students in schools with core times) at the end of grade 1, 2 and 3? How do these students develop in addition in consideration of the school setting's educational quality in cognitive and social/emotional areas? The results concerning the children's achievement in mathematics and in language show, that at the end of grade 3 children in all-day schools tend to do better than children in schools with core times. Findings concerning the non-cognitive area indicate a better development in socio-emotional behavioural strengths of children attending all-day schools. The same result can be found for the daily living skills.

The performance of Swiss school children in PISA 2000 alarmed both the public as well as education experts. As a response, action measures in various areas have been put forward with the aim of addressing weak points in the Swiss education system. One recommendation is the expansion of school-age careprograms. The need for these programs is also supported by societal and economic changes and consequent political demands. At present, Switzerland is debating the future priority of out-of-school and extracurricular programs and how they should be developed concerning the aspects of education and care for primary-school children. An important education policy argument for the expansion of these offers is that extracurricular activities can better facilitate a positive development of children with their individual strengths and competencies. There is no research on the effectiveness or the effects extracurricular programs in Switzerland yet. The international situation is similar. There are a few studies investigating these effects in relation to students' outcomes. These few studies focusing on afterschool programs are mostly evaluations of specific intervention programs in the USA. Several studies concerning afterschool programs for school-age children show positive effects on the cognitive outcomes such as higher achievement in reading, and science as well as doing better in standardized tests (e.g. Blau & Currie, 1984; Brooks et al., 1995).

A lot of studies that focus on the effects of family and out-of-family care in relation to developmental outcomes of children are set in the pre-school age. Overall most published studies on presumably high quality pre-school-care programs show positive effects on children's cognitive and social development independent of the families' social background. At the same time, there is a focus on the program's quality. However, the results of these studies and those of the afterschool sector cannot be generalised or applied without examining the varying Swiss circumstances. In comparison to other countries, such as the United States, England, or France, school-age education and careprograms in Switzerland are very different regarding their structure. There are offerings at different times of the day. It is not the rule in Switzerland that children are at school for the whole day. The research project EduCare presented in this paper is funded by the Swiss National Science Foundation and takes place in the German-speaking part of Switzerland. It is designed to provide empirical evidence and therefore a basis for decisions pertaining to (Swiss) educational policies. This longitudinal study addresses questions relating the quality of different settings of institutional (all-day schools and schools with core times [Blockzeiten]) and family care to their effects on children's cognitive and socio-emotional development in the first years of school (age 6-9). The research findings available emphasise the importance of the quality of childcare and education programs. As a conceptual framework of these study we developed a model on quality and effectiveness of school curricular and extracurricular activities based on Radisch et al. (2008) developed and applied in the StEG-Study, Helmke (2004) and Pekrun and Helmke (1991). For measuring quality, our study starts out from a structural/process model by Tietze (1998). The model attempts to combine dynamic and dimensional approaches. An important study that is based on models of this kind is the international comparative European Child Care and Education Study (ECCE 1999).

The hypotheses will be tested using a longitudinal survey with a quasi-experimental design using one test group (student attend all-day schools) and one control group (students attend schools with core times). Based on current forms of school hours and extracurricular programs in the Swiss cantons, we asked the cantonal education ministries of 11 cantons for permission to conduct the study. In drawing the sample, we asked all of the all-day schools - our smallest basic experimental group - that met our criteria to participate. Based on socio-demographic data on the municipalities in which the schools are located, we selected schools in comparable municipalities in the 11 German-speaking cantons of Switzerland (N= schools= 35; N=43 classes; N= 295 students). The municipalities are mainly urban or part of agglomerations. In order to gather information on quality aspects questionnaires, interviews, and observations were made use of. To measure quality the German version of the "School-Age Care Environment Rating Scale" (Harms et al. 1996) "HUGS" (Tietze et al. 2005) was applied. Cognitive and socio-emotional development was measured with standardised and non-standardised tests. These tests measure the developmental-psychological characteristics of primary-school children in the different settings (Schuepbach 2010). In our paper we are going to focus on the following questions: How do students in all-day schools develop compared to the control group (students

in schools with core times) at the end of grade 1, 2 and 3? How do these students develop in addition in consideration of the school setting's educational quality in cognitive and social/emotional areas?

Overall it is expected (general hypothesis) that primary-school children attending extracurricular activities have better developmental outputs compared to children with regular school-education and no specific institutional extracurricular activities (control group). The results of the univariate analysis of covariance concerning the children's achievement in mathematics and in language show, that at the end of grade 3 children in all-day schools tend to do better than children in schools with core times whereas up to grade 2 no advantage can be found. This effect at the end of grade 3 is found independent of the intensity of attendance of extracurricular activities. Findings concerning the non-cognitive area indicate a better development in socio-emotional behavioural strengths of children attending all-day schools at the end of grade 1, 2 and, 3. A positive overall picture for students in all-day schools completes the results concerning the daily living skills. The results of this study are consistent with the research overview and tend to be more favourable towards the cognitive area compared to previous results in Switzerland and Germany. Already after three years the available findings show amazingly concise effects of the different school forms. Future research with a larger sample is needed to validate these findings.

SYMPOSIUM

Do all-day schools make a difference to immigrant minority children's integration and success?

Deborah Vandell, University of California, Irvine, Germany; Jule Boehmer, Universität Hamburg, Germany; Nina Bremm, Universität Hamburg, Germany; Heinz Reinders, Universität Würzburg, Germany; Kim Pierce, University of California, Irvine, United States; Ingrid Gogolin, University of Hamburg, Germany

The paper reports on preliminary results from a research project that compared full-time and part-time schooling in Germany with regard to the integration and success of immigrant minority students. Due to a national investment program, the number of full-day schools in Germany doubled in the last decade. The project contributes to the identification of effects of this program. It is embedded in a theoretical framework of school effectiveness research, following the major idea to combine an evaluation model with school, classroom and student characteristics. We assume that intended curricula on the input level, measured by conditions and intentions, relate to school and classroom characteristics which show the degree of implemented curricula. Student's output measures are seen as appropriate for realized curricula. Contextual factors, such as age and duration of exposure to the language of schooling, are controlled. The school sample (70 schools, 2100 students) was selected via screening, identifying full-day and half-day schools with comparable intake of students. We will focus on preliminary results from secondary schools. Whereas positive effects were found with respect to interethnic friendships and social integration, the linguistic data did not show the expected effects. Language performance of the students shows a differentiation of "colloquial" and "academic language". Whereas the students in full-day schools performed significantly better in "colloquial language", no significant difference could be identified with respect to "academic language".

The paper reports on results from a research project that compared full-time and part-time schooling in Germany with regard to the integration and success of immigrant minority children. The increase of all-day schools in Germany was one of the education reforms that were initiated by the so called "PISA-shock". By PISA-results it became evident that the German school system was less prepared than expected to succeed in international knowledge-based competition. One assumption about improvement of the situation was that more all-day schools could be a powerful instrument, especially for the benefit of students who are in need of additional support – such as children and adolescents with a migration background. In 2003, the German Federal Ministry of Education and Research (BMBF) launched an investment program "Zukunft Bildung und Betreuung" (IZBB) (Engl. "A Future for Education and Care"). The funding allowed for a considerable increase of all-day schools since then. Their number more than doubled; today, roughly 40% of all schools in Germany are all-day schools. The investment program was accompanied by a number of research projects on questions of efficiency and effectiveness of the reform (see <http://www.ganztagsschulen.org/10249.php>). The research project presented in this proposal was carried out in this context. The overall aim of the project "Ganztagsschule und Integration von Migranten" (GIM) (Engl. "All-day school and integration of migrants") is to uncover effects of all-day schools on social integration, the development of intercultural competences and on second language achievement of children with a migration background in a longitudinal perspective. The guiding question is: Do all-day schools lead to positive effects on the performance of these children? The project is embedded in a theoretical framework of school effectiveness research (Scheerens & Bosker, 1997). The major idea is to combine evaluation models according to Stufflebeam's CIPP-model (Stufflebeam, 2000) with school, classroom and student characteristics. We assume that intended curricula on the input level, measured by conditions and intentions, relate to school and classroom characteristics which show the degree of implemented curricula. Student output measures (performance in home and school language, academic performance and interethnic relations) are seen as appropriate measures for realized curricula (Ditton, 2000). This model allows to

assort available and gathered data and enables to identify conditions of effective support of migrant students (Scheerens, 1990). Contextual factors, such as the age and time of exposure to the language of schooling, were considered.

The proposed presentation will focus on the language related aspects of the project. Performance in German (i.e. the language of schooling) is considered (a) as the basis for the acquisition of intercultural competence and social integration; (b) as an indicator for social integration. In the project, innovative instruments for bilingual language assessment have been applied (for language pairs German-Turkish and German-Russian); the same, but monolingual testing was carried out with monolingual German students of the sample schools as control group. The language related hypothesis of the project is that school achievement is less dependent on general (everyday) language competence ("basic interpersonal language skills") than on academic language competence ("cognitive academic language proficiency"; cf. Cummins 1991; Gogolin 2009; Schleppegrell 2004).

The tests applied were constructed and validated with reference to the differentiation of the two respective registers.

- Linguistic performance was controlled by (a) individual background variables (cognitive competence, social background, linguistic and migration background) and (b) school and classroom variables (input characteristics, intended curriculum). The longitudinal design of the project was realized by two measurements, each carried out in primary schools (1st and 2nd grade) and secondary schools (5th and 6th grade). The sample was selected via a screening, identifying full-day and half-day schools with comparable intake of students (with respect to social and migration background) in two German Federal States. The sample consists of 71 schools/ roughly 2100 students. Our presentation will focus on preliminary results of the data analysis from secondary schools. Whereas all-day schools seem to have positive effects on social integration, the language performance data showed a clear differentiation of "general" and "academic language" performance. Whereas the students in full-day schools performed significantly better in "general language" than those in half-day schools, no significant difference could be identified with respect to "academic language". This result leads to the hypothesis that time of exposure in full-day schools may not adequately be transferred to time on task (with respect to language education). Our further analyses of individual background, school and classroom variables will shed light on this assumption.

SYMPOSIUM

Student Outcomes Linked to Participation in High-Quality After-School Programs

Deborah Vandell, University of California, Irvine, United States; Kim Pierce, University of California, Irvine, United States

Associations between different sets of after-school contexts and relative changes in student functioning across 2 years were assessed in a large sample of elementary school ($n = 1,796$, M age = 8.7 years) and middle school ($n = 1,118$, M age = 11.7 years) youth. In contrast to students who regularly spent time with unsupervised peers during the after-school hours, elementary students who regularly attended high-quality after-school programs (either alone or in combination with other structured activities) had better math achievement test scores, work habits, task persistence, social skills, and prosocial behavior with peers, and less aggressive behavior and misconduct, controlling for baseline performance. Elementary students who participated in both programs and other activities also posted gains in teacher-reported academic performance relative to unsupervised students. Middle school students who attended high-quality after-school programs (either alone or in combination with other organized activities), compared to students who spent large amounts of their after-school time in unsupervised settings, earned better math achievement test scores and reported less misconduct and substance use and higher work habits, controlling for baseline performance. These findings are consistent with a developmental-contextual perspective in which after-school programs alone and in combination with other organized activities are posited to promote more positive developmental outcomes for economically disadvantaged students.

Substantial numbers of youth in the United States grow up in poverty. Studies suggest that education remains a critical pathway out of poverty for these young people, but activities within the school classroom alone cannot provide youth with the educational, social, and personal resources they need to overcome economically disadvantaged backgrounds. Children and youth also need varied opportunities, experiences, and supports after school. Programs that provide constructive, supervised activities during the after-school hours can help to meet this need. Some investigations have indicated that participation in after-school programs can improve academic and behavioral outcomes, whereas others have reported no effects or, in some cases, negative consequences of program participation. Critiques of the extant research have identified several factors that may contribute to these differences: investigation of a small number of programs, the quality of the programs, how frequently students attend the programs, availability of other types of after-school activities, family and child selectivity bias, and failure to use longitudinal designs that track outcomes over time. The Study of Promising After-School Programs was designed to

address many of the limitations of the prior research. The 2-year longitudinal study examined relations between participation in high-quality programs and academic and social outcomes for low-income, ethnically diverse students. It focused on high-quality programs, rather than a representative sample of programs, in order to assess the potential for programs to have positive effects on students. Nineteen elementary and 16 middle school programs located in 14 cities in 8 states across the U.S. participated in the study. All of the programs were characterized by features identified in other research as key to promoting positive youth development outcomes: positive relations (students-staff, peers), high student engagement, skill-building activities, mastery orientation, and appropriate levels of structure and organization.

A total of 2914 students (1796 in Grades 3-4, 1118 in Grades 6-7) were studied. Some were enrolled in the participating after-school programs, whereas others attended the same schools but not the programs. Daily attendance records were obtained from the programs over a 2-year period. In addition, students reported how often they participated in other types of organized activities and in unsupervised settings during the after-school hours. Academic and social outcome data were collected from students, teachers, and school records at baseline, at the end of Year 1, and at the end of Year 2. Using cluster analysis, groups of students who shared similar sets of experiences during the after-school hours were identified:

- (1) Program Only, comprised of students who regularly attended the high-quality programs;
- (2) Program + Activities, comprised of students who regularly participated in both the programs and other enrichment activities; and
- (3) Self-Care + Activities, including students who had high amounts of time in unsupervised settings (especially hanging out with peers), low attendance at the programs, and moderate involvement in other organized activities.

A fourth group was comprised of students who had low program and activity involvement, and low amounts of unsupervised time. HLM analyses controlled for multiple personal and family characteristics (child gender and ethnicity, family income, family structure, maternal education, and maternal work status) as well as school-level variation and baseline performance on the outcome measures.

Analyses were conducted separately for the elementary and middle school samples. Effect sizes were calculated for the statistically significant findings. Effect sizes for the 2-year analyses. Elementary students who regularly attended the after-school programs across 2 years, either alone or in combination with other structured activities, posted significant gains in math achievement test scores, work habits, task persistence, social skills, and prosocial behavior, and reductions in aggressive behavior and misconduct, compared to students who were routinely unsupervised by adults after school. Students who participated in both programs and other activities also posted gains in teacher-reported academic performance relative to unsupervised students. Middle school students who attended the programs, either alone or in combination with other activities, posted gains in math achievement test scores and work habits, and reductions in misconduct and substance use, compared to their unsupervised peers. Effect sizes were on par with or larger than those found in studies of the impact of instruction by Teach for America teachers and class size reductions. These results will be discussed in relation to other findings of the potential benefits of participation in high-quality after-school programs.

SYMPOSIUM

Creative methods for researching teachers' teacher identity in higher education

Chairperson: Anne Nevgi, University of Helsinki, Finland

Organiser: Vesa Korhonen, University of Tampere, Finland

Markus Weil, University of Zurich, Switzerland

Discussant: Kirsi Pyhalto, Helsinki University, Finland

This symposium aims to explore in what ways visualisations, metaphors and stories can be used as an empirical research material when exploring university lecturers' teacher identity and teacher self-concept. The symposium will involve discussions how to develop research methods to explore teacher identity by applying metaphors, visualisations and narrative approach in research. The first paper discusses the theoretical background of a narrative approach and the use of non-active role-playing assignments. The second paper focuses on the use of photos to probe for unconscious thoughts about teaching, and how these helped the interviewees to view their professional identity. The third paper discusses the use of visualisations in exploring university teachers' identity and what kinds of emotions are related to teacher identity and teacher self-concept. With the help of metaphors we may bring visible our thinking, our principles of action and the delimitations which are related to it (Johnson & Lakoff, 1980; 1999). The use of images and stories can give for the teacher a reflective tool to examine more consciously conceptions concerning their teacher role in different settings, like in intercultural teaching and learning situations. Images and

stories could be seen as metaphoric tools for representing the conceptual, experiential and self-regulative knowledge of teaching practice (Bereiter & Scardamalia 1993; Korhonen & Koivisto 2007).

SYMPOSIUM

Narrative role-playing as a means of researching lecturers' roles within internationalisation

Vesa Korhonen, University of Tampere, Finland; Markus Weil, University of Zurich, Switzerland

Teaching and learning in higher education has been influenced by increasing Internationalisation and cross-culturality. For many lecturers factors such as teaching in English, mobility, international study contents and cultural diversity challenge beliefs about their role as teachers and create needs for changing learning environments. These complex shifts have also been reflected by innovations within research methodologies taking lecturers' roles into account. The main aim of this theoretical presentation is to discuss possibilities of a narrative role-playing methodology when making visible different influences of internationalisation for university teachers' self-concept and practice. The idea of this methodology is to investigate the capacity of university teachers regarding their role as actors in an international higher education environment. However, finding and forming suitable sample episodes for research setting seems to be a critical factor when using narrative role-playing.

Introduction

Internationalisation and increasing cross-culturality have had an impact on universities in recent years, especially on teaching and learning settings. University lecturers have to engage in new tasks in these global changes like facing increasing student and staff mobility, taking part in international teacher exchange programs, participating in international co-operation networks of research and teaching and increasing „internationalisation at home“, e.g. teaching in English and dealing with multi-national student groups. The practices of teaching and learning have to be re-thought in intercultural learning situations. Kraus & Sultana (2010) discuss how multifaceted internationalisation within higher education learning and teaching environments is and that research methodologies have to take that into account. Additionally the research target group of university teachers face the challenge of internationalisation as severely testing beliefs about their role as teachers and of the for changing teaching and learning environments (Bodycott & Walker 2000; Svensson & Wihlborg 2007).

The set of innovative research methodologies, that aim to make the different influences of internationalisation visible, is an important resource for investigation (Vulliamy 2004). In this presentation we discuss reflections on the lecturers' roles in internationalisation of university teaching and learning with the help of a narrative methodology. Narrative approaches have become more general and popular in qualitative research – also in university teaching and learning related investigations (Lyons & LaBoskey, 2002; Moon, 2010). The idea of this methodology is to consider the capacity of lecturers regarding their role as actors in an international higher education environment. "Narrative role-playing" as a methodology has traditionally two versions: active (drama) and non-active (writing) role-playing (Cohen, Manion & Morrison, 2000). In an active version the person is asked for example to improvise a character and perform it in practice. In a non-active version the individual may perform a certain role merely by reading a description of a social episode and writing a possible continuum for it. This non-active version could be called "narrative role-playing", because it is based on personal stories – in the research setting they are written according to research instructions. For the non-active version also pictures can serve as a basis for story writing and reflection. Pictures can more easily make emotions – like anger, fear, compassion, anxiety and others – visible in an imaginary social setting (Cohen, Manion & Morrison, 2000).

An essential characteristic of the narrative role-playing method is that it produces cultural knowledge and representations on the phenomenon under investigation. Typical for the method is also the variation of role-playing instructions (i.e. positive and negative episode). With variations of instructions the researcher can reach a fuller understanding on (sub) cultural meaning making. The personalisation and the use of the subjective point-of-view include a narrative perspective for the story writing. The methodology has also a comparative potential for reaching a broader understanding of different cultural settings, which are all dealing with the internationalisation of higher education from lecturers' perspectives. Theoretical and educational considerations Narrative role-playing stories seem to be an appropriate methodology for research, which aims to investigate thinking, emotions, social relationships and personal self-conceptions (Moon, 2010). It is also quick, fairly comfortable and considering the ethical questions in data collection. However, finding and forming suitable sample episodes for stories seems to be a critical factor when using the narrative role-playing methodology. The sample episodes are also a crucial point for a comparative approach with data collection in different countries. Nevertheless the stories enhance understandings what demands internationalisation bring to teaching practice, and how university teachers deal with this regarding the conception of themselves. Preliminary findings of our cases show how on the surface level internationalisation and cross-culturality might be realised in curricula, in presentations and discussions, in teaching methods, practical experiences and group

dynamics. However, in the deeper level it might facilitate another significant learning perspective, that it sensitises to other cultural backgrounds and leads to deeper reflection of a cultural dimension of the study content as well (Weil et al. 2010). This is noteworthy and it is something what Boyer (1997) called the scholarship of discovery, meaning a new form of scholarship in university teaching that would contribute to a knowledge of teaching and transform and extend it (Boyer, 1997; also Lyons & LaBoskey, 2002).

Future perspective

So far, there has been little systematic reflection or data-collection on the effect of internationalisation for one's role and self-concept as a university teacher. The narrative role-playing methodology seems to provide means to make visible the possible influences of internationalisation and cross-culturality in higher education. Narrative role-playing might be developed towards being a reflective tool in the pedagogical training of university teachers. The research findings and the role-playing methodology both have the potential to support university teachers who are concretely facing the demands of internationalisation (teaching in English, working with exchange students, planning to participate into international teacher exchange etc.) in the near future.

SYMPOSIUM

Photo-interviews as a source for understanding university teachers' professional identity

Mari Karm, University of Tartu, Estonia; Marvi Remmik, University of Tartu, Estonia; Anu Haamer, University of Tartu, Estonia

The current research aims at developing understanding of Estonian early career university teachers' concepts of teaching and professional identity by using photo-interview as a one possible research instrument. Our research is based on the assumption that visual research methods have given good results for investigating professional identity and underlying concepts. The presentation is based on qualitative research of 15 teachers who specialize in various scientific fields in higher education. On the basis of the analysis we found that photos provided a tool for both for us as researchers to probe for unconscious thoughts about teaching, but they also helped the interviewees to view their professional identity and formulate their teaching concepts.

Background and aims

Professional development depends on several factors including teachers' psychological, social and career life histories, which fashion their attitudes, expectations and behaviours and also opportunities for professional development (Day, 1993). Teachers' knowledge includes connections within and between different domains: knowledge about the teaching processes (content knowledge, pedagogical knowledge, students' learning) as well as knowledge of academic life and pedagogical development (including the development of self awareness of teaching and pedagogical issues) (McAlpine, Weston, Berthiaume & Fairbank-Roch, 2006; Postareff & Lindblom-Ylänne, 2008). The previous research has shown that it is very complicated to investigate individual's ideals, concepts, beliefs and values that influence the professional development, because very often people aren't aware of the concepts their professional development is based on. Using visual research methods have given good results for investigating professional identity and underlying concepts, as well for investigating several other areas connected with meanings in one's philosophical background (Leitch 2006, Schuller 2004, Taylor 2002, Weber, Mitchell 1996). Photo-interviews give richer data than just verbal interviews: photos focus on and guide the process of interview (Tucker, Dempsey 1991). Photos also give the impulse for interviewees to conceive and verbalize their understandings. The current presentation focus on two questions: how photo-interviews open different aspects of university teachers' professional identity and teaching concepts? What limits us as researchers have to declare during the data collection and analyzing processes?

Methodology

We used photo-interviews as a research method for studying formation of professional identity and teaching concepts of novice university teachers. First, 15 professional biographical interviews were carried out. These interviews focused on novice university teachers' studies and professional career. With the same participants the next step was a photo-interview. The participants were requested to find photos that illustrate the answers to the questions on learning, teaching and the image of a university teacher (for example: what is your vision about teaching? Who is the university teacher?). Indirect analysis was used in interpretation of photos: interviewees selected and interpreted themselves the photos that they had brought along. All interviews were transcribed. In the process of analysis, the interpretations and explanations of interviewees were analysed but we didn't analyse photos as an independent material.

Findings

The analysis revealed that novice teacher's interpretation of university teachers' roles and identity is vague and undefined. Ideas of ideal self, ought self and actual self could be in conflict. University teachers' conceptions of teaching are not clearly stated. Photo-interviews proved to be muddled. Controversial statements were given on learning-centred versus teaching-centred axis. Contradictory statements appeared while comparing the results of in-depth and photo-interviews. Photo-interviews brought forward that on the one hand novice teachers might aspire for learning-centred teaching; on the other hand they might feel insecure and have the need for approving feedback which could drive them towards teacher-centred teaching. Theoretical and educational significance Photos appeared to be a tool for both researchers and novice teachers. Researchers got an opportunity to get a glimpse of novice teachers' unconscious thoughts about teaching, but they also helped the interviewees to view their professional self and their values in teaching.

SYMPOSIUM

Visualisations as means to explore university teachers' teacher identity, and related affects

Anne Nevgi, University of Helsinki, Finland; Erika Lofstrom, University of Helsinki, Finland

University teachers' teacher identity and teacher self-concept is a relatively sparsely explored area. In our paper we aim to explore university teachers' teacher identity and teacher self-concept through analysis of visual metaphors which university teachers use for describing themselves as teachers. Furthermore, we explore the affective connotations teachers attach to their teacher identity. The data consists of university teachers' drawings of themselves as a teacher (N = 90). The participants are university teachers who have attended basic courses of university pedagogy. The data were content analysed. First, the drawings were classified according to the composition as a metaphorical versus a realistic composition and as a whole image versus a fragmented composition. Secondly, the drawings were classified by applying as the theoretical framework for analysis the concepts related to approaches to teaching. A wealth of emotions could be identified in the drawings.

Introduction

Teacher's professional identity and its development has been largely explored (e.g. Sugrue 1997; Beijaard, Verloop & Vermunt, 2000; Walkington 2005; Flores & Day 2006;). However, research focusing on the university teachers' teacher identity and teacher self-concept has been only scarcely explored. Teachers' self-perceptions as a university teacher

have been explored from the perspective of teacher identity (Kreber 2010), teacher self-efficacy (Dunkin, 2002), teaching self-concept (Roche & Marsh; 2002), and teaching self (Olson & Einwöhner 2001). Åkerlind (2005; 2008) has approached academics' professional identity from the perspective of growth and development as a researcher (2008) and as an academic (2005). Furthermore, there is a long research tradition focusing on teachers' conceptions of teaching and approaches to teaching (Kember & Kwan, 2000; Prosser & Trigwell, 1999). Sfard and Prusak (2005) see identity as narrative and they claim that narratives are the discursive counterparts of one's lived experiences. If we assume this to hold true, discursive expressions, such as personal stories and metaphors can serve as a window to teacher identity. According to cognitive metaphor theory (known also as a conceptual metaphor theory), our everyday language is filled in metaphors, and human thinking and understanding is deeply metaphorical in nature (Lakoff & Johnson, 1980). Metaphors are not only figurative or descriptive ideas, instead, they structure our thoughts and actions, and the ways in which we perceive the world and us. There is research evidence that metaphors can be used to access and analyse personal beliefs (Lßfstrßm, Anspal, Hannula & Poom-Valickis, 2010; Lßfstrßm, Hannula & Poom-Valickis, 2010; Saban 2010; Saban, Beyhan & Aslihan 2007; Martinez & al. 2001). Our aim is to explore university teachers' teacher identity by applying analysis of visual data which university teachers have produced by drawing pictures of themselves as teachers.

Method

University teachers participating in the basic pedagogical development courses at the University of Helsinki between 2006-2010 were asked to visualise themselves as teachers and to draw an image describing their visual idea about themselves as a teacher. A total of 90 drawings were available for this exploration. The drawings were collected as a part of the workshop "Myself as a Teacher", which introduces the participants to the course and each other. Drawings were scanned into digital format and content analysed. For each picture a detailed description was written as a first step in the analysis. The descriptions helped to identify the symbols teachers used and allowed the researchers to classify the drawings based on the basic themes. The teacher symbols and metaphors were listed and arranged in categories. The categories were rearranged according to what kind of approaches to teaching the metaphors in the category represented. The symbols and metaphors of emotions were identified and classified as positive, negative and contradictory emotions.

Results

Teacher metaphors visualised in the drawings varied from realistic and traditional teacher image towards metaphorical, abstract and fragmented compositions. The most common metaphor was an information-transmission/teacher-focused approach metaphor as a lecturer in front of students or a teacher leading a seminar. In these images teachers were transmitting and delivering information to students who were passively sitting and listening or who were not included in the pictures at all, in which case the focus was solely on the teacher's actions. Second category was labelled as a conceptual change/student-focused metaphor. In these images teachers were pictured as a member of a group working together, or travelling with the students. The teacher could also be pictured in a traditional lecturing setting, but with other symbols like think balloons and arrows included in the drawing. The focus in these pictures was on the interaction and communication with the students and not on the delivery of information to students. By dividing the compositions as whole picture and as fragmented images, the teacher identity could be interpreted as expressions of a whole-person teacher-identity or a fragmented idea of being a teacher. The emotions in the images expressed as positive emotions arousal and happiness, stable positive emotions, contemplation, curiosity, anticipation, and neutral emotions. The negative emotions were identified as feelings of loneliness and isolation, uneasiness, anxiety, and faintheartedness. The contradictory emotions included insufficiency, tension, sense of control, security versus insecurity, separation vs belonging, a mix of various emotions, and anticipation. Theoretical and educational significance of the research Visualisations, such as drawings can be used as research data in order to explore teachers' teacher self-concept. However, drawings as data are challenging to analyse and interpret. In order not to over interpret, data were quantified and compared to the results of the qualitative analysis. The teachers' drawings varied greatly and the teacher identity and teacher self-concept revealed to be multifaceted and involving diverse affects related to teaching. The teacher images revealed that many teachers saw that being a teacher meant to be a lonely and isolated deliverer of information and separated from the students. This finding is in line with the findings from the research tradition focusing on teachers' conceptions of teaching and approaches to teaching (e.g. Kember & Kwan, 2000; Prosser & Trigwell, 1999). Most of the teachers participating in pedagogical development courses see teaching as information delivery in which emotions are not desirable or even allowed. In pedagogical development courses the aim is to help teachers to become more aware of student learning and to adapt more a student-centred approach to teaching. Drawings can be used as a tool in pedagogical development courses to help teachers explore their underlying beliefs about teaching and themselves as university teachers.

SYMPOSIUM

Social Capital as a Resource in Heterogeneous Educational Contexts

Chairperson: Markus Szczesny, University of Goettingen, Germany

Organiser: Markus Szczesny, University of Goettingen, Germany

Rainer Watermann, University of Goettingen, Germany

Discussant: Robert Brown, Toronto District School Board, Canada

The theory of social capital emphasizes the influence of group membership, social networks, social norms and trust for individual and social outcomes. It is a well known phenomenon that social capital plays a significant role in the psychosocial and cognitive development of adolescents.

The aim of the symposium is to explore the impact of social capital in heterogeneous social settings focusing on childhood and adolescence.

Emmanuel Acquah, Koen Veermans & Kaarina Laine (Finland) explore structural aspects of social capital in childhood. Their study uses Social Network Analysis of friendship ties of ethnic minority and majority children to identify bonding and bridging networks. Robert Brown, Erhan Roula & Roula Anastasakos (Canada) investigate the interplay of social capital embedded in neighbourhood and school districts. Their key research question is: which is the more important context for school achievement: school or neighbourhood? Markus Szczesny & Rainer Watermann (Germany) analyze the differential role of structural and process-based features of families' cultural and social capital for reading achievement and social competencies within academic (Gymnasium) and non-academic (Hauptschule) secondary schools.

SYMPOSIUM

Schools Make a Difference..... And so Do Neighbourhoods

Robert Brown, Toronto District School Board, Canada; Erhan Sinay, Toronto District School Board, Canada;

Roula Anastasakos, Toronto District School Board, Canada

We are looking at a cohort of approximately 19,000 Toronto District School Board (TDSB) students in their second year of secondary school (Grade 10) who completed the provincial literacy test (as a requirement for graduation it is the only truly 'high stakes' test in Ontario schools). Toronto is considered one of the most diverse cities in the world: over three quarters of our secondary students are first or second generation immigrants to Canada, and Toronto schools and neighbourhoods include both the most socio-economically advantaged and disadvantaged in the province.

Many of these students attend schools in a different neighbourhood from where they live. We have information on which of the 117 secondary schools attended by, and 140 City of Toronto neighbourhoods lived in, for each student. We also have a wide range of survey, demographic, and school variables providing key information on school and neighbourhood social capital. Our key research question is which is a more important influence on achievement: school or neighbourhood? We would use HLM as our key regression technique.

Background and Rationale

The question of why some schools seem to be better able to produce more positive educational outcomes than others is essential in education. It has been pointed out (Raudenbush & Willms, 1995) that "school effects" usually refers to the extent to which attending a particular school modifies a student's outcome. The term "school effects" is found throughout educational literature, and numerous studies have been done to identify effective schools and factors associated with the success and failure of schools.

There seems to be growing consensus that comparing schools by raw achievement scores is unfair. The achievements that students bring with them to the school, often linked with their access to social and cultural capital, can affect subsequent performance. Although schools are held accountable for the performance of their students, there are many factors influencing student performance that are not within school control. Other social institutions also influence student motivations, engagement, and success; therefore school effects on student performance need to be detangled from the effects of the other social contexts in which students are embedded.

In general, school effectiveness studies have focused on student academic achievement in the context the school provides for the student but without consideration of the ecological and social context in which school itself is situated. In other words, there has been little research that looks at school and neighbourhood characteristics coincidentally.

The public board of Toronto, the Toronto District School Board (TDSB), describes itself as one of the most "multiracial, multicultural and multilingual school boards in the world", and there is much to support this. Toronto is the largest

city in Canada and the TDSB is the largest board in Canada and among the largest in North America. Over a quarter of students were born outside of Canada in more than 175 countries; over half speak a language other than English; and over three quarters belong to a visible minority group. In addition, Toronto has great social diversity with among the most socio-economically advantaged, as well as among the most disadvantaged, communities in Canada.

While this diversity has been embraced as a strength, it provides challenges in providing school-level achievement results for the TDSB's elementary and secondary schools. An additional challenge is the mobility of the TDSB population: close to two thirds of the oldest Grade 12 students do not live in the immediate vicinity of the secondary school they attend. Given that Toronto secondary students are not necessarily attached to the geography of their school, this provides an opportunity to look at test results from both a school and neighbourhood perspectives. This may allow the convergence of multiple theories of capital. Discussions of neighbourhood disadvantages are often rooted in social disorganization theory or epidemic theory, whereas explanations for the advantages of living in higher-status neighbourhoods usually follow social capital theory (Pong and Hao, 2007).

Neighbourhood studies have consistently found that neighbourhood characteristics have effects on individual outcomes even after controlling for individual and family effects but usually neglected the school specific outcomes; school research has found that schools have effects on student achievement after controlling for individual and family characteristics but usually neglecting the neighbourhood contextual effect. This research will attempt to bring neighbourhoods, schools and students into the same model using advanced multilevel analytical techniques. The basic assumption of this research is that neighbourhoods differ in their effect on the schools and individuals embedded in them.

Methodology

Close to 19,000 students in their second year of secondary school wrote the Ontario Secondary School Literacy Test (OSSLT) for the first time in Spring 2010. The OSSLT is Ontario's only 'high stakes' standardized test in that passing the test is required for graduation. While students may retake the test, passing the test the first time it is offered is highly connected to on-time graduation and post-secondary access. For the most recent administration, Ontario's Education, Quality and Accountability Office (EQAO) released for the first time student-level scores for all students—previously we knew only who passed or failed. This score will serve as the dependent variable of our analysis.

This information has been connected to the TDSB's Student Information System. Consequently we have a number of important variables including: School attended when the student wrote the test City of Toronto neighbourhood that the student was living in when the student wrote the test. There are 140 City of Toronto neighbourhoods, compared to 117 secondary schools: see the attached map for a related example (http://www.tdsb.on.ca/wwwdocuments/about_us/external_research_application/docs/CSSE%202005%20Paper--%20Secondary%20SSI.pdf) Demographic information (gender, age, region of birth, arrival date in Canada, home language) Special needs status of the student Responses of a detailed survey written by the student during the test administration School level information including socio-economic challenge of the school Information on the 140 City of Toronto neighbourhoods including socio-economic data from the 2006 Canadian federal census.

At the heart of much educational research are hypotheses about the influence of policies or practices implemented at the school or district level and their effect on processes occurring within schools. Such hypotheses are implicitly multilevel. Methodologists have warned that the use of traditional linear models to study multilevel phenomena can produce misleading results (Raudenbush and Bryk, 1986). Therefore, in this research the hierarchical linear model (HLM) method will be utilized which enable researchers to utilize mean achievement and certain structural parameters.

SYMPOSIUM

Bonding or Bridging: Examining the Social Capital of Ethnic Minority and Majority Children

Emmanuel Opoku Acquah, University of Turku, Finland; Koen Vermaans, University of Turku, FINLAND, Finland;

The essence of social capital lies in networks that allow members to benefit from resources shared by the collective. Often, networks are organised around some key interest shared by members of a group or based on socio-demographic factors such as gender, race, age and social class. Relationship among members (bonding) are more numerous and often more important than relationships between members and non-members (bridging). This study uses Social Network Analysis of friendship ties to identify cohesive subgroups and analyse their bonding (within group) and bridging (between groups) networks by estimating the proportions of friendship ties they give out (outgoing ties), the friendship ties they receive (incoming ties) and the mutual ties (reciprocal friendship ties). The participants were 748 children, 7-8 years old (boys=52%, girls=48%, language minority=8%) from 49 classrooms in the Turku Municipality of Finland. The results indicate that friendship ties were concentrated within groups (bonding) with less bridging ties. However, the languages differed in terms of ties received from within group and from outside group as well as ties given out to own group members but did not differ in ties given to members outside group. In addition, the languages differed in all categories of nominations for bullying and victimization except for nominating members of other groups.

Introduction

Friendship and social standing in the classroom have strong effects on a variety of outcomes in a child's life, within and beyond the academic realm (Gifford-Smith & Brownell, 2003). There is consensus among social developmental researchers that children's peer relations provide unique and significant contribution to their social and emotional development (Asher & Coie, 1990).

Theories of friendship have identified elements that attract two persons to one another including homophily, propinquity, status and reciprocity (McPherson, Smith-Lovin & Cook, 2001). Homophily and propinquity have been found to produce high racial homogeneity in social networks (Feld, 1982). Of course, individuals come together to form groups when they share a common interest such as sports, debating etc. The reasons why people join groups are multifaceted. One such reason that has been highlighted in recent studies is that, by investing into social ties, individual actors pursue social capital (Frank & Yasumoto, 1998).

In this paper, we extend this view by investigating the social structure of cohesive subgroups within the classroom and how language background influences one's position within the group. Our model focuses on the child as an active actor who invests into social ties with members of his or her own subgroup (bonding) while establishing ties with members of other subgroups (bridging) in their quest for social capital.

Data

Data stems from the Origins of Exclusion Project, a longitudinal study of Finnish children's risk of social and academic exclusion in childhood (Laine, Neitola & Auremaa, 2003). This study uses data from 748 7-8 years-old children (boys=52%, girls=48%, language minority=8%) from 49 classes at 35 public schools. The mean class size is 15.3 (SD=3.56). In the spring of the first school year children were asked to rate their interest in playing with each of their classmates while being shown a class picture. Rating alternatives were: "always (Friendship), sometimes (Neutral), or never (Exclusionary) like to play. The resulting square matrix forms the basis for all analyses.

Analysis

A two step approach was followed to conduct our analysis. First, Frank's (1995) Klugefinder algorithm was used to identify cohesive subgroups in classrooms by looking at the social structure in terms of friendship ties within and between subgroups. Frank's algorithm uses a stochastic definition of cohesion; emphasising ties within subgroups relative to actors' propensities for engaging in ties and sizes of subgroups. For running the algorithm, we used ties based on both children's willingness to play with each other; either as "willing to play with sometimes" or as "always like to play with". Group membership is then categorized into "same group" and "other group" subgroup relative to the individual to show the boundaries between bonding and bridging ties. These results are then used to perform an Analysis of Variance (ANOVA) in which language background is used as independent variable for within group and across group friendship ties, within group and across group nominations for bullying, victimization, exclusion, and social withdrawal.

Results

Overall, the results indicate that both majority and minority students receive and give out more friendship ties to members of their own group than they receive from and give out to members of other subgroups but differ in terms of ties received and given out across all directions of flow of friendship ties.

When looking at bullying, the languages differ. Majority students receive less nominations from within and from outside one's own group whilst minority students received more nominations both from within and from members of other groups. Further, the findings indicated that majority students received fewer nominations for victimization

within and from outside one's group than did the minority indicating that minorities were more susceptible within the subgroup.

In other results, minorities received and gave out more exclusionary nominations within own group than did the majorities. They also received more from members of other groups but gave out less in return whilst a majority student received less but gave more to members of other groups. The languages did not differ in terms of nominations received within one's group for social withdrawal but differed in what they gave out to group members (minorities gave more). Considering other groups, minorities received more but gave out less whilst majorities received less and gave out more.

Discussion

We drew on a developing theory (Frank & Yasumoto, 1998) to argue that children pursue a single resource, social capital, by engaging in close social ties with their peers. The findings suggest that minorities are 'introverts', they focus more on their own group and less on the other group(s). Favours are not returned though so they are less well embedded/nested in their own group. Thus, although not excluded, they are in 'weak' positions (limited social capital) compared to their majority peers. Their 'weaker' position in the own group is also illustrated by the fact that they are more often identified as bullies not only from outside their own group, but also from within their own group. And probably in relation to their own 'weaker' position, they seem also more aware of, or willing to qualify, others in their own group as victims. Our findings underscore the basic fact that the minority student has limited social capital within the classroom and this has been found to have serious implications for their social and emotional wellbeing as well as academic success in school.

SYMPOSIUM

Effects of Social and Cultural Practices on Educational Outcomes in Different Academic Tracks

Markus Szczesny, University of Goettingen, Germany; Rainer Watermann, University of Goettingen, Germany

The relationship between students' social background and their educational outcomes is a rather universal phenomenon. In stratified school systems with different school types in secondary school, the link between structural features of the family background (socio-economic, level of education, migration status) and educational attainment was shown to be particularly strong. For Germany, it was shown that most effects of family background structures are mediated by process-based features of families' cultural capital (cultural practices), whereas process-based features of families' social capital (social practices) appear to play a minor role. However, the contribution of such family characteristics on educational outcomes within different school types in stratified school systems as well as their role for the acquisition of social competencies has rarely been studied together.

Drawing on data from 15783 students of the German extension of the PISA-2000-study and taking into account mechanisms on the individual and the institutional level we analyzed the relationship of structural features of the family background, process-based features and educational outcomes (reading literacy and social competence) by means of multilevel multi-group structural equation modeling.

The relationship between students' social background and their educational outcomes is a rather universal phenomenon. In stratified school systems with different school types in secondary school, the link between structural features of the family background (socio-economic, level of education, migration status) and educational attainment was shown to be particularly strong. For Germany, it was shown that most effects of family background structures are mediated by process-based features of families' cultural capital (cultural practices), whereas process-based features of families' social capital (social practices) appear to play a minor role. However, the contribution of such family characteristics on educational outcomes within different school types in stratified school systems as well as their role for the acquisition of social competencies has rarely been studied together.

Drawing on data from 15783 students of the German extension of the PISA-2000-study and taking into account mechanisms on the individual and the institutional level we analyzed the relationship of structural features of the family background, process-based features and educational outcomes (reading literacy and social competence) by means of multilevel multi-group structural equation modeling.

Theoretical framework

Our theoretical framework combines elements of capital theory (Bourdieu, Coleman), a bio-ecological perspective (Bronfenbrenner) as well as – with regard to varying learning environments in different school types – an institutional perspective on development.

In Bourdieu's theory of capital the social reproduction can be explained by family transmission processes. While Bourdieu sees social capital among the members of groups, Coleman suggests social capital not only on the availability of social networks. At the individual level, Coleman locates social capital in the structure of mutual expectations and obligations that are accumulated as trust or in the availability of relevant information. On the collective level social capital is seen as a social norm and their effective sanction.

Unlike Bourdieu and Coleman, Bronfenbrenner's theory of bio-ecological development includes individual forms of interaction with the environment of an organism to be designated as 'proximal processes'. Bronfenbrenner proposes to distinguish between the development of 'dysfunctions' and 'competencies'. While dysfunctions are understood as manifestations of social adjustment problems, competencies would be the ability to demonstrate knowledge and skills. Proximal processes are expected to have an effect on competencies in advantaged environments and on behavioral dysfunctions in disadvantaged environments.

Beyond curricular competencies school is also relevant for the acquisition and development of socially competent behaviors. In constant interaction with classmates, fellow students and teachers students can test their behavioral repertoire. For their social behavioral offers they immediately get feedback in the form of praise and blame, acceptance and rejection. Social competence is a complex combination of skills, ability and knowledge, attitudes and values. Furthermore it includes the basic capability to the decoding and interpretation of social information.

In Germany students are assigned to different school types already at the age of ten, where the lowest (non-academic) track and the highest (academic) track differ remarkably: Even though these tracks are comparable in quantitative terms (i.e., in the number of lessons timetabled), they differ markedly in qualitative terms. Specifically, there are differences in the compositional (e.g., mean achievement, parental SES) and institutional (e.g., lesson design, curriculum, teacher training) characteristics of the different tracks. The academic track seems to provide qualitatively better conditions for academic success: the learning group is positively selected in terms of social background and cognitive abilities, instruction achieves higher levels of cognitive activation, and there is less disruption in the classroom.

Research questions

Are the effects of structural features of family background on educational outcomes mediated by families' social and cultural practices?

1. Specifically, is there an independent effect of social practices on the development of social competencies?
2. Can differential effects of cultural and social practices be found in non-academic (Hauptschule) and academic (Gymnasium) schools? On the one hand we expect a positive association between cultural practices and reading literacy in academic schools. On the other hand, we expect a positive association between social practices and social competencies in non-academic schools.
3. Will the individual effects of cultural and social practices remain stable after controlling for compositional effects?

Method and Design

For the analysis, data from the national extension of the German PISA 2000 study was used. Overall, the sample consists of 15783 students that were 15 years old (10115 students from academic schools (Gymnasium) and 5668 students from non-academic schools (Hauptschule)). Missing values were imputed.

Multilevel multi-group structural equation models are computed. In a second step the analysis is reproduced with propensity-score matched data to estimate compositional effects.

Results

A random intercept model was specified, so the intercepts may vary between classes. The model had a very good fit (χ^2 [df = 323] = 3598, CFI = .96, TLI = .94, RMSEA = .036, SRMR = .032).

As was expected, at the individual level a mediating effect of cultural practices on reading achievement was only found in academic schools. A significant relationship between social practices and social competence appears in both, academic and non-academic schools. For non-academic schools there was no influence of cultural practices, but an effect of social practices on reading achievement. The individual effect of familial social and cultural capital remains stable even under the control of compositional effects.

Analyses with propensity-score-matched data indicate the stability of the findings: Although the differences between academic and non-academic school students regarding their family background are (statistically) eliminated, the differential effects of the school form persist.

Conclusions

Educational outcomes are mediated in a significant way through process-based features of families. The parental social practices in particular have an effect on the development of social competencies. The influence of cultural capital was only found in the academic-track. Relevant for the mediating effect of family capital on reading achievement and social competence are the differential school environments represented by less or more demanding school types.

SYMPOSIUM

Knowledge formation and use of language

Chairperson: Jesper Haglund, Linköping University, Sweden, Sweden

Organiser: Elsie Anderberg, Jonköping University, Sweden

Discussant: Tamer Amin, Lebanese American University, Lebanon

The problem focused in the present symposium is the function of language used in the development of (personal) knowledge: the epistemological role of language use in learning. The current dominance in socio-cultural research on learning of focus on the function of language use in communication and interaction has to some extent led to the neglect of inquiry into the interplay between language use and content of subject matter in terms of agency. Individuals' reproduction and the tendency to use scientific terms without any deeper understanding is nevertheless a well known problem in teaching and learning. The number of disciplinary concepts and vocabulary, as well as the various ways in which these concepts interrelate, increase dramatically in interdisciplinary contexts. This, in turn, is a serious challenge to pupils' and students' knowledge formation. The main aim with the symposium is to present and discuss theoretical and methodological approaches, as well as empirical findings relating to the research field, considering both individual, socio-cultural and disciplinary/theoretical aspects of language use, in relation to knowledge formation.

SYMPOSIUM

Resistance to Conceptual Change – the Role of Language

Tommy Tang and Tim Robinson, School of Economics and Finance, Queensland University of Technology, Australia

A lecturer often takes key concepts for granted in their organisation and presentation of a topic when the concepts can be quite problematic for the students. While students can reproduce and apply the concepts in academic settings, studies of student learning show that many still possess serious misunderstanding about these concepts. And they often relate to lay conceptions in everyday life situations. It is therefore important that we identify barriers to their conceptual acquisition. The paper reports on an empirical study of commencing economics students' understanding of the fundamental concept of efficiency. The data are written responses taken from 90 exam scripts to a structured final exam question. Phenomenographic analysis of the data reveals six conceptions of efficiency with five of them representing misunderstanding of the concept. These six conceptions are related but distinct, each dealing with a critical aspect of the process of production and exchange. Further examination of the structural and referential aspects of these misunderstandings provides insights into why and how students' everyday usage of the language can become barriers to understanding of this technical concept in economics. The results inform teachers to better design learning experiences for conceptual development.

Summary

Studies across disciplines at secondary and tertiary levels have shown that students can amass enough knowledge to perform well within the assessment standard but still possess a lot of misunderstanding about the topic. For example, students who have successfully completed university physics courses still hold the laymen's view that that on release, heavy objects will reach the ground before lighter ones because "heavy things have a bigger force" than light objects (Biggs 1989), and that an object travelling at a constant velocity implies a resultant net force acting in the direction of

motion (Marton 1988). In economics, students, who have passed economics 1, still believe it is the inherent value residing in a product that determines its price (Dahlgren 1997). In another study comparing the use of analytical skills and economics knowledge in the solving of economics problems, Voss et al (1986) found that students with formal training in introductory economics (the novice) and those without (the naïve), demonstrated similar economics knowledge and informal reasoning skills. The novice performed better than the naïve only on questions involving the use of technical knowledge. In the case of non-technical economic issues that provided opportunities for the novice to demonstrate economic knowledge acquired in formal training, no such knowledge transfer took place, and their answers were not qualitatively superior to the naïve. These findings suggest that to these students, the learning in the academic world has little impact on their thinking in real world in which they function.

In student learning research, students are found to possess multiple conceptions of a concept, and they can shift from one conception to another in different contexts to explain a phenomenon (Pong 1999). This leads educational researchers to propose that learning, as a process of conceptual development, is not a simple process of taking in a new conception, and replacing it for the old one. If we want to facilitate conceptual development and knowledge transfer, we need to find out what students have understood (or misunderstood) about a topic or concept, how they have come to acquire the various ways of making understanding it, and what the barriers are to students' conceptual development.

The paper reports on the findings of an empirical study of the ways economics students understand the concept of efficiency (or allocative efficiency as used in many economics textbooks). The data are written responses taken from 90 exam scripts to a structured final exam question in an introductory economics course. The question assesses students' understanding of the conduct and performance of a market under different market conditions. Phenomenographic method (Marton 1981) was used to analyse the data to investigate students' interpretations of the concept of efficiency from a second order perspective. Six conceptions of efficiency emerged from the data with five of them representing misunderstanding of the concept. These six conceptions are related but distinct, each focusing on a different, critical aspect of the process of production and exchange. Further examination of the structural and referential aspects of these misunderstandings provides explanations as to why and how students acquire various misunderstandings. For example, some misunderstandings arise out of interference from the everyday usage of language, where students replace the technical meaning of a term with their everyday life interpretations of it. Furthermore, the study shows that a student's misinterpretation of the concept can be 'meaningful' and 'logical' from their perspective. Thus, language interference can explain the resistance to conceptual change, and hence, inertia of student misunderstandings. This inertia was also found to be due to the student's ability to shift and/or distort the meaning of a concept to justify their explanation of the reality.

This paper argues that the knowledge of student learning product obtained from research utilising the second order perspective can inform teachers to better structure learning experiences for the facilitation of conceptual change and knowledge transfer. The implications from this study for teaching and learning apply to other disciplines.

SYMPOSIUM

The role of the referent in the history of science and in science education

Haglund, J., Strömdahl, H., and Jeppsson, F., Linköping University, Sweden

One way of approaching the interplay between language use and content of subject matter is to use methods from linguistics and philosophy of science in the analysis of central terms in science. Reference of concepts, an important question in the philosophy of science, has for a long time not been on the agenda in educational research. Taking a realist stance on the incommensurability controversy has meant that the referent is generally taken for granted as being invariant. Thus, the invariance and the current referents of concepts are not even explicitly stated in educational scientific studies on conceptual change. The present piece of research aims at demonstrating the importance of discerning and being explicit about the referent. To illustrate this claim, we use the example of the change of the meanings of central terms in the history of thermodynamics, particularly 'heat' and 'entropy'. Resting on post-Kuhnian research on incommensurability we concur with the idea that the communication between earlier and later uses of a term in consecutive theories is maintained by a continuous chain-of-reasoning against a background of accumulated knowledge. In that vein the incommensurability problem is a result of comparing the endpoints of a long process and not taking into account the fine structure in between. Adding the idea of science as the endeavour to explore 'the world as perceived', we show that the referents of 'heat' and 'entropy' have changed throughout the historical progression many times.

From an educational point of view it is essential to sort out how scientific terms are attached to 'the world-as-perceived' (cf. Andersen, 2001). One way to analyse this connection is to identify three semiotic elements of a term: word, concept and referent. Very briefly, a concept may be regarded as something that is in a person's mind, a word is a symbol for the concept and the referent is the corresponding entity in 'the world-as-perceived' outside ourselves. The aim of the present piece of research is to establish a 'working definition' of what a referent for physical quantities is and to bring to the discussion the following questions: Do the referents of the terms 'heat' and 'entropy' change or remain invariant during the historical development of the corresponding concepts? Does the referent of 'heat' change or remain invariant when a student makes a change from an everyday conception of 'heat' to the contemporary scientific concept of 'heat'?

Strömdahl (2009, under review) has proposed a two dimensional semantic semiotic analysing schema (acronym 2-D SAS), in order to analyse science terms for educational purposes. The schema shows on the horizontal axis the semiotic elements word, concept and referent. The vertical axis depicts semantics with the different meanings of a term. In this respect, a single term may correspond to several different, but related, concepts and referents, which may be used in different contexts and cultures. In the present study, 2-D SAS is used for an investigation of the character of referents for science terms. Literature on the issue of reference in the fields of history and philosophy of science, linguistics and science education has been reviewed and terms from the domain of thermal phenomena are used as examples.

Kuhn (1962) launched the idea that the scientific theories before and after a revolutionary change are incommensurable. As a consequence, a common standpoint in science education has been that the referent must remain unchanged, in order to save a realist assumption and therefore the focus had been exclusively on the conceptual domain. As a contrast, in philosophy of science the question of reference is an ongoing issue, and, in line with Arabatzis and Kindi (2008), we will argue that it may be interesting also for science education. Kripke (1972) and Putnam (1975) developed the 'causal theory of reference' partly as a response to Kuhn, but also as a criticism of prior views on reference, where reference of a term was assumed to be fixed by necessary and sufficient conditions. Kripke and Putnam claim that reference in the physical world of a term may be fixed by linking the term to the cause of an event in a baptizing moment. In this way, once a term is coined, there will always be a link to its referent in the physical world, regardless of theory changes about it. However, also the causal theory of reference has been criticised, primarily in two respects. First, it does not account for the 'qua problem', i.e. when you point to an object, phenomenon, etc., and claim that 'this is a giraffe', how can you convey that you have in mind the animal species, and not the classes of mammals or tall objects? Second, it does not provide a mechanism for how words may lose their reference. For example, in science the term 'caloric' was abandoned when it was found to lose its explanatory power of physical phenomena and therefore lost its reference.

Shapere (1989) claims that the communication between earlier and later uses of a term in consecutive theories is maintained by a continuous chain-of-reasoning. A term is not determined by some essence or necessary and sufficient conditions fixed once and for all, but by ascribed properties that are changing over time due to the scientific development in the form of empirical evidence from our interplay with the 'world-as-perceived'. The provisional character of scientific advances admits a seamless chain of reasoning, making incommensurability an obsolete feature independent of the change of concept and referent of a term. Hence, there is no objection any longer to the possibility for the referent of a scientific term to change when the concept changes. As examples, we show that the referents of 'heat' and 'entropy' have changed throughout the historical progression many times.

Andersen and Nersessian (2000) argue that theoretical concepts (like heat) cannot be pointed out in isolation, but rather as interacting participants in complex structures, understood in relation to each other by a theory or a law. This may be seen as an example of the 'qua problem', in that if you point to a model of particles in motion in a box and declare that 'this is entropy', how can a learner know what aspect of the model you have in mind? As a response to this challenge, in our views, the referent of a physical quantity is an aspect of a scientific model of the world-as-perceived, against a background of a particular theory.

Amin (2001) shows that laypeople share conceptions of heat, including heat as a verb, related to the process of causation of hotness, and heat as a noun, typically a spatially localised entity that is the causal source of hotness. In education, the challenge is to make the students expand their repertoire of interpretations of the term heat with the inclusion of the scientific ones. Carey (2009) states that if "our concepts of real entities (in contradistinction to fictional ones) are not appropriately connected to the world, they would not support learning about it." In other words, the establishment of the referent of a concept is crucial in the learning situation. In the case of heat, the intended referent would be an aspect of a model of two systems in thermal contact.

Learning to understand

Elsie Anderberg, Jönköping University, Sweden; Annika Åkerblom, Lund University, Sweden; Lennart Svensson, Lund University, Sweden

The aim of the paper is to introduce, describe and discuss a theory of learning to understand. The different ways that individual learning and understanding are described in various research traditions reflect differences, regarding how relationships between object, content, language and meaning are treated. In this paper, these entities are described as components in the intentional activity of the individual, having the character of internal relationships. These relationships are constituted in the process of discernment, through factors such as: variations, seeing and seeing-as, figure-ground, and part-to-whole relationships. These factors will be described as they have been developed in phenomenographic research on learning. They are related to an expressive conception of language meaning, developed in the intentional-expressive approach. This approach has been used in research on the epistemological role of language use, in regard to the function of language use in developing and expressing understanding of the object referred to. Research carried out in different subject matters, educational contexts and involving learners of different ages has shown that the constitution of relationships between the components object and content need to be related to the functions of key expressions' meanings in terms of agency. Such relationships need to be examined more thoroughly than has usually been the case. The proposed relational theory on learning to understand will also be related to research on conceptions, and approaches to learning and studying in phenomenography. The discussion will focus contributions of the theory regarding theories on learning in conceptual change and socio-cultural research.

How understanding of complex knowledge is developed is a central question in different perspectives and theories on learning. In theories on conceptual change, there is an analytical approach, primarily focusing competition between conceptual systems involved in knowledge construction (Vosniadou 1994). In socio-cultural theories (Wertsch 1990) there is a discursive approach. If individuals learn to appropriate patterns of talk in a specific discourse, it is considered that they also construct knowledge. These theories have in common that it is to some extent assumed that an identity exists between; language and content, and/or between content and object or/and between word and meaning. At the same time, the question of how to deal with the common reproduction of "knowledge" in education constitutes a fundamental challenge. Instead of seeing these issues separately, considering them together, as central components in the learning activity, allows us to address these questions more effectively. We need to consider how the relationships between these components are constituted and how this functions to build up the central core of learning. The aim with this paper is to introduce and present a theory on learning, where content, meaning, language and object are treated as important components.

The aim is formulated on the basis of the strong need to describe learning activities that deal with the problem of developing understanding of complexities from an individual point of view. The theory is an alternative to already well established traditions and theories in research on learning. Its contribution concerns shortcomings in those theories when focusing the relationships between language meaning and content of understanding. The main contribution of the theory concerns the epistemological role of language use, where the relationships between word meaning and content of understanding seem to play an more important role. The dynamic, contextual and ambiguous function of language meaning used in expressing content of understanding must be better accounted for in terms of the agency of the learner. The main point of departure is research developed both within phenomenographic perspective on learning (Marton 1981) and the intentional-expressive approach on the role of language in learning (Anderberg 2000; Anderberg et al. 2008).

Phenomenography as a perspective on learning involves a relational view of understanding parts of the world: "objects" referred to. Learning to understand is seen as an intentional activity involving the constitution of internal relationships (Svensson 1997). Learning is always about something, is directed and has to be understood in terms of the activity of constituting relationships, mainly between the components content and object, through the factors in the process of discernment; variations, seeing and seeing-as, figure-ground and part-to-whole relationships. These factors will be described in the paper, regarding how they have been developed in phenomenographic research on learning. In phenomenography, these factors in the intentional activity have mostly concerned the relationships between an object and content of understanding. In the intentional-expressive approach on intentional activity these factors are captured also with regard to language use.

The intentional-expressive approach to language use in learning was developed in phenomenography, based on the need to also focus how the intentional activity is constituted in learning, with regard to the function of language use in developing and expressing understanding of complexities. Research carried out in different subject matters,

educational contexts and ages of learners using the Intentional-expressive approach has shown that the constitution of relationships between the components object and content need to be related to the functions of key expressions and with which meanings these are used. How these functions are developed appears to be a central aspect of how the object referred to is constituted, in terms of content of understanding. In phenomenography, this is described as "ways of experiencing" or "conceptions". The factors described in phenomenography as involved in the intentional activity of the learner therefore also need to involve the intended language meaning used. This is important, since this knowledge can be used to minimize the use of language in reproducing "knowledge". The paper will draw on these results when outlining and suggesting a theory of learning to understand.

The intentional-expressive approach captures that language meaning used is expressing understanding, compared to the common view in research on learning that language meaning is representing (Vosniadou 1994) or mediating understanding (Wertsch 1990). In the paper, we will present empirical evidence, showing how pupils and students have major problems in their learning activity, regarding the function of language use. This particularly affects how the relationships between word meaning and content are constituted, illustrated by the base line of the Broken triangle (Anderberg et al. 2008).

We are then able to describe how understanding develops, also involving the use of language in the intentional activity. In the paper, the interplay between the components; expression, meaning, content and object will be clarified in terms of the agency of the learner. The paper will in detail describe what is meant with these components, and how internal relationships between them are constituted in the process of discernment, through factors such as; variations, seeing and seeing-as, figure-ground and part-to-whole relationships.

This paper on a relational theory on learning to understand will conclude with discussions of the theoretical and educational implications, concerning the common problem with reproduction in the learning activity. The theoretical implications will be discussed particularly regarding theories developed in conceptual change and socio-cultural theories on learning. Also, the theory will be related to different conceptions of understanding and research on conceptions of learning developed in phenomenography.

SYMPOSIUM

Teachers' work lives: Australian and international perspectives

Chairperson: Judy M. Parr, University of Auckland, Faculty of Education, New Zealand

Organiser: Christine Gardner, University of Tasmania, Australia

John Williamson, University of Tasmania, Australia

Discussant: Debra Myhill, Exeter University, United Kingdom

The studies described in this panel of papers focus chiefly on investigations of the perspectives and experiences of work lives of teachers and/or principals in two Australian states, New South Wales and Tasmania. The papers adopt a variety of foci. The first three studies each were conducted in one of two Australian States: the 'fractured' experiences of many beginning teachers; challenges faced by principals (head teachers) in remote schools; and, school leadership displayed by teachers during the course of one major curriculum change. The fourth paper reports data and findings from a 10-country study of teachers and principals' perspectives of teachers' involvement in responsibility-taking in school-based change. This final paper addresses two aspects of the study (1) data and findings from the Australian study, and (2) broader findings from the entire 10-country study. Use of qualitative and quantitative methods in each study enables the authors to report findings that are statistically significant and to provide rich data gathered from participants.

SYMPOSIUM

Beginning teachers: Great expectations, unfulfilled dreams

Marilyn Pietsch, Charles Sturt University, Australia

This presentation explores the work lives of beginning primary teachers in New South Wales (NSW), Australia, where a majority of beginning teachers enter their chosen profession in short-term employment as substitute or “casual” teachers. Initial employment situations vary significantly in the level of fragmentation in terms of the duration, location, status and expectations of responsibility of teachers’ employment.

Research has shown that the context in which beginning teachers enter the profession affects significantly the way in which they are able to extend their professional knowledge base (Grossman, 1990), acquire professional competency and negotiate professional identity. This paper suggests that the concept of “context” requires some adaptation in order to take account of contemporary employment circumstances now may include accommodating often daily changes in the schools and classrooms where teachers work.

This presentation focuses on how new primary teachers in both secure and fragmented employment contexts conceptualise their personal understandings of teaching. It examines the influence of differentiated contexts on teacher progress through the early phases of professional competency (Day, Stobart, Sammons, & Kington, 2006) and on the interplay of professional socialisation, practical classroom teaching and both formal and informal (Eraut, 2004) teacher learning. It considers the effect of differentiated employment contexts on the integration of personal and professional identity, on the level of teacher satisfaction and resulting professional commitment (Boreham, Gray, & Blake, 2006) and addresses the concomitant implications for retention of graduates in the teaching profession (Ewing & Manuel, 2005).

Aims:

The aim of the research on which this presentation is based was to examine the effect of differentiated employment context on the development of beginning primary teachers’ knowledge of teaching during the first two years in the profession. It aimed to extend the conception of the knowledge base of teaching beyond constructs of personal practical knowledge (Clandinin & Connelly, 1995) to include knowledge of the context of teaching and knowledge of self-as-teacher. The effect of differentiated employment circumstances on the development of each of these knowledges formed the primary focus of the research. In addition, empirical research was directed towards developing a more nuanced understanding of models of teacher development which related phases of experience, represented by time in teaching to stages of development of teaching expertise context (Berliner, 1995) and the effect on developmental progression of the employment context.

Methodology:

The study utilised both qualitative and quantitative methods of data collection and analysis. A collective case study (Stake, 1995) of the perceptions of eight beginning teachers provided data from a focus group interview and three individual, semi-structured interviews per participant over the following two years. The question-response format was complemented by classroom observation, stimulated recall from a photographic record of classroom events, document and artefact analysis and participant completion of graphic organisers. Case study data was complemented by numerical and non-numerical data obtained from a postal survey-questionnaire of beginning primary teachers (n=241) employed in public primary schools across the state of NSW.

Findings:

The findings of this research were as follows:

- Teachers who were employed in permanent positions, in one school, and on their own class for the first two years of teaching were able to acquire personal practical knowledge of teaching, participate in professional socialisation and negotiate and strengthen their professional identity. Their level of knowledge development was well beyond that of the novice stage by the end of the first year.
- Those whose employment remained fragmented?holding casual status, working in many schools, and teaching other teachers’ classes rather than working?were unable to extend their professional knowledge base. In many cases, they perceived themselves to have lost some of the skills they had demonstrated at the conclusion of their initial teacher education, and they remained “stuck” at the novice stage throughout the initial two years.

Significance:

Theoretical significance

The findings of this research suggest that differentiated employment experience, as an aspect of the contemporary context of career entry, led to significantly different levels of practical knowledge acquisition, professional socialisation, professional satisfaction and personal commitment to the profession and, in turn, to varying personal conceptions of teaching, schools and self-efficacy as a teacher, as teachers in fragmented or cohesive teaching situations responded very differently to the exigencies of their teaching situations.

This research expands existing studies of the work lives of beginning teaching by adding contextual detail from an Australian setting to the investigations of other researchers such as Bullough (1992) and Huberman (1993). It suggests that British, North American and European models of "learning to teach" are not immediately transferable to the current context in NSW, Australia, where fractured initial employment? that is, employment as a casual teacher? denies a majority of beginning teachers a supported, structured and sequenced induction to the profession, a situation which remains largely unacknowledged by employing authorities or researchers in Australia and elsewhere. It provides evidence that the employment context itself, as the location of early teaching experience in both place and time, is the site wherein the processes of professional socialisation, professional identity formation and practical knowledge acquisition occur and as such, is a critical factor in the development of knowledge and competence in early career.

In addition, this study moved beyond many present and previous conceptions of the process of learning to teach and of the concepts of experience and expertise and explored the extent to which the presumed nexus between experience and the development of expertise was disrupted by appropriate and cohesive or inappropriate and fragmented initial employment experience.

Educational significance

The above findings suggest that there are implications for teacher practice, especially in the work of schools in mentoring new teachers; for educational policy in relation to accreditation and employment of new teachers; for teacher education in preparing students adequately for a multiplicity of teaching roles; for systems in maintaining teaching quality; and for workforce planners in addressing issues of attrition and retention of beginning teachers.

SYMPOSIUM

Change and decline in remote Australian towns: Changing work lives of remote area school principals

Bruce Pietsch, University of Tasmania, Australia

This study elicited and analysed perceptions of principals in remote central schools in Australia's most populous state, New South Wales. In NSW, central schools enrol all ages of primary/elementary and secondary students and nearly all are located in remote inland areas and can be up to 1000 km from the major population centres in NSW. Typically, they require up to two hours driving to access the facilities of the nearest, small provincial town or city. The study investigated the leadership practices and work lives in the context of both remote area decline and devolution reforms of government schools in NSW. A global trend to decentralisation of public school systems has been reflected in Australian states and territories. Reasons provided for this devolution include reduction of costs and limitations of bureaucracy; increasing the responsiveness of public (government) schools (Scott, 1989) and educational advantages (Caldwell & Hayward, 1998). The study invited remote area principals to share their perceptions of the trend to school-based management and the effects of this trend on the length of time they worked and the nature of their work.

Aims:

International studies (PricewaterhouseCoopers, 2001; Smith, Brice, Collins, Matthews & McNamara, 2000) and studies in other states in Australia and in New Zealand (Gardner & Williamson, 2004; Hatton, 1995; Sahid, 2004; Saulwick Muller Social Research, 2004; Whittall, 2003) have pointed to an increase in stress and in hours worked. This study aimed to compare and contrast the work lives of the remote area principals with the work lives of principals in other areas and jurisdictions.

Methodology: A mixed-mode [qualitative and quantitative] approach (Burns, 2000) was utilised. A state-wide survey of central school principals in New South Wales in 2006 and a series of case studies of 12 of these principals (18% of this classification of principal) were conducted. This research focused on the principals' perceptions of their flexibility in their decision-making and perceived benefits in the quality of teaching and educational outcomes for students. All 64 rural central school principals were invited to complete the survey. Completed surveys were received from twenty-seven principals (42% of those sent surveys). Of these 27 principals, 12 were invited to participate in interviews. The survey was used to seek principal's perceptions of which of 28 typical tasks performed by principals contributed to their view of the ideal self-managing school and which of these tasks were carried out to meet department of education expectations. The interviews were used to investigate in more depth themes that emerged from the survey data.

Findings: The paper will report some of the data from the study. It will include: (i) The survey responses indicated that principals' self-perceptions of their duties (endogenous pressures) combined with the principals' perceptions of the employer's expectations (exogenous pressures) would combine to create a total pressure on principals to work significantly longer hours. (ii) The increasing pressure on principals and schools to be the central location of support in communities in which population and services were declining. In many cases the school was the only location of support to its community. (iii) Significant changes in the social life of the population brought about both by generational change and by demographic changes in the population, for example, people choosing these areas because they could afford to live there. One principal spoke of the "urban poor" and the "socially displaced" as comprising the school-age population. The principals mentioned physical and social decline and violence and child protection issues frequently. (iv) Tensions between expectations of the up-to-the-fifth-generation inhabitants and the newer arrivals. (v) A range of issues associated with the role of principal in a small community including: being viewed as the "department"; being vulnerable to community perceptions, particularly in the case of female principals; and professional and personal (family) isolation. (vi) The perceptions that schools had more flexibility respectively in student discipline, student welfare and teaching the core curriculum; however, flexibility in properties and maintenance was reduced. Mandated school reports (ostensibly designed to provide schools and their communities with useful data to improve educational programs) were seen as less helpful (rather than helpful). (vi) Despite describing a range challenges and tensions in their work principals reported positively and with enthusiasm and optimism about their schools and their schools' achievements and about solving school-level problems.

Significance: Theoretical concepts of leadership, such as distributed leadership and collegial support networks and communities of practice, need to be adapted considerably to provide for the special context of principals who lead schools in remote locations, especially in systems of education in which responsibilities have been at least partially devolved to the local school level. Concepts of school leadership in rural schools need to be disaggregated to consider some very different rural contexts. School leaders in larger provincial cities have many more features in common with their counterparts in suburban schools in the metropolitan area than they do with their colleagues in remote villages and townships. For principals of schools in remote and declining townships in inland New South Wales, the educational issues are very different to those being dealt with by their colleagues in larger towns or the growth areas along the coast.

SYMPOSIUM

Australian teachers' and principals' perspectives on teacher responsibility-taking in school change

John Williamson, University of Tasmania, Australia

This paper reports findings from an Australian study of teachers and principals' perspectives on teachers' involvement in responsibility-taking in change, which was part of a series of linked international studies conducted under the auspices of the Consortium for Cross-Cultural Research in Education (CCCCE). The Australian component of this study occurred in a context in which the Australian Federal (National) Government wields ever-increasing policy power over Government (Public) Schools whilst State Governments retain constitutional responsibility for state education. Principals were asked to indicate their preference, and their estimates of teachers' preferences, for teacher involvement in responsibility-taking in school change and were invited to comment on their responses during telephone interviews. Teachers were asked to indicate their preference, and their estimates of their principal's preference, for teacher involvement. Differences, some significant, emerged between actual preferences of teachers and principals for teacher involvement and between teachers and principals' beliefs about the preferences held by each other.

Aims:

The study is situated among a broad array of research on collegial approaches to school change, micropolitics and leadership (Achinstein, 2002; Ball, 1987; Blase, 1991; Fullan, 1993, 1999; Little, 1990; Henchey (1999) showed the early success of a teams-based approach to implementing a cross-curricula approach to learning valuing coherence, adaption, participation, flexibility and diversity. This study focuses on elements that strengthen a school through empowering teachers and fostering teacher leadership. Interpretive, comparative case study (Stake, 1995; Yin, 1994) framed this investigation with principals and teachers at each of the two participating schools, comprising the primary unit of analysis. Such an approach was deemed appropriate as a means of investigating the research questions which focused on teachers' perceptions (Yin, 1994) of factors affecting their professional autonomy and control.

Methodology: The participants for this study were two principals and 48 teachers from two rural government schools in Tasmania. The teacher numbers at each site were 36 and 12. Semi-structured interviews of 45 minutes to 90 minutes were the major method of collecting data from all participants and additional information was gleaned by observation, document analysis and participant survey questionnaire. Data gathering took place over the course of a full school year and follow-up interviews extended into the following year.

Findings: The paper will report on some of the data from the study. This will include:

1. The effect of principal leadership styles on empowering/encouraging teachers to lead. The way that formal school leaders operate helps to set the culture and ethos of the school (Williamson & Galton, 1998). Such culture helps to define levels of teacher autonomy and control (Mulford & Silins, 2009). Recent research has described how leadership style may have facilitating or hindering consequences for a particular group (Silins, Zarins & Mulford, 2000; Mulford & 2003). This pattern of impact was found at both school-sites investigated in this study.
2. Types of teacher leadership emerging within the two schools Aside from the principal, there were teachers in both schools who were identified by their colleagues as having leadership roles or behaviour. Types of leadership varied from formal roles , less formal roles arising for a particular purpose or mentoring. Whether collaborative activities generated distributive leadership depended on the spread of skills among the group, the extent to which group activities were focused on educational change and development and the way formal leaders nurtured and harnessed the leadership capacities within the organisation (Harris, 2004). Educational change initiatives mean little unless supported by those who are invited to implement them, as teachers actively decide for themselves what they will take into their classrooms (Churchill, Williamson & Grady, 1997). Churchill, Williamson and Grady found that, for teachers, the negative effects of educational changes were felt most strongly when new practices usurped existing ones, when they were externally mandated, multiple and when simultaneous innovations were implemented or when timelines were short. Extremes of work intensification may well run counter to teacher professional engagement in and control of change initiatives (Williamson & Myhill, 2008). Hurried or ill-conceived change initiatives fail to allow the school as a learning organisation to move forward as a community of professional learners (Mulford & Edmunds 2010).

Significance: Studies of this distributed kind of leadership in action until recently have been few (Bennett et al., 2003), yet it is important because it is the 'glue' of a common task or goal-improvement of instruction-and a common frame of values for how to approach that task" (Elmore, 2000). It is thus a powerful way to sustain school improvements. Teachers feeling empowered through distributed leadership have better self efficacy and morale (MacBeath, 1998; Mitchell & Sackney, 2001). It is important also to ensure that distributed leadership is not simply misguided delegation (Harris, 2002).

SYMPOSIUM

Teachers' and principals' perspectives on teacher responsibility-taking in school change

Christine Gardner, University of Tasmania, Australia, John Williamson, University of Tasmania, Australia

This paper reports broad findings from a 10-country study of teachers and principals' perspectives on teachers' involvement in responsibility-taking in change (about which a specific report of the Australian research is contained in the previous paper). The research reported in this paper was conducted in response to the findings of a previous study. The attitudes of teachers towards a particular change had been found to be most powerfully influenced by teachers' involvement in that change; that is, by their ownership of, interest in and receptiveness to change and satisfaction with their work lives (Collet, Menlo & Rosenblatt, 2005). The current study sought to investigate attitudes of teachers and of principals to teacher participation in responsibility-taking with respect to change decision and processes in schools. Key findings will be presented and discussed from an international perspective about first, teachers and principals' preferences for teachers' involvement in responsibility-taking in change processes in their schools and second, each group's beliefs about the others' preferences. Countries that participated in this research are located in Europe (Hungary, Israel and the Netherlands), Africa (South Africa), Asia/South East Asia (Australia, China, Japan and Singapore) and North America (Canada and the USA). Findings that emerged from the research are presented against a backdrop of political, cultural and educational circumstances in each of the participating countries.

Aims:

The research reported in this paper was conducted in response to the findings of a previous study. The attitudes of teachers towards a particular change had been found to be most powerfully influenced by teachers' involvement in

that change; that is, by their ownership of, interest in and receptiveness to change and satisfaction with their work lives (Collet, Menlo & Rosenblatt, 2005). The current study sought to investigate attitudes of teachers and of principals to teacher participation in responsibility-taking with respect to change decision and processes in schools.

Methodology:

Mixed mode methods (Burns, 2000) were used in the international and the Australian (Tasmanian) components of this study. The researchers sought to investigate first, teachers and principals' preferences for teachers' involvement in responsibility-taking in change processes in their schools and second, each group's estimates about the preferences of the other. Each country study was conducted in its individual political, cultural, and economic context. For example, in Australia, despite constitutional responsibility for education residing with State and Territory governments the Federal Government's increasing power is achieved through making available financial resources subject to systems and schools' adoption and implementation of national priorities (Hardy, 2008; Jaensch, 1997; Stillwell, 2000; Taylor, 2009). Australian trends include politicisation of education policy, curriculum change, conflict over roles, and mandated testing. The international study sought quantitative and qualitative data from 100 to 176 teachers and from 50 to 64 principals in each of the participating countries. Participants in the Australian study were 50 principals and 106 teachers. A questionnaire was developed comprising 20 items relating to school-level changes in which teachers could potentially take varying levels of responsibility. These items were grouped into four categories: administration and coordination, human relations, teacher support, classroom learning. The development and validation of these categories was underpinned by an examination of role theory (Guthrie & Reed, 1991; Hoy & Miskel, 1987; Sergiovanni, 1987). Fifty principals and 105 teachers completed questionnaires; all principals and 15 teachers were invited to contribute additional comments. Numerical data were analysed for reliability using Cronbach's alpha procedure. Qualitative data were used to provide richer accounts of participants' perspectives.

Findings:

Cross-country analyses will be presented including means for each of the four measures (teacher preference, teacher estimate of principal support, principal preference, and principal estimates of teachers' preference). Similarities and differences between individual countries and groups of countries and an exploration of possible cultural, political and historical influences on the results of this study will be presented. The Australian study revealed that teacher preferred a higher level of involvement in responsibility-taking than they estimated principals would support. Principals in the Australian sample preferred a higher level of teacher-involvement in responsibility-taking than they believed that teachers preferred. Means for the A, H, T and C indices revealed first, that the principals estimated that teachers preferred less involvement and second, that principals preferred teachers to have least to most involvement in the categories of activities of A, H, T and C in that order. Teachers' preferences, and estimates of principal support, reflected this rank order, although their preferences for involvement were to a lesser extent than either principals' estimates or principals' preferences. Both sets of principal means were higher than the teachers' preference means. Furthermore, these three means were higher than the teachers' estimates of principal preference, which were the lowest means of all four sets. Individual reference will be made to a variety of correlations between demographic data and some of the findings. A challenge that arises from these variations is to explore conditions that will facilitate sharing perceptions in order that the combined expertise of principals and teachers may be exploited: first, to augment the quality of change processes in schools; second, to enrich ongoing development of school leadership qualities and skills of teachers; and finally, to enhance and optimise progression towards shared goals.

Significance:

Implications for practices were identified as a result of this study. The study provided an opportunity for comparison between perspectives of teachers and principals about with respect to teachers' involvement in responsibility-taking that has not been addressed by other research about teacher involvement, teacher participation, teacher leadership and teacher-principal relationships (e.g., Chrispeels, 2004; Grubb & Tredway, 2010). Investigation of differences between teachers' and principals' perspectives of both groups' actual preferences for teacher involvement, and each group's estimates of the other's preference provides a new approach to identifying strategies that have potential to enhance school change processes.

SYMPOSIUM

Competence, Value, Achievement, and Interest: How Are They Related in Academic Motivation?

Chairperson: K. Ann Renninger, Swarthmore College, United States

Organiser: K. Ann Renninger, Swarthmore College, United States

Discussant: K. Ann Renninger, Swarthmore College, United States

Panelists from differing research and/or methodological traditions will use data from current projects to discuss their understanding of the relation among four variables that, while essential to academic motivation, have only recently begun to be considered in relation to each other: competence, value, achievement, and interest. Each panelist will provide a brief overview of the studies on which he or she is drawing and will then address the following session questions:

1. How are we defining our terms theoretically and how do we operationalize them in this study (-ies)? Related questions might include: How can the link between value and interest be theoretically explained? Is feeling competent a precursor for appreciating value? What is the relation between interest and intrinsic motivation (are situational and individual interest the same as situational and dispositional intrinsic motivation)? Does competence matter if you do not value a task? Is discovering value different from learning about value?
2. What is the role of content in the relation of competence, value, achievement, and interest? Related questions might include: Are the kind or type of values you pursue differentially predicting interest, achievement, and competence—and, what is the role of content? Does competence promote interest or does interest promote competence, or can both be true?
3. What can we say now and what are the next steps in the research needed in order to address these questions? A related question might include: What research methods are necessary for exploring these issues?

SYMPOSIUM

Who Continues to Pursue STEM in College? The Roles of Competence, Value, Achievement, and Interest

K. Ann Renninger, Swarthmore College, United States; Lynne Steurle Schofield, Swarthmore College, United States;

Margaret W. Nam, Swarthmore College, United States

Two current studies will be used to address session questions. Both studies address questions being posed by colleges and universities seeking to support their students to pursue majors in science, technology, engineering, or mathematics (STEM), especially women, underrepresented minorities (URM), and first generation students (e.g., Hill, Corbett, & St. Rose, 2010; Planty, Hussar, Snyder, Provasnik, Kena, et. al., 2008). For those working directly with students who could but do not elect to continue in STEM, understanding more about their motivational needs and preferences, and those of the students who do continue, is a priority. In the two studies on which this presentation draws, standardized achievement and institutional data are complemented by data on the students' perceptions of competence, value, achievement, and interest. Findings from these studies suggest that interest is a key indicator of academic motivation, and the decision to continue to major in STEM, when interest is assessed in terms of feelings, value, and knowledge. Those with more developed interest are those who continue in STEM. They value the content and they are willing to reorganize their learning strategies to be able to continue to engage with the discipline.

This presentation will address session questions by drawing on two current studies. The first is a study of 4182 (2317 f, 1672 m, 193 unidentified) first semester senior undergraduate students that suggest (using logistical regression analysis) that interest variables are far more predictive than those with the motivational orientation factors and that demographic variables become less significant when interest is also analyzed. In addition, the error rates of the logistic regressions with interest variables are much lower (17.9% compared to 29.9%) than those with the

motivational orientation factors. The second is a combined survey and interview study of 100 undergraduates (8 m, 8 f from each of 6 STEM disciplines, plus 4) who continued to pursue STEM disciplines in a rigorous academic setting. Discussion of session questions will focus on interest as a key indicator of academic motivation, when interest is assessed based on feelings, value, and knowledge. The coupling of survey and interview findings provides insight into the roles of competence, value, achievement, and interest for those who continue in STEM.

In the first study, confirmatory and exploratory factor analysis was used to determine the number of factors for each of five areas: career plans and choices (4), choice of major (4), instructional practices (3), motivational orientation (3), and interests and attitudes (4). On average, Cronbach's alpha was high for all 18 of the factors; the only alpha below 0.50 was the third factor in the motivational orientation and it was subsequently deleted from analyses.

Logistic regression and classification-tree analysis was employed. Findings suggest that for students who report beginning their college career with a plan to major in a STEM discipline, none of the motivational orientation factors (performance and learning goals) predict their continuing. Even when controlling for gender, URM, and first generation status, these variables are insignificant. Classification-tree analysis confirmed these findings.

Regressions conducted with interest variables are far more predictive than those with the motivational orientation factors and their error rates are much lower (17.9% compared to 29.9%). Moreover, the demographic variables become less significant when interest is also analyzed. The logistic regression model was no better at predicting whether students had decided to stay in STEM when demographic variables were analyzed alone, again suggesting that the predictive power of the demographic variables is small. This suggests that while race, gender, and first-generation status differentials remain among those who stay in STEM and those who leave, the choice to leave may be based more on interest factors and less on specific demographic variables suggesting that policy and practice might focus on exploring more the relation among interest and the choice to stay in STEM across different genders, races, and first generation statuses.

In the second study, results from the institutional data, surveys, and follow-up interviews revealed that those who continue in STEM have developed interest for their discipline, share demographic profiles based on institutional data, and reported changed perceptions of what it meant to achieve in STEM following their first STEM course work. Their stated reasons for choosing their major included interest (85.71%), career (34.69%), competence (28.57 %), experiences with professors in the department (21.51%), positive experiences prior to college (22.45%), practicality (13.27%), family influences (11.22%), no other options for a major (11.22%), the desire to succeed as a role model for others (6.12%).

The interview data suggest that these students' self-confidence as learners can be characterized by their comfort with their own ability levels and while they may have questioned whether they should pursue a STEM discipline on the basis of how much time this type of major requires, they did not question whether they could do the required work of the discipline. All of the students reported entering college highly confident in their abilities and while many had their confidence challenged in their first STEM course, they reported comfort with their present level of achievement (87.76%).

Many students identified their beliefs upon beginning undergraduate classes that competent students complete their work independently. The importance of transitioning to being able to work with others was mentioned by 57.14% of the students. Many (50.4%) also identified the need to shift learning strategies: to learn to work with others, to ask questions of professors, and to learn to put work down and return to it rather than expecting to get it correct the first time.

Findings such as these suggest first that the phase of student interest for a STEM discipline impacts the decision to continue. Despite the challenges associated with mastery of rigorous content, it is mastery that students who continue to pursue STEM value. They revise their understanding of achievement so that this is not only associated with grades, and change their learning strategies.

SYMPOSIUM

The Relation of Expectancy and Value to Outcomes, Is this Additive or Interactive?

Herb Marsh, University of Oxford, United Kingdom; Benjamin Nagengast, University of Oxford, United Kingdom;

L. Francesca Scalas, University of Cagliari, Italy; Man xu, Oxford University, United Kingdom; Kit-Tai Hau, Chinese University of Hong Kong, Hong Kong

Understanding why students are motivated to engage in specific subjects and fields of study and why they excel in them in terms of achievement is one of the most important questions in education. For more than half a century, expectancy-value theory (EVT) has been influential in understanding how motivation is related to effort, choice and achievement-related behaviour. Historically, a core assumption of EVT was that expectancy and value interact synergistically. However, in modern EVT approaches, this critical interaction term has been largely excluded from the model. Our large-scale study of science motivation ($n = 400,000$ 15-year-old students from 57 countries based on PISA2006) shows that the ExV-interaction contributes to the prediction of both science-related career plans and activities; the ExV interaction is statistically significant, highly reliable, generalizable over countries and supports the need to reinstate the ExV interaction into EVT.

Students' enrollments in sciences are declining worldwide. Previous research shows that self-concept, interest and achievement are reciprocally related and important predictors of coursework selection and career choice. In this presentation, session questions will be addressed by considering the methodology employed in and the findings from a study in which Expectancy Value Theory (EVT) is applied/extended. EVT posits that academic choice is a function of E = Expectations of Success (ASC =academic self-concept), V =Value (ENJ = enjoyment), and their interaction ($ExV = ASC \times ENJ$). The ExV interaction implies that students are most motivated when both E and V are high. However, this critical interaction has been largely dropped as non-significant from applied EVT research. We argue that the failure of modern EVT research to find ExV interactions is largely due to methodological limitations. We posit that new multilevel structural equation models (M-SEM) with latent interactions could help to resolve the problem of the missing ExV interactions in EVT.

Drawing on work with the OECD-PISA-2006 database that allows comparisons of educational outcomes across 57 countries ($n = 400,000$ students), the presence of the ExV interaction in EVT was assessed. Measures from this database that included science-related independent (ASC -expectancy; ENJ -value; $ASC \times ENJ$; achievement- ACH) and dependent (career plans; activities) variables were used. M-SEM with latent interactions was used to evaluate the presence of the ExV interaction in EVT.

The results show significant positive effects of ASC , ENJ and $ASC \times ENJ$ on both science-related career plans and activities in the sample as a whole. Multiple-group models (57 countries) further show that $ASC \times ENJ$ is statistically significant in the prediction of science-related career plans in 45/57 countries and in the prediction of science-related activities in 48/57 countries. In addition, the results show that $ASC \times ENJ$ is substantially related to country level values of individualism. Consistent with early EVT, but contrary to subsequent versions, the ExV interaction is statistically significant, highly reliable, and supports the need to reinstate the ExV interaction into EVT.

Theoretically, the results from this study demonstrate the need to re-introduce the expectancy-value interaction into expectancy-value interaction theory and to consider some of the reasons why it had been dropped. The notion of a multiplicative combination of expectancy and value has almost completely vanished in discussions of EVT. Analysis of surveys and questionnaires shifted the focus from within-person differences in the motivation to engage in different tasks to between-person comparisons of the engagement in identical subjects and tasks. Multiple regression and path analyses with scaled scores became the analytical techniques of choice—but both approaches make the detection of interaction effects unlikely. In the present study, we use models with latent interactions to provide strong and powerful tests of the interaction between expectancy and value in a large cross-cultural database—a substantive methodological synergy (Marsh & Hau, 2007).

Methodologically, the findings from this study are important in demonstrating new and evolving approaches to measure latent interactions in ways that control for measurement error. The large number and variety of countries that participated in PISA allow demanding tests of its universal generalizability and applicability (Matsumoto, 2002; Segall, Lonner & Berry, 1998). Although the EVT-model explicitly includes cultural background variables and hypothesizes that they influence academic motivation and choice, most tests of the model have been conducted in Western cultures (Wigfield, Tonks, & Eccles, 2004). Findings from this study are also important to substantive educational understanding. They demonstrate the importance of the intrinsic motivation component of interest, academic self-concept, and their interaction in predicting proximal (undertaking science activities) and distal (science-related career plans) of practical significance.

The present study addresses the critical issue of declining science enrollments, has profound implications for motivation theory, is based on cutting-edge, emerging methodology, uses the best available data, and fits well with our program of substantive-methodological synergy development. Each of these aspects will provide the basis of addressing the questions of the session.

SYMPOSIUM

The Relation of Utility Value, Competence Value, and Lesson Value to Interest

Carol Sansone, University of Utah, United States; Tamra Fraughton, University of Utah, United States; Jonathan Butner, University of Utah, United States; Joseph Zachary, University of Utah, United States; Sungchoon Sinclair, University of Utah, United States

The Self-regulation of Motivation (SRM) model suggests that both goals-defined motivation (i.e., value and expectancy of learning), and experience-defined motivation (i.e., whether the learning experience is interesting) are important for maintaining behavior. These motivations can be distinct but reciprocally related over time, and this reciprocal relation impacts both subsequent motivation and achievement. To illustrate, we used data from the Regulating Motivation and Performance Online (RMAPO) project. Undergraduates worked on an online HTML programming lesson, and their engagement behaviors (i.e., use of optional examples and exercises) were assessed. Initial lesson descriptions just described skills to be learned (no added utility value), or further described how these skills could be used when creating personal or organizational web-pages (added utility value). We examined whether the utility value information directly predicted value at lesson conclusion, or depended on the experience students created during the lesson via engagement behaviors. We compared two kinds of value at lesson conclusion: competence value (value doing well) and lesson value (value lesson content). Added utility value directly predicted subsequent competence value, and indirectly predicted subsequent lesson value by way of higher engagement levels. In turn, competence value was related to greater lesson interest, whereas lesson value was associated with greater interest AND learning, as well as greater future likelihood of learning more about HTML. We use these results to discuss the panel questions, noting that the relationships among value, interest and competence are complex, depend on which aspects of each construct are measured, and are reciprocal over time.

The Self-regulation of Motivation (SRM) model (Sansone & Thoman, 2005) suggests that both goals-defined motivation (i.e., the value and expectancy of learning), and experience-defined motivation (i.e., whether interesting while working towards those goals) are important for sustained learning. Rather than particular goals being associated automatically with interest, our model suggests that what is critical is whether the environment enables work toward those goals in ways that create or maintain an interesting experience. This is true even if the goal is to experience interest.

Goals-defined motivation is one source of the interest experience. Initial actions directed by goals also affect the experience. Subsequent (maintenance) actions may thus be in service of reaching goals or in service of making the experience more interesting, particularly over a longer time period. When applied to learning, the SRM model suggests that although initial goals-defined motivation is important, its effect on motivation and performance outcomes may depend on maintenance actions.

As part of the Regulating Motivation and Performance Online (RMAPO) project, Sansone and colleagues created a paradigm for examining this proposed regulatory process, implemented via an online HTML lesson. They varied the initial lesson description such that it just described the skills to be learned (control), or further added how these skills could be used when creating personal or organizational web pages (added utility value). Initial results (Sansone, Zachary, et al. 2010) suggested that adding utility value did not directly affect motivation (interest) and performance (quiz on HTML knowledge) outcomes. Rather, as compared to the control, the added utility value was associated with more manipulating and modeling of sample HTML codes in optional examples and exercises. Mid-level engagement (modeling only) predicted higher quiz scores, and higher level engagement (manipulating and modeling) predicted greater interest at the end of the 1 ½ hour session.

These previously reported results suggest that greater value for learning at the outset can lead to creating a more interesting experience, which, in turn, can lead to greater interest at the conclusion. However, the model also suggests that value and interest can be reciprocally related over time. To examine potential reciprocal relationships, we examined whether the utility value information added at the outset directly predicted value at lesson conclusion, or depended on the experience students created during the lesson via engagement behaviors. We also compared two kinds of value at lesson conclusion: Competence Value (value doing well) and Lesson Value (value lesson content).

Participants were undergraduates (n=108; 67% female) who came into the lab and worked on the online HTML programming lesson for 1 ½ hours. Students were randomly assigned to one of the three conditions described previously (control, personal applications, and organizational applications).

The lesson included optional examples and exercises that individuals could click on to see sample HTML codes. We measured patterns of engagement via the degree to which students: 1) clicked on the examples and exercises that showed sample HTML codes (Accessed); 2) further clicked on a button that displayed what the HTML codes would look like when published (Modeled); and 3) further clicked on a button that allowed them to modify the given HTML codes and then display the effects (Modified/Modeled). At lesson conclusion, learning was assessed via a quiz of HTML knowledge. Students also completed a questionnaire where students rated on 1 to 5 scales: Competence Value (4 items; e.g., It was important to me do well on the lesson), Lesson Value (3 items; e.g., Completing this lesson was very worthwhile), and Lesson Interest (5 items, e.g., I found the lesson very interesting). Finally, students were given a chance to request a code that would allow them to access the full online programming course (-1, no request; 1, request).

A hierarchical regression model was created that included two contrast codes for the manipulation of utility value (Value added v. No added value, Personal v. Organizational Value) (Step 1). When Competence Value was regressed on this model, there was a significant positive main effect of the Value Added contrast; for Lesson Value, there was a marginally positive effect of the Value Added contrast. Previously, we found that the Value Added contrast was significantly associated with greater Degree Modeled and Degree Modified/Modeled. In Step 2, therefore, we added the main effects (centered) of the three engagement behaviors (Degree Accessed; Degree Modeled; Degree Modified/Modeled) (Step 2). For Competence Value, the main effect of the Value Added contrast was unchanged, and none of the engagement behaviors were significant. For Lesson Value, in comparison, the effect of the Value Added contrast was reduced, and the effect of Degree Modified/Modeled was significant and positive. We then regressed the other outcome measures on the model to which we added Competence Value and Lesson Value (both centered) (Step 3). Both Competence and Lesson Value significantly and positively predicted Lesson Interest. In contrast, when Request Code and Quiz Score were each regressed on the same model, only Lesson Value was significantly related.

Results suggest that the added utility value at the outset of the lesson directly contributed to the importance of doing well, and indirectly contributed to valuing what was learned, by motivating higher levels of engagement during the lesson. Caring about achievement was related to finding the lesson interesting. In contrast, seeing the lesson content as valuable to learn was associated with greater interest and learning, and also greater likelihood of engaging the material again in the future. We will use these results to discuss the panel questions, noting that the relationships among value, interest and competence are complex, depend on which aspects of each construct are measured, and are reciprocal over time.

SYMPOSIUM

Goal-content, Intrinsic Motivation, Self-Regulated Learning and Performance

Maarten Vansteenkiste, Gent University, Belgium

Within Self-Determination Theory (Deci & Ryan, 2000; Vansteenkiste, Niemiec, & Soenens, 2010), it is maintained that not all goals are created equal because the content of individuals' goal pursuit matters in terms of predicting intrinsic motivation, well-being, and performance (Ryan, Sheldon, Kasser, & Deci, 1996). Specifically, a distinction is made between intrinsic goals (e.g., self-development, community contribution, affiliation) and extrinsic goals (e.g., wealth, fame, physical attractiveness) which are said to be differently related to the satisfaction of individuals' basic psychological needs for autonomy, competence, and relatedness. In this panel discussion, I will present findings from (a) a questionnaire study in which students' reported on their personal goal pursuit and (b) experimental study in which different goal contents were experimentally induced. Collectively, these studies suggest that intrinsic and extrinsic goals differently predict the enjoyment and interest in school work, self-regulated learning and students' performance, which is herein considered as a proxy for competence-building (Vansteenkiste, Lens, & Deci, 2006). These findings are discussed in light of expectancy-value theories and self-determination theory which are grounded in different meta-theoretical assumptions.

Within Self-Determination Theory (Deci & Ryan, 2000; Vansteenkiste, Niemiec, & Soenens, 2010), it is maintained that not all goals are created equal because the content of individuals' goal pursuit matters in terms of predicting intrinsic motivation, well-being, and performance (Ryan, Sheldon, Kasser, & Deci, 1996). Specifically, a distinction is made between intrinsic goals (e.g., self-development, community contribution, affiliation) and extrinsic goals (e.g., wealth, fame, physical attractiveness) which are said to be differently related to the satisfaction of individuals' basic psychological needs for autonomy, competence, and relatedness. In this panel discussion, I will present findings from (a) a questionnaire study in which students' reported on their personal goal pursuit and (b) experimental study in which different goal contents were experimentally induced.

In a first questionnaire-based study, we examined the relation between adolescents' intrinsic and extrinsic life goals, their achievement goals, intrinsic motivation, grades and self-regulated learning. Vansteenkiste, Soenens and Duriez (2008) argued that the valuation of extrinsic life goals at the expense of intrinsic life goals might shift students' attention away from the learning activity, thereby becoming less focused on mastering the activity at hand. Instead, because the pursuit of extrinsic goals yields an ego-validating character, the pursuit of extrinsic relative to intrinsic goals would be associated with a performance orientation as outperforming others is viewed as instrumental to bolster one's self-worth. Because of their different linkage to mastery-approach and performance-approach goal pursuit, intrinsic and extrinsic life goals would yield a different relation to students' academic intrinsic motivation, performance and indicators of self-regulated learning (e.g., time management). Regression analyses largely confirmed this pattern, even after controlling for several important teaching dimensions, including perceived autonomy-support and perceived structure. Further, person-centered analyses (i.e., cluster analyses) complemented these dimensional analyses, thereby indicating that different types of students could be retained depending on the type of life goals they value. The group of students valuing intrinsic goals alone was found to score highest on academic intrinsic motivation, self-regulated learning, and performance, even in comparison to students valuing both intrinsic and extrinsic goals.

A second experimental study build on this questionnaire based study by framing a specific learning activity in terms of the attainment of intrinsic and extrinsic goals. This allowed answering the question whether different goal-contents has causal impact upon achievement goals, intrinsic motivation, and performance. In line with the questionnaire-based study, intrinsic relative to extrinsic goal framing was found to produce more task-involvement, greater intrinsic motivation, better performance and more free-choice persistence. These two single goal conditions were also compared to a double goal condition in which the learning activity was framed in terms of the attainment of both an intrinsic and extrinsic goal. According to expectancy-value theories, increasing the utility value of a learning activity by indicating its instrumentality to attain two goals rather than only one of those two should result in higher motivation and more optimal learning. In contrast, self-determination theory posits that it is also important to take into account the content of the goal (intrinsic versus extrinsic) next to the quantity of provided goals. Contrast-cell analyses showed that the double goal condition fell in on several outcomes in between the two single goal conditions.

Collectively, the findings these two studies suggest that it is critical to consider the type of goals learners pursue or teachers refer to when increasing the utility value of a learning activity. Both the personal valuation of more goals (Study 1) and the experimental induction of more goals (Study 2) does not necessarily relate to more adaptive academic functioning. Intrinsic goals will primarily relate to higher intrinsic motivation and better performance, while extrinsic goals even tend to undermine the learning process, presumably because these goals are differently linked to the satisfaction of one's basic psychological needs.

SYMPOSIUM

Moral and democratic education within the context of science education

Chairperson: Jean-Luc Patry, Universitat Salzburg, Austria

Organiser: Jean-Luc Patry, Universitat Salzburg, Austria

Jostein Saether, NLA University College, Norway

Discussant: Dimitris Pnevmatikos, University of Western Macedonia, Greece

Teaching and teacher education are typically focused on content (subject matter). However, the society requires that teaching addresses also issues of moral and democratic education, as documented, for instance, in the curricula. Nevertheless teachers and teacher educators are reluctant to address these topics given the content pressure and because they do not have the appropriate methods to do so; further, they fear to interfere with the parents' moral convictions. The three papers in this symposium show conditions and ways for dealing adequately with this problem. The first paper addresses the conditions for the discourse on human dignity in teacher education with particular focus on life science, the second paper reports on an experiment about critical thinking as related to teaching about the greenhouse effect, and the third paper presents details on the Values and Knowledge Education (VaKE) concept that combines moral and content related teaching; the focus is on viability checks as a means to overcome the disadvantage low achieving students have in open teaching.

Human Dignity in Life-Science Research Practice: A Matter of Critical Socio-Historical Literacy

Anna Tapola, Linnaeus University, Sweden

The protection of human dignity (HD) is assumed to be a central task in education; no matter if we are talking about teacher education (TE), training for life-science research practice, or education for a global networked society (EGNS). However, the notion of HD can have different meanings. The aim of the study was to scrutinise the relationship between the notion of HD in life-science research practice, and discourse of HD within TE. Previous studies show that the discourse of HD within TE to a high degree was permeated by themes and arguments associated with life-science subject matters, for example, anatomy and physiology, but rarely in terms of an absolute and universal value that belongs to all people. The question is whether emphasise on bodily functions also denotes discourse of HD within life-science research practice. The study was a critical discourse analysis. The data (published articles and student theses that related to HD) consisted of more than two million words, which were analysed qualitatively. The findings show that it is accepted to discuss HD in terms of life-science subject matter, not least in terms of bodily (dys)functions. Notwithstanding this key finding, researchers and students of life-science rarely published articles, or wrote theses, which concerned HD. Conclusion: The modest number of contributions written by scholars and students of life-science might be explained by lack of a Critical Socio-Historical Literacy (CSHL), which is a new concept. It is also suggested that CSHL should be a crucial precondition for EGNS.

The aim of the study was to scrutinise the relationship between the notion of human dignity (HD) in life-science research practice, and discourse of HD within teacher education (TE).

Research questions: Does HD in life-science research practice relate to discourse of HD within TE? If so, how, why and under what circumstances, does HD in life-science research practice relate to discourse of HD within TE? If not, how can such findings be explained?

The background and relevance for the domain of EARLI is that protection of HD is a central task for any educational activities, as required, for example by the Universal Declaration of Human Rights (United Nations' General assembly, 1948), or the European Convention on Human Rights and Biomedicine (Council of Europe, 1997) – not least in terms of education for a global networked society (EGNS). To a significant extent, the documents above are grounded on insights from, and consequences of, atrocities committed by 'life-scientists' during WWII, for example, medical experiments (Proctor, 1988). Therefore, HD is assumed to be of importance for TE, as well for life-science research practice, especially since both spheres are grounded on educational activities, and thereby also related to learning and instruction – not least in terms of moral and democratic education.

Previous studies (Tapola, 2010) show that discourse of HD within TE to a high degree is permeated by themes and arguments that are associated with life-science subject matter, for example, anatomy and physiology. According to these studies, full HD is linked to what is considered to be a 'perfect' body and 'non-disturbed' bodily functions, and all the argument were assumedly grounded on outcomes of life-science research. The focus on the unproblematic body as a carrier of full-fledged HD can have severe consequences on how, for example, teachers may treat colleagues and pupils with disabilities. For an appropriate discourse in TE, it would be necessary to be based on contemporary discourse of HD within life-science research practice. However, so far, little has been known about this discourse. Therefore it is justified to analyse how this particular HD discourse is constructed by various categories of constituents.

The data comprised of four categories of constituents: * 91 university student theses at bachelor's or master's level (Swedish data);* 24 peer-reviewed published scientific articles within the area of science education research (International data);* 22 scientific articles published in peer-reviewed life-science journals (International data);* 43 articles published in popular scientific magazines (International data).

All constituents included any of the search terms (see below). In total, the data exceeded two million words, which were analysed qualitatively.

The data collection method constituted of searches at digitalised databases. Search terms: 'människovärde' (Swedish) and 'human dignity' (English). All theses and articles that included any of the search terms were incorporated in the data.

The methodology is grounded on critical discourse analysis (for example, Fairclough, 2010) and the discourse-historical approach (DHA) (Reisigl, & Wodak, 2009; Wodak, 2001a, 2001b). DHA is based on a Habermasian emancipatory knowledge interest in the sense that the analysis serves to reveal phenomena that, at a previous staged in the process, hindered the insights and meaning-making achieved after the analysis. Within DHA, three dimensions are of particular interest: (i) immanent dimensions that focus on functional linguistic characteristics of the constituents; (ii) socio-diagnostic dimensions that focus on properties related to power, democracy, morality, various

rationalities that inform our choices to act in certain ways, etc.; and (iii) historical dimensions, i.e. dimensions that focus on variations over time (the past, the present, and the future) of the phenomena under study. The analytical methods consisted of (i) transitivity analysis, (ii) argumentation analysis, and (iii) contextual analysis.

Ethical considerations: This study never included direct research on humans, or any other living creatures. All data consisted of open-access texts only. All findings were reported in a de-identified form.

The findings show, among others, that the thematic patterns of the discourse within TE reappear in student's theses, life-science articles published in scientific journals, and in articles published in popular scientific magazines, but hardly ever in scientific articles within the area of science education research. Findings showed there was a clear relationship between HD in life-science research practice, and discourse of HD within TE. However, there was a major difference. Ethicists and legal experts discussed HD in terms of human rights, which was highly unusual in the discourse of HD within TE. Furthermore, professional scholars of life-science rarely published articles that concerned life-science subject matter and the notion of HD. Therefore, it is suggested that the modest number of contributions written by scholars of life-science research can be explained by lack of Critical Socio-Historical Literacy (CSHL), which is a conclusion that may have great importance – not least in view of the dark history of 'life-science' during the last century. CSHL is a new concept that will be further clarified at the conference, but CSHL should also be a crucial precondition regarding education for a global networked society.

Stimulating autonomous thinking and learning intentions related to the greenhouse effect topic

Jostein Saether, NLA University College, Norway; Kristian Skaaraas, NLA University College, Norway

The hypothesis of this pilot study is that communicating relevant information, stimulating general independent/critical thinking, and academic self-concept and the use of learning strategies might strengthen the immediate intention to learn and act regarding the man-made greenhouse effect. In a four-groups posttest-only randomized experiment 89 16 year old students were randomly assigned to one of four groups. Each group had their own version of a questionnaire to answer which differed with regard to the introductions. Group 1: introduction (i) given to strengthen knowledge based attitudes. Group 2: (i), and (ii) given to effect general independent and critical thinking. Group 3: (i), (ii), and (iii) to stimulate academic self-concept and the use of learning strategies. Group 4 was the control group. The questionnaire was distributed without any opportunity for further elaboration, and in this way illustrates poorly elaborated subject matter. The experiment illustrates that stimulating general critical or autonomous thinking (group 2) might seem to function counterproductive as to increase the strength of the behavioural intentions we wish to promote. When divided into males/females this tendency is only significant among the males. The conclusion is that our efforts to stimulate critical thinking should be subject matter related rather than abstract and general. The study also exemplifies that social norms (e.g. the willingness to listen to experts) are of particular importance for learning intentions.

Stimulating autonomy is fundamental in moral and democratic education, which in this context is related to controversial conceptual change theory (Säther and Maridal, 2005) and to "the reasoned action approach" (Fishbein and Ajzen, 2010).

The aim is to show that the following factors might strengthen the immediate intention to learn and act regarding the man-made greenhouse effect:

- (i) communicating relevant information,
- (ii) stimulating general independent/critical thinking, and
- (iii) stimulating academic self-concept and the use of learning strategies.

Methodology: The project is at a pilot stage. It is based on the four-groups posttest-only randomized experiment presented below. A sample of 16 year old students from 4 classes were randomly assigned to one of four groups as follows:

Group 1 (Academic group, N=22): Introduction 1 & test; Purpose: To strengthen knowledge based attitudes (A);

Group 2 (Autonomy group, N=22): Introductions 1 & 2 & test; Purposes: A & to effect social norms regarding general independent and critical thinking (B);

Group 3 (Academic self-concept and learning strategies supported, N=22): Introductions 1 & 2 & 3 & test; Purposes: A & B & Stimulating academic self-concept and the use of learning strategies (the control factor) (C)

Group 4 (Control group, N=23): Only test.

Influenced by Fishbein and Ajzen's theory a questionnaire was developed using 7-point Likert scale items. The questionnaire with the four types of introductions were randomly distributed without any opportunity for additional text elaboration. This "weakness" of intervention seeks to illustrate the situation when subject matter is poorly elaborated.

Some test items might illustrate:

* Dependent variable (learning intention): "During this school-year I will really work hard to learn about the greenhouse effect so I can understand this topic properly."

* Social norm: "In fact I don't care about these experts that focus so much on the man-made green house effect with these alleged harmful effects."

* Attitude: "If the earth's living conditions are seen all together one must conclude that increased greenhouse effect can result in catastrophic consequences during this century."

Findings: The overall conclusion is that the differences between the groups often were not significant. The results indicate that the treatments probably were too weak, and demonstrate the well-known experience that passing on information without students' active/enduring participation in learning yields meagre changes.

What are the consequences of generally stimulating critical thinking? E.g. action intentions concerning the man-made green house effect was illustrated by some differences between group 1 and 2: Test item 6: "It is absolutely necessary to implement drastic measures to reduce the use of fossil fuel" (M1=6.6, SD1=0.8; M2=5.6, SD2=1.6) ($P=.02$). Test item 16: "It is not so important to work to reduce greenhouse gas emissions" (M1=6.8, SD1=0.5; M2=5.7, SD2=1.8 ($P=.02$). On both statements "the critical or autonomy group"(group 2) scored significantly lower than the "traditional academic group" (group 1). If further analysed, by removing 2 cases (contradicting answers in group 2) the analysis show even stronger results: Item 6 " (M1=6.6, SD1=0.8; M2=5.5, SD2=1.6) ($P=.01$); Item 16 (M1=6.8, SD1=0.5; M2=6.2, SD2=1.1 ($P=.04$). Splitting the cases shows gender differences: Among the females no significant differences were found when comparing group 1 and 2 regarding test items 6 and 16. However, among the males the differences are significant: Item 6 " (M1=6.5, SD1=0.8; M2=4.6, SD2=1.9) ($P=.05$); Item 16 (M1=6.8, SD1=0.4; M2=5.5, SD2=1.3 ($P=.03$). These results exemplify that stimulating general critical or autonomous thinking might function counterproductive as to increase the strength of the behavioural intentions we wish to promote. However, when the groups are divided into males/females this tendency is only significant among the males. Further analysis shows that gender has a significant impact on the behavioural intention test score in group 2 ($R^2=.26$, $F=6.2$, P

By constructing subscales we analysed the combined effects of attitudes, social norms and control factors on learning and action intentions in the four groups. This analysis revealed significant results only in group 1 and 2, and only for the social norm related to learning intention ($R^2=.55$, $F=21.5$, P

In summary, the results indicate that the social factor is the most influential factor on learning intention when students are confronted with a single academic text, or with an academic text in combination with stimulation of critical thinking. However, there are gender differences. The social factor shows a significant difference between the male and female students. The study does not reveal any significant effects of attitudes and control factors.

Theoretical and educational significance:

The study gives an example of the counterproductive effect that might occur when stimulating general/abstract critical thinking without making links to the subject matter. It seems as the male students are negatively influenced by this. The study also exemplifies that the social norm is of particular importance for learning intentions. One of the practical implications is about asking: Who are the experts in the area of interest? Who deserves to be listened to? How should critical thinking be integrated with subject matter learning?

This pilot study has some weaknesses regarding sample size, internal consistencies and distributions skewness. The design does not include subject matter elaboration. However, some results seem strong enough to encourage further research related to the proposed hypotheses. In addition to this, the study encourages further research on the background factors of the social norm (not only as an independent variable as in this study).

Multiple operationalism: VaKE with heterogeneous learning groups

Alfred Weinberger, Padagogische Hochschule der Diözese Linz, Austria; Jean-Luc Patry, Universität Salzburg, Austria

Do high and low achieving students profit equally from an adapted version of the teaching method VaKE (Values and Knowledge Education) which combines constructivist values education (e.g. Kohlberg, 1981) and knowledge construction?

The adapted version of VaKE (VaKEplus) implements repeated viability checks which are hypothesized to structure learning in order to support low achieving students but not to hinder high achievers in their knowledge construction. Two teaching methods are investigated: VaKE and VaKEplus. The sample consists of two classes (N=54) of a secondary school which are experimental and control groups in a quasi experimental cross over design.

Multiple operationalism (Campbell & Fiske 1959) in an extended version (Patry, 1990) is used. The study investigates the convergent and discriminant validities of the treatment (VaKE vs. VaKEplus), the dependent variable (trait: knowledge construction) and the design (influence of treatment). The instruments are teacher made tests, content analysis of student's essays, the WALK (Patry, 1999) and the Lesson-Interruption-Method (Patry, 1997).

Results corroborate partly the hypothesis and show a high validity of the study.

Patry, J.-L. (1999). WALK. A Summative Assessment of Constructivist Teaching. Salzburger Beiträge zur Erziehungswissenschaft, 5, 2, 49-63.

The research project aims at investigating an adapted version of VaKE (Values and Knowledge Education) in secondary school (VaKEplus). VaKE (Patry & Weinberger, 2004) is a constructivist teaching method combining values and knowledge education. It is based on Kohlberg's theory of moral development (e.g. Kohlberg, 1981) and Glaserfeld's theory of knowledge construction (e.g. Glaserfeld, 1997). Starting with a moral dilemma the students discuss not only their arguments but also search for relevant information in order to arrive at a convincing moral decision. An important step within their learning process is testing whether the moral and content-related solutions they come up are viable (Glaserfeld, 1981), i.e., they perform what we call a viability check: The students exchange their constructions and check whether they are compatible with each other.

According to ATI-research low structured constructivist teaching methods tend to benefit high achieving students whereas low achievers perform better with well structured traditional teaching methods (e.g. Cronbach & Snow, 1977; Snow 1989). VaKE with heterogeneous learning groups (e.g. secondary school classes) aims at facilitating the learning outcome of high achievers as well as low achievers. VaKEplus implements repeated content-related viability checks as a constructivist method to structure the lesson in order to promote high achievers as well as low achievers.

This is done by asking the students to interrupt their information search several times to discuss their findings and to adapt their further learning steps.

In this study VaKEplus (treatment group) is compared with VaKE (alternative treatment control group). It is supposed that the implementation of repeated viability checks in VaKEplus will be more beneficial to the students than one single viability check in VaKE. The hypotheses are that with VaKEplus a) high achievers construct more (applicable) knowledge than low achievers and b) all students construct more (applicable) knowledge. The sample consists of two school classes (A and B; grade 7) with 27 students in each class. A quasi experimental cross over design is used. In phase 1 (topic: nuclear power plants) class A was the experimental group (teaching method: VaKEplus) and class B is the control group (teaching method: VaKE). In phase 2 (topic: drugs) which started eight weeks after phase 1 class A was the control group (teaching method: VaKE) and class B was the experimental group (VaKEplus). Phase 2 represents a conceptual replication of phase 1 with inverted roles of the two classes.

An extension of the multitrait-multimethod approach (Campbell & Fiske, 1959) will be used as research methodology: multiple operationalism of different constructs (Patry, 1989). While the multitrait-multimethod concept addresses only the dependent variable, the approach presented here includes multiple operationalism on the independent variable as well. It is based on the idea that many treatment operationalizations (operationalizations of the independent variable) and of the measures (dependent variables) that differ with regard to irrelevant features are needed to triangulate on a construct. The central claim is that the construct validity of the design validity (with respect to the hypothesis) rests on the convergent relationships between independent operationalizations of the respective constructs of the hypothesis. Three different classes of validity will be investigated: a) Validity of the treatment: There should be a difference between measures of different treatments whereas there should be no difference between independent measures of one treatment. b) Validity of the dependent variable: There should be high correlations between independent measures of the same trait and no correlations between measures of different traits (Campbell & Fiske, 1959). c) Validity of the design: The treatment should have an influence on the trait according to the hypotheses whereas the alternative treatment should have no influence on the trait.

Several instruments are used for the dependent variable: Content analyses of student's essays and the WALK ("W" assessment of latent knowledge), a new instrument for the summative evaluation of constructivist teaching (Patry, 1999) assess the applicable knowledge. Teacher made tests evaluate the factual knowledge. As to the independent variable, the LIM (Lesson Interruption Method) ascertains the implementation of viability checks in different VaKE-units (Patry 1997). An intelligence test gives information about high and low achieving students.

The results of the ANOVAs with repeated measurement for the two experimental phases show highly significant mean differences and high effect sizes between VaKEplus-units and VaKE-units for LIM. These findings support that the viability-check was indeed implemented in VaKEplus-units and that there was no viability-check in VaKE-units; this can be interpreted as discriminant validity of the independent variable. With respect to the assessment of the validity of the trait the mtmm-matrix reveals significant correlations between WALK and content analysis within VaKEplus-units and VaKE-units, respectively (convergent validity), and no correlations between WALK and content analysis between VaKEplus-units and VaKE-units across phases (discriminant validity). The results of an ANCOVA show that high achievers as well as low achievers partly benefit from VaKEplus and all students construct more (applicable) knowledge with VaKEplus. This means, among others, that the disadvantages of low achieving students in VaKE can at least partly be compensated by VaKEplus. It is proposed to further test the hypothesis that using viability checks in open teaching in general might help to overcome the problems low achievers have with this type of teaching-learning situations in other contexts as well.

SYMPOSIUM

Teachers and Migrant Students' Home Cultures

Chairperson: Michele Grossen, University of Lausanne, Switzerland

Organiser: Ed Elbers, Utrecht University, Netherlands

Discussant: Charles Max, University of Luxembourg, Luxembourg

In this symposium we present research about the way teachers represent and construct relationships between the school and migrant students' home cultures. The studies encompass teachers, intercultural trainers and schools in Italy, Britain and the Netherlands. Surian's research (interviews, focus groups and Eurobarometer data for international comparison) is focused on intercultural education trainers who are themselves second generation migrants. Reflecting on their experiences as members of migrant families, the trainers have elaborated strategies for including families in school policies and in shaping and supporting young migrants' educational and career choices. Research by Abreu and colleagues (based on in depth interviews) is concerned with teachers' representations of immigrant students and their home cultures. They show that the teachers' understanding of the students' home background is a crucial dimension in the way they make sense of their students' transitions between home and school. These authors look, in particular, at the impact of teachers' views of themselves in their constructions of the students and their families. De Haan and colleagues (qualitative and quantitative analyses of actual conversations) observed teacher-parent conferences in the last grade of primary school. They found that the pedagogical views of teachers and parents influenced the way the child's school career is discussed. In their talks, teachers and migrant parents tended to emphasize differences, in terms of identity, knowledge of the educational system, language, pedagogical views and the responsibility of the teacher.

Migrant youth's experiences and educational narratives in Italian society

Alessio Surian, Università degli Studi di Padova, Italy

The type of transition across cultural (school-peers-family) contexts performed by "migrant" students is being given limited attention by educational institutions. The research addresses this issue; it is based upon data gathered in the Emilia Romagna region through focus groups involving, on the one hand, intercultural education trainers and secondary school students and, on the other hand, semi-structured interviews with "second generation" migrant trainers who run intercultural educational workshops in local secondary schools. Because the research was aimed at self-narratives and the assessment of educational choices, results provide both a rationale and concrete examples of "second generation" migrant trainers' educational approaches focusing on intercultural and citizenship education in both formal and non-formal educational settings. While secondary schools are facing significant discrimination attitudes, they are providing insufficient opportunities to young people of foreign origin to voice their transition strategies leaving a key role to youth groups and associations in elaborating transition strategies and in shaping and voicing young people needs and abilities for participation in social life. Based on their members' personal experiences these groups are now in a position to reflect upon ways to include families in educational policies as they have a key role in influencing school policies and in shaping and supporting young people's educational and career's choices. Results and educational implications are discussed within the framework provided by Frank Hutchinson (1996), linking young people's visions of the future (i.e. hopelessness, passive hope, active hope) and their social attitudes (i.e. low self-esteem, bland optimism, foresight and pro-social skills).

Aims

The research aims at understanding the key motivation, narratives and didactical approaches at the core of the educational practice implemented by a network of "second generation" migrant trainers in the Emilia Romagna (Italy)

region. The qualitative data are intended to explore both the self perception of the trainers' educational and social roles in dialogue with peers, schools, younger students, and their own families, as well as the key features of their intercultural narratives and educational projects. Methodology. The research is based upon data gathered in the Emilia Romagna region through, on the one hand, focus groups involving intercultural education trainers and secondary school students, and, on the other hand, semi-structured interviews with "second generation" migrant trainers who run intercultural educational workshops in local secondary schools. Seven semi-structured interviews were conducted with "second generation" intercultural trainers who play a pivotal role in local youth organisations that are part of an intercultural youth and education network in Emilia Romagna. Through direct reference to personal and professional experiences the interviews yield comparative data concerning the role of the family background and the social context in orienting the intercultural education and training choices made by the trainers and the organisations. The qualitative data are discussed within the wider context of quantitative data gathered through an on-line questionnaire addressing issues of lifestyles and discrimination among Italian youth, involving students from the same schools where the intercultural youth and education network runs its workshops. Selected items allow a comparison with European and Italian recent data provided by the Eurobarometer sources.

Findings

Particularly through self-narratives and the assessment of educational choices, focus group and semi-structured interview results provide both a rationale and concrete examples of "second generation" migrant trainers' educational approaches focusing on intercultural and citizenship education in both formal and non-formal educational settings. The citizenship dimension seems particularly relevant as a vehicle for intercultural issues -- as a right and a claim which is being perceived and communicated as legitimate by "second generation" migrant students who are not granted it by the Italian law. The qualitative results helps to identify a common position that rejects the "second generation" label: in terms of identity, young people of foreign origin who have raised their awareness through shared educational activities would rather opt for a reference to "article 3", the part of the Italian constitution granting equal rights to all citizens. While secondary schools are facing significant discrimination attitudes, they are providing insufficient opportunities to young people of foreign origin to voice their transition strategies leaving a key role to youth groups and associations in elaborating transition strategies and in shaping and voicing young people needs and abilities for participation in social life. Based on their members' personal experiences these groups are now in a position to reflect upon ways to include families in educational policies as they have a key role in influencing school policies and in shaping and supporting young people's educational and career's choices. Theoretical and educational relevance of the research "Migrant" secondary school students represent 4% of the total secondary students population. The type of transition across cultural (school-peers-family) contexts performed by "migrant" students is being given limited attention by educational institutions. Who are the institutions and educational roles that have an influence on such transition and what are the issues at stake in adapting to the demands of the various cultural contexts are key questions that are analysed within this research project according to Alberto Melucci's notion of challenging codes and Néêstor Garcia Canclini's multiculturalism mapping in terms of the different, disparate and disconnected categories. Results and educational implications are discussed within the framework provided by Frank Hutchinson (1996), linking young people's visions of the future (i.e. hopelessness, passive hope, active hope) and their social attitudes (i.e. low self-esteem, bland optimism, foresight and pro-social skills).

Teachers' representations of immigrant students and their home cultures: a dialogical self analysis

Guida de Abreu, Oxford Brookes University, United Kingdom; Sarah Crafter, University of Northampton, United Kingdom; Hannah Hale, University of Derby, United Kingdom; Ria O'Sullivan Lago, University of Limerick, Ireland

The understanding teachers have of their students' home backgrounds is a crucial dimension in the way teachers make sense of students' transitions between home and school. Research in this area has addressed issues about the cultural nature of school knowledge and how "everyday cognition" differs from "school cognition". As societies become increasingly diverse due to globalisation and migration, it is apparent that the mismatch between teachers' and students' cultural backgrounds is not only an issue of cognition but also an issue of identities. Research with teachers has mostly focused on the teachers' constructions of culturally diverse students, yet the ways in which teachers construct students are not independent of the way they construct themselves. In this paper, we question what new insights using concepts from Dialogical Self Theory can reveal about teachers' constructions of self and other in the school. Focusing on cultural contact zones where individuals must struggle to negotiate their lives and identities between cultures, Dialogical Self Theory holds that identities are constructed in dialogue, interdependent with the cultural context. This enables the study of the mutual relationships between self and other. We argue that modifying the traditional identity question "Who am I" to "Who am I in relation to the other" must also consider "Who

is the other in relation to who I am?" We illustrate this in our analysis of the impact teachers' constructions of themselves have upon their constructions of the students and their families.

Aims

This paper aims to examine how an analysis using concepts from the Dialogical Self can contribute to further understanding of the processes involved in teachers' constructions of their immigrant students, and their family backgrounds. Focusing on "Who is the other in relation to who I am?" We aim to empirically examine the impact of teachers' constructions of themselves in their constructions of their students and families.

Introduction

The understanding teachers have of their students' home backgrounds is a crucial dimension in the way teachers make sense of students' transitions between home and school. Research in this area has addressed issues about the cultural nature of school knowledge and how "everyday cognition" differs from "school cognition". As societies become increasingly diverse due to globalisation and migration, it is apparent that the mismatch between teachers' and students' cultural backgrounds is not only an issue of cognition but also an issue of identities. Research with teachers has mostly focused on the teachers' constructions of culturally diverse students, yet the ways in which teachers construct students are not independent of the way they construct themselves. In this paper, we question what new insights using concepts from Dialogical Self Theory can reveal about teachers' constructions of self and other in the school. Focusing on cultural contact zones where individuals must struggle to negotiate their lives and identities between cultures, Dialogical Self Theory holds that identities are constructed in dialogue, interdependent with the cultural context. This enables the study of the mutual relationships between self and other. We argue that modifying the traditional identity question "Who am I" to "Who am I in relation to the other" must also consider "Who is the other in relation to who I am?" We illustrate this in our analysis of the impact teachers' constructions of themselves have upon their constructions of the students and their families. Methodology: The empirical data examined consists of in-depth qualitative interviews from two studies that explored teachers' experiences and representations of their immigrant and minority students.

One study focused on teachers of Portuguese students in schools in England and Jersey (Abreu & Hale, 2003). The other study focused on teachers of ethnic minority children in England (Crafter, 2004). The rationale for drawing on interviews from more than one study follows on principles of cultural-psychological investigations. It involves an idiographic scientific methodological stance where the production of new knowledge is achieved from the analysis of single-cases to understand and explain the phenomena in other cases. Analytical framework and some illustrative findings: The interviews with teachers were coded firstly in terms of talk about the self in relation to the other, and secondly talk about other teachers. In the first, two constructions are paid particular attention: the self in relation to the construction of the student, and the self in relation to the construction of the students' families. In the second, particular attention was paid to talk about the other teachers in relation to the student and secondly in relation to the construction of the families. Below some findings from teachers' interviews that demonstrate attempts to make sense of the other (the student) using the self as the filter are presented. In the conference examples about constructions of families will be included.

1. TALK ABOUT THE SELF IN RELATION TO THE OTHER (the student) Positioning the self as the same a teacher with non-English background reflected on her own identity and trajectory as a mechanism to empathise with the students' experiences. Referring to her French cultural background she said "I've been through that myself". Positioning the self as different a native English teacher expressed aspects of her identity (language skills) which limited access to the immigrant students: "I don't feel very happy talking about her because um she's just so very quiet and I'm only just beginning to gain confidence enough for her to tell me what's going on. I don't speak Portuguese." Positioning the self as an "empathiser" one teacher drew on her professional identity to reflect on how she could empathise with her students' experiences: "I don't know where I have got it particularly from. Being an English teacher, I suppose you have got a natural empathy for other people."

2. TALK ABOUT OTHER TEACHERS IN RELATION TO THE SELF Extracts from the teachers' interviews also demonstrate attempts to make sense of other teachers' constructions of the student through comparisons with the self: Positioning the self as different (distancing from the "others"): Those teachers, who felt that they developed strategies that enabled them to empathise with aspects of the students' identities, also talked about differences between "other" teachers and self. As an example, one teacher reflected on attitudes in relation to school uniform: "I think with teachers you've got to be aware of this as well. You know, that it's one step to have them in full school uniform for instance. And then you don't want other staff members saying, 'Why haven't you got shoes on today?', 'Why are you wearing your trainers?'. Whereas I know perfectly well that there's a very good reason for that." Here the teacher was able to position herself as more aware of students' troubles than other teachers in the school.

Conclusion

A more detailed analysis will be presented at the conference. The illustrative findings suggest how the varying positioning of the self are involved in the construction of the other. They offer a theoretical contribution, demonstrating the development of an analytical framework to understand processes underlying teachers' understanding of their students. Moreover making these processes explicit has an enormous potential of contributing to teachers' professional development. This is particularly relevant, as the data illustrate how teachers can draw on both on their cultural and their professional identities to empathise with, or to distance themselves from, their students' experiences.

Parent-teacher conversations: The dialogical nature of culturally diverse pedagogies

Mariette De Haan, Utrecht University, Netherlands; Ed Elbers, Utrecht University, Netherlands; Inge Wissink, University of Amsterdam, Netherlands

We analyse parent-teacher conferences at the end of primary education in the Netherlands -- part of a formal procedure in which the child's future school career is decided upon. The conversations teachers have with migrant parents are contrasted with those teachers have with non-migrant, Dutch parents. Dialogues between parents and teachers are analyzed in order to see (1) how parents and teachers in their dialogues explain the child's school success (or the lack of it), (2) to what extent teachers, migrant parents and native Dutch parents differ in their explanations of the child's school success, and (3) how conversational partners, if they have different views, deal with these differences dialogically. We recorded and analysed 54 conversations using a combination of quantitative and qualitative (content and discourse) methods. In the conversations with migrant parents, the issue of effort was more prominent, while in the conversations with native Dutch parents attitudes and personality were brought forward for explaining the child's school career. In particular, this study shows how the process of creating 'common ground' needed for the coordination of actions in the conversation as well as for the creation of partnerships between parents and teachers, differs between non-migrant and migrant parents. We focus not so much on the differences between the referential frames, but rather on the process through which they are enacted. The study shows how expressions of difference are dialogical in nature: they are reactions to perceived oppositions and therefore can only be understood in their 'reactive' context.

Aims

In the Netherlands, like in many other Western countries, ethnic minority children (and especially minority children with a non-Western ethnic background) generally attain lower educational levels than ethnic majority children. The first moment that these differences become apparent more clearly is in the final year of primary education, when the child is about to make the transition to secondary education. According to the procedure regulating this transition in the Netherlands, the primary school teacher formulates an advice for the level of secondary education for each child. This advice is presented to and discussed with the child's parents in a series of formal talks. The advice is based on the child's score on a national test but it also depends on the teacher's impression of the child's abilities. In this presentation we will analyse the parent-teacher conversations at the end of primary education in which the child's future school career is decided upon. We take a comparative approach by contrasting the conversations between teacher and migrant parents with those between teachers and non-migrant, Dutch parents. We aim at gaining insight in (1) how parents and teachers in their dialogues explain school success (or the lack of it), (2) to what extent teachers, migrant parents and native Dutch parents differ in their explanations of the child's school success, and (3) how conversational partners, if they have different views, deal with these differences dialogically. We refer to theories of culture as dialogue (Clifford, Hannerz, Tedlock & Mannheim), from which we borrow the idea that cultural meanings and differences are not 'given', but constructed and managed in dialogical encounters. In addition, Communication Accommodation Theory (Jones et al, 2009) provides us with models of how partners with a diverse background try to bridge perceived differences in terms of discursive strategies.

Methodology

We audio recorded 54 formal talks about the child's transition to secondary school in four Dutch primary schools with a large percentage of migrant pupils. We transcribed the recordings which involve 15 native Dutch children, 22 Moroccan-Dutch children and 17 children of various migrant backgrounds. The talks lasted on average 16.46 minutes. Five teachers participated in the conferences, which were conducted in Dutch. All Dutch parents, but none of the migrant parents, had attended school in the Netherlands. In the majority of cases, one parent (father or mother) was present in the conference; in some conferences both parents participated; in a small number of cases another member of the family (sister, aunt) attended the conference. The study takes a mixed method approach as quantitative methodologies are combined with qualitative analysis. The quantitative analysis focused on the

attributions and accounts parents and teachers make to explain the school success or lack of success of the child. The qualitative analysis, which we did on a sample of 34 Dutch and Moroccan-Dutch parents, consisted of a content analysis and discourse analysis of the talks, concentrating on how teachers and parents constructed these accounts dialogically, how they dealt with differences conversationally, and to what extent they succeeded in creating a common view on the child's future.

Findings

Both the quantitative and qualitative analyses revealed that there were thematic differences between the two groups of parent-teacher conversations. In the conversations with migrant parents, the issue of effort was more prominent, while in the conversations with native Dutch parents attitudes and personality were brought forward for explaining the child's school career. The qualitative analysis showed that, since the attributions were made in an interactive context, they were always responsive to previous utterances of the other conversation partner and to perceived oppositions. Because of their institutional position teachers dominated the talks. The conversations with the native Dutch parents were mostly characterized by a partnership relationship, in which the teacher and parents often succeeded in co-constructing explanations and continued each other's ideas and suggestions. In contrast, many conversations with migrant parents were characterized by either opposition or by a passive position of the parents. In the conversations with the migrant parents differences were emphasized, both by the teacher and the parents, in terms of identity, knowledge of the educational system, language, pedagogical views and the responsibility of the teacher. Often these differences could not be overcome, despite attempts by the teacher and parents to bridge the distance. Scientific and educational significance. This study provides an analysis of parent-teacher conferences in schools with a large population of children from migrant families. This is not the first study that addresses this type of conferences. However, in contrast to other studies, it is not based on interviews or questionnaires, but on actual conversations which were recorded, transcribed and analysed with both quantitative and qualitative methods. The quantitative analysis provides a first insight into the accounts and attributions of the partners. We did not consider the accounts and attributions as separate or isolated contributions. Therefore, we applied a qualitative analysis (content and discourse analysis) to put the accounts and attributions into the context of the conversation. This study revealed that the distance between the teacher and the parents, as well as between the school and the home (as perceived or constructed in the talk), defined the possibilities for both co-constructing explanations for the child's school success or lack of it and the possibilities for constructing a view on the child's future. The implication is that schools should be pay explicit attention to how diversity operates in contacts with parents and in processes of decision making.

SYMPOSIUM

Current Trends in Metacognition Research

Chairperson: Stephanie Pieschl, University of Muenster, Germany

Organiser: Stephanie Pieschl, University of Muenster, Germany

Roger Azevedo, McGill University, Canada

Discussant: Zemira Mevarech, Bar-ilan University, Israel

The goal of this symposium is to present an overview of the (future) SIG coordinators' work as examples of current trends in metacognition research. In all three presentations, metacognitions are not investigated as stand-alone constructs. Rather, metacognitions such as planning, monitoring, and evaluation are embedded in complex models of self-regulated learning (SRL) that is assumed to unfold in multiple phases over time. These studies take this into account, for example, by using methodologies that can concurrently trace SRL processes (e.g., log files or think aloud protocols; Azevedo, Pieschl) or by specifically addressing different phases of SRL in different studies (Pieschl, Wirth). Further common themes of all presentations include the use of hypermedia or simulation technology, scientific learning content, and scaffolding metacognitive and SRL processes. However, these studies also reflect different focuses and avenues, especially with regard to scaffolding: Pieschl tested scaffolding on the level of epistemological

beliefs and in interaction with contextual conditions. Azevedo's work revolves around the design of adaptive (metacognitive) hypermedia systems such as MetaTutor and pedagogical agents that can deliver prompts and feedback. Wirth focused on scaffolding via very specific prompts in different phases and regarding different demands of SRL. Therefore, these presentations illustrate current trends in metacognition research, especially regarding new methodologies to capture and analyse data, new ways to scaffold metacognition and SRL, and use of new technologies for these purposes.

Adaptation to Complexity and Learners' Epistemological Beliefs as Important Aspects of SRL

Stephanie Pieschl, University of Muenster, Germany

Within a series of empirical studies we investigated learners' self-regulated learning (SRL) processes in hypermedia learning scenarios in detail. For this purpose, we focused on two important but rarely investigated issues: (1) Learners' adaptation of their SRL processes with regard to the contextual condition of task complexity. (2) And the impact of learners' epistemological beliefs on their SRL processes, especially on this kind of adaptation. Our empirical studies focus on different phases of SRL and utilize multiple methodologies to capture learners' SRL processes in detail, for example computer-generated log files and task-specific questionnaires. Consistently results show that learners systematically adapt their SRL to task complexity (1): They set more elaborate goals, (plan to) use more elaborate learning strategies, spend more time, and generate more elaborate products of learning (e.g., essays) for more complex tasks. Their SRL processes systematically co-vary with task complexity. Therefore we conclude that learners are well-calibrated in this regard. Results regarding epistemological beliefs are less consistent (2): Mostly, more sophisticated epistemological beliefs in complex and tentative knowledge are associated with better SRL processes and products, especially for complex tasks. Therefore, epistemological beliefs seem to be especially relevant for dealing with complex learning material. The theoretical and educational implications of these results will be discussed.

In this presentation I will argue that self-regulated learning (SRL) and associated metacognitive processes are highly dependent on external and internal conditions. Based on Winne and Hadwin's (1998) model of SRL and elaborations (Bromme, Pieschl, & Stahl, 2010a; Greene, Muis, & Pieschl, 2010; Pieschl, 2009). I will use the following exemplary hypotheses for illustrating these assumptions: (1) Good self-regulating learners systematically adapt their SRL to the external condition of task complexity. (2) And learners with more sophisticated epistemological beliefs (internal condition), namely in the complex and tentative nature of knowledge, demonstrate better SRL and better adaptation to task complexity. These hypotheses were investigated in a series of studies where learners used a hypermedia learning environment to learn about the topic of genetic fingerprinting (DNA analysis). Two studies will be reported in detail, one about the first goal setting and planning stages of SRL and one focusing on the later enactment stages.

In the first study (Bromme, Pieschl, & Stahl, 2010b) 52 biology students and 50 humanities students answered questions about their domain-specific and domain-general epistemological beliefs. In the main part of the study, they were given a list of six tasks of different complexity according to Bloom's revised taxonomy (Anderson et al., 2001). This constitutes the within-subject independent variable task complexity. For each of these tasks they filled-in a questionnaire about their goal setting and planning. While answering this questionnaire they had to envision solving the tasks with the help of a hypermedia learning environment about genetic fingerprinting. A factor analysis of the questionnaire items yielded three scales that were used as dependent variables: Deep processing, superficial processing, and use of multiple information sources. Results consistently indicate that learners systematically adapt their (planned) SRL to task complexity: A repeated-measure MANOVA showed significant effects of the within-subject factor task complexity for all dependent variables. And within-subject correlations between task complexity and the dependent variables were significant and of large effect size for all dependent variables. For example, the correlation of $G = .74$ (Goodman-Kruskal's Gamma) between task complexity and the scale use of multiple information sources indicates that learners planned to use few information sources for simple tasks but multiple information sources for complex tasks. To investigate the effects of epistemological beliefs, these scales (as well as the prior knowledge groups) were included in the MANCOVA. Results indicate predominantly main effects of learners' domain-specific epistemological beliefs in the variability of knowledge: Learners who believed in variable knowledge planned more use of deep processing strategies ($F(1,97) = 5.23, p = .024$) and more use of multiple information sources ($F(1,97) = 7.58, p = .007$) than those who believed in static knowledge.

In the second study (Pieschl, Bromme, & Stahl, in prep.) we used a similar paradigm to investigate these effects in the later enactment stages of SRL. This time, however, students' epistemological beliefs were experimentally manipulated: Students with an epistemological sensitisation that elicited more sophisticated epistemological beliefs were compared with students with a neutral treatment that did not change their beliefs. In the main part of the study, 14 biology students and 21 humanity students had to solve five tasks of different complexity according to Bloom's

revised taxonomy (Anderson et al., 2001) with a hypermedia environment about genetic fingerprinting. As dependent variables their SRL processes were captured via logfiles and concurrently verbalized thoughts were recorded and categorized. Results consistently indicate that learners systematically adapt their SRL to task complexity: Repeated-measure MANOVAs showed significant effects of the within-subject factor task complexity for all dependent variables. And within-subject correlations between task complexity and the dependent variables were significant and of large effect size for all dependent variables. For example, the correlation of $G = .94$ between task complexity and time-on-task indicates that learners spent little time on simple tasks but more time on complex tasks. To investigate the effects of epistemological beliefs, the groups of the experimental manipulation (as well as the prior knowledge groups) were included in the MANOVAs. Results indicate significant interactions between task complexity and these groups. For example, students with the epistemological sensitisation spent more time on the complex tasks but less time on the simple tasks than their counterparts with the neutral treatment ($F(4,96) = 3.41, p = .012$).

To summarize, our empirical results consistently show that learners systematically adapt their SRL to task complexity (1): They set more elaborate goals, (planned to) use more elaborate learning strategies, spent more time, and generated more elaborate products of learning for more complex tasks. Results regarding epistemological beliefs are less consistent (2): Mostly, more sophisticated epistemological beliefs in complex and tentative knowledge were associated with better SRL processes and products, especially for complex tasks.

These results have theoretical as well as practical implications: First, the results regarding adaptation indicate that the external context of SRL always has to be taken into account, for example the domain of learning and the concrete learning materials and tasks. Second, the results regarding epistemological beliefs imply that such beliefs might act as an apprehension structure for the content to be learnt.

Self-Regulated Learning with Multi-Agent Technology-Enhanced Learning Environments

Roger Azevedo, McGill University, Canada

This presentation will focus on current issues and future challenges regarding the role of self-regulation processes during learning with multi-agent technology-enhanced learning environments. More specifically, it will focus on issues related to the: (1) conceptualization and measurement of self-regulated learning (SRL); (2) measurement of SRL during learning with multi-agent AI-based intelligent systems; (3) detecting, tracking, and modelling these processes while learning about complex learning material (e.g., human body systems); and, (4) how these data are used to foster students' SRL during learning. These issues will be discussed based on the results of a recent lab experiment that was conducted to test the effectiveness of MetaTutor, an intelligent and adaptive multi-agent hypermedia system designed to prompt and scaffold the use of self-regulated learning (SRL) processes during learning about the human circulatory system. In this study, 77 non-science college students were randomly assigned to one of three conditions (prompt and feedback [PF], prompt-only [PO], and control [C] condition). All participants had two hours to learn using a 41-page hypermedia environment which included texts describing and static diagrams depicting various topics concerning the human circulatory system. We collected pretest and posttest data and log-file, eye-tracking, concurrent think-aloud protocols, and facial recognition data were collected during learning. Results showed significant difference those in the PF condition significantly outperformed those in the other two conditions.

Learning with MetaCognitive tools such as MetaTutor poses challenges for learners. This presentation will highlight the importance of using self-regulated learning (SRL) as a framework to understand the complex nature of learning with MetaCognitive tools. More specifically, I will focus on illustrating the benefits and challenges of using a theoretically-based approach to understand the nature of key processes of self-regulated learning, how they unfold in real-time, their roles during various phases of learning (for example, knowledge acquisition versus knowledge integration), and the qualitative and quantitative changes in self-regulated learning processes during the course of extended learning. This comparison will be supported by illustrative examples of product and process from a recent study. In the study, seventy-seven ($N = 77$) non-science college students were randomly assigned to one of three conditions (prompt and feedback [PF], prompt-only [PO], and control [C] condition). The PF condition received timely prompts from pedagogical agents to engage in planning processes, monitoring processes, and learning strategies and also received immediate directive feedback from the agents concerning the deployment of the processes. The PO condition received the same timely prompts, but did not receive any feedback following the deployment of the processes. Finally, the control condition learned without any assistance from the agents during the learning session. All participants had two hours to learn using a 41-page hypermedia environment which included texts describing and static diagrams depicting various topics concerning the human circulatory system. We collected pretest and posttest data and log files, eye-tracking data, concurrent think aloud protocols, and facial recognition data were collected during learning. Results showed significant difference those in the PF condition significantly outperformed those in the other two conditions. Those in the PF condition also spent significantly more time creating relevant sub-goals, spent more time on relevant text and diagrams, and deployed significantly more self-regulated learning processes associated with learning gains.

These results are discussed in the context of development of a fully adaptive hypermedia learning system intended to scaffold self-regulated learning. In addition, we provide a synthesis of our previous work by emphasizing the convergence of product and process data to trace the deployment of self-regulated learning processes and relate them to different learning outcomes (for example, declarative, procedural, and inferential knowledge, and mental models of biological systems). Classifying these processes at various levels of granularity is important for several reasons. For example, macro-level (for example, monitoring process) and micro-level classifications (for example, monitoring process such judgment of learning [JOL]) supplemented with valence (i.e., positive or negative [e.g., JOL+]) is key to understanding the multi-level nature of these processes (and inter-related feedback mechanisms) and serves to augment current conceptions and theoretical frameworks of SRL. Also, from a design perspective this multi-level classification is crucial for building adaptive systems with the ability to detect, model, trace, and foster SRL during learning. Lastly, we provide quantitative and qualitative data from learning outcomes, SRL processes, and log-file data with MetaTutor and discuss how this data can be used to design an adaptive version of MetaTutor to detect, trace, model, and foster students' self-regulated learning about complex and challenging science topics. The presentation will end with recommendations for future research that emphasize work on the conceptual, methodological, and analytical issues and approaches that allow researchers and educators to understand the role of these processes during self-regulated learning with MetaCognitive tools. For example, the use of sensors will be necessary to collect and analyze various physiological, cognitive, metacognitive, and affective states during learning. Also, new data analytical techniques and visualization tools are necessary to represent and analyze complex multi-channel data stemming from the use of computers as MetaCognitive tools.

Different Ways of Supporting Self-Regulated Learning

Joachim Wirth, Ruhr-University Bochum, Germany

Self-regulated learning can be modeled as a process with different phases (fore-thought, performance, and reflection) with each phase setting specific demands (goal setting, planning, observing, evaluating, and reacting) on learners. Since demands differ between phases, learners need different competencies to meet these demands. In several experimental studies we investigated how learners can be supported to meet a specific demand within a specific phase. In the first study, we investigated which goal type is most effective in fostering learning. It turned out that especially specific problem solving goals hinder learning whereas non-specific goals as well as learning goals were equally effective. In a second study, we used prompts in order to support planning and executing strategy use. We investigated whether the point of presentation time of strategy prompts has an effect on strategy use and learning outcome. It turned out that prompts delivered before learning were not effective. But prompts presented during the learning process were all equally effective independently from their point of presentation time. In a third study, we investigated feedback on strategy use as a support measure for evaluating strategy use. It turned out that feedback can enhance the effect of strategy prompts on strategy use. In sum, the studies show that there are multiple ways of supporting self-regulated learning. But what is still missing is a comprehensive set of measures focusing on the

competencies needed to meet the different demands. This could be an even more effective way of supporting self-regulated learning than focusing on demands only.

Theoretical models on self-regulated learning can be categorized in either component models or process models. Component models (e.g., Boekaerts, 1999) focus on pre-requisites and competencies of learners whereas process models (e.g. Winne & Hadwin, 1998; Zimmerman, 2000) describe the learning process in terms of different phases and different demands on learners. Schýtte, Wirth, and Leutner (in press) suggest integrating both kinds of models taking into account that learners encounter different demands in different phases of the learning process and therefore also need different competencies in different phases (Figure 1). Schýtte et al. identify three phases, a forethought phase which entails two main demands, i.e. goal setting and planning, a performance phase including the demand of observing oneself, and a reflection phase that comprises the demands of evaluating and reacting. They also specify nine different competencies learners need in order to meet the different demands (Figure 1). This integrated model can be used, on the one hand, as a framework for the assessment of the different competencies self-regulated learners need. On the other hand, it is also useful in order to create support measures for the learners that help them to meet the demands. In this paper, we focus on the support measures. Concerning goal setting, Wirth, Kýnsting, and Leutner (2009) conducted an experimental study with students learning in a computer-simulated science lab. Between groups, students received different kinds of goals according a 2-by-2 design with the two factors goal type (learning goal vs. problem solving goal) and goal specificity (specific vs. non-specific).

Results revealed that specific problem solving goals hinder learning what is partly due to the use of inappropriate learning strategies whereas the other three conditions did not differ concerning learning outcome. Thus, self-regulated learning can be supported either by setting non-specific goals or, even better, by setting specific learning goals. Concerning planning and using learning strategies, Thillmann, Kýnsting, Wirth, & Leutner (2009) investigated whether prompting can be an effective support measure, and whether the timing of the different prompts fosters strategy use and learning outcome. Again, students learned in the computer-simulated science lab. All students received identical prompts concerning the use of different learning strategies. Groups differed concerning the point of presentation time of the prompts. While the control group received all prompts before learning, experimental group 1 received prompts while learning and according to an optimal course of strategies. Experimental group 2 was also prompted while learning but received prompts opposite to the optimal course of strategies. It turned out that both experimental groups outperformed the control group concerning strategy use and learning outcome. However, experimental groups did not differ. One reason could be that prompts initiated general monitoring processes independent from the specific strategy prompted, and that these monitoring processes led to good strategy use and learning outcome. Nevertheless, prompting while learning turned out to be an effect support measure for planning and using learning strategies. In a recent study, we combined prompting with feedback information in order to support evaluating and reacting. Learners learned with the computer-simulated science lab, and their strategy use was assessed continuously by the computer. Students were assigned to one of four groups. In three groups students received prompts at several points of time while learning.

Group A received prompts concerning the use of different learning strategies according to a generally optimal course of strategies. Group B received respective prompts adapted to their current strategy use. Learners of group C received feedback about their strategy use always followed by an adapted prompt. Group D, the control group, received neither prompts nor feedback. It turned out that students of group C outperformed students in the other groups concerning strategy use and also motivation. Adapted prompts only (group B) had no significant effect compared to non-adaptive prompts or no prompts. Thus, it seems that evaluation of current strategy use, as it was triggered by feedback, can lead to an understanding why a certain strategy is prompted. As a consequence, learners accept and use the prompt information in order to improve their strategy use. To sum up, all studies presented are examples for successful ways of supporting self-regulated learning. They differ concerning the particular phase of self-regulation and the respective demands. But all of them have in common that they do not explicitly address the different competencies needed to meet the demand. It is an open question whether support measures also addressing each single competency could be even more effective than measures focusing only on demands and phases.

SYMPOSIUM

Metacognition in children with special educational needs

Chairperson: Gerhard Buettner, University of Frankfurt, Germany

Adina Shamir, School of Education, Bar-Ilan University, Israel

Organiser: Gerhard Buettner, University of Frankfurt, Germany

Adina Shamir, School of Education, Bar-Ilan University, Israel

Discussant: Ruth Kershner, University of Cambridge, United Kingdom

Metacognition is perceived in the literature as a powerful predictor of learning and accountable in great part for individual differences in children's development as learners. Yet, despite the wealth of theory and research the findings regarding the role of metacognition in promoting Special Educational Needs (SEN) students needs further investigation. The symposium will include presentations of researchers from Belgium, Israel and Germany. Desoete's and De Weerd's presentation will focus on metacognition and arithmetic in children with an isolated and comorbid learning disability. The authors will present a study aimed at validating a parent and teacher questionnaire for assessment of metacognitive skills as well as examining the relationship between metacognition and arithmetic. In joining the effort to introduce some clarity into the discussion about the effectiveness of electronic books (e-books) for promoting preschoolers at risk for learning emergent literacy Shamir and Lifshitz will present a study aimed at examining the effect of an activity with an educational e-book (with and without metacognitive guidance) on the vocabulary and rhyming ability of kindergartners at risk for learning disability. Deficits in metacognition are assumed to be a significant condition of the development and maintenance of cognitive problems of children with low intelligence. The third presentation (Buettner) refers to a study aimed at investigating both declarative knowledge and procedural metamemorial skills in two groups of children with mild and borderline intellectual disabilities and in control groups with both the same mental and chronological age. Ruth Kershner from Cambridge University, Great Britain, will discuss the presentations.

Are children with dyscalculia and dyslexia more impaired in metacognition than children with isolate Learning disabilities

Annemie Desoete, Ghent University, Belgium; Frauke DeWerd, University Gent, Belgium

In this paper it is investigated if a triangulation of parent and teacher questionnaire can be used to get a good picture of metacognitive skills in elementary school children. In addition the relationship between metacognition and arithmetic is investigated in children with an isolated and comorbid learning disability. For this purpose the parents and teachers of 48 children with dyslexia, 26 children with dyscalculia, 52 children with dyslexia and dyscalculia and 93 control children without learning disabilities completed the BRIEF (Goia et al., 2000). All children were at least average intelligent. Our dataset suggests convergent validity for teacher and parent ratings, as well as a significant relationship between the metacognition and procedural calculation and fact retrieval. Consequences for the assessment of metacognitive skills and for the concept of comorbidity will be discussed.

Although some researchers question the trustworthiness of teacher questionnaire data, reviews indicate that teachers' judgments can serve as worthy assessments of students' achievement-related behaviors triangulated with data gathered by other protocols. In this paper it is investigated if a triangulation of parent and teacher questionnaire can be used to get a good picture of behaviour regulation and metacognitive skills in elementary school children. In addition it is studied if children with a combined learning disability differ on behaviour regulation ('hot' executive functions) and metacognition ('cold' executive functions) from children with isolated dyslexia or dyscalculia on metacognition. For this purpose the parents and teachers of 48 children with dyslexia (27 boys and 21 girls), 26 children with dyscalculia (10 boys, 16 girls), 52 children with dyslexia and dyscalculia (23 boys, 29 girls) and 93 control children without learning disabilities (43 boys, 50 girls) completed the BRIEF (Goia et al., 2000). The BRIEF measures 'hot executive functioning' or behaviour regulation (inhibition, cognitive flexibility and emotion regulation) as well as 'cold executive functioning' or metacognition (taking initiatives, working memory, planning, precision and behaviour

evaluation). The MANOVA with as dependent variable the parent ratings as dependent variable and the group (DL, DC, DC+,Co) was significant for the behaviour regulation index as well as for the metacognition index. This was also the case for the MANOVA on the parent ratings as dependent variable. For M and SD and post hoc indexes we refer to Table 1.

There was a significant correlation between the behaviour regulation rating of parents and teachers ($r=.39$, $p \leq .0005$) and between the metacognition rating of both respondents ($r=.56$; $p \leq .0005$). There was also a significant correlation between the metacognitive ratings of parents and procedural calculation ($r=-.30$, $p \leq .0005$) and fact retrieval ($r=-.39$; $p \leq .0005$). and between the metacognitive ratings of teachers and procedural calculation ($r=-.39$, $p \leq .0005$) and fact retrieval ($r=-.34$; $p \leq .0005$). One of the education implications of this study is that parent and teacher questionnaires can be used to assess metacognitive skills in elementary school children. In addition it might be good practice to try to enhance and train less developed skills or adapt our instruction to ensure that children with learning disabilities are not placed at a substantial disadvantage compared to non-disabled students. From theoretical perspective children with DC+ might have a problem with hot and cold executive functioning, whereas in children with isolated DC or DL only the cold component (metacognition) seems impaired. In addition children with DC+ seem to show few initiatives and were found to have problems with tasks depending on working memory and planning. Planning and working memory was also impaired according to the teachers in DC, whereas DL was only a problem of working memory according to them. The implication for the concept of comorbidity will be discussed

E-books and Metacognitive Guidance for Promoting Emergent Literacy among Children at Risk for Learning At-risk students

Adina Shamir, School of Education, Bar-Ilan University, Israel

The aim of the research was to examine the effect of an activity with an educational electronic book (e-book) (with and without metacognitive guidance) on the vocabulary and rhyming ability of kindergartners at risk for learning disability. Seventy seven kindergartners aged 4.5-7.0 years ($M=5.88$, $SD=.67$) participated in the research. The subjects were randomly divided into three groups: the first experienced 5 intervention sessions with an educational e-book that contains metacognitive guidance ($n=26$), the second experienced 5 sessions with an identical book without metacognitive guidance ($n=25$), and the third group (control) participated in the regular kindergarten program ($n=26$). The children's cognitive level (verbal and nonverbal), rhyming level and vocabulary were examined pre-intervention. The children's vocabulary and rhyming level were again evaluated post-intervention. The research findings indicate a significant improvement in vocabulary and rhyming among the two groups of subjects who worked with the e-book compared to the control group. The greatest improvement in rhyming was found in the group that received metacognitive guidance. However, the group that received metacognitive guidance did not exhibit greater improvement in Vocabulary than the other experimental group. The findings will be discussed during the symposium.

Many children with learning disabilities have a history of difficulties in acquisition of the spoken language and mastery of its components (Catts, Fey, Zhang and Tomblin, 2001; Carroll and Snowling, 2004). These difficulties may later affect the ability to acquire reading and reading comprehension (Carroll and Snowling, 2004; Torgesen, 2002) and place them at risk for learning disability (NJCLD, 2006). It is therefore important to investigate unique methods for improving the emergent literacy of these children, taking into account their special needs, before they develop an adverse attitude towards this field. In this spirit, the aim of the current study was to examine the effect of an activity with an educational electronic book (e-book) on the vocabulary and rhyming ability of kindergartners at risk for learning disability. We also examined the effect of an activity with an e-book that combines self-regulation (planning before and evaluating after the task) metacognitive guidance, based on researches that indicated a deficit in the metacognitive skills of students with learning disabilities (Desoete and Roeyers, 2002). The e-book was developed for the purposes of the current research based on knowledge which has accumulated from the development of earlier e-books (Shamir and Korat, 2007) found to promote emergent literacy among young children.

The present book was adapted to the population of children at risk for learning disability both in terms of content and in terms of activities intended to contribute to the development of emergent literacy and metacognitive awareness. Few studies have been performed to date on the effect of an activity with an educational e-book on emergent literacy among children at risk for learning disability. In a recent study performed in order to compare the effect of an activity with an e-book to an activity with a written book on the emergent literacy of kindergartners at risk for learning disability, a significantly greater improvement in vocabulary and phonological awareness was found among the e-book group compared to the printed book group (Shamir, Fellah and Korat, 2010).

To the best of our knowledge, the effect of an activity with an e-book on the rhyming ability of young children and the effect of an activity with an e-book that combines metacognitive guidance have not been investigated so far. Seventy seven kindergartners (72.7% boys and 27.3% girls) participated in this study. Most of the subjects (except five) attended special education kindergartens for children with developmental delays. All subjects spoke Hebrew as their mother tongue, came from an average socioeconomic background and had a mental potential within the normal range but a low linguistic ability for their chronological age. They had no additional complex problems. The subjects' age was 4.5-7.0 years ($M=5.88$, $SD=.67$). All subjects were diagnosed by the educational psychological services as having specific developmental delays or learning difficulties which place them at risk for learning disability. The subjects were randomly divided into three groups: two experimental groups that experienced intervention with an e-book, one with a book that contains metacognitive guidance ($n=26$) and another with an identical book without metacognitive guidance ($n=25$), and a third group (control) that participated in the regular kindergarten program ($n=26$). The study included three stages: pre-intervention, intervention and post-intervention. The pre-intervention testing stage included an evaluation of the children's cognitive level (verbal and nonverbal), an evaluation of the level of their phonological awareness (rhyming) and an assessment of their vocabulary. The intervention stage included a total of 5 sessions. In the first session the story was presented to small groups of subjects (3-4 subjects per group), who were given an explanation on how to work with the software. The children then worked with the book individually in 4 additional sessions. The children's vocabulary and rhyming level were again evaluated post-intervention. Regarding recognition of rhyming words the analyses performed in order to examine the differences between the research groups yielded a significant difference between the group that received metacognitive guidance and the group that did not receive metacognitive guidance, $F(1,47)=8.30$, $Ph2=.15$, and between the group that received metacognitive guidance and the control group, $F(1,48)=4.56$, $Ph2=.09$. No significant difference was found between the group that did not receive metacognitive guidance and the control group, $F(1,47)=1.47$, $P>.05$.

These findings support the research hypothesis according to which the greatest improvement in the recognition of rhyming words would be found among subjects in the group that received metacognitive guidance, but do not support the hypothesis that the achievements of the group that did not receive metacognitive guidance would be greater than the achievements of the subjects in the control group. The analyses performed in order to compare the pre and post-intervention Vocabulary measurement in each of the research groups separately yielded a significant difference between the two measurements among the intervention group that received metacognitive intervention, $F(1,25)=26.76$, $Ph2=.52$, and the intervention group that did not receive metacognitive guidance, $F(1,24)=35.19$, $Ph2=.59$. However, no significant difference was found among the control group, $F(1,25)=1.58$, $P>.05$. In accordance with the research hypothesis, a difference was indeed found between the achievements of the subjects in the two intervention groups compared to the control group. However, the group that received metacognitive guidance did not exhibit greater improvement than the group that did not receive metacognitive guidance. In sum, the research findings indicate a significant improvement in vocabulary and rhyming among the two groups of subjects who worked with the e-book compared to the control group. One of the educational implications of the current research is that activity with an educational e-book comprises a good opportunity for cultivating the emergent literacy of children at risk for learning disability, in the event that it has a structure that supports literacy and is not software that only affords amusement. Activity with an educational e-book (with and without metacognitive guidance) promotes vocabulary and phonological awareness at the rhyming level among children at risk for learning disability. From the theoretical aspect, the findings of the present research present new findings on the unique effect of metacognitive guidance as part of an activity with an e-book in general, and indicate its effectiveness in advancing phonological awareness at the level of rhyming among children at risk for learning disability in particular. Nonetheless, the unique effect of self-regulation metacognitive guidance integrated within an activity with an educational e-book on the promotion of emergent literacy among children at risk for learning disability should be investigated in future studies. The findings of the research and their educational implications will be discussed at the conference.

Metacognitive competencies in children with low intelligence

Gerhard Buettner, University of Frankfurt, Germany

According to many theoretical approaches in cognitive psychology, metamemory is an important determinant of cognitive performance. Children with low intelligence (IQ below 85) are characterized by poor cognitive performance. From the perspective of cognitive psychology, deficits in metamemory are assumed to be a significant condition of the development and maintenance of cognitive problems of children with low intelligence. The study aimed at investigating declarative knowledge on memory as well as procedural metamemorial skills in two groups of children with low intelligence (both mild and borderline intellectual disabilities) and in age matched control groups. After answering some questions on their knowledge about memory the children had to learn lists with easy and difficult paired associated pictures until each pair could be remembered. Subsequent to finishing the learning process they had to

predict the retrievability of the second picture of a pair two minutes after finishing the learning procedure, when prompted with the first picture (judgment of learning). Although all groups overestimated their memory performance, they were able to assess the retrievability of items above chance. The fourth graders with normal intelligence better predicted their learning outcome than the other groups which were very similar in their results. The average study time for easy and for difficult paired pictures was comparable in both the experimental and the control groups. The findings suggest that children with intellectual disabilities have some basic metacognitive competencies and are in their metacognitive development rather delayed than structurally different from children with normal intelligence.

Theoretical Background According to many theoretical approaches in cognitive psychology, metacognition is an important determinant of cognitive performance. One component of metacognition is metamemory. In line with theoretical core assumptions of the information processing approach empirical evidence shows a significant relationship between metamemory and memory performance (Schneider & Pressley, 1997). Based on the work of John H. Flavell (1971) and Ann L. Brown (1978) declarative and procedural components of metamemory are distinguished. Declarative metamemory refers to knowledge about structural aspects of memory, conditional knowledge about strategies, and knowledge about task difficulties. Procedural metamemory includes knowledge about both monitoring and control processes (e.g., planning, evaluating) necessary to manage memory efficiently. Based on this general perspective two metacognitive processes are distinguished in the influential procedural metamemory model developed by Nelson and Narens (1994): (1) monitoring of one's own learning processes (self-monitoring), and (2) allocation of study time. According to this procedural metamemory model, monitoring one's own learning process allows the learner to assess the current state of mastery of a given item and to predict future memory performance. Depending on the judgment of learning (JOL), either more study time is allocated to the item, or the learning process is finished. Children with low intelligence (IQ below 85) are characterized by poor cognitive performance. From the perspective of cognitive psychology, memory is a core condition of the efficiency of cognitive processes.

Consequently, deficits in several aspects of memory (memory capacity, strategy use, knowledge base, metamemory) are assumed to be significant conditions of the development and maintenance of cognitive problems of children with low intelligence (e.g., Ferretti & Cavalier, 1991). From an educational perspective, metamemory is especially interesting as a condition of memory performance since it is assumed to be changeable more easily than memory capacity or knowledge base. **Aims** The study aimed at investigating declarative knowledge on memory as well as procedural metamemorial skills in two groups of children with low intelligence (mild intellectual disabilities with IQ between 50 and 69, and borderline intellectual disabilities with IQ between 70 and 84). Using a design with two control groups (both same mental and same chronological age) it was investigated to what extent children with low intelligence are delayed in their development of declarative and procedural metamemory. **Method** The study included 20 fourth graders with mild intellectual disabilities, 25 fourth graders with borderline intellectual disabilities, 25 fourth graders with normal intelligence (same chronological age), and 45 first graders with normal intelligence (same mental age). After presenting two booklets with easy (e.g., sun – moon) and difficult (e.g., traffic light – parcel) paired associated pictures respectively, the children were asked to assess how difficult it would be to learn the pairs in the two booklets, and to justify their choice. In addition, the children were asked three questions on strategy use (e.g., What can you do to facilitate learning of difficult paired pictures?).

Subsequently, the children had to learn lists with easy and difficult paired associated pictures until each pair could be remembered. The pictures were presented on a computer screen. The allocation of learning time was measured. Following learning the total list of pairs the children were given the opportunity to learn the list a second or even a third time if they had the feeling that they could not retrieve all items. After finishing the learning process they had to predict the retrievability of the second picture of a pair two minutes after finishing the learning procedure, when prompted with the first picture (judgment of learning). The accuracy of the prediction of the retrievability of the items was assessed by Gamma correlations. The data were analysed with analyses of variance and post-hoc-tests for independent samples.

Results

Generally, the two groups of children with intellectual disabilities showed similar results. About two-thirds of the disabled children precisely assessed the difficulty of the two booklets. However, only few could justify their judgment. In addition, only a small percentage was able to correctly answer the questions on strategy use. Similar results were found in children with the same mental age. In contrast, the fourth graders with normal intelligence showed better results. They outperformed the other groups in all aspects of the declarative metamemorial knowledge. Although all groups overestimated their memory performance, they were able to assess the retrievability of items above chance. The fourth graders with normal intelligence better predicted their learning outcome than the other groups which were very similar in their results. With regard to allocation of study time more children with normal intelligence than

intellectually disabled children used the opportunity to learn the items a second time. However, surprisingly, the average study time for easy and for difficult paired pictures was similar in both the experimental and the control groups.

Discussion

The results show that the two groups of children with intellectual disabilities were very similar in their metacognitive competencies. This finding is somewhat challenging for the differentiation between borderline and mild intellectual disabilities. Further studies are necessary to clarify if the two groups are different in other cognitive competencies (e.g. working memory). Although all groups showed similar patterns in allocating study time to easy and difficult items the disabled children less often used the second opportunity to learn the list of items. This pattern of behaviour may reflect a mild metacognitive deficit. Generally, the children with intellectual disabilities and the matched same mental age children showed comparable competencies in both declarative and procedural metamemory. This finding suggests that the intellectually disabled children have some basic metacognitive competencies and are in their metacognitive development rather delayed than structurally different from children with normal intelligence.

SYMPOSIUM

Processing and storing approximate numerical magnitudes during mathematical operations

Chairperson: Ernest Van Lieshout, VU University Amsterdam, Netherlands

Organiser: Ernest Van Lieshout, VU University Amsterdam, Netherlands

Discussant: Denes Szucs, University of Cambridge, United Kingdom

Research in the last decades has shown that mathematical knowledge is not only acquired in school or during experiences with numbers outside school. Besides the ability to build exact mental representations of Arabic number symbols and number words, there is also an innate ability to deal with quantities in an approximate way. These quantities are mentally represented in an analogue code. There is growing evidence that analogue magnitude representations play a role in exact symbolic mathematics. One of the very important questions is how the different mental representations of numbers are linked to each other. Sophie Batchelor and Camilla Gilmore will present a study that addressed this question by contrasting predictions derived from Dehaene's Triple Code Model with predictions derived from Campbell and Clark's Encoding Complex Model. Children can differ either in the ability to process analogue information or in their capability to transform symbolic numerical information, which they encounter in school, into this analogue code. Bert De Smedt will cover this intriguing issue by contrasting Butterworth's Defective Number Module Hypothesis with Rousselle and Noël's Access Deficit Hypothesis. There is also the interesting question of which working memory resources are necessary to store and update an approximate representation of a number of objects after this number is changed. Iro Xenidou-Dervou, Ernest van Lieshout, and Menno van der Schoot will report on a dual task experiment that tried to isolate the relevant working memory components in terms of Baddeley's Tripartite Working Memory Model.

Semantic processing of Arabic numerals, written number words and nonsymbolic numerosities

Sophie Batchelor, University of Nottingham, United Kingdom; Camilla Gilmore, University of Nottingham, United Kingdom

When adults and children perform arithmetic they make use of multiple representations of numerical information. As well as number words and Arabic numerals that provide symbolic representations of exact number, nonsymbolic representations provide information about approximate numerical magnitudes. The ability to flexibly map across these representations supports the learning and performance of formal arithmetic (Gilmore et al., 2010; van Loosbroek et al., 2009). However the role of these different representations of number in numerical magnitude processing is unclear. Previous research has investigated whether we represent and process numerical information independent of notation. To date, the evidence is mixed and it has centred on the adult population, who have years of experience in using multiple representations of number. By testing 7-9 year old children's ability to compare numbers in different formats, the present study provided a stringent test of this question. Results showed that all children were able to make cross-notation comparisons, indicating that the ability to use multiple representations interchangeably develops early on in formal schooling. There were no differences in performance amongst different types of cross-notation comparison, suggesting that the act of crossing the boundary between representations, rather than the type of representations involved, is of central importance.

There is a growing body of evidence suggesting that humans possess two systems for representing number; an approximate nonsymbolic system which enables us to represent and manipulate quantities nonverbally, and a precise

symbolic system which facilitates exact number comparison and manipulation (Dehaene, 1997). When we learn to use symbolic representations such as Arabic numerals and verbal number words, the approximate number system is not overridden; rather the two systems become mapped onto one another (Temple & Posner, 1998; Dehaene et al., 1990). Recent research suggests that being able to flexibly map across multiple representations of number is an important factor in the learning and performance of formal arithmetic. Both the ability to transcode between number words and Arabic numerals, and the ability to map between symbolic and nonsymbolic representations are predictors of arithmetic performance in children (Mundy & Gilmore, 2009; Gilmore et al. 2010; van Loosbroek et al., 2009). Children who struggle to learn arithmetic appear less able to convert between verbal and Arabic symbolic representations or to draw on nonsymbolic representations from symbolic representations (Geary et al., 2000; De Smedt & Gilmore, in press; Hanich et al., 2001).

Whilst it is understood that learning to map across numerical representations is an important developmental process, less is known about the exact nature of this mapping and the role of multiple representations of number in numerical magnitude processing. Two models of number processing provide contrasting accounts: Dehaene & Cohen's (1995) Triple Code Model, proposes that numerical information is processed in a notation-independent fashion engaging an analog magnitude code; Campbell & Clark's (1988) Encoding Complex Model proposes that numerical processing is notation-specific, with numerical magnitude information being accessed more efficiently in the notation an individual is more familiar with. Experiments designed to test these models have provided mixed evidence and they have involved adults with years of experience with symbolic representations. Research with children is necessary to provide a more rigorous test of the hypothesis that numbers are processed in abstract fashion. Thus, in the present study we tested children's ability to compare numbers across different numerical notations.

Twenty-one children (aged 7;8 – 9;5, $M=8;3$) and 29 adults (aged 18 – 49, $M=27$) completed a computer based comparison task, in which they had to indicate which of two stimuli was numerically larger. In total there were 120 experimental trials with numerosities ranging between 4-9. The numerical distance between the numerosities being compared was varied; half of the pairs had a small numerical distance (a distance of 1 or 2) and half of the pairs had a large numerical distance (a distance of 3, 4, or 5). The notational format of the number pairs was also varied. Each of the number pairs was presented in 6 different formats; 3 within-notation formats (Arabic numeral vs. Arabic numeral, verbal number word vs. verbal number word, dot array vs. dot array) and 3 cross-notation formats (Arabic numeral vs. verbal number word, Arabic numeral vs. dot array, verbal number word vs. dot array). All 6 notational formats were randomly intermixed and the order of the trials was randomised. Prior to the comparison task, children were given 2 number reading assessments to ensure that they had sufficient symbolic number knowledge to complete the task.

Accuracy and reaction time data was submitted to a series of repeated measures ANOVAs. First, 2 by 2 ANOVAs were conducted with repeated measures factors of numerical distance (small/large) and numerical notation (within/cross). For children, there was a significant main effect of notation; children were faster ($F(1,20)=18.14$, $p=0.001$) at making within-notation comparisons compared to cross-notation comparisons. Adults also showed a performance advantage for within-notation comparisons but only for trials with a small numerical distance. This interaction between distance and notation was significant for both accuracy ($F(1,27)=5.26$, $p=0.03$) and reaction time ($F(1,27)=4.19$, $p=0.05$) data. These findings show that there is a cost of working with numbers across different notations but that once individuals have more experience using multiple numerical representations, this cost lessens. This contradicts the Triple Code Model, according to which, numbers are converted into an analog magnitude representation before comparison and thus, there should be no effects of notation on performance.

A further ANOVA was carried out to compare the different cross-notation formats. Both adults and children showed no main effect of notation; there were no differences in accuracy amongst the different types of cross-notation comparisons. These results suggest that the act of crossing the boundary between representations, rather than the type of representations involved, is of central importance. This is difficult to reconcile with the Encoding Complex Model, according to which magnitude information can be accessed more efficiently in the notation an individual is more familiar with.

To summarise, neither of the two models of number processing are able to account for our pattern of results. We found that all children were able to compare numbers across different notations as well as numbers in the same notation. Thus, all representations are mapped in children aged 7 and above. The ability to use multiple numerical representations interchangeably develops early on in formal schooling. Given that both adults and children showed a performance cost for cross-notation comparisons but no difference in performance amongst the different types of cross-notation comparison, we can conclude that the act of crossing the boundary between representations is a fundamental challenge for learners. Further work with younger children will help to elucidate the exact nature of the mapping between representations. A deeper understanding of such processes may provide us with new ways of supporting symbolic arithmetic learning which is typically lengthy and arduous for many children.

Numerical magnitude processing in first graders with mathematical difficulties

Bert De Smedt, University of Leuven, Belgium

This study investigated numerical magnitude processing in first graders with severe and mild forms of mathematical difficulties, i.e. children with mathematics learning disabilities (MLD) and children with low achievement (LA) in mathematics, respectively. Participants were 20 children with MLD, 21 children with LA and 41 regular achievers. All children completed a numerical magnitude comparison task and an approximate addition task, which were presented in a symbolic and a non-symbolic (dot arrays) format. Children with MLD and LA were impaired on the symbolic tasks, which involved the access of numerical magnitude information from symbolic representations, with the LA children showing a less severe performance pattern than children with MLD. They showed no deficits on the nonsymbolic tasks. Our findings indicate that this performance pattern occurs in children from first grade on and generalizes beyond numerical magnitude comparison tasks. These findings shed light on the types of interventions that may help children who struggle with learning mathematics.

Aims

Mathematics learning represents a stumbling block for many children in primary school. In order to devise appropriate interventions, we need to have good understanding of the cognitive deficits underlying children's poor achievement in mathematics. One source of these deficits may be in the types of numerical representations that underlie mathematics learning (Dehaene, 1997). Indeed, studies have demonstrated that children with mathematical difficulties have particular impairments in understanding and processing numerical magnitudes (Rousselle & Noël, 2007). Two accounts for these impairments have been put forward. The defective number module hypothesis (Butterworth, 2005) proposes that a highly specific deficit of an innate capacity to understand and represent quantities leads to difficulties in learning number and arithmetic. The access deficit hypothesis (Rousselle & Noël, 2007) states that mathematical difficulties originate from impairments in accessing numerical meaning, i.e. their quantity, from symbols rather than from difficulties in processing numerosity per se. To disentangle between both hypotheses, performance should be compared on numerical tasks with and without a symbolic processing requirement. If children with mathematical difficulties perform more poorly on both types of tasks, this favours the defective number module hypothesis; if they perform more poorly on symbolic tasks but not on non-symbolic tasks, this supports the access deficit hypothesis. Specifying the locus of this impairment provides a crucial building block for developing appropriate interventions, which should then either focus on the representation of quantity or on the mapping between symbols and the quantities they represent. Therefore, the aim of the present study was to contrast both hypotheses in children with mathematical difficulties in the middle of first grade.

Methodology/Research design

Participants were 82 first graders (34 boys, 48 girls) with a mean age of 6 years and 8 months ($SD = 4$ months), which were recruited from a larger sample of 290 children from 11 regular primary schools. All children completed the curriculum-based standardized general mathematics achievement test Math up to Ten (Dudal, 1999) as a screening measure. From this sample, we selected children with mathematical difficulties, i.e. those children whose performance was below the 25th percentile on this screening measure. We divided our sample of children with mathematical difficulties into children with low achievement (LA) in mathematics ($n = 21$), if they had math achievement scores between the 16th and 25th percentile, and children with mathematics learning disabilities (MLD, $n = 20$), if they had math achievement scores below the 16th percentile. For each child with mathematical difficulties, we selected from the total sample a child from the same school that performed above the 35th percentile on the screening measure. This yielded a sample of 41 typically achieving (TA) children who were matched in terms of educational environment to the children with mathematical difficulties.

All children completed a numerical magnitude comparison task and an approximate addition task, which were presented in a symbolic and a non-symbolic (dot arrays) format. In the numerical magnitude comparison task (number domain 1-9), children indicated the numerically larger of two simultaneously presented Arabic digits (symbolic condition) or dot patterns (non-symbolic condition). In the approximate task addition task (number domain 5-58), children had to solve problems such as "Daniel has some marbles and puts them in a box" and an array of blue dots fell down behind a grey occluder. Next, a second array of blue dots fell down behind the same grey occluder and the experimenter stated "and he puts some more into his box. Now, all Daniel's marbles are in his box". Finally, an array of red dots appeared and the experimenter stated "Look. Polluto has also some marbles" and asked "Can you tell me who has more?". Again this task was administered in a symbolic (Arabic numerals) and non-symbolic (dot arrays) version.

Findings

The overall accuracy on the numerical magnitude comparison tasks was high and there was no significant main effect of group ($F(2,79) = 2.36, p = .10$). With regard to speed, there was a significant group \times task interaction ($F(2,79) = 5.12, p t(59) = 3.33, p t(60) = 1.22, p = .45$) or from the children with MLD ($t(39) = -1.87, p = .16$); there were no group differences on the non-symbolic task (t

On the approximate addition task, there was also a significant group \times task interaction ($F(2,60) = 5.05, p t(47) = 4.11, p t(43) = 3.50, p t t(43) = 1.72, p = .20$; TA vs. LA: $t t$

Theoretical and educational significance

Children with mathematical difficulties, who are at the earliest stages of learning mathematics, have particular impairments in the ability to access numerical magnitude information from symbolic representations, with the LA children showing a less severe performance pattern than children with MLD. The children with mathematical difficulties did not show any deficits in underlying nonsymbolic magnitude representations. There is no doubt that difficulties in accessing the numerical meaning from Arabic numerals will have a tremendous impact on the acquisition of other mathematical concepts and procedures. Without knowing that numbers represent quantities, mathematics learning runs the risk of becoming a meaningless endeavour (Griffin, 2002). The current findings have important implications for teaching and intervention. These should provide plenty of opportunities where children learn to connect symbols and the quantities they represent in rich and meaningful ways.

Nonsymbolic approximate arithmetic and working memory: A dual-task study

Iro Xenidou-Dervou, VU University Amsterdam, Netherlands; Ernest Van Lieshout, VU University Amsterdam, Netherlands; Menno van der Schoot, VU University Amsterdam, Netherlands

Preschool children have been proven to possess nonsymbolic approximate skills before learning how to manipulate exact nonsymbolic or symbolic math and thus before the acquisition of any formal math learning instructions. Nonsymbolic approximate math tasks necessitate the allocation of working memory (WM) resources. Research has consistently shown WM to be a predictor of prime importance for children's math development and achievement. Until now, however, the relationship between approximate math and WM had not been investigated. The present study focused on answering the following research question: Which of the three WM components – phonological loop, visuo-spatial sketchpad, central executive – influence preschool children's nonsymbolic approximate addition processing? For this purpose, a dual-task study was conducted with phonological, visual, spatial and central executive interference during the implementation of an addition nonsymbolic approximate dot-task. As expected, results showed a breakdown in children's performance on the central executive interference condition. Surprisingly, the phonological loop was also proven to play a role in nonsymbolic approximate math processing. Our findings provide insight in the cognitive process of storing and updating nonsymbolic approximate representations of magnitudes during arithmetic. These results can foster the early prediction of children's math development and consequently the opportunity of enhancing early personalized interventions for the advancement of children's math skills.

Introduction

Recently, research has flourished around the question of how children's early ability to learn mathematics develops (e.g. Mundy & Gilmore, 2009). It has been found that preschool children, who have not yet had any formal mathematic instructions, possess an ability to estimate and manipulate approximate numerical magnitudes (Gilmore & Spelke, 2008). Barth and colleagues (2006) assessed children's nonsymbolic approximate (NA) addition skill utilizing a computerized dot-task. In this, a blue dot array appeared on the screen followed by a rectangle covering the dots and an additional array of blue dots hiding within the rectangle; lastly a set of red dots appeared. Children had to remember the summed hidden blue set and decide whether there were more blue or red dots. It has been postulated (Mundy & Gilmore, 2009) that exact symbolic verbal mathematic skills – i.e., as taught in school – develop on top of and are fostered by these NA arithmetic skills. Thus, it is important to understand and uncover the cognitive processes underlying these skills.

Working memory (WM) is an important cognitive predictor of children's mathematic development and achievement (e.g., Raghubar, Barnes & Hecht, 2009). It reflects a cognitive architectural system responsible for storing and manipulating limited amounts of elements. According to Baddeley (2001), WM is comprised of three main subsystems: a) the visual-spatial sketchpad (VSSP) which is responsible for retaining and manipulating visual-spatial information, b) the phonological loop (PL), which is responsible for maintaining verbal information and c) the central executive (CE), which is characterized by a limited-capacity supervising master system that integrates and allocates memory resources to the previous two subsystems and to the long-term memory.

Despite the strong relationship between WM and math, however, no previous study examined the WM resources allocated for NA arithmetic processing. This was the focus of our study. Rasmussen and Bisanz (2005) explored the differential effects of the different WM components on symbolic and nonsymbolic problems but not approximate. They found that preschoolers while solving nonsymbolic problems utilize a mental model for arithmetic that requires VSSP WM. Thus, we hypothesized that NA arithmetic processing would depend on VSSP components and not on the PL WM component. Furthermore, given the nature of the task which necessitates memory updating on the elements presented, we also hypothesized CE involvement (Morris & Jones, 1990).

Method

Participants were 53 first graders (31 girls, 22 boys; mean age: 5.95 years) from 5 regular Dutch primary schools. In order to examine the differential contribution of the WM components, a dual-task interference design was used. The primary task was a NA addition task (dot-task; array numerocities ranging from 6-70) with trials where the numerocities of the sum (two blue dot sets) and the comparison array (red dots) differed by ratios 4:7, 4:6, 4:5. Testing trials were designed in order to control for the usage of non-addition strategies with ratio-based distances. Continuous quantity cues such as summed dot surface area and circumference, total array area and density were controlled for. Children solved the dot-task in a standalone manner (i.e. no interference) and in four WM interference conditions. In these conditions, the dot-task was executed alongside another task that was developed to interfere with each WM component respectively: 1. PL - adapted Letter Span task (LS), 2. Visual- adapted Abstract Patterns task (AP), 3. Spatial - adapted Corsi Blocks (CB) and 4. CE - Continuous Choice Reaction Time Task-Random (CRT-R task). These secondary tasks were also conducted in standalone control conditions with a 15 sec delay replacing the primary task. All tasks were computerized. Children responded on the dot-task by pressing on either a blue or a red response button. Secondary task responses were vocal and were registered by the experimenter. First, all children performed the dot-task, then participants were counterbalanced based on intelligence level (assessed with the Raven's) between two task-order presentation conditions: AP, LS, CB, CRT-R, dual-AP, dual-LS, dual-CB, dual-CRT-R or the opposite order.

Results

Children succeeded on the primary task (63.44%, chance = 50%, $t(52) = 11.71$, $p F(2,104) = 28.66$, $p F(4,208) = 15.39$, $p F(4,208) = 7.84$, $p F(4,208) = 13.51$, $p p t(51) = 7.34$; p the PL ($t(52) = 3.14$; p

Discussion

Our results showed that preschoolers allocate primarily CE but also, surprisingly, PL WM resources to process NA arithmetic problems. We found that the process of updating WM, which characterizes the CE, is the most important for NA math processing. The involvement of the PL indicates children's attempt to phonologically code the numerical magnitudes they saw in order to process them (Krajewski & Schneider, 2009).

"Non-symbolic, approximate representations are central to human knowledge of mathematics" (Gilmore & Spelke, 2008; pp.943). Our findings are relevant to the enhancement of later math development prediction and early intervention. Does a math-specific skill like approximate math play a role in later math performance or are non-specific WM components that mediate approximate math performance more important?

SYMPOSIUM

Learning math with multiple representations: In search for dimensions of representational flexibility

Chairperson: Shaaron Ainsworth, University of Nottingham, United Kingdom

Organiser: Wim Van Dooren, K.U. Leuven, Belgium

Discussant: Shaaron Ainsworth, University of Nottingham, United Kingdom

In school mathematics, the use of external representations has increasingly attracted attention. Students are often exposed to multiple representations of the same idea, with the hope that such exposure will positively impact their learning and problem solving performance.

Despite the potential that multiple external representations in supporting students' learning and problem solving, several studies have shown that they can also negatively affect them. One of the reasons is that students are sometimes lacking representational fluency, being unable to use a given representation to solve a problem. Another reason why students do not always benefit from solving problems using multiple external representations is that they lack representational flexibility which prohibits them from optimally using the variety of representations that is available to solve a given problem.

The notion of representational flexibility in mathematical learning and problem solving will be the core of this symposium. In the literature, many conceptualisations of representational flexibility are used, each stressing particular aspects of flexible problem solving behaviour and/or the way in which this flexibility can be learned. The three contributions will introduce their conceptualisation of representational flexibility, and substantiate these with empirical results. The different studies introduce various dimensions of representational flexibility, such as task, student, and context characteristics, and discuss the educational implications.

Facilitating Representational Fluency and Flexibility through Sequencing Multiple Representations

Martina Rau, Carnegie Mellon University, United States; Vincent Aleven, Carnegie Mellon University, United States; Nikol Rummel, Institute of Education, Ruhr-Universität Bochum, Germany; Zelha Tunc-Pekkan, Carnegie Mellon University, United States; Laura Pacilio, Carnegie Mellon University, United States

We investigate how to balance two aspects of learning with multiple graphical representations that are provided in addition to symbolic representations: Representational fluency and representational flexibility. Being fluent with a graphical representation requires learners to relate it to the more abstract symbolic representation. On the other hand, we view the ability to make comparisons across graphical representations as an aspect of representational flexibility: It requires recognizing similarities and differences between graphical representations, which is prerequisite for knowledge about strengths and weaknesses of each graphical representation. We conducted an in vivo experiment using an online tutoring system for fractions to investigate a key aspect of this issue: The temporal sequencing of graphical representations presented one-at-a-time. Specifically, we investigated the effects of blocking vs. interleaving multiple graphical representations. Results show an advantage for interleaving representations and an increasingly interleaved sequence, demonstrating the importance to provide opportunities for students to acquire representational flexibility.

Theoretical background

Understanding fractions is foundational for more advanced mathematics (NMAP, 2008), yet fractions pose a significant challenge for students. Multiple graphical representations of fractions are widely used in paper curricula because each of them provides a slightly different conceptual interpretation of fractions. In an earlier study we found that students working with multiple graphical representations of fractions learn better than students working with a single graphical representation, when prompted to explain how the graphical representations (e.g., a circle) relate to the symbolic representation (e.g., $1/2$) (Rau, Aleven, & Rummel, 2009). This finding is in line with a number of studies that demonstrate benefits of learning with multiple representations (Ainsworth, Bibby, & Wood, 1998). However, providing students with multiple representations is not always beneficial (see Ainsworth, 2006), which has been attributed to the fact that they require learners to acquire several cognitive competencies: Learners need to understand the particular representations and to use them appropriately; in other words, they need to acquire representational fluency with each representation (Ainsworth, 2006). In addition, students need to develop representational flexibility (Spiro & Jehng, 1990): students need to understand the differences and similarities between them, which will enable them to make adaptive representational choices as they use representations for problem solving (Acevedo-Nistal et al., 2009). We argue that representational flexibility requires students to make comparisons across representations. In our project, we strive to help students integrate the different conceptual interpretations that are being emphasized by different graphical representations into one coherent mental model

Problem Statement

At this point, it is an open question how to balance the support of representational fluency and representational flexibility in order to help students integrate them into one single, complex mental model of the to-be-learned content. In the present study, we consider the temporal sequencing of multiple graphical representations presented one-at-a-time. This question is often being disregarded when designing learning material with multiple representations, even though literature on sequencing tasks with different properties (Van Merriënboer & de Croock, 1992) suggests that the temporal sequences of different representations may also have an influence on students' learning. However, we know of no study that has systematically investigated the sequence of different graphical representations. Specifically, we contrast blocking representations (e.g., AAABBBCCC, where A may be a circle, B a rectangle, and C a number-line representation), versus interleaving them (e.g., ABCABCABC). When practice with representations is blocked, students have the opportunity to develop fluency with one representation before the next one is introduced. On the other hand, when practice with different representations is interleaved, students may have greater opportunity to (spontaneously) make comparisons between representations and develop representational flexibility along with fluency. If the development of representational flexibility relies on students' fluency with the individual representations, students should learn best when practice with the representations is blocked. If, on the other hand, representational flexibility can develop along with or even contribute to students' acquisition of representational fluency, students should learn best when practice with the representations is interleaved. We think

that making comparisons between representations without having acquired fluency with each of them will come at a certain cost (e.g., students may then tend to make surface-level comparisons). We therefore hypothesize that students' benefit from the opportunity for comparison making builds on fluency, and thus predict an advantage for a condition where students first learn with each representation in a blocked fashion and then gradually shift into a mode where they encounter the different representations in an interleaved fashion (i.e. the frequency of switching is increased).

Methods

We conducted an experimental study with 690 4th- and 5th-graders who worked on different versions of an intelligent tutor for fractions during their regular class time. Students were randomly assigned to either of four conditions that varied regarding the degree to which practice with the representations was blocked versus interleaved: blocked, moderate, interleaved, or increased. Students in all conditions worked on the same numerical problems. Students in the blocked condition encountered the representations in three blocks: They worked on the first third of all problems with one graphic, on the second third of all problems with a second representation, and finally on the last third of all problems with a third representation. In the moderate condition, the blocks were much smaller: Students switched representations after every twelve problems. Students in the interleaved condition switched representations after every single problem. And finally, in the increased condition, the length of the blocks was gradually reduced from eighteen problems at the beginning to a single problem at the end. Students' knowledge of fractions was assessed three times: Before, immediately after, and one week after working on the fractions tutor.

Results and discussion

Results show an aptitude-treatment-interaction demonstrating that low prior knowledge students benefit significantly more from an interleaved sequence of graphical representations and an increasingly interleaved sequence than from a highly blocked sequence and a moderately blocked sequence. This finding demonstrates that interleaving graphical representations results in the best integration of multiple conceptual interpretations of fractions into a single mental model. The advantage of the increasingly interleaved sequence further demonstrates that students may require a certain amount of practice with each graphical representation by itself before benefiting from more frequent opportunities to make cross-representational comparisons. A thorough analysis of students' interactions with the tutoring system is underway to compare learner profiles between the interleaved and the increasingly interleaved conditions. A follow-up think-aloud study on the interleaved condition demonstrates that students tend to not make explicit comparisons between the graphical representations and thus supports the interpretation that the benefit from interleaving graphical representations stems from repeatedly eliciting different conceptual interpretations rather than from supporting students' active processing of correspondences and differences between the different graphical representations. Future research is planned to investigate explicit support for conceptual connection-making between multiple graphical representations.

Two approaches to evaluating students' representational flexibility

Ana Acevedo Nistal, K.U.Leuven, Belgium; Wim Van Dooren, K.U. Leuven, Belgium; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

This study evaluated students' representational flexibility while they solved linear function problems. Eighty-six secondary-school students solved problems under one choice (C) condition, where they could choose a table, a formula, or both to solve each problem, and two no-choice (NC) conditions, a NC-table and a NC-formula condition, where one representation was forced upon them. Two approaches to the evaluation of representational flexibility were used: a groupwise approach, where students were considered to make a flexible choice if they selected the representation that yielded the best NC condition performance for the problem at hand for their grade, and an individualised approach, where a student's choice in a particular problem was considered flexible if he selected the representation that, according to his own performance in the NC conditions, was the most likely to help him reach the solution to that problem. A strong positive correlation between groupwise flexibility and C condition performance was found, but an even stronger positive correlation between individualised flexibility and C condition performance was also found, especially in the highest grade. In this grade, where students' representational fluency profiles were very diverse, individualised flexibility scores that took into account each student's fluency with each representation were better at predicting C condition performance than groupwise flexibility scores that ignored individual differences in representational fluency.

Aims

We live in a world where representational material is omnipresent. Not surprisingly, teaching students to extract information from representations and encouraging them to adopt a critical approach towards such information is an important goal of today's mathematics education (Greer, 2009). It has been claimed that, for students to benefit from using external representations in mathematical tasks, they need to possess two main skills:

1. Representational fluency, defined as "the ability to work within and translate among representations" (Bieda & Nathan, 2009, p. 637).
2. Representational flexibility, which involves making appropriate representational choices. As we have explained elsewhere (Acevedo Nistal, Van Dooren, Clarebout, Elen, & Verschaffel, 2009) not all authors conceptualise representational flexibility in the same way. For some authors (e.g. Schnotz & Bannert, 2003) a choice is flexible if it matches the demands of the task at hand. We refer to this as task-based flexibility. However, other authors (e.g. Acevedo Nistal, Van Dooren, Clarebout, Elen, & Verschaffel, 2010) consider a choice as flexible if it takes into account task demands and the characteristics of the subject making the choice, for example his representational fluency. We call this task ' student-based flexibility. In this paper we compare two task ' student-based approaches to the evaluation of representational flexibility – a groupwise approach and an individualised approach. The purpose of this comparison is to determine which approach better predicts performance in problems about linear functions where a representational choice is required. Methodology

Eighty-six ninth, tenth, and eleventh graders participated in the study. All had prior knowledge about solving linear-function problems using tables and formulae.

All students solved paper-and-pencil tests concerning the refilling of two fuel tanks in a gas station. Half of the problems asked how much fuel a tank contained at a specific moment (value problems). The other half asked when both tanks contained the same amount of fuel (intersection problems).

The choice/no-choice (C/NC) method (Siegler & Lemaire, 1997) was used. In the C condition, students could choose a table or a formula to solve each problem. In the NC-table and NC-formula conditions, students could only use the representation provided. There were 8 problems per condition. The problems in the 3 conditions were parallel. The C condition was administered first. Half of the students received the NC-table condition next, the other half the NC-formula condition. Students were instructed to show their work and not to use a calculator.

Findings

Two (task ' student-based) approaches to the evaluation of flexibility were used: a groupwise approach, and an individualised approach.

Groupwise Approach

A student's choice was considered flexible (and given a flexibility score of 1) if he selected the representation that, according to the NC data from his grade, yielded the highest accuracy for the problem at hand. A score of –1 was given if the student failed to choose that representation. Average flexibility scores obtained using this approach were correlated with C condition performance to determine if flexible students performed better than less flexible students. As Table 1 shows, this was indeed the case.

Individualised Approach

A choice was considered flexible (and given a flexibility score of 1) if a student chose a representation with which he successfully solved a parallel problem in the corresponding NC condition. A score of –1 was given if he chose a representation with which he was unable to solve a parallel problem in the corresponding NC condition. Correlations between individualised flexibility scores and performance in the C condition were calculated. As Table 2 shows, a link between individualised flexibility scores and C condition performance was also found.

Individualised flexibility scores were more strongly correlated with C condition performance than the scores obtained using the groupwise approach, especially in eleventh grade. In this grade, where students' representational fluency profiles were very diverse, individualised flexibility scores that took into account each student's fluency with each representation were better at predicting C condition performance than groupwise flexibility scores that ignored individual differences in representational fluency.

Implications for instruction

Judging by the close link observed between representational flexibility and choice condition performance, teaching students to make flexible representational choices might be a skill worth developing in the mathematics classroom. A dilemma that remains, however, is: Which instructional approach should we adopt – a groupwise approach, where all students within a grade are taught to make the same representational choices for the same types of problems based

on their average fluency with the different representations, or an individualised approach, where each student is encouraged to use the representation that fits not only the task at hand but also his own fluency with the different representations. When teaching representational flexibility, one is unavoidably faced with a trade-off between adopting a groupwise, normative approach that is relatively easy to implement but that ignores individual differences, and an approach that is sensitive to individual differences but that is challenging for instruction.

How successful learners deal with changing task demands in learning from multiple representations

Rolf Schwonke, University of Freiburg, Germany; Alexander Renkl, University of Freiburg, Germany

Limitations of working memory suggest that mental model construction in learning from multiple external representations (MER) is most successful when the most essential aspects of the learning material are visually inspected in close temporal succession. Furthermore, such visual integration activities should be most beneficial when they occur early during the inspection of a set of related external representations. Learning from MER can further be expected to be most successful when such patterns as well as the amount of visual attention are flexibly adapted to changing task demands. In a correlative lab study 31 psychology students studied the product rule of combinatorics from correct and incorrect worked examples. Each example provided a problem description, a tree diagram, and equation. In incorrect examples one of these external representations provided incongruent information regarding the product rule. During learning gaze data were registered. Learners who showed successive gaze shifts between the three most relevant elements of correct examples early during inspection acquired highest amounts of conceptual understanding. The amount and pattern of visual attention differed markedly during the inspection of correct and incorrect examples. Importantly, those learners who showed the largest differences in the amount and pattern of visual attention (e.g., total number of fixations and gaze shifts) were those who acquired highest amounts of conceptual understanding. Thus, successful learning from MER seems to be positively related to an early (visual) integration of semantically related pieces of information as well as to the ability to flexibly adapt visual attention to changing task demands.

In order to benefit from external representations in learning and problem solving contexts, students are supposed to have two related subskills. First, learners need to be able to interpret (and construct) external representations (i.e., representational fluency; Acevedo Nistal, Van Dooren, Clarebout, Elen, & Verschaffel, 2010). Second, learners need to be able to make appropriate choices between external representations given a certain learning situation (or problem-solving situation) and given certain personal characteristics (e.g., the acquaintance with certain representational formats). This skill has been referred to as representational adaptivity or flexibility (Acevedo Nistal et al.).

In the present study we compared the self-regulation of visual attention during the inspection of correct and incorrect worked examples in the domain of probability. During the inspection of correct examples (consisting of a problem description, a tree diagram, and an equation), we expected successful mental model construction (Schnotz & Bannert, 2003) to be reflected in attempts to visually integrate the most relevant aspects as soon as possible. During the inspection of incorrect examples, we expected successful learners to inspect the examples more holistically (i.e., to compare each external representation more extensively) in order to detect the error. As task demands between correct and incorrect examples differed, we expected to find respective differences in the allocation of visual attention (e.g., more gaze shifts in the error detection task). Moreover, successful learners were expected to be better able to adapt their allocation of visual attention to task demands.

Method

After reading a written introduction into the product rule of combinatorics, first year psychology students ($N = 31$; age: $M = 23.35$, $SD = 6.41$) studied sixteen worked examples of combinatorics problems. Each example consisted of a problem description, a tree diagram, and an equation. The first line of each problem description referred to the number of drawings (which was always two), the second line to the number of possibilities at the first drawing, the third line to the question (stem), and the fourth line to the instantiated mathematical rule (with/without replacement).

In order to understand a worked example, at least the fourth line of the problem description and both layers of the diagram (representing the two successive drawings) had to be integrated. As an indicator of attempts of visual integration of these central pieces of information, we analysed successive gaze shifts between these semantic units. The first occurrence (in terms of the number of fixations) of such an 'integrative' gaze shift was taken as an indicator of visual integration.

After four correct worked examples the participants were asked to study four incorrect worked examples (followed by another four correct and four incorrect examples). In incorrect examples, two of the three external representations

(e.g., problem description and equation) suggested one rule (e.g., 'with replacement'), whereas the remaining external representation (e.g., the tree diagram) suggested another rule (e.g., 'without replacement'). In order to detect the incongruent representation, learners had to process each individual external representation to a sufficient degree as well as to relate all external representations to one another. We examined the total time spent on each type of representation and the frequency of gaze shifts between them.

Directly before and after the learning phase all participants worked on identical pre- and post tests (procedural and conceptual knowledge). In procedural tasks (6 items) learners were asked to solve combinatorics problems. In conceptual tasks (8 items) learners had, for example, to explain the product rule or had to decide whether a problem was solvable.

Results

Conceptual understanding (post-test) was, as expected, positively related to an early occurrence of an integrative gaze shift (i.e., a successive gaze shift between that line of the problem description from which the mathematical rule could be inferred and both layers of the tree diagram) during the inspection of correct examples, $r_p = -.47$, p

Both the amount and the pattern of visual attention devoted to the worked examples differed between correct and incorrect examples (i.e., as a result of the change in task demands). When studying incorrect worked examples, learners spent more time inspecting each individual representation compared to the inspection of correct examples – with largest increases in inspection times of equations (Table 1). Similarly, the frequency of gaze shifts between representations increased during the inspection of incorrect examples – with largest increases in the frequency of gaze shifts between diagrams and equations (Table 1).

Importantly, those learners with the largest differences (here, increases) in the amount of visual attention devoted to incorrect examples (as indicated, for example, by the total inspection time of the examples) were those who acquired the highest amounts of conceptual understanding in the post-test, $r_p = .41$, p $r_p = -.50$, p

Summary and Discussion

The aim of the reported analyses was to get a better understanding of how learners regulate their visual attention during learning from multiple external representations and how learners adapt their allocation of visual attention to changing task demands.

Results show that in learning from multiple representations representational fluency is reflected in early attempts to visually integrate central related aspects of the learning content. As expected, both the amount and pattern of visual attention differed between the inspections of correct versus incorrect examples. Importantly, those learners who showed the largest differences in the amounts and patterns of visual attention were those who developed the deepest understanding of the subject matter. These results suggest that in learning from multiple external representations representational adaptivity is reflected in changes of both the amount and the pattern of visual attention as a reaction to changing task demands. Overall, the results suggest that representational fluency and flexibility have behavioural correlates at the level of the self-regulation of visual attention.

SYMPOSIUM

Identifying key learning activities in strategy instruction in various ill defined do-mains. Part I

Chairperson: Tanja Janssen, Universiteit van Amsterdam, Netherlands

Organiser: Gert Rijlaarsdam, University of Amsterdam, Netherlands

Discussant: Patricia A. Alexander, University of Maryland, United States

The symposium aims at the identification of effective instructional strategies in various domains of learning, in ill structured tasks. General idea is to bring together and to analyze intervention studies that focus on strategy development. The symposium will address the question 'What works in strategy instruction and why?' with variations in content (the strategy learned), the learning activity and the content domain.

Therefore, we selected studies that were set up as componential analysis of instructional components (e.g. Fidalgo et al. in this symposium), studies that analyzed data from complex interventions with multi-components to isolate the contributions of each component to the total effect (for instance Glaser et al. in this symposium), and experiments that aimed at studying the effect of a single learning activity (Groenendijk et al., focusing on observation as learning activity). In three sessions, the symposium will deal with various domains (visual arts: divergent thinking; history: historical thinking and language arts: writing and reading literary texts). The domains have in common that they aim at thinking skills, and are seen as ill-structured.

Analysis of Instructional Components in the Strategy Instruction in Writing

Raquel Fidalgo, University of Leon, Spain, Spain; Mark Torrance, Nottingham Trent University, United Kingdom; Gert Rijlaarsdam, University of Amsterdam, Netherlands; Patricia Robledo, University of Leon, Spain; Huub Van den Bergh, Utrecht University, Netherlands

This research explores the effectiveness of four subcomponents of a strategy-focused writing program for 6th Grade students. This program taught process and product strategies in four stages: (1) student observation of teacher modeling, (2) declarative teaching, supported by mnemonics, (3) emulation with teacher and peer feedback on strategy use, and (4) individual emulation with teacher feedback. Stages 3 and 4 both involved students thinking aloud while writing. Our sample comprised 62 Spanish students with a full range of abilities, in three classroom groups. Components were evaluated with a lagged and cross-panel design across two ten-week phases. In Phase 1, Group A and Group B received the intervention, with Group B lagging one component behind Group A. Group C acted as a normal curriculum control with matched writing practice. In Phase 2, Group C received the intervention, but with instruction focusing on a different text genre. Groups A and B returned to the normal curriculum. All groups received writing tests at baseline and at the end of each intervention component (or matched times in the control). Findings confirm the benefit of strategy focused writing instruction with relatively large effect sizes. We found, however, that nearly all gains resulted from the two-session modeling and observation component with only small further increases in text quality resulting from subsequent declarative instruction and student practice.

There is considerable evidence that strategy-focused instruction is successful in developing the writing skills of both typically developing and struggling writers (Graham & Perin, 2007a; Graham & Perin, 2007b; Fidalgo, Torrance, & García, 2008; Torrance, Fidalgo, & García, 2007). Strategy-focused writing interventions aim to develop self-regulation in both writing process – the use of effective planning and revision strategies – and written products. They typically involve several different instructional strategies. In the intervention employed in the present study (Cognitive Self-Regulation Instruction – CSRI – previously evaluated in Fidalgo, Torrance, & García, 2008; Torrance, Fidalgo, & García, 2007) these instructional strategies included (1) student observation of teacher modeling, (2) explicit (declarative instruction), (3) emulation with peers, and (4) emulation alone. During the first instructional component, students observe their teacher composing text in front of the class whilst "thinking aloud". The think aloud is part-scripted so as to illustrate specific writing strategies, and therefore provides a "mastery" model. Students then reflect on what they have observed, noting the important features of the teachers writing (both text and process). The second component involves explicit teaching of process and product strategies, supported by the teaching of mnemonics. During the third component students emulate the model that they have observed, but with procedural facilitation by both peers and teacher. Students work in pairs. One thinks aloud while composing text which the other observes and comments on the extent to which they are successfully emulating the model. They then swap roles. The teacher also provides some feedback on the students' emulation. The fourth component is similar to the third. Students emulate the model while thinking aloud, but working alone and relying on just teacher feedback. Our previous research has demonstrated that when these components are combined the resulting intervention has large, positive benefits for the quality of students' texts. What is not clear is whether all components are necessary. The present study therefore aimed to explore their relative efficacy. Our sample comprised Spanish sixth-grade students (11-12 years) in three extant full-range class groups taken from the same cohort at the same school: Group A (N = 21), Group B (N = 20), and Group C (N = 21). Evaluation was completed in two phases. Both phases involved delivery of all four instructional components, in the order indicated above, and with each delivered over two sessions of between 60 and 90 minutes by the same instructor (the students regular literacy teacher). In Phase 1 both Group A and Group B received the full intervention, with Group B lagging one component (two sessions) behind Group A. Group C were taught under the school's normal writing curriculum in the same number of sessions and completing the same number of writing tasks. Instruction in Phase 1 focused on the composition of compare-contrast texts. In Phase 2, which focused on texts that expressed an opinion, Group C received the intervention and Groups A and B formed a normal curriculum control. Students' writing performance was evaluated in all three groups at the start of Phase 1 and then at two-session intervals throughout both phases (i.e. at the end of each instructional component for intervention groups and at equivalent times for controls). This design allowed (a) assessment of the cumulative effects of the components, (b) replication of this finding (in the lagged group B in Phase 1), (c) replication of this finding in a different text genre (Group C in Phase 2), and (d) multiple transfer and maintenance measures (in Groups A and B during Phase 2). We evaluated writing performance through both holistic and text-analytic measures of writing quality, and with measures of writing process derived from notes taken during planning and analysis of revisions made to the final text. Results confirmed the efficacy of CSRI, with substantial and sustained gains in the quality of students' texts. Given the similarity of CSRI to other strategy-focused approaches, notably Self-Regulation Strategy Development (Harris & Graham, 1996) this provides further evidence of the general efficacy of strategy-focused writing instruction. However, gains in performance appeared to be associated almost entirely with the initial, observation component. This finding was consistent across all three groups (A and B in Phase 1, C in phase 2). This suggests that in writers with fairly well developed language skills, but who have previously been exposed only to traditional instructional approaches (focused

on feedback on finished products), then just observing good use of strategies may be sufficient to improve text quality. Our findings do not however rule out the possibility that other components are necessary if these benefits are to be maintained beyond the end of the intervention.

The Effect of Observational Learning on Artistic Production

Talita Groenendijk, University of Amsterdam, Netherlands; Tanja Janssen, Universiteit van Amsterdam, Netherlands; Gert Rijlaarsdam, University of Amsterdam, Netherlands; Huub Van den Bergh, Utrecht University, Netherlands

Previous research has shown that observation can be effective for learning in various domains, e.g. argumentative writing and mathematics. It provides strategic knowledge to the learner and also changes students' conception of what the modelled skill involves. The question in this presentation is whether observational learning can also be beneficial when learning to perform creative tasks in visual art. We designed an intervention that enables students to learn from observation of video models. The models in the video carried out creative tasks (the making of a collage) while thinking aloud. In a pretest-posttest experimental design we assigned 131 Dutch students (tenth grade, 16 years old) randomly to one of three conditions; two observational learning conditions and a control condition (learning by practicing). The observational learning conditions varied in instructional focus when students had to evaluate the thinking processes of two peers on video: focusing on the weakest or the more competent student. We measured posttest performance on a collage task. As a process indicator, amount of 'revision' (or production that did not end up in the final work) was registered. A questionnaire was used to measure motivation. We found that both observation conditions were more effective than the regular practicing activities with regard to creative products, creative processes, and motivation.

In contemporary curricula, creativity is mentioned as a skill that should be developed in schools. However, we know little about how to develop creative skills of students in secondary education. In art education, teachers aim to improve students' creative processes, but little is known about the effectiveness of strategies they use to teach creativity. In the present study we test the effectiveness of observational learning, a process oriented learning arrangement. Before the phase formal schooling, apprenticeship was the most common means of learning (Collins, Brown, & Newman, 1986). In cognitive apprenticeship, an expert model externalizes usually internal processes. Collins et al. (1986) describe how observation, as an element of cognitive apprenticeship, may provide strategic knowledge to the learner, and also may change students' entire conception of what the modelled skill involves. In writing, for example, students may be unaware that good writing involves organizing one's ideas about a topic, elaborating goals to be achieved, thinking about what the audience is likely to know about the topic, etcetera. Observation may enhance this awareness. Couzijn (1999) and Braaksma et al. (2004) found that observational learning is indeed an effective learning tool for students when learning to write informative texts. Students who observed (weak and strong) peer models performing a writing task, afterwards wrote better texts than students who performed the writing task themselves. Observation affected students' writing processes; students who had learned to write by observing more often engaged in metacognitive activities during writing, such as planning, analyzing and goal-orientation. Braaksma et al. (2002) also found that similarity in competence between the model and the observer influenced the learning effect positively (the 'model similarity effect'). Observational learning proved to be an effective learning activity in various domains, such as mathematics (e.g. Schunk & Hanson, 1985), argumentative writing (e.g. Braaksma, 2002; Couzijn, 1999), learning to collaborate (Rummel & Spada, 2005), and learning argumentation skills (Schworm & Renkl, 2007). There is still no research on observational learning and creative tasks. In this study we focus on the effect of observation on students' performance on a creative task: the making of a collage. Research question & hypotheses: observational learning more effective than learning by practicing? Our hypotheses were that observational learning would have a positive effect on visual art making: (1) higher quality collages in the observational learning conditions than in the control condition; (2) more revision in the observational learning condition as a result of more creative exploration, and (3) higher motivation in the observational learning conditions.

We expected weak students to learn more from focusing on the process of a weak model as contrast to the process of the stronger model, and stronger students to learn more from focusing on the process of a strong model, contrasted with the process of a weaker student.

Method

An experiment with a pre- posttest control group design and three conditions (two experimental conditions and a control condition) was carried out to measure its effectiveness. During the intervention students either observed other students at work (observational learning) or carried out the tasks themselves (control group). The models in the videos thought aloud, while doing the task, so observers could understand demonstrated creative processes. Participants were asked to watch videos carefully, make notes, evaluate the models' behaviour, and elaborate on the observed behaviour. The students in the observational learning conditions watched four videos of pairs of students (weak and strong). The observational learning conditions varied with respect to instructional focus (elaboration on the weakest or the more competent model of a pair). 131 students, about 16-year old, in 10th grade of pre-university education, participated and were randomly assigned to conditions. As a pre- and posttest, all students made a collage. No differences between conditions on the pretest were observed. We measured differences between the conditions on the posttest; differences in product quality, in the process and in motivation. The quality of students' collages was determined making use of Amabile's consensual assessment technique, a procedure that provided reliable and valid creativity scores in previous research (Amabile, 1982). We reached a reliability of .77 on the pretest and .72 on the posttest.

Results

The hypotheses on main effects were largely confirmed; students in the observational learning conditions (1) made better collages than students in the control condition, (2) these students revised more and (3) showed higher rates on motivation than students in the control condition. We had to reject the hypothesis on model similarity; no effect of similarity in competence between model and observer was found. The study contributes to the acquisition of knowledge on creativity and modeling. It provides insight in the possibilities for enhancing creativity in the classroom through observation, providing new possibilities to connect productive, receptive and reflective activities in art education.

Improving children's writing through parental intervention

Patricia Robledo, University of Leon, Spain; Jesus-Nicasio Garcia-Sanchez, University of Leon, Spain

The empowerment of linguistic communication from schools frequently focuses on oral language and reading, relegating writing to the background (Torrance, Fidalgo, & García, 2007). Thus, the family could prove to be an effective alternative for its teaching (Robledo, García, & Díez, 2009). The objective of this study is to verify whether it is possible to improve students' writing competence through the mothers' implication in their teaching.

The sample consists of 50 students, enrolled in the 5th and 6th grade (10-12 years old). 26 of them formed the experimental group (mothers received a program to assisting children with writing homework, providing them with

models of writing composition processes) and 25 formed the control group (mothers only received information to help children with writing homework).

We tested the effectiveness of parental collaboration on students' writing compositions through the evaluation of text quality (text based and reader based measures) in a comparison-contrast texts (pre-posttest), and the activation of writing processes. We also evaluated the maintenance (three months later) and generalization to other textual typologies (argumentative).

Results shows that students from the experimental group improved their writing compositions more than the control group did, and they maintained these improvements over time and generalized them to other texts. We conclude that mothers can contribute to students' successful acquisition of writing competence if they receive specific training.

In Spain, the achievement levels of learning goals and requirements has significantly increased as a result of the Organic Education Law (2006) which was adapted to meet the proposals made by the European Union. As a result, the impact of any extrinsic factor or agent, such as the family, on their process of teaching-learning is particularly important to the student.

With the implementation of European educational guidelines, young people must have acquired eight competences on completion of their compulsory education. The importance of the linguistic communication competence, which refers to the use of language as a tool for oral and written communication is emphasized. The school must prepare competent communicators who can successfully navigate in different communicative contexts and conditions.

In Spain, the empowerment of linguistic communication in school usually focuses on oral language and reading. At school, writing is in the background, which is a bit strange when we know that writing is cognitively demanding and requires explicit instruction. Therefore, we focus in this study on the contribution of the family on writing development. The family could be an effective alternative for the lack of school teaching, because we know from Spanish research that the habit of writing is more common in students whose families provide models and positive attitudes toward writing tasks (Reyes, Alexandra, & Azuara, 2007; Romero, Arias, & Chavarría, 2007). Also, depending on the different parental variables (education level and degree of involvement in education) the family can contribute to better quality of texts (Robledo, García, & Díez, 2009). Therefore, the objective of this study is to verify whether it is possible to improve students' writing competence through the mothers' implication in the teaching of writing. We based the family intervention on research experiments in schools on the teaching of writing strategies that showed to be effective on text quality and writing process measures. (Fidalgo, Torrance & García, 2008; Torrance, Fidalgo & García, 2007)

Method

The sample consisted of 50 students, enrolled in the 5th and 6th grade (10-12 years old). 26 of them formed the experimental group and 25 formed the control group. These were distributed over four different classes within two similar schools.

In the experimental group the students' mothers (all the familiar participants were women and mothers) participated in a specific program to support children with writing homework by providing them with models of writing composition processes. The mothers' program, implemented by an expert researcher, consists of seven sessions, carried out twice a month, to coincide with the teachers' suggested writing homework. The objective of this program was that mothers (1) learn different strategies for planning, editing and revision of writing using different methods (exposure of content by the instructor accompanied by pictures or graphic organizers, mnemonic devices, role-playing, working in pairs of mothers), and (2) learn techniques (cognitive modeling, thinking aloud, working collaboratively with children, providing feedback and procedural support) to teach the writing strategies to their children with them.

In the control group, the mothers, interested in the study but without possibility of assisting the training program, received information to help children with writing homework.

All children received the same number of homework tasks.

At the same intervals, pre-post and follow-up, the two groups of students were assessed. We used individual writing practice of the genre that was taught (compare-contrast) and an argumentative essay as generalization measure.

Measures of the written product, including text based measures (productivity, coherence, etc.), and reader based measures (structure, coherence, overall quality) were employed. The writing process measures included time delivered in planning, drafting and revision processes, through on-line records (Writing Log).

Results

The preliminary results suggest that students from the experimental group improved their writing compositions more than control group, and maintained these improvements over time. The effect can be generalized to other texts. The study demonstrate that the mothers, if they receive specific training, can contribute to the students' successful acquisition of the writing competence, as has been demonstrated in reading (Persampieri, Gortmaker, Daly, Sheridan, & McCurdy, 2006).

Acknowledgements

During this research project, we received competitive funds from the Ministry of Research, Science and Innovation- from the Spanish Government; project EDU2010-19250 (EDUC) for 2010-2013, in addition to European Union FEDER funds. Excellence Research Group funds from Junta de Castilla y León (GR259), and European funds for 2009-2011 (BOCyL 27, April 2009). Both were awarded to the Director/ Principal Researcher (J. N. García). P. Robledo received a grant to finance the hiring of recently graduated research staff from the Junta de Castilla y León.

SYMPOSIUM

The relationship between learning conceptions and approaches to learning

Chairperson: Carol Evans, University of Exeter, United Kingdom

Organiser: Carol Evans, University of Exeter, United Kingdom

Jan Vermunt, Utrecht University, Netherlands

Discussant: Sari Lindblom-Ylänne, University of Helsinki, Finland

The aim of this symposium is to enhance knowledge and understanding of the role of students' and teachers' conceptions of learning and teaching in affecting their approaches to learning and teaching within higher education environments. Discussion of the implications for enhancing student and teacher learning will be a focus of the symposium. Interventions aimed at promoting deeper approaches to learning frequently report unintended effects with learners adopting more surface approaches to learning (Balasooriya et al., 2009; Papinczak, 2008). As articulated by Gijbels et al. (2009, 50) "investigating complex learning in new learning environments in higher education remains a challenge for future research." Advances in styles research are highly relevant to this context. Developments within the styles research field stress the need for coherent theory building; methodological development and enhanced links with pedagogy (Rayner & Cools, 2010; Evans et al., 2010; Kozhevnikov, 2010). This symposium represents a response to this call by aiming to consolidate and enhance understanding of the nature of the interaction between conceptions of learning and approaches to learning through a focus on cross-sectional and longitudinal studies to explore the nature of such relationships including notions of stability and change. In addition, links to other individual differences will be identified in an attempt to cohere understandings of how these concepts are applicable to differing

contexts. Consolidation of existing knowledge and development of new concepts to inform learning are discussed so as to inform practice along with identifying future collaborative directions for research within this area.

Stability and variation in concepts describing learning for understanding in higher education

Noel Entwistle, The University of Edinburgh, United Kingdom; Velda McCune, University of Glasgow, United Kingdom

This paper uses conceptual analyses of related empirical studies that have a common focus on learning for understanding, although using contrasting concepts. This methodology is best described as a focused, integrative literature review of carefully chosen related studies, leading to a conceptual analysis of the findings. The intention would be to pool related analyses in order to develop clearer perspectives on the relationship between broader, more stable student characteristics and concepts describing narrower and more variable aspects of learning, such that the nature of the underlying capabilities becomes clearer. In this way, the analyses would make an important contribution to theory in the field of learning for understanding in higher education. Conclusions from this review could be used to guide future research in this area in which theoretical developments are tied in closely to pedagogical innovations. Considering the interplay between stability and change in student learning will help to draw out pedagogical implications for promoting students' development as learners, and that will be the main focus of the presentation for the symposium.

Aims

The paper explores the value in carrying out conceptual analyses of a set of related empirical studies that have a common focus on describing high quality learning at university level, although using contrasting concepts. The main aim is to investigate the relationships between broad, relatively stable and narrow, more context dependent concepts describing aspects of student learning, as a way of exploring the theoretical and pedagogical implications of these contrasting conceptualisations.

Methodology

The first analysis focuses on a group of cross sectional studies selected to provide a breadth of perspectives on concepts describing learning for understanding in higher education. The review would include studies by Perry (1970), Säljö (1979), Vermunt et al., (2001, 2007), Perkins & Tishman (2001), Fyrenious et al. (2007), Entwistle & McCune (2009), Richardson (2010, in press) and Vermunt & Vermetten (2004). These studies were all based on samples of university students, using interviews and/or inventories and broad and/or narrow concepts showing elements of stability and variation, to investigate related ways of describing aspects of student learning and studying. The analysis looks at the pattern of relationships obtained across these studies, and also at evidence from student interviews about the nature of the concepts describing high level academic functioning.

Differences in academic functioning within these studies are described, firstly, in terms of the relatively stable concepts of dispositions to understand and conceptions of knowledge and learning. The more variable concepts include approaches to learning and studying and learning patterns. The second analysis looks more closely at the issue of stability and change in students' learning. This analysis draws on longitudinal studies relating to learning for understanding in higher education, such as those conducted by Baxter Magolda (2009), Hofer and Pintrich (2007), McCune (2000), Neiminen et al. (2004) and Vermetten et al. (1999). In order to shed greater light on the interplay between stability and change in students' learning in higher education, the second analysis also considers how learners' trajectories (Wenger, 1998) can shape their perspectives on learning for understanding in higher education. Learners' trajectories are important aspects of their identities as learners, which describe their perspectives on where they have been and the direction in which they are moving, in relation to particular communities of practice. A trajectory that takes a student into closer engagement with a community of practice can support a stronger commitment to learning for understanding in the long term (McCune, 2009).

Findings

Based on previously empirical investigations, dispositions are seen in terms of ability, intentions to understand, and awareness of context. The more sophisticated conceptions of learning, as well as learning patterns, show a similar pattern of awareness of the purpose and possibilities involved in studying, with empirical relationships linking them to approaches to learning and cognitive processes that focus on meaning and understanding. The disposition to understand for oneself, which is a newly introduced concept, brings together existing learning strategies that facilitate understanding, the strong intention to understand, and the awareness of opportunities both to develop understanding further and to use existing understanding productively in meeting new situations or problems. Such an interwoven combination of abilities, motivation, and awareness represents a set of necessary conditions for high quality learning outcomes.

The attributes reviewed in this paper are affected, to differing extents, by students' experiences of the teaching-learning environments, but there was also evidence of individual differences in the extent of that contextual influence. Where an individual is already 'reading the academic game' confidently and effectively, as shown through their responses in inventories and interviews, there is, as expected, less likelihood of change as a result of subsequent teaching seeking to encourage that way of thinking. The implications of this conclusion are considered in relation to aspects of the relationships between, stable and, variable conceptualizations of learning for understanding.

Theoretical and educational significance

Currently, there is a recurring debate about the extent of stability in learning for understanding, where learning is also understood as a situated endeavour. A clearer understanding of the implications of relative stability and variability for student learning and university teaching is needed. Carrying out focused conceptual analyses of empirical findings into similar concepts describing high quality student learning helps to clarify the nature of those concepts. This approach allows a pooling of related analyses that clarifies the nature of the contributory concepts, while having a clearer idea of the relationship between broader, more stable student characteristics and the narrower and more variable ones helps to make pedagogical implications clearer. This approach can then be used to guide future research in this area in which theoretical developments are tied in closely to pedagogical innovations.

Student teachers' learning orientations in school-based teacher education programmes

Maaiké Endedijk, Utrecht University, Netherlands; Vincent Donche, University of Antwerp, Belgium

One of the key tasks of pre-service teacher education nowadays is to support student teachers to develop a learning orientation necessary for lifelong learning. In order to design teacher education programmes in a way to stimulate this development in student teachers, scientific knowledge is needed about the influencing personal and contextual factors, as well as how these learning orientations develop over time. The main research question central to this study is: How are student teachers' learning orientations related to various personal and contextual variables and how do these orientations develop over time? Across six different studies, student teachers' learning orientations have been measured with the Inventory Learning to Teach Process (ILTP) (Oosterheert, 2001). In these ILTP-studies measurements of several personal, contextual and time-related variables took place. Drawing on the results of these studies as well as presenting cross-validated research results, we aim to present in this paper an emerging framework on student teachers' learning orientations. In particular, the study will present a state of the art regarding the present ILTP-studies investigating student teachers' learning orientations and how they are related to contextual, personal and time related variables in a work-based learning environment. This model can be used as a basis for new studies, as well as for teacher education programmes to design their curriculum in way to stimulate the development of beginning teachers in view of lifelong learning.

Aims

One of the key tasks of pre-service teacher education nowadays is to support student teachers to develop a learning orientation necessary for lifelong learning (Hagger et al., 2008). In order to design teacher education programmes in a way to stimulate this development in student teachers, scientific knowledge is needed about the influencing personal and contextual factors, as well as how these learning orientations develop over time. A vast body of research into learning styles, learning approaches, and learning orientations has been carried out in the context of higher education contexts in which students learn in an academic setting. Studies have now shown that these characteristics are

influenced by several personal and contextual factors (Vermunt & Vermetten, 2004) and are variable across time (Donche, Coertjens, & Van Petegem, 2010). Just as in the case of research into learning approaches in student learning, Oosterheert (2001), using qualitative and quantitative research, established a number of consistent relationships between different learning approach components within a work-related context of learning-to-teach during internships. Consistency in relationships is here regarded as different 'orientations' of learning to teach by way of analogy with the concepts of 'learning styles' or 'learning approaches'. Moving beyond the academic setting, this specific research on individual differences in learning to teach, makes a distinction between open meaning-oriented; closed meaning-oriented; closed reproduction-oriented; and survival-oriented learners (Oosterheert, 2001).

In the last five years, multiple cross-sectional and longitudinal studies have been carried out using the Inventory Learning to Teach (ILTP) as a valid way to assess these differences in learning during internship. In these ILTP-studies measurements of several personal, contextual and time-related variables took place. Drawing on the results of these studies as well as presenting cross-validated research results, we aim to present in this paper an emerging framework on student teachers' learning orientations. In particular, the study will present a state of the art regarding the present ILTP-studies investigating student teachers' learning orientations and how they are related to personal, contextual and time-related variables in a work-based learning environment.

The main research question central in this study is: How are student teachers' learning orientations related to various personal and contextual variables and how do these orientations develop over time?

Methodology

Across six different studies, student teachers' learning orientations have been measured with the ILTP (Oosterheert, 2001). The ILTP questionnaire consists of 10 scales, including learning conceptions, learning and regulation activities and emotion regulation. Besides assessing learning orientations, data is collected throughout these studies about on the one hand, personal variables such as age, teaching experience, gender, teaching efficacy, self-determination and on the other hand, contextual variables such as type of teacher education programme, perception of school learning environment and university learning environment, and time investment. For these variables, scales were developed or adapted versions of existing scales were used.

Different cross-sectional and longitudinal datasets are included in this study, such as a longitudinal dataset with three measurements occasions on 81 student teachers in a one-year university based teacher education programme, a dataset with a two-wave design including 253 third-year student teachers from a pre-service teacher education institute, and several cross-sectional datasets from different teacher education programmes. To cross-validate results from separate studies, new data analyses on several data sets will be carried out. Longitudinal multilevel analysis will be carried out for discovering changes over time, multivariate analyses to find relations between groups of students and structural equation modelling to find relationships between multiple background variables and scale scores.

Findings

Across all available data sets the postulated four learning orientations within the model of Oosterheert were not always found. In particular the open meaning oriented way of learning could not always be identified as a distinct orientation. Several personal variables turned out to be related to the learning orientations. Older student teachers were more often found to have a meaning-oriented learning orientations which was also related to their level of experience as a teacher. Different learning orientations were related to differences in motivation. For instance, survival oriented student teachers were found to be the most a-motivated and least autonomously motivated learners. Results based upon structural equation modelling show that 25% of the variance of teaching efficacy can be explained by specific components of learning orientations, in particular emotion regulation. The contextual variables showed that student teachers who are following a teacher education programme with more responsibility for teaching and more teaching practice have more often a meaning-oriented way of learning. However, their learning orientations are more stable than their peers who are having less teaching tasks.

Looking at changes over time, in both longitudinal data sets, it appears that, overall, student teachers' orientations to learning to teach change during time in the direction of more meaning-oriented learning. Changes within learning orientations were also present across different measurement times. In addition also one third of the student teachers in one data set changed in the direction of independent meaning-oriented learning. It appeared that changes with respect to student teacher learning are found predominantly among survival-oriented students and to a lesser extent among students who exhibit closed reproduction-oriented and closed meaning-oriented orientations of learning to teach.

Theoretical and educational significance

Orientations to learning to teach are found to be subject to a relative degree of change. Especially survival oriented student teachers appear to have undergone a greater degree of change after the long teaching practice placement. Also, student teachers with more teaching experience seem to more often have a meaning oriented way of learning. Regarding curriculum development, the results suggest that introducing longer teaching practice placements and related activities during teacher education degree courses, may be a lever for motioning survival oriented learners to change their orientation to learning to teach. The emerging framework that will be presented from these analyses, will provide an intricate view on how learning orientations, time-related factors and personal and contextual variables are interrelated. It will also provide more insights for practice and future research into the factors that can stimulate the development of student teachers' learning orientations.

Approaches to studying in deaf and hard-of-hearing students

John Richardson, The Open University, United Kingdom

This contribution to the symposium reviews recent research on the influences on approaches to studying in deaf and hard-of-hearing (DHH) students in institutions of higher education. DHH students who use sign language are more likely to exhibit a reproducing orientation in their studies, apparently because they are more likely to hold a reproductive conception of learning. Teachers on separate programmes for DHH students are more likely than teachers on mainstream programmes to adopt a student-focused approach to teaching that is aimed at bringing about conceptual change in their students. Sign-language interpreters often hold a reproductive conception of interpreting and tend to adopt a literal approach to interpreting. This in turn promotes a reproductive conception of learning among deaf students who use sign language. However, interpreters who hold a reconstructive conception of interpreting are likely to adopt a free approach to interpreting that promotes a reconstructive conception of learning among deaf students who use sign language.

The role of the learner

Hearing students in higher education adopt different approaches to their studies: some adopt an approach oriented towards the meaning of their course materials; others adopt an approach oriented towards being able to reproduce the course materials for the purposes of assessment (Laurillard, 1979; Marton, 1976). These are influenced by the students' perceptions of their academic environment, such that students who have more positive perceptions of the quality of their courses are more likely to adopt desirable approaches to studying (Richardson, 2005). However, they are also influenced by their underlying conceptions of learning: students who hold a reconstructive conception of learning are more likely to adopt a meaning orientation, but those who hold a reproductive conception of learning are likely to adopt a reproducing orientation (Van Rossum & Schenk, 1984).

Some deaf and hard-of-hearing (DHH) students attend separate programmes or institutions that are specifically intended for deaf students, but most DHH students attend mainstream institutions along with their hearing peers. Very few studies have concerned the approaches, conceptions, and perceptions of deaf and hard-of-hearing (DHH) students. Nevertheless, questionnaire surveys in both the United States and the United Kingdom have found that DHH students in mainstream institutions exhibit a meaning orientation and a reproducing orientation to their studies, but that in comparison with hearing students they are more likely to exhibit a reproducing orientation (Richardson et al., 2000, 2004). The difference is more pronounced in DHH students who use sign language. This is not because they perceive their courses as lower in academic quality. On the contrary, they may rate their courses more highly because of the additional forms of learning support that they receive in their studies. When variations in the students' perceptions of their academic context are statistically controlled, DHH students still tend to be more likely than are hearing students to adopt a reproducing orientation (Richardson, 2008). This suggests that DHH students who use sign language are more likely to hold a reproductive conception of learning and are less likely to hold a reconstructive conception of learning than are hearing students.

The role of the teacher

Hearing teachers in higher education adopt different approaches to teaching: some adopt a teacher-focused approach aimed at the transmission of information, but others adopt a student-focused approach aimed at bringing about conceptual change in their students (Trigwell & Prosser, 1993). These approaches to teaching are influenced by the teachers' perceptions of their teaching context, such that teachers who feel that their departments value teaching, that their class sizes are not too large, and that they have control over their teaching are more likely to adopt a student-focused approach and are less likely to adopt a teacher-focused approach (Prosser & Trigwell, 1997). Nevertheless, teachers' approaches to teaching are also influenced by their underlying conceptions of teaching. Teachers who hold a reproductive conception of teaching are likely to adopt a teacher-focused approach to teaching that promotes a reproductive conception of learning in their students. Teachers who hold a reconstructive conception

of teaching are likely to adopt a student-focused approach to teaching that promotes a reconstructive conception of learning in their students (Trigwell & Prosser, 1996).

Most of the research that has been carried out to date on approaches to teaching has involved hearing teachers teaching hearing students in mainstream educational institutions. Marschark et al. (in press) used a questionnaire survey to compare approaches to teaching among teachers on either mainstream or separate programmes within the same institution in the United States. They found that teachers on separate programmes were more likely than teachers on mainstream programmes to report seeking to promote conceptual change in their students and adopting more student-focused approaches to teaching. Marschark et al. inferred that the teachers experienced in teaching separate programmes were better able to recognise the strengths and needs of DHH students.

The role of the sign-language interpreter

Teachers on separate programmes are usually able to communicate with students using both sign language and spoken language. In mainstream programmes, however, the relationship between teachers and deaf students who use sign language is mediated by sign-language interpreters (Richardson et al., 2010). The latter adopt different approaches to interpreting: some use a literal approach, but others use a free approach. Observational studies have shown that these approaches are influenced by the interpreting context: in particular, some interpreters adapt their approach to the properties of the material being interpreted (Napier, 2002). Nevertheless, interpreters' approaches to interpreting also seem to be influenced by their underlying conceptions of interpreting: some hold a reproductive conception based on the idea that the interpreter is a passive, neutral communication link or conduit, whereas others hold a reconstructive conception based on the idea that the interpreter is an active, engaged participant (Roy, 1993). The training and assessment of sign-language interpreters have traditionally promoted a reproductive conception, but it has been argued that the demands of real-life interpreting (including educational interpreting) are accommodated better by a reconstructive conception (Turner & Harrington, 2001). An interpreter who holds a reproductive conception of interpreting is likely to adopt a literal approach to interpreting that in turn promotes a reproducing orientation among deaf students who use sign language. This may undermine the efforts of teachers who adopt a student-focused approach to teaching aimed at bringing about conceptual change in their students. If these students are repeatedly exposed to a literal approach to interpreting, it is also likely that they will persist in holding a reproductive conception of learning. An interpreter who holds a reconstructive conception of interpreting is likely to adopt a free approach to interpreting, to be an active participant in the classroom, and to take into account the students' needs and expectations. This may promote a meaning orientation among deaf students who prefer to communicate using sign language and encourage them to acquire a reconstructive conception of learning (Richardson, 2008).

SYMPOSIUM

Social and individual aspects of regulation in collaborative group learning activities

Chairperson: Simone Volet, Murdoch University, Australia

Organiser: Simone Volet, Murdoch University, Australia

Deborah Pino-Pasternak, , Australia

Discussant: Valeska Grau, Pontificia Universidad Catolica deChile, Chile

Research concerning the nature and significance of social and individual aspects of regulation in collaborative group learning activities is growing. This development is consistent with an increasing focus on pedagogical practices based on social constructivist models of learning present in all sectors of education. Reaching a better understanding of the role played by individual and social regulatory processes on the quality collaborative learning is therefore critical. The purpose of this symposium is to bring together researchers who are grappling conceptually, methodologically and empirically with these issues, and more specifically with distinctions between socially-based metacognitive regulation, productive coconstruction of knowledge, and the quality of interactional exchanges. The role of different task variables such as difficulty level, mode of interaction, and task goals are also explored. Pino-Pasternak and Whitebread investigate the nature of individual and social regulation in young children's problem-solving, and the extent to which it relates to the quality of dialogue and task understanding. Iiskala et al. explore the extent to which metacognition appears as socially-shared within school age dyads and groups. Finally, Khosa and Volet examine the effectiveness of an intervention aimed at enhancing university students' engagement in productive metacognitive coregulation, coconstruction of complex knowledge and collaborative learning. The discussant, Valeska Grau, expert in the analysis

of group regulation, will comment on common conceptual and methodological threads and will highlight future directions in the area.

Metacognitive regulation as socially shared in collaborative processes

Tuiki Hannele Iiskala, University of Turku, Finland; Marja Vauras, University of Turku, Finland; Erno Lehtinen, University of Turku, Finland; Riitta Kinnunen, University of Turku, Finland

This paper aims to discuss social aspects of metacognitive regulation. The concept of 'socially-shared metacognition' (Iiskala et al., 2004, 2010) is used to refer to the consensual monitoring and regulation of joint cognitive processes in demanding collaborative problem-solving. The research question is as follows: Does metacognition appear as socially shared within dyads' face-to-face and small groups' virtual collaboration? STUDY 1 involves four high-achieving dyads (4th grade, 10 year olds). The dyads worked face-to-face solving 251 problems of three difficulty levels. Lessons were videotaped, and verbal/nonverbal behaviours were transcribed as turns. STUDY 2 involves 6 small groups (6th grade, 12 year olds, $n = 25$). The small groups worked in an asynchronous CSCL environment during 22 lessons, participating in research-like processes of inquiry (Hakkarainen, 2002). In both studies, an episode (set of turns/notes), was used as a unit of analysis. According to results, socially-shared metacognition within both groupings was found. Examples of typical episodes and quantitative outcomes are presented. In STUDY 1, episodes were found in 75% problems. The tests indicated that episodes appeared significantly most often in the most difficult problems. In STUDY 2, preliminary results show that emergence of episodes varies according the phase of the process. Comparison of socially-shared metacognition between two different contexts is discussed.

Introduction and aim

Although the social nature of learning is emphasized to gain a more profound understanding of learning (e.g., Lehtinen, 2003; Resnick et al., 1991; Salomon & Perkins, 1997), social aspects of metacognitive, regulatory processes are yet rarely looked from social, interpersonal perspective (Vauras et al., 2008; Volet et al., 2009b). We have argued that both the self and social forms of regulation are needed in order to understand regulation of actual collaborative learning processes, and that inter-individual metacognition is not equivalent to individual metacognition, and cannot be reduced to the group members' individual characteristics or processes, and, thus, should be conceptualized differently (Iiskala et al., in press; Volet et al., 2009b). Only scarce empirical evidence exists (cf., Iiskala et al., 2004, Iiskala et al., in press; Volet et al., 2009a) on how the social forms of regulation play out in real-life collaborative group learning activities, and how the individual and social regulation interact. This also means that the study of metacognitive regulation in collaborative learning is characterized by only emerging operationalization and methods for data analysis. This paper aims to discuss the role of social aspects of metacognitive regulation on the basis of evidence from two studies, one on dyads' face-to-face and the other on small groups' virtual collaboration between young, primary school pupils'. The concept of 'socially-shared metacognition' (Iiskala et al., 2004; Iiskala et al., in press; cf., Molenaar et al., 2010; Whitebread et al., 2007) is used to refer to the consensual monitoring and regulation of joint cognitive processes in demanding collaborative problem-solving situations (Iiskala et al., 2004; Iiskala et al., in press; Vauras et al., 2003). We argue that in a genuine collaborative learning process the participants' regulatory activities are shared and reciprocal, depending on each other; in this case, collaboration referring to a certain degree to symmetry, shared goal and low division of labor in the interaction (see, Dillenbourg, 1999). The questions raised in this paper are as follows: Does metacognition appear as socially shared within dyads' and small groups' collaboration, and does it appear similarly in face-to-face and virtual collaboration?

Method

STUDY 1 involves four high-achieving dyads, altogether eight (4th grade, 10-year-old) pupils, ranking in the top 11% of their schoolmates ($n = 393$) in mathematical word-problem solving and reading comprehension. The dyads worked face-to-face in the computer-supported, game-format learning environment, and solved altogether 251 problems of three difficulty levels during 56 (45 min) lessons. Working sessions were videotaped, and verbal and nonverbal behaviors were transcribed as turns ($N = 14\,675$). STUDY 2 involves 6 small groups consisting of four to five (6th grade, 12-year-old) pupils ($n = 25$). The small groups worked in an asynchronous CSCL environment during 22 (45 min) lessons, participating in research-like processes of inquiry (see, Hakkarainen, 2003; Scardamalia & Bereiter, 1996), and solving complex open-ended problems concerning the universe. Working was partly scripted and divided into overlapping phases as follows: creating the context and setting up research questions, making hypotheses, planning study methods, studying deepening knowledge, and publishing findings. Data revealed pupils' written productions, i.e. notes ($N = 4771$). In both studies, an episode, i.e. a set of turns/notes, was used as a unit of analysis. Hence, metacognition was not coded via individuals' single actions but a dyad or a small group was treated as a system, in which individuals' regulatory actions were inseparably interrelated, i.e. socially shared.

In STUDY 1, the inter-coder agreement was measured in 30% ($n = 76$) of the problems, where the second coder was asked to trace the episodes of socially-shared metacognition. The coders reached 86% ($k = .63$) agreement. In STUDY 2, the inter-coder agreement has not been measured yet. In all respects, ethical code for scientific research has been followed, and ethical aspects of original research plan were accepted according to the guidelines of the ethical committee of the University of Turku. Results and conclusions In this paper, we first present qualitative results from both studies by giving examples of typical socially-shared metacognition episodes. The qualitative analysis is based on the application of an interaction flowchart analysis (Sfard & Kieran, 2001), specifically, preoccupational analysis, which deals with how interacting participants move between different channels of communication (individual, interpersonal) and different levels (cognitive, metacognitive). Second, quantitative outcomes are presented.

In STUDY 1, 385 socially-shared metacognition episodes in 187 (75%) problems out of all the 251 problems were found. The number of episodes per problem at three difficulty levels was compared. The Kruskal-Wallis test indicated a significant effect of difficulty level, $\chi^2(2, N = 251) = 47.37, p < .001$. To conclude, the results suggest that it is possible to find socially-shared metacognition within the dyads' face-to-face and small groups' virtual collaborative learning processes. Episode analyses showed that metacognitive regulation fluctuated between individual cognitive and metacognitive processes and shared metacognitive regulation. However, the emergence of episodes seems to vary according the level of difficulty (e.g., apparent most likely in difficult problems) and the phase of process. Further, more in-depth comparison of socially-shared metacognition between the two different contexts is discussed. The significance of the studies is discussed in terms of impact on current theories and methods in metacognition research are highlighted. Particularly, we discuss how empirical evidence from these studies helps us to conceptualize and relate individual and social regulation in different real-life collaborative group learning activities in the case of young learners.

Fostering metacognitive coregulation and co-construction of knowledge in collaborative learning

Deep Khosa, Murdoch University, Australia; Simone Volet, Murdoch University, Australia

Interest in understanding the significance of social regulatory processes taking place in real-time, student-led collaborative learning activities has gained substantial momentum in recent years. There is growing evidence that engagement in genuinely shared metacognitive regulatory processes is associated with effective collaborative learning processes. Empirical studies with different age groups have revealed that although such productive processes can be found across a range of collaborative learning activities, most students do not spontaneously engage in high-level coregulation of their content learning, and therefore miss out on unique opportunities for learning from each other. Gaining further insight into this phenomenon while trying to address the educational challenge, naturally calls for design experiments. This paper presents the design and findings of a field-based intervention aimed at fostering high-achieving, highly motivated university students' engagement in metacognitive coregulation adapted to their learning content and activity, with a view to enhance their co-construction of complex knowledge and valuable learning from each other. Data involves video-footage of twelve groups' interactional processes while working on a clinical case in two meetings, one informal, the second involving a cognitive scaffold, with follow-up interviews. Data analyses also explore the added value of a cognitively scaffolded activity in fostering high-level metacognitive coregulation, and the nature and relationship of metacognitive coregulation to co-construction of knowledge.

Introduction

Educational psychologists' interest in understanding the significance of the social regulatory processes taking place in real-time, student-led collaborative learning activity has gained substantial momentum in recent years (Iiskala, Vauras, Lehtinen & Salonen, in press; Järvelä & Järvenoja, in press; Rogat & Linnenbrick, 2010; Volet, Vauras & Salonen, 2009). This development parallels the growing importance, given to pedagogical practices grounded in social constructivist models of learning, such as group projects, collaborative learning tasks, and case-based or problem-based learning. Yet, empirical studies using microgenetic designs show that even high achieving students may not spontaneously engage in high-level shared regulation of learning (Salonen, Vauras & Efklides, 2005; Summers & Volet, 2010) unless instructed to do so (Khosa & Volet, 2010).

To date, there is a paucity of intervention research investigating how to promote genuinely shared metacognition and high-level co-construction of knowledge embedded in regular instruction. Gaining further insight into this phenomenon while trying to address the educational challenge, naturally calls for design experiments. This paper presents a field-based intervention aimed at enhancing high-achieving, highly motivated university students' engagement in productive metacognitive coregulation, co-construction of complex knowledge and collaborative learning from each other.

Aims

The aims of the study were to determine: a) the effectiveness of a metacognitive intervention on groups' engagement in high-level shared regulation of learning and co-construction of complex knowledge b) the additional impact of co-constructing a cognitive representation of content knowledge; c) how effective co-construction of knowledge is supported by productive metacognitive coregulation and specific individual and group processes.

Participants were 12 groups of 5-6 high achieving veterinary science students (n= 69), required as an integral part of their regular study in physiology, to learn from an authentic clinical case (in own time, over seven weeks, different case per group). Each group was required to generate their own learning objectives, undertake background research on selected parts of the case, and present their collective findings in class at the end. Observational data from a prior cohort (control group in this study) had displayed limited spontaneous engagement in the target behaviours, students spending most of their time managing the task (Summers & Volet, 2010).

Intervention and embedded data collection process

The intervention comprised three consecutive components, administered by a veterinarian-researcher not teaching in the unit: 1. Metacognitive instruction; 2. Stimulated metacognitive reflection; 3. Customised concept map as cognitive representational scaffold. Multiple data sources were collected. Only data reported in the presentation is described.

1. Metacognitive instruction aimed at fostering high-level metacognitive coregulation and co-construction of knowledge of the clinical case. A set of selected interactional strategies and stem-questions (inspired by King, 1998 customised to the veterinary task) were introduced, commented and supported by two short films: one featuring student-actors enacting the strategies and questions (to show what effective collaborative learning can "look like"), and one featuring professional collaborative learning in a real veterinary clinical setting (to stress relevance). Short- and long-term benefits of effective peer learning were emphasised.

Data: (a) Video-footage of each group's first informal meeting (ten days into the project); (b) audio-recorded group interview (a few days after the meeting).

2. Stimulated metacognitive reflection aimed at providing customised, consolidation of the metacognitive instruction. It was elicited during (b) on the basis of a 2-minute segment of the group's best content-related interactions, that is, featured metacognitive coregulation and co-construction of knowledge.

3. Customised concept map or cognitive representational scaffold aimed at providing a visual support for enhancing metacognitive regulation and co-construction of shared knowledge of the case. Support material comprised pre-prepared cards of key concepts, a large board, markers for connections, a set of instructions and a sample concept map.

Data: (c) Video-footage of each group's construction of the cognitive representation of their clinical case (customised concept map); (d) audio-recorded group interview (immediately after) eliciting metacognitive reflections on the concept map learning experience.

Data analysis

The group is the main unit of analysis and video footages provide the primary data sources. Selected individual level complement group level analyses. To address the first research question, the analytical framework of Volet, Summers & Thurman (2009) is used. The ratio of content- to management-related group interactions, and proportion of time spent on high-level co-regulation (as conceptualised by Volet et al) are compared across intervention and control groups. To address the second research aim, data analyses involve within-groups' comparisons of high-level co-regulation episodes across activities (spontaneous shared understanding in informal meeting; co-construction of customised concept map). The third research aim involves within groups and across activities' analyses of content-related interactional processes and overall style, with a view to establishing the extent to which cognitive representational scaffolding might create stronger opportunities for metacognitive coregulation - with possible variations in the take-up of opportunities across groups (Gresalfi, 2004). Episodes of metacognitive coregulation and co-construction of knowledge also need to be disentangled in order to determine how effective co-construction of understanding is supported by productive metacognitive coregulation, separately for each activity. Individual level analyses of patterns of participation across activities within groups are examined in relation to group analyses, and combined with metacognitive reflections from interviews. Preliminary findings suggest a higher proportion of in-depth content discussion in the customised concept map activities compared to the informal meetings relying on spontaneous shared understanding. A different style of interactions also emerges. While episodes of metacognitive coregulation in informal meetings display formal, turn-taking approaches where students respectfully allow each other to present their research findings, the customised concept map construction activities exhibit rapid interjections

of questions and answers, elaborative fact clarification and supportive or dismissive discussions of physiological principles related to the case. Co-constructing a customised concept map appears to enhance metacognitive coregulation, increase members' participation and generally improve the collective effort to share understanding, which was consistent with students' metacognitive reflections. This research provides insight into how university students' learning and understanding of complex knowledge can be enhanced in collaborative learning groups.

Young children's regulation during group-work: Links with dialogue and understanding

Deborah Pino-Pasternak, , Australia; David Whitebread, University of Cambridge, United Kingdom

Though the value of transactional and mutually regulated processes during groupwork has been widely acknowledged (Iiskala et al., 2004, 2010; Volet et al., 2009) fine distinctions on what constitutes co-regulatory processes versus collaborative processes of co-construction of understanding are yet to be clearly established. Moreover, the majority of empirical work concerning this issue has been carried out with older students. The aims of this paper are therefore to explore the extent to which young children engage in individual and social forms of regulation when working in groups and the extent to which these regulatory processes relate to the groups' quality of dialogue and understanding. The dynamics of 4 groups engaged in 4 problem-solving activities is analysed looking at individual and social forms of regulation as well as aspects of the activity targeted by regulatory actions. These regulatory episodes are explored in relation to productive (exploratory) and less productive (disputational & cumulative) forms of dialogue (Mercer, 2000). Based on prior research, it is hypothesised that these groups will engage in different forms of regulation (individual & social) and that regulation will be directed towards different task-related aspects (understanding, task procedures, and social interaction). We also hypothesise that higher incidences of social forms of regulation, particularly those targeting task understanding, will be positively associated with higher incidences of exploratory talk within the groups. Evidence supporting these hypotheses is presented.

Research concerning the quality of students' group-work has identified successful collaborative processes as those characterised by the presence of mutual regulatory exchanges between members that attempt to achieve a shared understanding of the goals and contents of the task at hand (King, 1998; Goos et al., 2002; Volet et al., 2009). The value of these transactional and mutually regulated processes has been highlighted by researchers within the Self-Regulation literature (Iiskala et al., 2004; Vauras et al., 2003; Volet et al., 2009) as well as by those investigating forms of group dialogue and collaboration that lead to positive academic outcomes (Howe et al., 2007; Mercer & Littleton, 2007; Tolmie et al., 2010). However, fine distinctions between what constitutes co-regulatory processes versus collaborative processes of co-construction of understanding are yet to be clearly established. From a developmental perspective, the majority of this empirical work has been carried out with late primary, secondary school, or university students. We still lack an understanding of how these processes emerge earlier in development, and more importantly, what are the key characteristics of contexts that facilitate the emergence of these forms of interaction. The aims of this paper are therefore to explore the extent to which young children (5-6 year olds) are able to engage in individual and social forms of regulation when working in groups and the extent to which these regulatory processes relate to the quality of dialogue and understanding evidenced in the groups' exchanges. The study reported here examined the following research questions: (1) To what extent do young children engage in individual and social forms of regulation when working in small groups?, (2) Which aspects of the task do groups seem to regulate?, and (3) Which forms and aspects of regulation relate more closely to productive forms of dialogue between group members? The results presented in this paper are part of a larger study assessing the effectiveness of an intervention designed to enhance young children's regulation of learning, conceptual understanding, and productive forms of classroom dialogue. As part of this larger study, 6 Year 1 classes in the UK participated in 8 activities which encouraged children to collaboratively work in small groups (normally 3 participants) to jointly solve problems in the curriculum areas of Science and Arts/Music. Video recorded data for each one of these activities was collected for 2 target groups in each class (12 groups, n= 36, 96 group-work sessions). This paper will focus on the analysis of 4 of these groups (n=12, 6 boys & 6 girls) belonging to 2 of the intervention classes. These classes were selected as they constituted the richest examples in terms of the appropriation of the forms of dialogue and general principles fostered by the intervention. The selection of optimal classroom contexts was deemed as the most productive strategy to target the research questions and a particularly suitable one when exploring the early development of individual and social forms of regulation in young students.

Four intervention sessions were selected for the purposes of the analysis presented in this paper (Sessions 1, 4, 5 and 8). The underlying rationale for this selection was: (a) to address the chronological dimension of the intervention, and (b) to provide a representative selection of the different curriculum areas and types of activities. In addition to the video data, the dialogue of the 4 target groups was transcribed for each one of the selected sessions, leading to 16 transcribed episodes of group-work.

In order to capture individual as well as social aspects of regulation a multi-layered analytic strategy has been developed. In agreement with prior research (Molenaar et al., 2010), the first analytic layer codes individual turns in terms of their regulatory function (prior knowledge, planning, monitoring, control, & evaluation) or absence of it, leading to an exhaustive coding of all utterances and associated non-verbal actions present in the dialogue. Subsequently, these regulatory turns are categorised on the basis of the task-related aspects being targeted (i.e.: task-understanding, task-procedure, & social interaction). The presence of consecutive regulatory codes within the interaction is then explored, leading to the identification of social regulation episodes which, in turn, are categorised as other-regulation or shared-regulation on the basis of the direction and reciprocity of the regulatory utterances or actions (Iiskala et al., 2010). Episodes of other-regulation are characterised by uni-directionality (from one student to the others) and lower reciprocity, while episodes of shared-regulation are characterised by multi-directionality and high reciprocity. In order to explore relationships with the quality of dialogue Mercer's (2000) framework is used, identifying episodes of productive (exploratory) versus less productive (disputational & cumulative) forms of dialogue. Relationships between regulatory episodes and dialogue quality are explored quantitatively and qualitatively.

On the basis of prior research (Iiskala et al., 2010, Whitebread & Grau, in press), we hypothesise that these groups will engage in different forms of regulation (individual & social) and that regulation will be directed towards different task-related aspects (understanding, procedures, and social). We also hypothesise that higher incidences of social forms of regulation, and particularly those targeting task understanding, will be positively associated with higher incidences of exploratory forms of dialogue within the groups. Evidence supporting these hypotheses is presented. From a theoretical perspective, this paper attempts to shed further light on distinctions between social forms of regulation, dialogue, and the joint construction of task understanding during group work. In addition, it provides an indication as to how these processes might emerge in young children's development.

SYMPOSIUM

Students' reasoning about the past: from understanding towards improving

Chairperson: Carla Van Boxtel, University of Amsterdam, Netherlands

Organiser: Jannet van Drie, University of Amsterdam, Netherlands

Carla Van Boxtel, University of Amsterdam, Netherlands

Discussant: Carla Van Boxtel, University of Amsterdam, Netherlands

The aim of the symposium is to deepen our understanding of how students reason about history and how we can use this understanding to improve students' historical reasoning. Since the 1990s there has been an increased interest from researchers in the subject of historical thinking and reasoning. The majority of empirical studies analyses students' ways of reasoning about the past and the conceptions that underlie this reasoning. There is a growing interest in how students' ethnic, cultural and national identities affect their reasoning. There is also a growing amount of research focusing on teaching methods to enhance historical reasoning. This symposium brings together these different lines of research. The papers focus on students aged 16 to 19. In the first presentation we will look at students' thinking when confronted with conflicting interpretations of the past. What are students' ideas about why historical disagreement arises? The second presentation is about how students' ethnic identities influence their ascription of historical significance. What criteria do students employ when selecting significant events? The third presentation looks at the potential of a task that explicitly asks students to give their own opinion about and discuss the significance of historical persons and events. To what extent does such a task provoke and enhance historical reasoning? All papers will discuss implications for history education. The discussant will reflect on the contribution of the three different lines of research. How can we proceed from understanding towards improving students' historical reasoning?

A case study exploration of students' explanations for variation in historical interpretation

Arthur Chapman, Edge Hill University, United Kingdom

There is widespread agreement that history education should aim to help students engage with plural interpretations and accounts of the past, however, research suggests that understanding plural interpretations can present challenges for students and that educators need to consider students' preconceptions about historical knowing if they are to facilitate progression in understanding. Drawing on case study research this paper poses the question 'How do 16-19 year old English students explain variation in historical accounts and what conceptions of historical knowing underlie the explanations that students offer?' and proposes a typology of modes of explaining variation in historical accounts.

Twenty-four 16-19 year old students completed three written tasks over the course of one academic year and twelve students were also interviewed. Data are analysed qualitatively, through a process of inductive coding, and a model of five 'ideal typical' explanations for historical disagreement is posited. The assumptions about historical knowledge construction implied by each mode of explanation are explored. Whilst this paper's findings are consistent with, lend support to and further develop existing work they also demonstrate the importance of a focus on developing students' understandings of conceptual and hermeneutic aspects of historical interpretation.

There is widespread agreement that history education should aim to help students engage with plural interpretations and accounts of the past (von Borries, 2009). However, as an important body of research has shown (Ashby, Gordon & Lee, 2005; Lee & Shemilt, 2004; Maggioni & VanSledright, 2009), understanding plural interpretations can present challenges for students and educators need to consider students' preconceptions about historical knowing if they are to facilitate progression in understanding. Drawing on case study research (Chapman, 2001 and 2009) that set out to build on and extend existing English work modelling 7-14 students' understandings of historical accounts (Lee, 1997 and 2001) this paper poses the question 'How do 16-19 year old English students explain variation in historical accounts and what conceptions of historical knowing underlie the explanations that students offer?' and proposes a typology of modes of explaining variation in historical accounts. Although, as is inevitable in case study research, the findings of this paper cannot be generalised to a wider population, it is argued that the analytical tools it develops are suggestive and will have analytical value in helping educators model student thinking.

A written research instrument was developed, drawing on existing work (Lee, 1997 and 2001), piloted with seventy students in three institutions (Chapman 2001) and refined, extended and deployed in a case study of students in one institution (Chapman, 2009). Twenty-four 16-19 year old students, twelve in the first and twelve in the second year of their advanced level history studies, completed three written tasks over the course of one academic year. Each task presented a different historical controversy, in the form of paired texts in which two historians made differing claims about an historical topic. Students were asked the same questions in each task, designed to elicit data about the students' understandings of historical interpretations. Three tasks were used to explore the extent to which students' ideas could be considered stable or variable across a series of controversies raising conflicts of interpretation of different kinds. Twelve of the twenty-four students, six from each year, were also interviewed at the end of the academic year, using questions that mirrored the written task questions but that were general in nature, in order to explore students' thinking in greater depth.

Data analysis focused on the students' ideas about explaining why historical disagreements arise and students' underlying understandings of how historical accounts are constructed. Data was analysed qualitatively, through a process of inductive coding, and a model of five 'ideal typical' explanations for historical disagreement was posited on the basis of this analysis: explanation for variation in terms of (1) author background and beliefs, (2) archives consulted, (3) author bias and manipulation, (4) author interpretation and meaning construction and (5) author questioning and research focus. All task responses could be characterised as making reference to one or more of these explanatory moves and nineteen out of the twenty four students made reference to the same move or moves in two or more tasks. Patterns of opposition emerged also in the types of move that many students made: for example, whereas four students made reference to move (3) but not to move (4) in two or more tasks, three students made reference to move (4) but not to move (3) in two or more tasks.

The assumptions about historical knowledge construction implied by each mode of explanation were explored, through detailed discussion of individual students' responses to task questions, and ideas that may inhibit or facilitate progression in understanding were considered and explored. Key themes developed in the discussion include student ideas about evidence and, for example, the extent to which explanations for account variation in terms of author bias and manipulation depended upon testimonial conceptions of historical evidence. It was apparent also that although students who explained account variation in terms of author interpretation were often aware of the importance of processes of meaning construction in historical interpretation these students did not have a conceptual apparatus available to enable a coherent account of such processes. Whilst it will be argued that this paper's findings are consistent with, lend support to and further develop existing work on student understandings of historical accounts (Lee and Shemilt, 2004; Maggioni and VanSledright, 2009), it will also be argued that the data presented demonstrates the importance of a focus on developing students' understandings of conceptual and hermeneutic aspects of historical interpretation.

Students' ethnic identities and their narrative constructions of Canadian history

Carla Peck, University of Alberta, Canada

In this paper I explore findings from a study that investigated the relationship between students' ethnic identities and their ascriptions of historical significance to moments in Canada's past. Twenty-six grade 12 students living in an ethnically diverse urban centre in British Columbia participated. Students were asked to discuss and select, out of a possible thirty, the ten most significant events in Canadian history. Students were asked to describe their ethnic identity and then reflect about the ways in which their ethnic identity may have influenced the decisions they made during the timeline task. Findings show students employed three different narrative templates to construct the history of Canada and used specific types of historical significance depending on the narrative(s) they used. The student's ethnic identities played a central role in determining the shape of the narrative he/she created and the criteria he/she employed to select the events for his/her narrative. Many students articulated complicated notions of their identities, with some perceiving that particular "sides" of their identity were at play, or in use, during the research task. Implications for history and citizenship education are explored.

In this paper I present research that investigated the relationship between students' ethnic identities and their ascriptions of historical significance to moments in Canada's past. Previous research has demonstrated that socio-cultural factors, including ethnic identity, can influence students' understanding of various aspects of history and cause them to have different ideas about "what counts" as historically significant (Barton & McCully, 2004; Epstein, 2000; Lévesque, 2005; Levstik, 1999; Seixas, 1993). In this paper I argue that the history education community has not sufficiently theorized the nature of ethnicity and its relationship to students' historical understandings. In previous work, researchers have made evaluative statements about the relationship between ethnic identity and understandings of history (generally, or regarding specific aspects of historical understanding such as significance) but have not based these conclusions on a complex understanding of ethnic identity (Bhabha, 2001; Hall, 2003) or on students' reflections on the nature of such a relationship.

The research presented in this paper attempts to respond to this gap in the literature. Twenty-six grade 12 students living in an ethnically diverse urban centre in British Columbia, Canada participated in this study. In groups, students completed a "timeline task" during which they were asked to make decisions about the historical significance of particular events and themes in Canadian history and then to explain their timeline. Students were also asked to describe their ethnic identity and reflect about the ways in which it may have influenced the decisions they made during the timeline task. I found that the students employed three narrative templates to explain their timelines and used specific types of historical significance criteria (Cercadillo, 2001) depending on the narrative(s) they used. Many students articulated complicated notions of their ethnic identities, with some perceiving that particular "sides" of their identity were at play, or in use, during the research task. Students who collaborated on the timeline activity often used different narrative templates to explain their timeline. The students' ethnic identities played a central role in determining which narrative template(s) they employed and the historical significance criteria they selected to

construct these narratives. These findings suggest that students come to the study of history with pre-existing criteria for historical significance that closely match those discussed in the literature and that their ethnic identities influence how they use these criteria to story the nation.

In the remainder of the paper I argue that the three narrative templates that the students in my study used can be mapped onto Westheimer & Kahne's (2004) framework of citizenship. Westheimer and Kahne theorize three types of citizens: the "personally responsible citizen," the "participatory citizen" and the "social justice oriented" citizen. In the latter half of this paper I explore the ways in which the three narrative templates employed by the students in my study may be aligned with Westheimer and Kahne's three types of citizens and suggest implications for policy and practice in history and citizenship education.

Enhancing students' historical reasoning: the potential of discussing historical significance

Jannet van Drie, University of Amsterdam, Netherlands; Carla Van Boxtel, University of Amsterdam, Netherlands; Brenda Stram, University of Amsterdam, Netherlands

Developing students' abilities in historical reasoning is an important goal in history education, but also raises the question of how to enhance and stimulate students' historical reasoning in the classroom. In this paper we study whether discussing the historical significance of persons and events is such a suitable approach. A lesson unit on determining historical significance was developed in which group work and whole-class discussions were systematically alternated. Two teachers and their students (in sum 43, pre-university education) participated in the study. Analyses included both learning outcomes, measured through a pre- and posttest and student-essays, and learning processes (whole-class discussions). The outcomes suggest that engaging students in issues of historical significance does enhance historical reasoning, however it also revealed that students have difficulties with different aspects of it, for example, contextualization and the use of meta-concepts.

Developing students' abilities in historical reasoning is an important goal in history education. This requires that students get ample opportunities to practice this. But what are powerful approaches that elicit and stimulate students' historical reasoning? Although this is an important question, for teachers as well as for researchers, who want to gain insight in the effects of instructional approaches on learning outcomes and processes, it has received relatively little attention in the history domain. Here, we present a study that investigated the question whether engaging students in questions of historical significance is a powerful approach to enhance historical reasoning. Determining the significance of people, events, and developments is a key activity of historians, however, students in secondary education are not often confronted with it. Instead, they are confronted with the outcomes of these debates through selections and ready-made stories. Hunt (2000) suggests that enabling students to make sophisticated decisions about what is important from the past and why, may be a fruitful and motivating approach. Discussing historical significance may include many components of historical reasoning as described by van Drie and van Boxtel (2008). In order to make judgments about the significance of a person or events one should not only consider facts related to this person/event and relate this to the context of the time people lived or events took place,

but also consider the changes that it brought about, the impact of these changes, and its' causes and consequences. The question of historical significance is an evaluative question which stimulates historical reasoning (Van Drie, Van Boxtel, & Van der Linden, 2006). At this point, there is hardly any empirical evidence that engaging students in thinking about historical significance elicits and stimulates historical reasoning, since most studies on historical significance focus on students' ideas about what is significant and why, and how this relates to socio-cultural factors (e.g. Epstein, 2000; Peck, this symposium).

A lesson unit of five lessons was developed on the question of which person or event was most important for the development of the Dutch democracy from 1800 till present. Starting from a socio-constructivist perspective on learning, group-work, whole-class discussions, and writing tasks were included (cf. Engle & Conant, 2002; Leinhardt, 1993; Mercer, Dawes, Wegerif, & Sams, 2004). Students studied in groups one of ten preselected persons and events, determined their significance based on various criteria and presented this to the rest of the class, which finally resulted in a class top ten.

Participants of the study were two experienced history teachers and their classes (of 29 and 14 students) from one school in the Netherlands (pre-university education, 16-17 years of age). The concept of historical significance was new to the students, since it is not an aspect of the official history curriculum. Data included transcripts of the final whole-class discussion, student essays (in which they made a case for their personal favorite), and a pre- and posttest, containing items measuring concept knowledge, and knowledge of important periods and dates by constructing a time-line and writing a short text. Whole-class discussions and essays were analyzed on their occurrence of components of historical reasoning (see Van Drie & Van Boxtel, 2008). All analyses were conducted by the first two authors separately and differences were discussed until agreement was reached.

The results showed that students were actively engaged in historical reasoning during the whole-class discussion, making many substantive contributions that included a lot of comparing and evaluating persons and events and less explaining. In their reasoning the students did make use of substantive concepts (almost 40% of the utterances), but to a lesser extent they used meta-concepts as change, cause, and consequence. In addition, the various criteria to determine historical significance were discussed. However, in the essays the students almost all used the criteria is important for its' own time and is important for present times, whereas the criteria is a symbol was only used in 30% of the cases. Although students did contextualize in time and used meta-concepts, this was not done by all students to the same extent. Comparisons between the pre- and post test showed significant differences on the concept knowledge task, and on the knowledge of dates as measured in the timeline-task, indicating that students improved on the level of concept knowledge and overview knowledge. Additional outcomes of student questionnaires and teacher interviews indicated that both teachers and students found it an interesting and motivating approach. Despite the limitations of this study in (only two teachers and their classes), these results suggest that discussing historical significance can be a promising approach for enhancing historical reasoning, for it elicits different components of historical reasoning. However, the quality of the reasoning displayed by the students can still be improved. More research is needed to generalize these outcomes, and additional qualitative analyses may shed more light on the learning processes elicited.

SYMPOSIUM

Symbiotic Relationship between Disciplinary Literacy & Understanding: Scientific Literacy Examples

Chairperson: Vaughan Prain, La Trobe University, Australia
Organiser: Larry Yore, University of Victoria, Canada
Discussant: Elizabeth Moje, University of Michigan, United States

This symposium addresses the foundation, current research, and future agenda of exploring the essential roles of texts in doing and learning science. Specific attention is given to positioning scientific literacy with the broader literature and research into disciplinary literacy across academic domains and school curricula. First, presenters will provide a contemporary developmental view of science literacy that incorporates fundamental literacy in science, derived understanding of science, and socioscientific applications as well as a discussion of how these integrated senses of literacy guide and help interpret professional learning for primary, middle, and secondary teachers of science. Second, the presenters will provide a framework and research results on the functionality of texts across learning and teaching phases. Finally, the presenters will report on their current and future research agenda involving multiple representations and the transformation between modes to enhance scientific understanding and multi-representation competence.

Moving Disciplinary Literacy beyond a Slogan: Vision III of Scientific Literacy

Elizabeth Moje, University of Michigan, United States; Larry Yore, University of Victoria, Canada; Christine Tippet, University of Victoria, Canada; Kenneth Tang, University of Michigan, United States

The awareness and acceptance that discipline-specific language results from and in disciplinary understanding is becoming more common in language, literacy, and science education communities. The developmental view of scientific literacy posits that literacy in science and scientific understanding of the big ideas in science interact to enhance proficiency within and with each other, leading to fuller participation in the public debate about science, technology, society, and environmental issues to produce informed decisions and sustainable actions. The developmental nature of disciplinary literacy in any domain evolves from basic to intermediate to discipline-specific forms. Differences in assumptions about knowledge, what counts as warrants, the nature of available representational forms, and the larger goals of the discipline shape how one sets a purpose and previews a given text. Taken together, these assumptions establish a framework for defining and developing pedagogical content knowledge for scientific literacy teaching by primary, middle, and secondary school teachers of science. This paper will report theoretical work on what makes literate practice unique in science, research on scientific literacy teaching across 20 urban schools, and the results of a 5-year case study of middle school teachers of science.

Science Literacy is a long-promoted, but ill-defined, general expectation (Hurd, 1958) with international cache (McEneaney, 2003). Earlier visions of science literacy focused on scientific knowledge (Vision I) or contextual application of scientific knowledge (Vision II), but neither vision addressed the literacy component of science literacy (Roberts, 2007). More recently, Vision III has addressed the literacy, knowledge, and applications components and how these senses interact to enhance meaningful learning and abilities (Norris & Phillips, 2003; Authors, 2007a, 2007b, 2008). Disciplinary literacy in science and other disciplines evolves from basic (aspects common to production and use of most texts) to intermediate (aspects common to some texts) and finally to disciplinary (aspects common only to discipline-specific texts) literacy (Shanahan & Shanahan, 2008). In addition, developing theorization of the continuum of generic to disciplinary literacy practices suggests that the differences among disciplinary literacy practices are less about stark differences in underlying literate practices and more about how epistemological assumptions of each discipline shape the way generic, or common, practices are enacted. Previewing and purpose setting, for example, are strategies readers of any text engage in before and as they read; what it looks like to preview and set a purpose for text reading in science, however, is unique from the previewing and purpose setting when reading a primary source in history. Differences in assumptions about knowledge, what counts as warrants, the nature of available representational forms, and the larger goals of the discipline shape how one sets a purpose and previews a given text. Taken together, these assumptions establish a framework for defining and developing pedagogical content knowledge for scientific literacy teaching by primary, middle, and secondary school teachers of science.

This paper will report theoretical work on what makes literate practice unique in science: research on scientific literacy teaching. One study explored the classroom practices of both teachers and students across 20 urban schools. Most notable was the finding that the teachers made literacy teaching distinct from science teaching, despite co-constructed professional development activities that sought to integrate literacy with science teaching. We also noted that, of all literacy teaching practices, vocabulary teaching seemed to be taken up with the most enthusiasm (Authors, 2010). In this paper we will draw from various theories of scientific literacy and of science learning to offer possible explanations for these practices.

Another study examines the stark contrasts between two sets of texts and literate practices that deal with more or less the same physics phenomena; one from high school physics and the other from everyday media that adolescents are familiar with (e.g., magazines, websites, sci-fi, videos). Findings indicate that although there are many thematic similarities between these texts (thus opportunities for meaningful science learning), there are also vast divergences in terms of their epistemological assumptions in framing the phenomena and what can be counted as knowledge about those phenomena. Through these divergences, we were able to better understand how the disciplinary literacy of high school physics presents major challenges for the students to master its thematic content, and consequently how literacy teaching practices needed to be modified to cater to such challenges.

The third study reports on a 5-year case study of middle school teachers of science. Generalist teachers (limited science content backgrounds) from three Grades 6–8 middle schools in a suburban Canadian school district were tracked as they set the research and development agenda of a community-based project, participated in professional learning activities identified by the participants and project staff, developed instructional resources related to a subset of strategies and literacy tasks for their schools' science program, and later disseminated these resources to colleagues in their schools. Results indicated that these teachers gravitated toward intermediate literacy strategies and tasks (general reading strategies, vocabulary development, concept mapping, using visual representations, designing informational posters and brochures), implemented these strategies and tasks into their science program and other disciplinary studies (social studies, mathematics), and were willing and effective professional development providers in their school. However, even teachers who participated in the study from the beginning were reluctant to conduct professional development workshops in the other district schools and elsewhere.

The combined results of these studies indicated that both teachers and students approach the idea of scientific literacy teaching as a matter of inserting literacy instruction into science teaching, rather than considering the teaching of scientific language and literacy practices as part and parcel of learning science. Possible explanations for this stance include the teachers' own past science learning experiences, a conflict between stances toward science learning as the construction of knowledge and literacy learning as discrete and didactic, and/or the possibility that students' skills and learning practices shape what teachers believe they can accomplish in regard to deep scientific literacy learning.

Cognitive and Pedagogical Functionality of Literacy Tasks and Texts in Learning and Teaching Science

Jennifer Tilson, University of California, Berkeley, United States; P David Pearson, UC Berkeley, United States; Jacqueline Barber, University of California, Berkeley, United States; Megan Goss, UC Berkeley, United States

This paper examines a model of science-literacy integration that embeds literacy learning within inquiry science in a way that supports students' development of science knowledge, practices, and dispositions. Using the logic of design research, we present an analysis of literacy tasks and texts in the middle school curriculum (USA Grades 6–8) and its role in supporting students' acquisition of these phenomena, with special emphasis on understanding earth science concepts, argumentation (oral and written) skills, and collaborative knowledge building dispositions. Early field trials within the first round of design experiments revealed a great deal about the constraints and affordances of the ecology in which we embed literacy texts and tasks; namely, middle school organizational structures, the science curriculum (both content and process), the developmental characteristics of adolescent learners, and the cultural practices of middle school science teaching. These factors dramatically shape the ways in which text can be used to support the science learning goals. The overarching insight thus far is that there is an important role for text in the

acquisition of knowledge, skills, and dispositions in science, but it involves much more than simply applying the default practices of language arts classrooms (and narrative text) to science classrooms.

Literacy educators and science educators alike are gathering evidence that these two domains are inexorably linked. In science education, reports such as the National Research Council's *Taking Science to School* (2007) recognize the centrality of the language in science and call for a high level of student participation in scientific discourse and practices; in literacy education, recent documents such as the Carnegie Foundation's *Time To Act* (2010) acknowledge the critical role of discipline-specific knowledge and literacy strategies as a factor influencing student achievement. These calls raise essential questions about how to achieve the aims of enabling students to reach a high degree of facility with scientific ideas and practices (in particular, the ability to read science texts with deep understanding). How can science teachers be supported in helping students develop the sophisticated literacy skills associated with the domain?

In this paper, we describe our work on a curriculum development and research project (January 2010–December 2013), the aim of which is to provide teachers and students with materials specifically designed to support inquiry science and disciplinary literacy learning simultaneously. Over the past 6 years, the authors have designed a successful approach for the elementary level and have instantiated this approach in educative curriculum materials; currently, we are working to adapt and revise this approach for middle school. Though just beginning, we have already found some key ways in which the contextual differences between elementary and middle schools affect the curriculum design as well as the instructional supports offered to teachers and students. This paper describes our initial insights based on 3 months of design research; we expect others will emerge as well. Some areas in which we have found unique constraints and affordances are middle school organizational structures, the science curriculum (content and practices), the developmental characteristics of adolescent learners, and the cultural practices of middle school science teaching. These factors dramatically shape the ways in which text can be used to support the science learning goals of the project.

The organizational structures of American middle schools shape the curriculum and approaches that can be used. Middle schools are typically organized into periods of 40–50 minutes in length; thus, the typical student sees 5–7 teachers per day and the typical teacher teaches over 100 students per day. These constraints on time and the number of students per teacher have implications for the use of text in the science classroom as well as for the tasks in which students engage.

In addition, the science curriculum itself, with an emphasis both on content knowledge and processes such as gathering and interpreting scientific evidence and engaging in scientific argumentation, shapes the curriculum and the texts associated with it. The complexity of the content as well as the ways in which the content is connected has implications for the use of text in the science classroom. At least two influential dimensions have emerged so far—complexity (how many variables are involved in the domain) and abstractness (how easy is it to represent how things work in the domain).

In reviewing and revising our curricular model, we have hypothesized that special attention must be paid to the developmental characteristics of the adolescent learner. By middle school, students have developed perceptions of themselves as learners and as readers. We hope to share some insights from our research design about supporting the science learner as part of teaching students to be sophisticated readers of science texts and engage in scientific inquiry and discourse.

The cultural practices of middle school science teaching also affect the use of text in the science classroom. Many American elementary school teachers are facile with literacy teaching but lack preparation in teaching science; thus, an integrated curriculum at the elementary level provides a measure of familiar territory to K–5 teachers by combining literacy and science. However, most American middle school science teachers are trained as disciplinary experts but are not typically as familiar with literacy teaching methods, may not be as confident supporting students in reading science texts, and may, as we have found, view teaching reading skills and strategies as someone else's responsibility. We are investigating ways to support teachers in acquiring strategies for supporting students in their literacy development in science through educative curriculum materials as well as ways to carefully structure the texts themselves so that students are supported in their reading and interpretation of these texts.

Finally, our initial work indicates some differences in the design of texts as well as the ways in which texts are linked to firsthand science experiences. Our elementary model posited that text played five essential roles: providing context, supporting firsthand inquiry, providing data for students to interpret, modeling processes, and delivering content (Authors, 2009). In middle school, an additional role, providing critique, is emerging as key for supporting students in

engaging in argumentation around scientific ideas. We will report on these and other aspects of text design that impact the pairing of science inquiry and text to support student learning.

We are confident that what we learn over the next 8 months (November–June) will prompt us to revise these insights and to develop new ones that have not yet presented themselves. We remain committed to the overall goal, however, of creating a curriculum and a pedagogical approach that finds a key role for literacy and language in supporting the acquisition of knowledge and inquiry skill among middle school students.

The Cognitive Power of Transforming/Translating between Representations in Science Learning

Brian Hand, University of Iowa, United States; Vaughan Prain, La Trobe University, Australia

There has been a strong emerging interest on students' use of multimodal representations in which research has concentrated on students learning from interpreting and interacting with prepared representations. Our focus has been on students constructing their own representations and on examining how students engage with challenges of representing science claims, the relationship between elements of a concept expressed in a single modal form, as well as students' understanding of a concept across modal forms, and how students engage with an idea within and between modal forms. The movements between and within representation forms are critical in helping students build a meta-representational competency where they are able to use knowledgeably and regulate a representational focus to build new knowledge. We have focused on several approaches to explore how students engage in the use of multimodal representations to build science understanding. These approaches are centred on pedagogical actions needed as critical elements of instruction as well as writing activities to be completed at the end of a unit of work that require students to explain the modal forms used to represent a concept. The shift in emphasis—from something given to students (prepared representations of a concept) to something students construct and critique about the target concept—places different demands on students from interpreting others' texts. Results indicate that embedding multimodal representation-making within the context of learning has the potential to increase the cognitive demands, and hence learning outcomes, for students.

Various studies have investigated the value of student-generated representations to promote understanding in science (Greeno & Hall, 1997; Ritchie, Rigano, & Duane, 2008). Greeno and Hall (1997) pointed out that student engagement only with authorized representations may constrain opportunities for learning. They argued that student construction and interpretation of their own representations had various consequences:

- Forms of representations can be considered as important tools for constructing and communicating understanding;
- Constructed representations are adapted for the purposes at hand;
- Students need to be more actively engaged in constructing and interpreting representations by actively discussing the properties of representations, including their strengths and limitations.

Ford and Forman (2006) emphasized the construction and critique (interpretation of the persuasiveness) of a representation in developing students' understanding. They suggested that unless students learnt to construct and interpret representations of their observations, become active participators in the learning process, and recognise the role and function of their constructions then learning could be constrained and superficial. They acknowledged that such an approach required students to use skills often learnt in other disciplines as they constructed and interpreted their representations of emerging understanding.

Pursuing this pedagogical focus, various researchers have sought to identify cognitive and communicative conditions that supported knowledge-building in science and advocated that students construct a diverse range of representations to enable this learning (Authors, 2006; Gunstone, 1995). This approach asserts that students should use a more diversified range of representations, both formal and informal, to engage with the practices and intent of

scientific investigation. In advocating text diversification, these researchers accept that students need to demonstrate a capacity to use accurately the current vocabulary and multimodal representations of science discourse. However, they argue that there are motivational gains and enhanced learning opportunities when students engage in a cycle of planning and guided revision of different text types where there is a strong emphasis on clarification of claims in science and their justification for both self and others.

This paper reports on two different approaches to promoting student engagement in generating their own representations. Both studies involve students in the process of constructing explanations of phenomena that place cognitive demands on them to transform representations across different modal forms. These studies are centred on immersing students in the experience of construction and critique of their representational transformations.

The first case study with two teachers and their upper elementary classes examined the use of a series of representational challenges to develop students' understanding of the concept of evaporation. These sequences focused on students making multimodal representations to justify causal claims to other class members and the teacher about the topic. Data collection entailed researcher observational notes of lessons, analyses of key aspects of the teachers' role in the sequences, student and teacher interviews on the learning effects of this approach, extensive analyses of the representational choices and conceptual content of students' artefacts throughout the unit of study, and subsequent student testing for transfer to new contexts. We found that this explicit teacher focus on the form/function of representations, and on guided student judgment of the clarity, comprehensiveness, and adequacy of their own representations, and coherence across modes, resulted in (a) strong student motivation, (b) strong gains in students' reasoning about claims in science, and (c) improved learning performance on subsequent topic tests.

The second case involved 1,000 middle and secondary school students, divided equally into treatment and control groups. Their science teachers were provided with professional development related to incorporating multimodal writing exercises into their teaching units. The teachers were asked to conduct a lesson with the treatment in which students generated a set of criteria for examining multimodal representations within text, for example, textbooks, publications, and websites. Students were asked to use these criteria as a support for the production of their written piece. Control students were given the same writing assignment but were not exposed to the development of criteria. Examination of written products and test scores indicates that there is a strong correlation between coherence of text and test scores; that is, the students who were able to construct strong links between the modes they used to explain the concept and the text used to describe these modes were able to perform better on tests.

SYMPOSIUM

Diversity as Intercultural Competence

Chairperson: Susanne Weber, Ludwig-Maximilians-Universitat-Munchen, Germany

Organiser: Hans Gruber, University of Regensburg, Germany

Susanne Weber, Ludwig-Maximilians-Universitat-Munchen, Germany

Discussant: Frank Achtenhagen, Institute for Business and Human Resource Education, Germany

Dynamics of globalization are accompanied by processes of migration. The increasing flow of people creates new challenges for governments, national economies, single enterprises, workplaces and individual. Migrants and their descendants make up a considerable share of the overall population in many EU countries. Although much has already been done in many countries about migrants' structural integration there is still an imbalance between migrants and local population with regard to their participation in society and especially, the labour market which is a crucial factor in the integration of migrants to the new society. Beside formal restrictive regulations (e.g., non-accreditation of foreign qualification certificates) studies show that there exist prejudice, uncertainty and anxiousness of employees in hiring people from abroad. These might be rooted back to a public recognition to others' distinctiveness on a

collective level as well as to individuals' cultural incompetent acting. The first paper maps out the first generation migrants' experiences, how the Finnish society has recognized their competence and provided chances to jobs; it is also shown how intervention strategies may foster commonly shared understanding. The second paper suggests a method for measuring intercultural competencies in business on an individual level by a cognitive achievement test and essays. The third paper measures the development of intercultural sensitivity of engineers in comparison to different treatments. The main theoretical and educational significance is getting insight into collective and individual processes of recognition to others' distinctiveness. This is a huge challenge and point of departure for learning and training measures.

Recognition and access: immigrants' workforce competence

Johanna Lasonen, University of South Florida, United States; Marianne Teras, University of Helsinki, Finland

Immigration and migration in a broader sense are pertinent phenomena of our globalizing world. The increasing flow of people creates new challenges for governments, national economies and workplaces. Employers look for specific skills and competencies, while migrants arrive with qualifications that are not described in terms that are used, recognized and understood in the receiving country. A critical social theory and developmental work research guide the conceptual framework of the paper that discusses some issues of the recognition of migrants' education and competence among the first and second generation immigrants and their integration to new environments. The answers for the following questions are searched: (1) To what extent migrants' prior learning is recognized and accepted? (2) How does this contribute to their career prospects and influence their access to jobs? (3) To what extent are pathways open for minority secondary education students to education and work? - The data have been collected by face-to-face interviews, a questionnaire and by an intervention method. The data have been analyzed using both qualitative and quantitative methods. The study has revealed that the immigrants in Finland are stratified into 'ethnic minority disadvantaged' groups which show a similar pattern of stratification, found in other Western countries (Heath and Cheung 2007). In addition, a pattern of immigrants' children's access to work and education is studied.

Aims

Immigrants and their descendants make up a considerable share of the overall population in many EU countries, and also in Finland. Because educational level and occupational placement have proved crucial factors in the integration of immigrants to the society of their new home country, their position in the labour market is a central topic in public and political debate. Although much has already been learnt in many countries about immigrants' structural integration, the amount of research knowledge is not yet sufficient. There is still need for comparative studies, and the mechanisms attributable to ethnic inequalities in the labour market call for further theoretical exploration, even though many analyses have already described the situation fairly well. Many earlier studies have shown that migrants coming from outside Europe and also their descendants are treated unequally with regard to employment. In this respect, discrimination exists in the societies of EU countries. The aim of this paper is (1) to map out the actual situation for ethnic minorities in Finland and to produce new knowledge that illuminates why and how immigrants are stratified into 'ethnic minority disadvantaged' groups and (2) to demonstrate possible collective learning and development by implementing a socio-cultural intervention. By the results social institutions and organisations are challenged to stop ethnic inequalities from transferring them from one generation to another.

Methodology

Identity, self-definition and recognition have been linked to struggles for dignity, respect and autonomy. Taylor and Honneth, who have conceptualized theories of multicultural politics of recognition, emphasize that individuals require membership in social groups with recognition to their distinctiveness rather than rights and resources. According to Taylor (1994), human life has a dialogical nature, and it is bound up with public recognition for the ethnic, religious and national groups. Identities are revised, affirmed and developed. Honneth (1992) indicates that recognition requires a measure of "social acceptance for a person's method of self-realization within the horizon of cultural traditions of a given society" (p. 191). Fraser goes further and says that social justice is at issue when a society's "dominant cultural patterns of interpretation and valuation" (1997, p. 39) establish unequally the social bases of self-respect for different social groups. Fraser emphasizes a basic discord between a "theory of cultural justice" that enhances the recognition of difference and a "theory of distributive justice" that advocates the just distribution of resources (p. 6). To produce new knowledge that illuminates why and how immigrants are stratified into 'ethnic minority disadvantaged' groups and whether this pattern of stratification, found in other Western countries (Heath & Cheung 2007), is true in Finland, face-to-face interviews and a questionnaire survey all over Finland have been run and discussed in the context of "The Integration of the European Second Generation" project (TIES, 2010), the EU Labour Force Survey (EULFS 2000) (Kalter & Kogan, 2002) as well as the studies of Heath & Cheung (2006). For demonstrating and initiating collective learning and development processes a second study was run also on the bases of the Vygotskian socio-cultural approach to learning which emphasizes social interaction and activity in the process of

knowledge and skills construction (Vygotsky, 1987). Psychological and material tools mediate the competence construction that occurs in historical and cultural settings. Personal and event histories are seen as combinations of social actions in specific contexts. These are not predefined environments but include the dimensions that are relevant to the participants in the activity. The participants themselves produce and create the contexts in their joint activity. Teräs (2007) analyzed the challenges of intercultural learning and development and included the voices of immigrant students in a multicultural dialogue in Finnish vocational schools. The intervention was based on the generic Change Laboratory method (Virkkunen, Engeström et al., 1997); embedded in a one-year-long Preparatory Immigrant Training program for students who, after the training, intended to study in regular vocational education and training. Teräs developed and implemented a new intervention called the Culture Laboratory, to meet challenges of everyday life inside the school. The Culture Laboratory is a participatory method for observing, comparing and creating new cultural activity. However, there is a need to understand how young minority students' competence and experiences are identified and faced in secondary schools.

Many studies concerning intercultural education and immigrant students' experiences in Finland have been done in comprehensive schools, in teacher training contexts and in working life, but secondary schools have not been in the focus. One central pathway to a new society and to working life goes through vocational education and training. The empirical research material consists of nine two-to-three-hour meetings of the Culture Laboratory, which were audio- and videotaped (altogether 20 hours). The participants included 17 students who were natives of eight different countries (Estonia, Russia, Somalia, Iraq, Chile, Italy, Afghanistan, and Japan), four teachers, a school assistant, a counsellor, the project coordinator, the chief interventionist, and a researcher.

Findings

In Helsinki, ten percent of young people and 8.2 percent of the whole population speak a language other than Finnish or Swedish as their mother tongue. The results of the first study show the first generation immigrants' experiences, how the Finnish society has recognized their competence and provided chances to jobs and experiences of the second generation, that is children and adolescents who develop their agencies in multiethnic and multicultural settings, and whose voices are not listened to, at least not in the public debate going on in Finland.

The results of the second study – the Culture Laboratory intervention - shows and explores the dynamic movements of intercultural encountering, and how this situation can enrich learning and development. Theoretical and Educational SignificanceThe research has focused on children of immigrants in transition phases of their educational paths. Schools do not only transfer the skills and knowledge needed in the community but also the prevailing practices and cultural values and symbols of dominant groups. The results give first hints for effective and efficient ways to develop migrants' workforce competence.

Instilling Global Competence in Baccalaureates Through International Experiences:

Jonathan Gordon, Georgia Institute of Technology, United States; Amy Henry, Georgia Institute of Technology, United States; Jack Lohmann, Georgia Institute of Technology, United States

This study presents the results of a longitudinal evaluation of the Georgia Tech International Plan, a curricular and co-curricular initiative designed to give students the opportunity to develop intercultural competence skills through a combination of language study, coursework, and long term international work and study opportunities. The evaluation measures gains in intercultural sensitivity through the use of the Intercultural Development Inventory (IDI), a reliable, psychometrically validated instrument designed to ascertain the degree of cognitive complexity people bring to their experiences with different cultures. A quasi-experimental cohort study employs the use of multiple control groups in addition to the population of interest.

Aim

Our research stems from the Georgia Tech International Plan (IP), an initiative to increase the number of undergraduate students who graduate with global competence in the practice of their majors. Through a combination of foreign language study, coursework in international relations, global economics, and cultural studies, and extensive work and/or study abroad experiences, the IP is designed to produce graduates who have an understanding of global relations, intercultural communication, and international disciplinary practice. Over the past five years, we have evaluated student achievement of learning goals associated with the IP utilizing multiple methods of assessment including pre/post surveys, externally normed and validated instruments, and quantitative methods such as focus groups. This paper shares the results from one instrument designed to measure the degree of cognitive complexity

that an individual brings to perceptions of cultural difference—the Intercultural Development Inventory (IDI). The IDI was developed by Bennett and Hammer to measure intercultural sensitivity and has been found to be a reliable and reasonably valid measurement tool (Paige, et al., 2003). The IDI is based on Bennett's (1986) Developmental Model of Intercultural Sensitivity (DMIS). The DMIS postulates six stages of increasing sensitivity to cultural difference. As one's experience of cultural difference becomes more sophisticated, one's competence in intercultural relations increases.

People truly bicultural or multicultural; do not define themselves in terms of any one culture (very rare) The DMIS posits three ethnocentric stages of development and three ethnorelative ones—each associated with more sophisticated cognitive ability to recognize and appreciate cultural differences.

Methodology

The study utilizes a quasi-experimental longitudinal model comparing three groups: students who participate in the IP, students who participate in some international experience (e.g., short-term study abroad programs), and students who engage in no international experiences. Students were asked to complete the IDI in their first year of undergraduate study, and again upon graduation. Using a matched-pairs design, we can measure the difference in developmental ability over the course of the undergraduate experience. To date, a total of 3,781 first-year students have completed the instrument; we have administered the post-test to 685 seniors. We will continue to collect data and expect to substantially complete data collection in 2011. Among the questions we will address in the paper:· Do intentional curricular and co-curricular interventions like the IP affect development of intercultural sensitivity?· Does second language fluency have an effect on intercultural sensitivity?

What is the role of gender and ethnicity as it pertains to intercultural sensitivity? Does it matter where a student travels as it pertains to intercultural sensitivity? Does the degree of "foreignness" affect IDI scores? Are there differences in intercultural sensitivity gains based on the type of international experiences? For example, do students who work abroad have higher gains than those who study at foreign universities?

Findings

We have sufficient data to draw some preliminary conclusions regarding the development of intercultural abilities as measured by the IDI. Analysis of Variance (ANOVA) demonstrates a significant difference ($p = .008$) between those who have enrolled in the IP and those who had other or no abroad experiences. Table 2 provides preliminary results on the change in Developmental Score on the IDI. Post-hoc tests show that the first two groups—those who enrolled in the IP and graduated with the designator and those who enrolled in the IP and completed some (but not all) of the requirements—manifested significantly higher gains in development compared with those who participated in less rigorous abroad experiences.

Measuring Intercultural Competence

Susanne Weber, Ludwig-Maximilians-Universität-München, Germany; Matthias Hofmuth, University of Munich, Germany; Michael Fretschner, University of Munich, Germany

Intercultural competence is nowadays indispensable for effectively coping with challenges at the workplace. Thus, it is no wonder that intercultural competence is claimed for as a 21st century skill (Binkley et al., 2010). Here we conceptualize intercultural competence according to Ting-Toomey (1999) as "Mindful Identity Negotiation" and operationalize it according to the pragmatic competence construct of Weinert (2001): intercultural competence as a professional action competence that integrates and coordinates cognitive, motivational and social abilities. Such multifaceted construct can be approached and measured by various measures (Kanning, 2009). In this paper we are going to discuss two of them: The measurement of intercultural knowledge about critical incidents by running a cognitive achievement test and of modes of intercultural negotiation skills by running an open test format using essays. Responses to both studies ($N=545$ for the cognitive achievement test and $N=61$ for the essay study) are calculated with methods of Item Response Theory (IRT). On the base of our empirical data we could confirm our theoretical models by acceptable fit values.

Aims

Intercultural competence is nowadays indispensable for effectively coping with challenges at the workplace. Thus, it is no wonder that intercultural competence is claimed for as a 21st century skill (Binkley et al., 2010). Here, we conceptualize intercultural competence according to Ting-Toomey (1999) as "Mindful Identity Negotiation" and operationalize it according to the pragmatic competence construct of Weinert (2001): intercultural competence as a professional action competence that integrates and coordinates cognitive, motivational and social abilities. It is assumed that these abilities can be learned and trained. The situations in which the competencies are realized and shown have to be complex and challenging. For visualizing and measuring social competencies – like intercultural

competencies – Kanning (2009) suggests four approaches: (1) capturing intercultural knowledge by running cognitive achievement tests, (2) observing intercultural behaviour in real clash situations, (3) summarizing and describing the behaviour running self-reports e.g., by modes of questionnaires or essays and (4) drawing inferences from distal indicators. In our project we, therefore, identified critical intercultural overlap and clash situations for the field of business, and operationalized intercultural competence according to the "Mindful Identity Negotiation" approach of Ting-Toomey (1999). We created construct maps for intercultural knowledge (ad 1) and intercultural negotiation skills (ad 2) and measured these facets of intercultural competencies on the individual level implementing methods of Item Response Theory (IRT) (Wilson, DeBoeck & Carstensen, 2008). Our research questions are: (1) Is it possible to visualize different ability levels of these facets of intercultural competence for individuals? (2) Is it possible to create items/tasks on different levels of these facets of intercultural competence?

Methodology

For measuring the first facet of intercultural knowledge competence we identified real-life case studies in the field of business. We constructed ranked-order multiple choice (MC) items (Wilson, 2005), sequenced from totally wrong, over partly and quite correct choice opportunities to a best answer option. The sequencing strategy followed the affected identity dimensions (Ting-Toomey, 1999) of the acting participants within the intercultural clash situations presented in the case studies. By means of an online questionnaire 650 complete responses were generated. After profound proofs of data quality we estimated the model with 545 data lines. For data analyses and proving our theoretical construct map we applied the Partial Credit Model (Masters, 1982), an IR-Model of the Rasch-family as our MC Items were rank ordered. The IRT measurement was run by using the software Conquest (Wu et al., 2007). For measuring the facet of intercultural negotiation skills we used critical incidents raised from intercultural training methods (e.g., Pedersen, 1996) and asked the testees for their intentional behaviour to solve an intercultural clash situation. The verbal data were analysed by a content analysis according to categories created in a second construct map (Weber, 2005; Wilson, 2005; Weber & Achtenhagen, 2010) dichotomously. Here a simple IR-Model was run by using Conquest (Wu et al., 2007).

Findings

The confirmatory check of our items and the model fits was very successful: (1) With regard to our first model of intercultural knowledge all MNSQ-values fitted significantly in the hypothesized theoretical model. We also found interesting results by analysing the different item functions (DIF) of meaningful sub-samples (vocational experience, foreign background, sex, cross-cultural experience). E.g.: One significant finding was that people with a foreign background scored in average 0.56 logits better than people without. (2) With regard to our second model of intercultural negotiation skills we also can confirm our hypothesized model (resp. construct map) by acceptable fit values (separation reliability = .970; $\chi^2 = 527,83$; $df=19$, p Theoretical and educational significance of the research Describing and visualizing facets of intercultural competencies is an essential step for fostering these important 21st century skills in a sustainable way. By IRT we can map out the item estimates separately from the individuals' ability estimates – and therefore, analysing individual competencies in relation to other facets of intercultural competencies as well as other variables of linked to intercultural competent acting. The detailed analyses allow made to measure training methods.

SYMPOSIUM

Integrated tool support for learning through knowledge creation

Chairperson: Sten Ludvigsen, University of Oslo, Norway

Organiser: Crina Damsa, University of Oslo, Norway

Hanni Muukkonen, University of Helsinki, Finland

Discussant: Gijsbert Erkens, Utrecht University, Netherlands

In this symposium we discuss a pedagogical design involving technology that aims to support and foster learning through object-bound collaboration. The Knowledge Practice Environment (KPE) is a Web 2.0 application that provides participants with integrated tools and functionalities for learning through open-ended, collaborative inquiry. The designs employed have emerged from the knowledge creation approach (Paavola & Hakkarainen, 2005), which depicts learning as a collaborative activity aimed at creating shared knowledge objects. Technology-mediation has a prominent role in supporting collaboration processes, iterative development of products, and reflection of knowledge practices. The KPE environment (www.knowledgepractices.info/module-pages-display-pageid-42.html) is an integrated, modular open source software. It is designed to enable various visual views on the collaboration process and the related knowledge practices. The Content view provides a space for manipulating files, tasks, comments, and their relationships. The Process view can be used to view and edit tasks, timelines, and milestones. The Community view shows the members of the learning community, makes possible to create groups, and view responsibilities and products of members. Other integrated tools and functionalities support, for instance, conceptual modelling, tagging, collaborative authoring, and reflection of practices. We present three empirical studies that examine ways of supporting higher education learning and teaching activities, and pedagogical design for practices where the participants develop knowledge objects (e.g., manuals, designs, software applications, research reports). The three research studies attempt to explain how the different functionalities of the KPE can enhance collaboration and development of shared knowledge objects.

Iterative co-construction of knowledge objects by student teachers

Crina Damsa, University of Oslo, Norway; Sten Ludvigsen, University of Oslo, Norway; Patrick Sins, Leiden University, Netherlands

Abstract: In this contribution we investigate how student teachers collaborate to create and elaborate knowledge objects using web-based technological support. Creating settings that support students to solve problems with open-ended character is a challenge for the current educational practice. This contribution presents an empirical study of object-oriented collaboration, where groups of student teachers work on knowledge objects (e.g., didactic materials, guidelines or manuals for teachers) intended to address problems signaled in their internship places. We analyzed groups' collaboration processes and developing knowledge objects, with the aim of understanding the mechanism of both these processes. Also, we investigated how technology can support these specific activities. Findings show various degrees of idea sharing and co-elaboration of knowledge objects. Functionalities that support visualization of the object iterations, links to sources and commenting were most used. The findings assist us in formulating recommendations for future research and pedagogical design.

Introduction and theoretical considerations

In this contribution we investigate how teacher students work in collaboration to create and develop knowledge objects that will be employed at their internship places. We examine the processes revolving around collaborative and iterative knowledge object development and the way student groups employ features of technology designed to support this type of activities. We focus on variation in collaborative mechanisms across groups and we provide a more detailed insight into how knowledge objects are developed by a number of groups. Exposing students to knowledge practices they will perform as professionals seems to be a challenging task in higher education. In this study, the prevalent idea in the KP-lab project is that problems with an open-ended character entice students to engage with knowledge and make their own knowledge explicit. This involves theoretical and practical knowledge being materialized in objects (e.g., in educational material, evaluation instruments, research reports, etc.), where this knowledge becomes transparent for the participants involved.

Nevertheless, becoming actively involved and successful in such complex processes, and creating sophisticated knowledge objects, is a challenging task for students. The knowledge creation approach to learning (Paavola & Hakkarainen, 2005) can serve as a guide to develop new practices of learning and instruction, which places

collaborative creation of knowledge objects at its core. Knowledge creation processes not only shape the knowledge objects constructed but are also transformed by the actions that are performed on these objects (Stahl, 2006). Pedagogical designs should explicitly scaffold these practices through incorporating collaborative co-construction activities revolving around knowledge objects. This involves also providing various types of technological scaffolds. Whilst various studies showed how (online) technology features enhance dialogic interaction for learning (see for a review Ludvigsen & Mørch, 2010), technology that supports interaction through knowledge objects received less attention. Empirical setting, methods and data In the KPE, each group had its own shared workspace. Inside these spaces, students were expected to employ functionalities that supported organization and management of the collaborative process (i.e., task creation and planning functionalities) and iterative developing knowledge objects (i.e., item creation, versions, commenting, linking, sources display through web links, linking and chatting). We collected a rich set of data, consisting of: a) interaction data; b) knowledge objects, both produced in KPE or during fieldwork and c) reflection data. The analyses include frequencies of individual contributions to the collaborative work, coding of groups' interactions, and a detailed analysis of knowledge object development and iterations by one group.

Findings

Results indicate that groups employed different strategies to organize their work – division of labor was frequent. In terms of object development, there are a number of aspects that stand out. Co-construction moments occurred in some groups' work, such as discussing ideas and concepts, and then following up and materializing these ideas into iterations of the objects. Elaboration of object sections was often done individually, and the outcomes were placed in the group's shared space, where the other group members could read it and provide it with feedback. However, some groups had difficulties to collaboratively expand their knowledge on the matter and to build on it together, or to concretize this knowledge into the objects in-progress. Most recurrent situation in these groups was that ideas were discussed but not taken-up and not materialized. In these groups, mutual feedback and revisions on iterations of the objects were less common. Of the 20 participating groups 17 used the shared work spaces provided in KPE. Groups that employed co-construction strategies registered were also registered to be most active in using KPE, and received a positive final assessment of their final product by their tutor. Majority of groups used the shared spaces to store and organize their knowledge objects. Twelve of the groups used the Process view and task creation functionalities to plan and organize their collaboration, and reported on these functionalities as being good support for this purposes. The types of items mostly created were document files, web links (to online sources), and comments on document versions. Twelve groups used the system to visualize versioning of their knowledge objects, and indicated this functionality as supporting well the work on the knowledge object. To conclude, these results show that most students became engaged in co-constructing shared knowledge objects, but individual elaboration and strict division of labor without much feedback on object iterations occurred too. Theoretical and practical implicationsThe study indicates that the challenging task of managing and constructing knowledge objects and the use of complex web-based technological support suits students who are able to employ productive strategies, but that other students need more intensive support and scaffolds. Hence, these findings call for attention to students' understanding this pedagogical setting and of technology; also, to how these types of designs can provide a more clear scaffolds for students when entering the knowledge co-construction process. Furthermore, more focused studies are needed especially on how tools can support collaborative elaboration.

Modeling professional practices and object-bound collaboration - a higher education customer project

Hanni Muukkonen, University of Helsinki, Finland; Kari Kosonen, University of Helsinki, Finland; Minna Lakkala, University of Helsinki, Finland

The rapidly evolving knowledge practices of present professional settings generate novel demands for education. The knowledge creation approach to learning (Paavola et al., 2004; Hakkarainen et al., 2004) provides theoretical background to address learning and teaching organized around authentic problems and the development of shared knowledge objects. The investigation examined a higher education course involving students and teachers from 3 study programs and 4 customer companies. The students worked in 11 teams of 3-6 members to produce and iterate business ideas and plans, user stories, mock-ups, project reports, software applications and service concepts. The

teachers and customers were involved in weekly steering group meetings around the advancement of teams' business solutions and applications. The processes of two student teams were followed intensely. The Knowledge Practices Environment (KPE) was the main virtual collaboration environment in the course. As an outcome of the process, students generated several software applications and service concepts ready for further exploitation. The students faced difficulties related to focusing their business plans and coordinating the engagement and practices of students with multiple domain backgrounds. The customers and teachers facilitated especially turning attention to end-user needs and explaining the team's ideas to potential clients of their business solution. Similar collaboration and knowledge creation challenges have been reported in relation to global virtual teamwork in professional practices. Such a course appears, therefore, to provide a valuable experience resembling professional practices of teamwork.

Introduction

The rapidly evolving knowledge practices of present professional settings generate novel demands for education. The knowledge creation approach to learning (Paavola et al., 2004; Hakkarainen et al., 2004) provides a theoretical background to address learning and teaching organized around authentic problems and the development of shared knowledge objects, such as reports, products, and new practices. This approach highlights those aspects of social interaction and artefact-mediated activities, which focus on the development of shared objects in addition to the pursuit of personal learning and collaborative discourse interaction. The present study examines a higher education course which involved students, teachers, and customers in a complex tryout of knowledge creation. Multidisciplinary student teams from three degree programs, media engineering, industrial management, and communication, were asked to develop a business idea and make it happen for real. Teachers from these degree programs and customers from four companies were participating in the process for six months. Students were provided with various analytical, reflective and managerial documents (Omicini & Ossowski, 2004) that functioned as templates. The documents were intended to promote professional practices and object-bound knowledge creation (Eckert & Boujut, 2003; Ewenstein & Whyte, 2009; Paavola & Hakkarainen, 2005). We investigated how these documents and related guidance from teachers and customer representatives contributed to student teams' advancement in their projects. The advancement was expected to manifest itself in the produced business ideas and plans, user stories and mock-ups as well as in the management of workflow and project reporting, creation of functioning technical solutions, and communication with potential end-users. Three research questions were posed: 1. How the analytical, reflective and managerial documents were iterated (starting from templates); 2. How the various collaboration tools were used and what kind of mediation for joint activities they provided in the teams; 3. What kinds of questions and comments the teachers and customers provided in the weekly mentoring sessions and how this feedback was observed to influence the knowledge objects developed by the teams?

Research methods

A total of 50 students from 3 study programs of the Helsinki Metropolia University of Applied Sciences participated in the course. The Knowledge Practices Environment (KPE) software was used as the shared environment of the course, but student teams utilized several tools for their teamwork (e.g., GoogleDocs, Dropbox and project planning tools) in parallel. The course was one of the Finnish test sites in the EU-funded Knowledge Practices Laboratory project (KP-Lab; see <http://www.kp-lab.org>). An intensive follow-up of two multidisciplinary student teams was carried out. The following data were collected: video recordings of teacher and customer guidance during the weekly steering group meetings from the two intensively followed teams, as well as weekly self-reports on project advancement and KPE data on the versioning of central knowledge objects developed by all teams. Interviews with teachers, and the students and the customer representatives of the two teams were conducted at the end of the course, including questions about the use of the collaboration tools, team functioning, and the advancements of team productions.

Qualitative data analysis of the video recorded steering group sessions was carried out to examine what the mentoring focused on. A second qualitative content analysis focused on the progress reports and major editions found in the project documentation. The results of these two analysis were compared to gain an understanding of how the comments were observed to influence the iteration of knowledge objects. Further, a thematic examination of the interviews provided evaluations of the strengths and weaknesses of the course design, the tools used, and reflections on the process and its outcomes. Findings The templates provided a starting point for project documentation. Teams faced difficulties related to learning how to focus their business plans and to coordinate the engagement and practices of students with multiple domain backgrounds. The customers and teachers facilitated especially turning attention to end-user needs and explaining the team's ideas to potential clients of their business solution. Work on the intermediate documents and their versioning in conjunction with related guidance resulted in considerable changes in the successive versions of the business ideas and software applications in the two investigated teams. Three teams were actually able to accomplish all the steps involved in designing and implementing a software application and engaging clients for their business, which was in fact beyond the teachers' initial expectations. Most other teams accomplished either the application or acquiring the client, which was also major achievement. Several

teams used the KPE, which enabled the student teams to organize their sub-tasks visually as well as explicate the iteration of versions and interdependencies between diverse intermediate documents. Comparison of tool use is in progress. Theoretical and practical implications.

The findings suggest that the teams were faced with demands for efficient practices in analytical business procedures, work flow management, and coordination and communication with the customer representatives and potential clients. Similar collaboration and knowledge creation challenges have been reported in relation to global virtual teamwork in professional practices (compare Faraj & Sproull, 2000; Hyysalo, 2005). Such course with an assignment to produce business solutions for real customers appears, therefore, to provide students with a valuable experience resembling professional practices of teamwork. Based on the results, we encourage pedagogical design to include shared knowledge objects and modelling of professional knowledge practices in various forms.

Making use of artefacts in processes of open-ended inquiry

Christoph Richter, Christian-Albrechts-Universität zu Kiel, Germany; Heidrun Allert, Christian-Albrechts-Universität zu Kiel, Germany

In this work we focus on the utilization of artefacts in processes of open-ended inquiry. We investigate the affordances different kinds of artefacts provide and how they are appropriated by project teams in higher education. Even though the importance of shared artefacts for learning and knowledge creation has been emphasized by various scholars, the affordances of different kinds of artefacts and their materiality in processes of open-ended inquiry has hardly been investigated yet. This contribution presents an empirical study on the creation and utilization of various kinds of artefacts by project teams working on a design task over the period of one semester, making use of the Knowledge Practices Environment. We analyzed both the artefacts created and used by the project teams, as well as the kind of activity they were used in. Findings show that the same kind of artefact can be used in quite different ways, depending on the purpose it is used for, but also the inherent affordances and properties of the artefact itself. The careful selection of the type of artefact to be used but also the tools to create and work with these artefacts hence appears to be crucial in fostering processes of open-ended inquiry. Implications for the design of future collaborative learning environments are discussed.

Introduction and Theoretical Considerations

This contribution focuses on creating and utilizing artefacts in processes of open-ended inquiry. We investigate how project teams create and make use of various kinds of artefacts in order to solve complex design tasks. We examine how different kinds of artefacts are used at different stages of the inquiry process and how their utilization is shaped by the properties of the artefacts chosen. Even though the importance of shared artefacts for learning and knowledge creation has been stressed by various scholars (e.g. Stahl, 2006; Bereiter, 2002) and is also at the core of the KP-Lab project, the affordances and materiality of different kinds of artefacts in processes of open-ended inquiry has hardly been investigated yet. While shared artefacts have been studied as means for grounding and coordination of collaborative efforts, their potential role as objects of joint exploration and inquiry is only poorly conceptualized and understood. Building on the work of Gedenryd (1998) and Knuutilla (2005) we conceptualize artefacts as dynamic entities, which can fill multiple roles depending on the type of activity they are used in, while yet being constrained by their material and sign-related properties. Rather than treating artefacts as mere representations or carriers of information and ideas, we are particularly interested in their material and sign-related qualities with regard to fostering and impeding their utilization for epistemic processes. From a pedagogical perspective artefacts are particularly interesting as they provide important means to scaffold and support but also to monitor learning processes. Therefore a better understanding of the properties of artefacts and their utilization for different activities can provide for better guidance in the complex endeavour of open-ended inquiry.

Empirical setting, methods and data This study was carried out in a project-based course at the University of Applied Sciences in the bachelor program "Communication and Knowledge Media". In a compulsory first-year bachelor course, project teams of 3-6 students were asked to develop an educational scenario drawing on existing web 2.0 technologies. The course was meant to promote an understanding of design as a process of open-ended inquiry. All in all 26 students in 8 teams took part in the study. To support the design process students were introduced to Knowledge Practices Environment as well as a variety of techniques and design artefacts to document their understanding of the design space at stake. Typical design artefacts included journey frameworks, conceptual models of the design space, various types of prototypes for probing as well as reports.

The set of data used for this study consists of: a) project-logs on students' activities filled in by each team, b) periodic interviews with the teacher on her intentions and experiences with the different interventions, c) retrospective group interviews with each team at the end of the course, d) log files from KPE and VME, e) artefacts and documents uploaded or linked to KPE. The analysis is focused on the contents of the various artefacts and the kind of activities they were created in and used for.

Results

Even though the design task and instructions have been the same for all groups, we found considerable differences in the overall flow of activities as well as in the utilization of the design artefacts. While most of the artefacts used can be directly traced back to the assignments given, we also found artefacts such as a dedicated project plan or a questionnaire for market analysis introduced by the teams themselves. The introduction of these artefacts is reportedly due to team-members prior practices and project experiences. Despite these variations in the types of artefacts used we also found differences in the way the same kind of artefact has been used by different groups. For example, some groups used the journey frameworks as a means to record and synthesize their ideas about user needs while other teams used the journey frameworks as a probe to depict envisaged usage scenarios and tried to enact these scenarios themselves. Similarly, prototypes were found to be used as means to describe and communicate ideas on the user interface level, to explore different design options but also to test for usability problems and probe experiences. The way the artefacts are used appears at least partly due to the particular kind of material chosen. Tool use turned out to be heavily dependent on the actual tasks at hand. While the KPE was primarily used to collect, document, and organize, links, notes, and documents, as well as to create visual models of the design space, most other artefacts were created by third party tools such as In design, MS Word and Excel but also pen, paper and scissors to create prototypes. It is obvious that students like to use flexible tools such as Word and paper-based notes, as they can easily edit, reuse, and share the artefacts created.

Theoretical and practical implications

The result of this study suggest, that processes of open-ended inquiry draw on a multiplicity of artefacts each of them providing unique affordances and constraints. Besides its content, the epistemic use of an artefact is also shaped by its material and sign-related properties. From a pedagogical perspective it appears important to be sensitive to the way these artefacts are appropriated by the students and the actual purpose(s) they are used for. From the perspective of tool development, these findings point to a major limitation of collaborative learning environments currently available. While existing collaborative learning environments usually provide a broad array of functionalities to share, comment, and trace resources as well as documents, they are often quite restricted in their capability to collaboratively create and work with artefacts beyond text, conceptual models and or simple sketches.

SYMPOSIUM

The Performative Realisation of Competence in Asian and Western Mathematics Classrooms

Chairperson: Yoshinori Shimizu, University of Tsukuba, Japan

Organiser: David Clarke, University of Melbourne, Australia

Discussant: Minoru Ohtani, Kanazawa University, Japan

The three papers in this symposium employ different analytical approaches to the study of the performative realization of competence in Asian and Western mathematics classrooms. Comparison across such culturally-disparate sites poses powerful questions regarding the way in which competence is conceived, promoted and performed by both teachers and students. All three studies make use of the extensive data set generated by the Learner's Perspective Study (LPS). Data generation conformed to a common research design focused on sequences of at least ten lessons, documented using three video cameras, and supplemented by the reconstructive accounts of classroom participants obtained in post-lesson video-stimulated interviews (Clarke, 2006).

Each paper exploits the capacity of international comparative analyses to generate insights into local assumptions regarding competent practice. The first paper uses teacher questioning in two classrooms in Germany and Japan to draw significant distinctions between the function of questioning in the two classrooms and the connection between competent practice and the encompassing culture. In the second paper, it is suggested that distinct discourses exist in any cultural setting in and about the mathematics classroom and that both discourses frame the nature of classroom participation for participants in different cultural settings. The final paper examines didactical situations in Sweden and the Philippines and exploits this particular activity to reveal differences and similarities in the practices of competent teachers in both cultural settings and to call into question the application of the same analytical construct at the level of both the whole class and the small group.

Competent teachers in different cultures: An analysis of teacher's questioning in the mathematics cl

Yoshinori Shimizu, University of Tsukuba, Japan; Yuka Koizumi, University of Tsukuba, Japan

Mathematics teaching is situated in a specific cultural setting and has evolved in ways that are valued in that culture (Stigler & Hiebert, 1999). Consequently, a "competent" teacher can be valued and conceptualised in different ways in different cultures. This paper reports an analysis that explored the characteristics of the mathematics classrooms taught by experienced teachers in Germany and Japan, who were identified for their locally-defined 'teaching competence'. The analysis focused on teacher's questioning at the phase of introducing mathematical concepts and found that there are great similarities in the teacher's questioning with respect to the same goal in each of the German and Japanese classrooms. In both classrooms, however, the significant difference between the German and Japanese lessons was found that the German teacher developed a procedure employing the elicitation-response sequence, while the Japanese teacher utilised a time period between posing a task and sharing and discussing the solution. Therefore, the teachers' questions were seemingly similar, but, in fact, the meanings to the questions for the student were different. The result of the analysis reveals that the enactment of competence for the same purpose can be different in each educational setting.

The study reported in this paper analyzed two mathematics lessons that were collected in Learner's Perspective Study (LPS, Clarke, Keitel & Shimizu, 2006), taught by experienced teachers who were identified for their locally-defined 'teaching competence'. One class was on simultaneous equations in a public junior high school in Tokyo (J3), and the other was on complex mathematical expressions in gymnasium in West Berlin (G2). These lessons were selected to minimize the differences in teaching method that arise because of differences in the content, and also because "algebra" is regarded as important learning content in each country. The particular lessons were selected because they involved introducing mathematical concepts and they were located at a critical point in the lesson sequence in each classroom.

The procedure for analyzing the teacher's questioning in G2 and J3 consisted of the following: (1) identifying the episode that starts with posing or formulating a task that is related to learning new things for the student and ends with some tasks for practice, (2) segmenting the transcript into the parts related to the mathematical topic taught in the lessons, and (3) comparing the teacher's questioning in those episode. The tasks treated in J3 and G2 have similarities in the way that students were asked to transform expressions to a previously-learned form.

The results of our analysis reveal that there were great similarities in the teachers' questioning between the Japanese and the German classrooms, while the things that the students were afforded by the teachers' questions were different. In both the German and Japanese lessons, the teacher asked the students for a suggestion about the solution, and then developed the solution of the problem based on the students' responses. However, a significant difference between the German and Japanese lessons was that the German teacher developed the procedure in an "elicitation-response" sequence, while the Japanese teacher used an extended time period between posing a task and sharing and discussing the solution.

The similarities in classrooms between Germany and Japan identified by the TIMSS 1995 videotape study were corroborated in that both the German and the Japanese teachers developed the lesson by incorporating students'

response into classroom process at the phase of learning new things. In particular, there were quite similar conversations in which the teachers asked students about strategies and concrete calculating processes. On the other hand, there were discrepancies in that the G2 teacher constituted the learning process through the teacher's and students' conversation after presenting the tasks, while the J3 teacher set individual activity after presenting the task and then conducted a discussion based on the things generated in the individual activity.

For that reason, the things that the teacher's questions required of the student were superficially similar, but the functions for the German students were to guide and cue students to think about the current task in the G2 lesson, while the teacher's questions functioned for Japanese students as reminders of the things that they generated in the individual activity in the J3 lesson.

Based on the comparison of the feature of the teacher's questioning, it emerged that the G2 teacher broke the task into small parts, focused on each step and aimed to develop a more general procedure, while the J3 teacher expected the students to find a strategy and solution through individual activity and questioning was intended to promote the students' individual activities and to look back on what processes they generated.

The mathematics teachers in each education system participating in LPS were identified for their locally-defined 'teaching competence' and for their situation in demographically diverse government schools in major urban settings (Clarke, 2006). Applying the same definition of teaching competence across countries would misrepresent local practice. Local criteria included such things as status within the profession, respect of peers or the school community, or contributing to teacher professional development programs. Comparative analyses, such as the one reported here, illustrate what is valued as quality mathematics teaching in each education system, as well as revealing the cultural values behind what can be counted as quality mathematics teaching in different contexts.

The Cultural-Specificity of Accomplished Practice: Contingent Conceptions of Excellence

David Clarke, University of Melbourne, Australia

Of the contingencies relevant to any consideration of excellence in education, cultural norms and values are arguably among the most significant. Both classroom discourse and professional discourse about classrooms constitute forms of social performance undertaken within affordances and constraints that can be both cultural and linguistic. The nature of those discourses performed in mathematics classrooms provides a key indicator of pedagogical principles underlying classroom practice and the theories of learning on which these principles are implicitly founded. The discourses about mathematics classrooms give expression to these pedagogical principles sometimes explicitly and sometimes through embedding privileged forms of practice in the naming conventions by which the mathematics classroom is described. Research will be reported to suggest that each of these discourses is culturally and linguistically specific. As a consequence, conceptions of accomplished practice (or excellence) are contingent on the history of custom and insight embedded in the conventions of practice and the language with which that practice is described. In the same way that the differential promotion of fluency in spoken mathematics in different classrooms around the world enacts a different classroom mathematics, teachers, other educators, and researchers in different countries have at their disposal very different linguistic tools by which to conceptualise, theorise about, and research the mathematics classroom. International comparative research offers significant insights about how excellence in mathematics education might be performatively realised both in our classrooms and in our discourse about those classrooms.

In this paper, excellence in mathematics education is examined through consideration of conceptions of "accomplished practice." Research is reported that examines the accomplished practice of students and of teachers. In this research, the role of students' "spoken mathematics" is employed as a point of comparison between the performances valued and promoted in mathematics classrooms in different countries. Other research, also reported here, has examined the professional vocabulary available to mathematics teachers to describe their practice and the events of the classroom. One of the consequences of the international adoption of English as the lingua franca of educational research is that the international community of researchers, theoreticians and practitioners has only limited access to many sophisticated, technical, classroom-related terms in languages other than English, which might

otherwise have contributed to our understanding of classroom instruction and learning. An unnamed activity will be absent from any catalogue of desirable teacher actions and absent from the analyses of classroom researchers.

Our capacity to discuss and theorise classroom practice is critically dependent on the pedagogical vocabulary at our disposal. The extent and sophistication of this vocabulary varies greatly from language to language. If a teacher action can be named, then its occurrence can be identified and its contribution to classroom practice and learning examined. Actions considered as essential components of the teacher's repertoire in one country: for example, *kikan-shido* (Japan), *esclarece duvidas* (Portugal) or *jiang ping* (China), may be entirely absent from any catalogue of accomplished teaching practices in English.

The differences that we find in discourse about the mathematics classroom are also evident when we consider discourse in the mathematics classroom. Mathematics learning can be conceptualised in terms of participation in forms of social practice, where discourses form key components of that practice. Contemporary advocacy regarding desired forms of discursive practice in mathematics classrooms has become particularly strident. This advocacy derives from a valuing of mathematical classroom discourse as the means to effective learning, but also from a valuing of mathematical discourse as a major learning outcome in its own right. Both forms of advocacy, however, appear to be based entirely on research conducted by western researchers in western settings.

Comparative studies that include both Western and Asian classrooms have demonstrated that the instructional practices of teachers in classrooms in different cultures are predicated on pedagogies that privilege different forms of student action and these pedagogies appear, in turn, to be based on very different theories of learning. Our research into the practices of classrooms must draw on (and contribute to) theories that accommodate culture as one essential aspect of the situated nature of learning, rather than ignoring the pervasive role of culture in framing our attempts at theorizing. The need to safeguard against the unintended insularity of our theorizing suggests a key role for international research consortia that share a common research purpose but combine culturally diverse perspectives in the interpretation of research data and the consequent process of theory generation.

Judgements of what constitutes accomplished practice in mathematics classrooms can be considered in two broad categories. The simplest category presumes the existence of a consensus concerning the characteristics of good practice and the capacity to recognise performances aligned with this consensus. The second category is predicated on the warrant for the first: accomplished practice is identified with the achievement of valued outcomes. It is the contention of this paper that culture enters into the consideration of both categories: both through the culturally-situated nature of the valued outcomes by which accomplished practice is empirically identified; and, through the evolution of the practice itself, which must reflect cultural values regarding acceptable modes of classroom communication.

It is worth noting that the emphasis in this paper is on practice, not on the attributes of individuals. For example, much has been written on the knowledge needed to teach mathematics effectively. Ultimately, however, any such knowledge must be performatively realised through classroom practice. For the purposes of this paper, the entry point is discourse, and we have at least three levels of discourse to consider in classroom research: (i) the discourse of the classroom, as practiced in situ by the participants; (ii) the discourse about the classroom, as utilised by teachers and others to describe and reflect on the classroom; and (iii) the discourse of the researcher, in which particular constructs guide data generation, selection, configuring, interpretation, analysis and reporting. Each form of discourse represents the culmination of an evolving educational tradition and each form of discourse can constrain, frame, influence, and even determine the performative realisation of teaching competence in each mathematics classroom.

Adidactical situations in mathematics classrooms in Sweden and the Philippines

Jonas Emanuelsson, The University of Gothenburg, Sweden; Florenda Gallos Cronberg, University of Gothenburg, Sweden

In this study, analysing data materials from the LPS-project (Clarke, 2006), we provide analytical descriptions of competent teaching as enacted in Philippine and Swedish classrooms. The analysis draws upon Brousseau's idea of adidactical situations in mathematics classrooms (Brousseau, 1997).

In mathematics education research, many exemplary teaching practices in mathematics classrooms have been studied. However, it is often argued the perspectives of learners are not often scrutinized in the analyses and that

little has been learned from research about what teachers can do in order to support classroom discourses (Franke, Kazemi and Battey, 2007).

Results show that these competent teachers organized didactical situations in different ways, yet these ways of organizing are apparently suited to their respective class sizes and availability of resources. Also, learners' reasoning skills were evident in classrooms of both countries, although not in a huge number of cases. Some students showed skills in convincing their seatmates of the correctness of their mathematical statements using mathematical arguments and not relying on calculators or the authority of their respective teachers. Another result was that it was problematic to adopt the framework of didactical situations when considering the whole class as a unit of analysis during these situations.

The Learner's Perspective Study (LPS) is an in-depth study examining the patterns of participation in mathematics classrooms of locally nominated competent teachers in sixteen countries (Clarke, 2006). Didactical situations in mathematics occur when students are assumed to have agreed to work on the mathematical tasks on their own until they arrive at answers and where the teacher refrains from interfering (Brousseau, 1997). Competent teachers, as locally defined, from the Philippines and Sweden are expected to teach differently because of issues that might be related to language use, class size, availability of resources etc. What is meant by the phrase "competent teacher" may also differ in different local communities. Students working by themselves in mathematics classrooms without the teacher interfering is in Sweden an often occurring and much criticized way of organising teaching. This particular way to teach seems partly chosen by pedagogical reasons partly based on a rational based in time and hence cost effectiveness. In the Philippines, due to constraints related to the huge number of students in the classroom teacher exposition might sometimes be regarded as the most manageable way.

In the field of mathematics education research, many exemplary teaching practices in mathematics classrooms have been studied. However, it is often argued that in these studies the perspectives of the learners are not often scrutinized in the analyses and that little has been learned from research about what teachers can do in order to support classroom discourses, especially on learners mathematical argumentation (Franke, Kazemi and Battey, 2007). Researchers from the Philippines have already analyzed such data on private conversations among students (Gallos Cronberg, 2010; Gallos, 2006) and researchers from Sweden have made studies on mathematical conversations (Emanuelsson & Sahlstrom, 2008; Liljestrand & Runesson, 2006). These studies form one base for further analysis, this time looking into the ways students validate or provide mathematical arguments among themselves during didactical situations and into the ways the teachers handles such situations.

In this study, we aim to provide contrasting analytical descriptions of competent teaching as a situated practice that is enacted in different, but still competent ways, as defined in the respective local context. The situations chosen for comparison are didactical situations. The present study mainly uses a non-emergent qualitative research design and draws upon Brousseau's idea of didactical situations in mathematics classrooms.

Results show that these competent teachers organized didactical situations in different ways, yet these ways of organizing are apparently suited to their respective class sizes and availability of resources. Also, learners' reasoning skills were evident in classrooms of both countries, although not in a huge number of cases. Some students displayed mathematical skills in convincing their seatmates of the correctness of their mathematical statements using mathematical arguments and not only relying on calculators or the authority of their respective teachers. Another result was that it was problematic to adopt the framework of didactical situations (Brousseau, 1997) when considering the whole class as a unit of analysis during these situations. When analysing smaller groups of students working cooperatively the concept of didactical situations is more appropriate.

Discussant: Barbara Hofer, Middlebury College, United States

Learning about science topics often involves a process of conceptual change, or the restructuring of one's existing knowledge to align with the scientific perspective (Vosniadou, 2002). Complex science topics such as biological evolution, emergent systems, and climate change, will likely require the learner to undergo conceptual change as they come to learn about these dynamic systems (Chi, 2008). Such complex topics may be challenging for the learner as they grapple with understanding the scientific explanation. These topics may elicit strong emotional reactions, such as anxiety and frustration that may, in turn, influence the conceptual change process. The recent warming trend (Sinatra, 2005) in conceptual change research provides an avenue for examining the influence of hot factors, including motivation and emotions, when learning about complex problems. An international panel of researchers exploring hot constructs (i.e., interest, goal orientation, and emotions) in relation to complex problems and conceptual change will present the findings of their empirical research.

Complex Problems and Interest: A Comparison of Problem-Based, Lecture-Based, and Self-study Formats

Sofie Loyens, Erasmus University Rotterdam, Netherlands; Jeroen Mikkers, Erasmus University Rotterdam, Netherlands

These studies investigated whether working on complex, ill-structured problems is more interesting for students compared to listening to a lecture or reading a text individually (i.e., self-study). Situational interest was measured three times (i.e., pre-test, post-test immediately after the instruction, and a follow-up after one week) across two topics: evolutionary theory (Study 1) and Newtonian laws (Study 2). Participants were randomly assigned to the problem-based learning, the lecture-based or the self-study condition. Results of both studies were similar: There was a significant decrease of situational interest over time in all three conditions and no significant interaction effects between time and instructional format. The nature of the topics is put forward as a possible explanation for these results.

One of the goals of student-centered instructional formats such as Problem-Based Learning (PBL) is to make students intrinsically motivated to learn (e.g., Hmelo-Silver, 2004). To foster this goal, students in PBL work on complex, ill-structured problems before they receive any other curriculum input. Ill-structured problems are problems that can be solved in multiple ways or, in case they cannot be solved, need to be understood in terms of their underlying mechanisms. These problems are therefore especially appropriate for eliciting discussion (Otting & Zwaal, 2006). They also better represent problems encountered in daily life and are, thus, more realistic. Working on problems is therefore believed to be engaging and interesting for students.

Empirical evidence for these claims is, however, scarce. The present studies investigate whether working on ill-structured problems is more interesting for students compared to listening to a lecture or reading a text individually (i.e., self-study). More specifically, students' situational interest is examined across three instructional formats: PBL, lecture, and self-study.

Situational interest is triggered by certain stimuli in the environment and implies short-term involvement (Hidi & Renniger, 2006; Mason, Gava, & Boldrin, 2008). It refers to the present state of interest in terms of focused attention and affect (Hidi & Renniger, 2006) and can be captured by text- (e.g., a text's vividness and coherence), task- (i.e., readers' approach of the text), and knowledge-based (i.e., prior knowledge) factors (Schraw & Lehman, 2001). These

factors underline that situational interest is context-dependent. Therefore, the present studies were carried out in two different domains: evolutionary theory (Study 1) and Newtonian laws (Study 2).

Previous research within a PBL environment has shown that situational interest increased after the presentation of a complex problem (Rotgans & Schmidt, in press). However, this study could not answer the question whether complex problems are better able to increase interest in students compared to other instructional formats. Given the robust finding that interested learners are more likely to master a topic (e.g., Krapp, Hidi, & Renninger, 1992; Renninger, Ewen, & Lasher, 2002; Schraw & Lehman, 2001), it is important to investigate interest in relation to instructional formats.

It is hypothesized that complex problems can increase students' situational interest because these problems have characteristics that are believed to promote interest. Because these problems describe a realistic, puzzling situation, often related to students' future professional practice, they can be considered vivid. Problems also consist of a coherent text, addressing one issue at a time. As mentioned, vividness and coherence are important factors within situational interest (Schraw & Lehman, 2001).

Method

Participants

71 psychology students participated in Study 1 and 77 different psychology students in Study 2. All participants were randomly assigned to one of the three instructional formats.

Materials

Situational interest was measured by 10 items that had to be rated on a 5-point Likert scale, varying from 1 (not at all true for me) to 5 (totally true for me). This test was designed by Rotgans and Schmidt (in press) and is based on the four-phase model of interest (Hidi & Renninger, 2006). This test was administered three times to each participant. For Study 1, Cronbach's alpha was .77 (pre-test), .83 (post-test), and .79 (follow-up). For Study 2, Cronbach's alpha was .75 (pre-test), .86 (post-test), and .73 (follow-up), reflecting good internal consistency.

Procedure

In all three conditions, participants started with filling in the pre-test and ended with the post-test. Time on task was equal (i.e. 60 minutes). In the PBL-group, a complex problem was then presented with a discussion about evolutionary theory (Study 1) or falling objects such as jumping from a swing (Study 2). In order to activate prior knowledge, students discussed possible explanations of the problem. Unresolved issues were formulated as learning issues. Subsequently, they received a study text about evolutionary theory (Study 1) or Newtonian laws (Study 2) in which answers on the issues could be found. After studying the text, students discussed the text and answered the learning issues. The meeting was guided by a tutor, who stimulated the discussion if necessary (Schmidt, Loyens, Van Gog, & Paas, 2007).

In the lecture-based condition, students entered an auditorium where the experimenter started a lecture about evolutionary theory (Study 1) or Newtonian laws (Study 2).

Participants in the self-study group were tested in a lab-room. Then, participants studied the text about evolutionary theory (Study 1) or Newtonian laws (Study 2).

In all three conditions, students came back 7 days later to take the follow-up-test.

Results and Discussion

Table 1 depicts mean interest scores across conditions in both studies.

Table 1: Mean and standard deviations in parentheses for situational interest

Repeated measures analyses showed a significant effect for time [$F(2,65) = 36.334$, $p < .001$]. Similar results were found in Study 2: A significant effect for time was found [$F(2, 67) = 47.205$, $p < .001$]. Students' situational interest decrease over time is not surprising given its temporary nature (Schraw & Lehman, 2001) and previous research (Rotgans & Schmidt, in press). The fact that complex, ill-structured problems are not better able to promote situational interest was unexpected. A possible explanation could lie in the nature of the complex problems used. They were designed for these studies and were not part of the psychology curriculum, which might have lowered their appeal. The lower scores for the problem on Newtonian laws compared to evolutionary psychology could be an indication for this explanation. Further research is needed in this respect.

Emotions and Misconceptions about Complex Topics in Science

Suzanne H. Broughton, Utah State University, United States; Reinhard Pekrun, University of Munich, Germany;
Gale Sinatra, University of Nevada, Las Vegas, United States

Learning in science classrooms is a complex and dynamic process that involves both cognitive and affective components (Pintrich, Marx, & Boyle, 1982). Over the past several decades, social psychologists have investigated the relationship between cognitive processing and emotions at a general level (Lazarus, 1982; Rosenberg, 1998). More recently, researchers have begun to explore emotions related specifically to academic contexts (Pekrun, Goetz, Titz, & Perry, 2002).

The aim of this exploratory study was twofold: First, to investigate which emotions may be present when learning about three specific controversial topics in science: climate change, genetically modified foods, and airport body scanners. Second, to identify which misconceptions may be commonly held by individuals in relationship to these three topics. Graduate students enrolled in a research methods course from a southwestern US university participated in the study. Participants completed individual interviews and related topic emotions surveys. Emotions reported as moderate to strong were: anxiety, curiosity, interest, frustration, and confusion. Curiosity and interest increased in intensity across each topic from pre- to post-interview. A variety of misconceptions were reported across each topic. For example, misconceptions for causes of climate change included weather changes and extreme seasons. This suggests that participants may not understand differences between changes in weather patterns and deep-time climate change. The present results confirm that controversial topics in science such as climate change and GMFs may spark strong emotional reactions from learners, especially when students hold misconceptions about such topics. Emotions such as curiosity, interest, and anxiety may influence conceptual change learning.

Learning in science classrooms is a complex and dynamic process that involves both cognitive and affective components (Pintrich, Marx, & Boyle, 1982). Over the past several decades, social psychologists have investigated the relationship between cognitive processing and emotions at a general level (Isen, 2008; Lazarus, 1982; Rosenberg, 1998). More recently, researchers have begun to explore emotions related specifically to academic contexts.

For example, Pekrun and colleagues (2002; 2006) have investigated emotions students may experience while attending class, studying for class, and taking exams, defining these emotions as academic emotions. Academic emotions include positive and negative emotions such as enjoyment, anxiety, frustration and boredom. Positive emotions may increase motivation and foster creative learning strategies, while negative emotions such as boredom may exert the opposite effect, dampening motivation and promoting superficial cognitive processing (Pekrun, 2006). However, some negative emotions, including anger and anxiety, may increase motivation to avoid failure and facilitate analytical, detail-oriented styles of processing information.

Previous research on academic emotions has focused on the influence of emotions at a general level across a range of disciplines including mathematics (Frenzel, Pekrun, & Goetz, 2007) and psychology (Pekrun, Daniels, Goetz, Stupinsky, & Perry, 2010). Few empirical studies have investigated the emotions experienced by students when learning about specific topics, including controversial topics in science.

Learning science topics often involves a process of conceptual change, which occurs when the student's prior knowledge conflicts with the scientific viewpoint (Chi, 2009). In these situations, the learner must revise their prior knowledge to align with the scientific explanation. Recent models of conceptual change include an affective component. For example, the Cognitive Reconstruction of Knowledge Model (Dole & Sinatra, 1998) suggests that change is less likely to occur when the learner has a strong emotional commitment to their prior beliefs. Although these models acknowledge emotions as a factor of conceptual change, it is yet to be understood which emotions may facilitate change and which emotions may impede that process.

The aim of this exploratory study was twofold: First, to investigate which emotions may be present when learning about three specific controversial topics in science: climate change, genetically modified foods (GMFs), and airport body scanners. Second, to identify which misconceptions may be commonly held by individuals in relationship to these three topics. We selected these topics based on pilot study data.

Method

Participants Graduate students (n=10) enrolled in a research methods course from a southwestern US university received extra credit for participating. Participants ages ranged from 23 to 58 years (M=31.07, SD=10.82) and were primarily female (70%), White (70%), and in their first year of their Master's program (60%).

Procedures and Materials

Participants completed individual interviews that lasted approximately 35 minutes each. During the interviews, participants completed a topic emotions survey followed by the topic-related interview. Next, participants completed the topic emotions post-survey. The purpose of the post-survey was to investigate whether topic emotions may have changed as a result of the interview and, if so, in what direction. Participants also completed a Demographics survey.

The Emotions about Climate Change survey consisted of 12 topic emotions based on Pekrun et al.'s (2002) taxonomy of academic emotions. These emotions are listed in Table 1. Participants rated the level of each emotion experienced on a scale of 1 (not at all) to 5 (very strong). The Emotions about Genetically Modified Foods survey and the Emotions about Airport Body Scanners survey each consisted of a similar format.

The Conceptions about Climate Change interview consisted of seven open-ended questions. A sample item is, "Do you think the earth's climate is changing? Why or why not." The purpose for these questions was to explore participants' understanding of climate change and to identify any existing misconceptions.

The Conceptions about Genetically Modified Foods interview also consisted of seven open-ended questions. An example item is, "What are genetically modified foods?" Our goal was to uncover participant's existing conceptions about GMFs, including misconceptions.

The third interview survey, Conceptions about Airport Body Scanners, consisted of nine open-ended questions intended to uncover participant's conceptions related to airport body scanners. A sample item is, "What does the Transportation Safety Administration official see when examining the graphic produced by body scanners?"

Results

Emotions

A range of emotions were reported in relation to the three science topics (Table 1). Emotions that were reported as moderate to strong, by topic, were: Climate change: anxiety, curiosity, interest, frustration; GMFs: anxiety, curiosity, interest, fear, confusion; and Airport body scanners: curiosity, interest. Climate change and GMFs had the greatest variety of topic emotions as well as the highest level of intensity of those emotions. Curiosity and interest increased in intensity across each topic from pre- to post-interview.

Interview data

Content analysis was conducted on participant interviews to identify which misconceptions were present for these science topics (Table 2). Examples of misconceptions for causes of climate change included weather changes, extreme seasons, and more natural disasters. This suggests that participants may not understand differences between changes in weather patterns and deep time climate change. Misconceptions about greenhouse gases included: greenhouse gases come from plants, consist of all the pollutants in the air, and come from carbon monoxide.

Misconceptions of GMFs included cloned animals, cloned fruits and vegetables, and processed foods. Participants also stated that GMFs were those that had been given hormones to increase growth, size, and production. These responses suggest that participants held the belief that scientists are primarily responsible for GMFs but participants did not acknowledge that GMFs can also occur through natural processes.

Participant misconceptions about the graphic image produced by airport body scanners included bone structure, tissue, and not seeing inside the body.

Conclusion

Science learning is a complex process involving both cognitive and affective factors. The present results confirm that controversial topics in science such as climate change and GMFs may spark strong emotional reactions from learners, especially when students hold misconceptions about such topics. Emotions such as curiosity, interest, confusion, and anxiety may influence conceptual change learning. Future research is needed to investigate the impact of emotions on conceptual change.

To Master Or Perform? Exploring Relations Between Achievement Goals and Conceptual Change Learning

Krista Muis, McGill University, Canada; John Ranelucci, McGill University, Canada; Melissa Duffy, McGill University, Canada; Xihui Wang, McGill University, Canada; Lavanya Sampasivam, McGill University, Canada; Gina Fraco, McGill University, Canada

We examined relations between achievement goals, use of deep versus shallow processing strategies, and conceptual change. Seventy-three undergraduate students were assessed on their prior knowledge and misconceptions about Newtonian Mechanics, and then reported their achievement goals and participated in think aloud protocols while reading Newtonian physics texts. Results revealed that a mastery-approach orientation negatively predicted shallow processing strategies, positively predicted deep processing strategies, but did not predict conceptual change or recall. In contrast, a performance-approach orientation did not predict processing strategies, but negatively predicted conceptual change, whereas a performance-avoidance goal orientation negatively predicted deep processing strategies. Moreover, deep and shallow processing strategies positively predicted conceptual change and recall. Results are discussed in relation to Dole and Sinatra's (1998) Cognitive Reconstruction of Knowledge Model.

Introduction

Given the negative effects misconceptions can have on subsequent learning, researchers have called for a conceptual change approach to addressing students' misconceptions (diSessa et al., 2004). Conceptual change involves the restructuring of existing knowledge structures and the integration of new information into memory (Sinatra, 2005). Recently, researchers have noted that "conceptual change in the affective domain, particularly involving interests and motivation has had limited attention" (Treagust et al., 2008, p. 300). In particular, Pintrich et al. (1993) called for more research that investigates "hot conceptual change" by including "personal, motivational, social and historical processes" (p. 170) in relation to conceptual change research. The present study aims to advance understanding of the role of achievement goals in conceptual change.

Theoretical Frameworks

Achievement goals explain the motives for behaviours in achievement activities (Ames, 1992). Under the trichotomous framework (Elliot & Church, 1997; Pintrich, 2000), individuals adopt performance-approach, performance-avoidance, or mastery goals. Learners who adopt a mastery orientation are motivated to develop competence and master the material. In contrast, learners who adopt a performance-approach orientation strive to demonstrate their ability to others. Finally, a performance-avoidance orientation is characterized by learners who fear failure or looking incapable.

The literature has generally found support for the positive outcomes associated with mastery-approach goals (e.g., use of deep processing strategies) and negative outcomes associated with adopting performance-avoidance goals (e.g., use of shallow-processing strategies) (Elliot & McGregor, 2001; Senko & Miles, 2008). Although consistent patterns have been found with these two goal orientations, results have been mixed for performance-approach goals. They have been found to relate to negative outcomes (Elliot & McGregor, 1999) and positive outcomes (Harackiewicz, Barron, Pintrich, Elliot, & Thrash, 2002). Although a considerable number of outcomes have been examined in relation to achievement goal theory, there is a paucity of research on its relationship with conceptual change.

We adopted the Cognitive Reconstruction of Knowledge Model (CRKM; Dole & Sinatra, 1998) of conceptual change. Key to conceptual change under this model is depth of cognitive engagement (Dole & Sinatra, 1998). For change to occur, one's level of engagement must be high on the continuum, which involves "deep thinking and processing of the information and reflection on one's progression through the process" (Dole & Sinatra, 1998, p. 125). Dole and Sinatra note that researchers have largely ignored the role that engagement plays in conceptual change. Consequently, they advise that further studies explore the role of motivation and depth of processing on conceptual change to advance research in this area. Our study responds to this call.

Current Study

With the exception of Linnenbrink and Pintrich's (2002) study, little research has examined the relationship between conceptual change and achievement goal orientation. Linnenbrink and Pintrich conducted two studies to investigate conceptual change in students' comprehension of Newtonian physics. They found that mastery goals were related to conceptual change, whereas performance-approach goals were not related to conceptual change. They also investigated the mediating role of affect, self-reported depth of processing, and metacognitive strategy use to explore relations between these constructs. Results indicated that mastery-approach goals were positively related to increased depth of processing, and a decrease in negative affect, which predicted greater conceptual change. Despite these findings, theorists have identified issues with relying solely on self-report measures of learning (e.g., Winne, Jamieson-Noel, & Muis, 2002). To address this, Winne et al. (2002) suggested researchers use data about actual studying events recorded while learners study. Our study addresses this issue by exploring relations between achievement goals, depth of processing, and conceptual change learning in the context of learning about Newton's Laws of physics using refutational text and a think aloud protocol.

Method

Seventy-three undergraduate students (N = 57 females) participated in the study. The Patterns of Adaptive Learning Scale (PALS, Midgley et al., 2000) was used to measure students' goal orientations. A coding scheme was created to assess participants' think-aloud comments for evidence of deep and shallow processing. The Force Concept Inventory (Hestenes, Wells, & Swackhamer, 1992) was used to assess students' prior knowledge and misconceptions relating to Newtonian physics. Recall achievement was measured by asking participants to recall as much as they could from the text. Two science texts were used to increase amount of processing. The science texts consisted of refutational passages adapted from Kendeou and van den Broek (2007), which were initially based on a college-level physics textbook (Hewitt, 2002). Participants were tested individually in a laboratory setting.

Results

A path model was conducted. Our hypothesized model resulted in a poor fit, $\chi^2 = 112.40$, $df = 8$, $p < .001$. We removed non-significant paths, tested for mediation, and reran the model. No mediation was found. The subsequent model resulted in the best fit, $\chi^2 = 229.21$, $df = 8$, $p < .001$. Specifically, mastery goal positively predicted deep strategies (.23), shallow strategies (.15) and conceptual change (.16). In contrast, performance-approach goal did not predict the processing strategies, but negatively predicted conceptual change (-.20) and recall (-.19). Performance-avoidance goal negatively predicted deep strategies (-.11) and recall (-.28). Moreover, as predicted, deep processing strategies positively predicted conceptual change (.38) and recall (.39). Interestingly, shallow processing strategies also positively predicted conceptual change (.33) and recall (.27), but not to the same extent as deep processing strategies.

Discussion

Consistent with Dole and Sinatra's (1998) CRKM, the more that learners engaged in deep processing of the information, the more that conceptual change occurred. However, the moderately positive relationship between shallow processing and conceptual change was not predicted. Rather, the CRKM predicts that shallow processing will result in weak or no conceptual change. In contrast, the magnitude of the relationship between shallow processing and conceptual change indicated that an indiscriminate amount of conceptual change took place in relation to depth of processing. To explain this, we present one plausible reason. Specifically, it is possible that the refutational nature of the information presented in the text was very powerful, and thus reduced the importance of depth of processing. If participants were able to clearly identify the dissonance between their held conceptions and the new conceptions that were introduced, then level (shallow or deep) of processing may not have been a particularly important factor. We further elaborate our results and theoretical implications in the full paper.

SYMPOSIUM

Teaching Motivations in Different Countries: Comparisons using the FIT-Choice scale

Chairperson: Helen Watt, Monash University, Australia

Organiser: Helen Watt, Monash University, Australia

Discussant: Paul W. Richardson, Monash University, Australia

Researchers from different contexts, experiencing problems of teacher shortage, discuss findings concerning teachers' motivations and perceptions, using data yielded by the FIT-Choice scale (Factors Influencing Teaching Choice; Watt & Richardson, 2007; Figure 1). Grounded in expectancy-value theory, the scale provides an integrated, theoretically guided, psychometrically sound framework. It was developed and validated in the Australian context; this symposium offers the possibility to examine how and why teaching motivations are similar or different across settings.

Berger and D'Ascoli (Paper-1) examine VET teachers' motivations, in German and French speaking parts of Switzerland; they further derive motivational profiles to discover 5 distinct groups. Fokkens-Bruinsma and Canrinus (Paper-2) in the Netherlands, measure FIT-Choice factors among preservice teachers commencing training, and, subsequent relationships with planned effort, involvement, professional commitment and self-efficacy at completion of teacher education. Taimalu, Luik, Voltri and Kalk (Paper-3) from Estonia, explore preservice and first-year teachers' motivations and perceptions.

The scale appeared robust across samples and settings. Perhaps surprisingly, highest rated motivations were similar (perceived teaching ability, intrinsic value, social utility value); the same applied to least important motivators (fallback career, dissuasion, social influences). In contrast, perceptions about the profession were more variable, presumably due to actual differences across settings. Extensions within studies, such as motivational profiles in Paper-1, longitudinal correlates in Paper-2, shed further light on sources and consequences of teaching motivations. Paul

Richardson's expert commentary highlights commonalities and particularities in light of sociocultural variations, poses fruitful directions for further research, and implications for attracting and sustaining new teachers.

Motivational profiles of Swiss VET teachers and trainers using the FIT-Choice framework

Jean-Louis Berger, Swiss Federal Institute for Vocational Education and Training, Switzerland; Yannick D'Ascoli, Swiss Federal Institute for Vocational Education and Training, Switzerland

Teacher shortage is a problem many European countries are currently facing for multiple reasons. In Switzerland, there is a lack of attractiveness of the occupation of VET teachers or trainers and thus a problem of ageing (39% of the VET teachers are over 50 years old). Hence, an important question concerns the motivations of people who choose to become VET professionals after several years of practice in a specific occupation. The present study aims at analyzing the motivations to become VET professional using a person-centered analysis to uncover motivational profiles. The FIT-Choice framework and scales were translated and adapted to the study context. Using cluster analysis, five groups were identified based on the motivations of 605 VET teachers and trainers from both the German and French speaking parts of Switzerland. Groups were then described regarding their socio-demographic characteristics, their beliefs about the profession, and their job satisfaction. Results indicated significant differences between profiles in terms of socio-demographic characteristics, suggesting for example that part-time VET teachers tend to adopt a different motivational profile from full-time VET teachers. Additionally, adoption of a motivational profile has implication for beliefs about teaching and training in VET, as well as for job satisfaction. On the contrary, pedagogical beliefs did not differ among the profiles. The results suggest that VET teachers and trainers may adopt five specific motivational profiles and that these are associated with several variables important for their career. Implications of the results for the FIT-Choice framework and for education will be discussed.

Teacher shortage is a problem many European countries are currently facing (OECD, 2005). In Switzerland, the occupation of VET teacher or trainer (VET professionals) suffers from a lack of attractiveness and, consequently, a problem of ageing (39% of the VET teachers are over 50 years old; FSO, 2010). Hence, an important question concerns the motivations of people who choose to become VET professionals. These people decided to leave either partly or completely their former profession to become, in the same professional domain, teachers for apprentices. In fact, understanding what drives people toward teaching in VET is of utmost importance both for the quality and the management of the VET system. Little information is however available on this topic. In particular, the motivations and beliefs of these people, which have important implication for involvement and commitment to the profession (Watt & Richardson, 2007), are rarely investigated. The present study aims at analyzing the motivations to become VET professional using a person-centered analysis to uncover motivational profiles. Furthermore, between-profile differences in socio-demographic characteristics, satisfaction with the choice of a career in teaching, antecedent socialization constructs, and beliefs about the occupation are investigated.

Theoretical Framework

For our research purpose, the FIT-Choice model was adapted according to the specificities of the VET Swiss system. Items from the FIT-Choice scales were translated from the original English version to German and French and some scales were removed or added. For example, because of its inadequacy to the study context, the scale fallback career was replaced by a scale assessing how much the choice of the career was done simply because the opportunity was present (a quite frequent phenomenon in Swiss VET teachers). Moreover, two scales (from the Teaching and Learning International Survey; OECD, 2009) regarding pedagogical beliefs were included to evaluate to what extent participants held beliefs oriented toward a constructivist or a classical conception of teaching (called direct transmission).

Method

Participants were 605 in-service VET professionals (467 VET teachers and 138 VET trainers) from the German (n = 413) and French (n = 192) speaking parts of Switzerland, two linguistically but also culturally different regions. All the participants had first trained in a professional field as apprentices and practiced for several years before beginning a (second) career as VET teachers or trainers; they teach profession-specific knowledge. The sample consisted of all those who were undergoing training at the Swiss Federal Institute for Vocational Education and Training during Spring 2010 in order to get a diploma or certificate as VET professionals. The FIT-Choice scales were administered (as part of a larger survey) by research personnel during a class period. The survey was pretested on a sample of 144 VET professionals to check the relevance of the items and the quality of the translation.

Results and discussion

Confirmatory factor analyses were first conducted to assess the equivalence of the translated scales with the original ones. Scales mean scores were then computed. Considering the whole sample, intrinsic career value, perceived teaching ability, and social utility value were the dimensions rated as the most important in the choice of a career as

VET professional (akin to Watt & Richardson, 2007). Contrarily, personal utility value, dissuasion, and social influences were rated as the least significant dimensions. The sample may however be heterogeneous, and consist of several subgroups differing in their combinations of motivations. Therefore, a two-step clustering method was employed in order to determine if there were subgroups and their number. The scores on five of the motivation to teach scales (intrinsic career value, ability, social utility value, personal utility value, and opportunity) were introduced to construct motivational profiles as they are considered the fundamental expectancy and value components of the framework. A five-cluster solution was selected based on statistical arguments, interpretability of the solution, and adequate size of the clusters. Based on their mean scores, the clusters were named respectively:

C1: "Low intrinsic career value, aptitudes, & social utility" (n = 51); C2: "High intrinsic career value & low opportunity" (n = 111); C3: "Low intrinsic career value and aptitudes, high personal utility" (n = 99); C4: "Low personal utility and high opportunity" (n = 172); C5: "Multiple motivations" (n = 170).

The distribution of German vs. French speaking, and type of VET professionals differed among the clusters. The distribution by language suggests a tendency for the German speakers, overrepresented in C2, to be less opportunistic than the French speaking in their choice to become VET professionals. Furthermore, part-time teachers were underrepresented in C5, whereas full-time teachers were over-represented in this same cluster. VET trainers were over-represented in C4. Cluster membership was neither related to age, number of years working with apprentices, nor to diploma level.

The subgroups differed significantly in all beliefs about task demand and task return, but not in their pedagogical beliefs (constructivism and direct transmission). Post-hoc analyses revealed that the participants in C5 perceived teaching as both a more demanding and more rewarding activity than the participants in the other clusters. In contrast, teachers in C1 and C3 had a different perception of teaching: Less demanding but also less rewarding. Satisfaction with the choice of a career in teaching was the most varying variable between clusters with C1 as the least satisfied. Concerning the antecedent socialization constructs, differences were observed in prior teaching & learning experiences and social influences but not in dissuasion.

The cluster analysis revealed that there was not a single motivational profile in VET professionals but five groups with different motivational profiles. Our analysis revealed significant differences in the composition of clusters according to their socio-demographic characteristics and antecedent socialization constructs. Additionally, adoption of a motivational profile has implications for beliefs about teaching and training in VET, as well as for job satisfaction (hence undoubtedly for professional engagement). On the contrary, pedagogical beliefs did not differ among the profiles. Educational and theoretical implications of the results will be discussed.

Motivation to become a teacher in a Dutch university-based teacher training programme

Marjon Fokkens-Bruinsma, University of Groningen, Netherlands; Esther Canninus, University of Groningen, Netherlands

The Netherlands is facing a growing problem of teacher shortage. Dutch politics have acknowledged this as a serious problem, yet implemented actions have not succeeded in countering the shortage (Ministry of Education, Culture, and Science, 2007). According to Sinclair, Dowson, and McInerney (2006), more insight into teachers' motivation for teaching is essential to understand how prospective teachers can be attracted and retained. Sinclair et al. furthermore state it is important to attract students with the "right" motives; these students will be more engaged and committed to their training and profession.

Using the FIT-Choice theory, 187 Dutch university-based preservice teachers' motives to become a teacher were listed. It was investigated how these teachers' motivation for teaching relates to planned effort and involvement, professional commitment, and, additionally, to self-efficacy. Data were collected at the beginning and end of the training programme.

Our findings are comparable to the findings of the Watt and Richardson studies. Teaching abilities, intrinsic career values, and making a social contribution were the motives rated highest by our respondents. Multiple motives were positively related to the preservice teachers' self-efficacy and professional commitment. Fallback career was negatively related to both self-efficacy and factors of professional commitment. This study provides a Dutch perspective on the FIT-Choice factors and gives more information on how motivation to become a teacher influences preservice teachers' planned effort, professional commitment, and self-efficacy. As such it provides us with starting points on how to improve retention during training and in the profession.

The Netherlands is facing a shortage of teachers. Dutch politics have acknowledged this as a serious problem, yet implemented actions have not succeeded in countering the shortage (Ministry of Education, Culture, and Science, 2007). According to Sinclair, Dowson, and McNerney (2006), more insight into teachers' motivation for teaching is essential to understand how prospective teachers can be attracted and retained. Sinclair et al. furthermore state it is important to attract students with the "right" motives; these students will be more engaged and committed to their training and profession. In this study we investigate how Dutch preservice teachers' motivation for teaching is related to teachers' planned effort, professional commitment, and, additionally, to their self-efficacy.

Our conceptual framework starts from the perspective of the Factors Influencing Teaching Choice (FIT-Choice) model (Watt & Richardson, 2007). They developed a detailed theoretical model on the motivation to become a teacher and specified five sets of constructs that are important to the decision to become a teacher: socialization influences, perceptions of the task, perceptions of one's abilities, values, and teaching as a fallback career. Teachers' planned effort and involvement are included as outcome variables in the FIT Choice model.

The FIT-Choice framework is used to relate teachers' motivation for teaching to their professional commitment. Meyer, Allen, and Smith, (1993) distinguished three factors of professional commitment: 'affective commitment' (in terms of positive emotions towards the profession and a strong desire to remain in the profession), 'normative commitment' (in terms of the feeling of obligation to remain in this profession), and 'continuance commitment' (in terms of being aware of the costs of leaving the profession).

Furthermore, we relate the FIT-Choice factors to teachers' self-efficacy, which concerns beliefs concerning a person's capacity for bringing about the desired learning outcomes even when pupils are difficult or unmotivated (Tschannen-Moran & Woolfolk Hoy, 2001). Self-efficacy beliefs have been positively related to perceptions of relevance of teacher preparation, to enthusiasm for teaching, to commitment to teaching, to wellbeing, and, importantly, to retention in teaching (Aelterman, Engels, Van Petegem, & Verhaeghe, 2003; Rots, Aelterman, Vlerick, & Vermeulen 2007;).

Our study aims to answer the following research questions: What are Dutch university-based preservice teachers' main motives to become a teacher? How are these teachers' motives to become a teacher related to teachers' planned effort, involvement, professional commitment and self-efficacy?

Methodology

Data were collected as a part of a longitudinal project at the University of Groningen in the Netherlands. A sample of 187 university-based preservice teachers (58% female; mean age=25.2 years) completed a questionnaire in October 2009. Their motivation to become a teacher, beliefs about teaching and engagement was measured by a Dutch version of the FIT-choice questionnaire (Watt & Richardson, 2007). Preservice teachers' self-efficacy was measured by Friedman and Kass' (2002) questionnaire, and professional commitment was measured by an adaptation of Meyer et al.'s (1993) questionnaire.

Findings

Analyses indicated that the highest rated motives for the group were: teaching abilities, intrinsic career values, and making a social contribution. This result is in line with the findings of Watt & Richardson (2007; Richardson & Watt, 2006), who additionally found that the motives shaping the future of children and working with children were important. Our results also coincide with those of Bastick (2000) who also found the need to make a difference to students and society as an important theme. Other researchers have indicated these types of motives as relevant as well (Brookhart & Freeman, 1992). Choosing the teaching profession as a fallback career or based on social influences were two motives that were found to be least important for the preservice teachers. Again, this corresponds with Watt and Richardson's (2007) and Richardson and Watt's (2006) findings.

The motives work with children, make a social contribution, job transfer, intrinsic career value, enhancing social equity, and ability were positively related to teachers' self-efficacy. Fallback career was negatively related to teachers' self-efficacy. Both beliefs about teaching as an expert career and a career with a high social status and motives such as teaching abilities, intrinsic career values, and working with children were positively related to affective commitment. The more importance teachers ascribed to these motives and beliefs, the higher their desire to remain in the profession. Fallback career was negatively related to affective commitment. Whenever preservice teachers had chosen the teaching profession as a fallback career, their desire to remain in the profession was low. The relationships with continuance commitment were less clear. Social influences and fallback career were positively related to continuance commitment. In contrast to our expectations, fallback career was positively related to normative commitment as well. We found that both motivation to become a teacher, in terms of social influences, job security,

making a social contribution and beliefs about teaching in terms of salary were positively related to normative commitment.

Similar to the Watt and Richardson 2007 study, we found the motives intrinsic career values, shape future, work with children, teaching abilities and fallback career to be related to planned effort in the profession. We also found that the beliefs about teaching as an expert career were related to planned effort. In contrast to the Watt and Richardson study we found enhancing social equity and make social contribution, both social utility values, to be related to planned effort. The Watt & Richardson (2007) study also examined relationships with involvement in the profession. Similar to their study, we found positive relationships between intrinsic career value, shape future, job transfer, teaching ability, fallback career and involvement. The beliefs about teaching as an expert career and a career with a high social status were also positively related to involvement.

Theoretical and educational significance This study contributes to the theoretical development of the motivation to become a teacher. It provides a Dutch perspective on the FIT-Choice theory and gives more information on how motivation to become a teacher influences preservice teachers' planned effort, professional commitment and self-efficacy. As such it provides us with starting points on how to improve retention during teacher training and in the profession.

Teaching Motivations among Teacher Trainees and First-Year Teachers in Estonia

Merle Taimalu, Tartu University, Estonia; Piret Luik, University of Tartu, Estonia; Olivia Voltri, University of Tartu, Estonia; Karmen Kalk, University of Tartu, Estonia

In Estonia there has been, and still is, a quite critical situation in the popularity of teaching and the social status of the profession. At the same time we have shortage of young teachers. Among young people's occupational preferences teaching has been among the least preferred occupations (Krips, Taimalu, Luik, & Kukemelk, 2009). Many young graduated teachers do not remain in the teaching profession, but, choose some other job, or quit after only a few years of teaching. Therefore it is important to find how to increase the motivations to teach, among students and beginning teachers. Before that, it is necessary to investigate what motivates those people who have chosen to become a teacher. Our presentation gives an overview of teaching motivations among teacher trainees and first-year teachers. The sample consisted of 107 respondents from 2 Estonian universities. Items from the FIT-Choice Scale (Watt & Richardson, 2007) were selected (26 motivation items, 12 perceptions about the profession items), which comprised 7 motivation factors and 4 perception factors, similar to those developed by the scale authors. The highest motivations in the teacher career choice were found to be teaching ability, intrinsic career value, work with children/adolescents and shaping the future of them, enhance social equity, prior teaching and learning experiences, and job security. For the perceptions about the profession the highest means found for expertise and difficulties, and satisfaction with choice.

Teachers' motivations influence their students, and hence the processes, quality and outcomes of learning (Butler & Shibaz, 2008). Motivations for choosing to teach vary, including a desire to work with children and adolescents and the potential for the job to provide for intellectual fulfilment (OECD, 2005; Watt & Richardson, 2007), positive self-evaluation of their capabilities to be teachers (Richardson & Watt, 2006; Sinclair, 2008), salary, job security, and career status (Watt & Richardson, 2008).

Teaching is a challenging, and therefore, often stressful job. As in Australia we have the similar problem in Estonia, of negative representations of teachers' work in the mass media, political ideology, and shifts in public opinion, all impacting on the popularity and reputation of teaching as a career choice (Richardson & Watt, 2006). In Estonia, the situation has become critical over the last decade, where only few students enrol in teacher training programs, and only one-third of graduates enter into the profession (Ots et al., 2008). Many teachers are older than 55 years (Statistics, 2009). Among young people's occupational preferences, teaching has been among the least preferred (Krips, Taimalu, Luik, & Kukemelk, 2009). It is therefore important to find ways to increase the teaching motivations of students and beginning teachers. Before that, it is necessary to investigate what motivates those people who have already chosen to become a teacher.

Aims

We aim to give an overview of teaching motivations among teacher trainees, and teachers in their first year in Estonia, and contrast those results with previous findings using the FIT-Choice scale.

Sample

Our target populations were teacher trainees during the start of their teaching practice, and first-year teachers at the start of their first year, from preschool, elementary and secondary school teacher curricula. In Estonia, the first year of teaching is an "induction year", during which they need to develop a teaching portfolio, and participate in university meetings and seminars, while they are beginning teachers. The teacher trainees were sampled from Tartu University in the 2010/2011 academic year, and, the first-year teachers from Tallinn University. The total sample was 107 respondents from these 2 universities (mean age 26.7 years; 21 teacher trainees and 86 first-year teachers; 106 women and 1 man, reflecting the highly feminised profession in Estonia). The response rate was 100%.

Methodology

We used the FIT-Choice Scale (Watt & Richardson, 2007) with selected items (26 motivation items, 12 perceptions about the profession items) to investigate teachers' and teacher trainees' motivations and perceptions. We translated all items into Estonian, and discussed the comprehensibility of each within the research team. Some items were left out because of obscurity in the Estonian context. After translation a pilot study was carried out with 41 teacher trainees and first year teachers in Spring 2010. According to respondents' comments some items were reworded for better clarity, and some more items left out.

Analyses and findings concerning teaching motivations

We used exploratory factor analyses (PCA with varimax rotation) to find the structural pattern of teaching motivation according to our sample. We identified 7 motivation factors, similar to the scale authors (Watt & Richardson, 2007):

1. Ability and intrinsic career value combined ($\alpha=.80$; these were 2 separate factors in the FIT-Choice Scale);
2. Work with children/adolescents, shaping the future of children/adolescents, and enhance social equity combined ($\alpha=.82$; these were 3 separate factors contributing to a higher-order factor in the FIT-Choice Scale);
3. Time for family and income ($\alpha=.78$; these were 2 separate factors in the FIT-Choice Scale);
4. Prior teaching and learning experiences ($\alpha=.79$);
5. Social influences ($\alpha=.74$);
6. Job security (single item);
7. Fallback career (single item).

For the perceptions about the profession, we found 4 factors similar to the scale authors:

1. 1. Expertise and difficulty combined ($\alpha=.55$; these were 2 separate factors contributing to a higher-order factor in the FIT-Choice Scale);
2. 2. Social status and salary combined ($\alpha=.64$);
3. 3. Workload and high morale ($\alpha=.19$)
4. 4. Satisfaction with choice ($\alpha=.94$)

Scale means were computed for averaged composites. The highest motivations for choosing teaching as a career were teaching ability, intrinsic career value, work with children/adolescents and shaping the future of them, enhance social equity, and prior teaching and learning experiences; similar to previous studies elsewhere (Watt & Richardson, 2007). In contrast to prior studies, job security was also rated high. The lowest motivators were fallback career and social influences, similar to previous findings. The highest means for perceptions about the profession were for expertise and difficulties; lowest assessments were for the social status of the profession and salary. Yet, satisfaction with choice was high; a pattern also noted previously (Richardson & Watt, 2006).

The most important motivators seem to be universal across several different cultures. Social influences (e.g., family's and friends' opinion) did not substantially impact on young people's career choice; these beginning teachers made their decisions on the basis of other motivators. It seems somewhat surprising that although participants rated the demanding nature and difficulties of the teacher profession high, they remained satisfied with their career choice. The lowest values of social status and salary are expected results in the Estonian context, where teachers do not feel themselves valued by society, and where the teaching profession offers sustained, but quite low income.

Limitations

The study offers important first indications of Estonian beginning teachers' motivations and perceptions about the profession, using an established scale which allows opportunities to interpret findings in relation to other settings. Our continuing study will add cohorts to increase the sample size, follow cohorts longitudinally through their early years teaching, and, administer the full scale rather than selected items which do not allow the possibility to make exact comparisons with findings elsewhere.

SYMPOSIUM

Mathematics education in pre-school years

Chairperson: Franziska Vogt, Pädagogische Hochschule des Kantons St. Gallen, Switzerland

Organiser: Franziska Vogt, Pädagogische Hochschule des Kantons St. Gallen, Switzerland

Discussant: Elisabeth Moser Opitz, Institut of Educational Research, Switzerland

In early childhood education, children develop fundamental mathematical understanding. This development depends not only on characteristics of the individual child but also on the stimulation of the learning environment at home and in pre-school. The symposium aims at bringing together empirical papers researching mathematics education for children aged 3 to 7 years in order to determine how mathematics can best be fostered. The Finnish contribution examines motivational characteristics of the child and the impact of parents' engagement in teaching their child mathematics. Children with lower mathematical skills and with higher task avoidance are being taught more intensely by their parents, this, however, does not support their motivation. The German contribution is based on extended video-based observational data on children in open play settings. The selected research results show on the one hand which semiotic resources children use to express their mathematical ideas and on the other hand, how early childhood educators could foster mathematical understanding without using an instructional training program but in enhancing the play activities on offer. The Swiss contribution is based on an intervention study comparing the effects on mathematical skills for five years old children in kindergarten of a training program and a play-based approach. The results show a significant effect on the mathematical competency for the play-based approach but not for the training program. The three research papers conceptualize core elements of mathematics education in pre-school: interaction, play and motivation.

Children's mathematical skills, task-avoidant behaviour, and parents' involvement in kindergarten

Riikka Hirvonen, University of Jyväskylä, Finland; Kaisa Aunola, University of Jyväskylä, Finland; Jari-Erik Nurmi, University of Jyväskylä, Finland

Besides cognitive factors, children's learning at school can be influenced by more dynamic phenomena, such as motivation and achievement-related task-avoidant behaviour. The present study examined the developmental dynamics of task-avoidant behaviour and mathematical skills from kindergarten to Grade 2, and the role of parents' education and parents' teaching of mathematics in this relationship. A total of 217 children were tested for their mathematical skills in kindergarten, Grade 1, and Grade 2. Children's task-avoidant behaviour in learning situations was rated by their teachers. Parents' educational level and their teaching of mathematics were assessed in kindergarten and Grade 1. The results showed that children's task-avoidant behaviour predicted lower skills in mathematics, and on the other hand, low skills in mathematics predicted task-avoidant behaviour. Parents' educational level was positively related to their children's performance in mathematics, whereas parents' teaching of mathematics was related to children's lower skill level.

Background

The importance of motivation and related classroom behaviour in the development of academic skills is well recognized (Wigfield & Cambria, 2010). Students' achievement-related behaviours have been found to contribute to the development of their mathematical skills (e.g., Aunola, Nurmi, Lerkkanen, & Rasku-Puttonen, 2003; Kikas, Peets, Palu, & Afanasjev, 2009). Less research has been carried out on the extent to which previous math learning experiences contribute to subsequent achievement-related behaviours (e.g., Aunola et al., 2003). However, it is reasonable to assume that the relationship between academic skills and achievement-related behaviours is reciprocal. The key idea behind this assumption is that a positive self-concept and beliefs of self-efficacy, originating from previous learning experiences (Wigfield & Eccles, 2000), promote students' expectations of success concerning a particular learning task. These expectations further lead to better motivation, increased effort, and task-relevant behaviour in new learning situations. High effort and task-focused behaviour then provide a basis for successful learning. By contrast, negative self-concepts of ability and low efficacy beliefs, originating from repeated failures in previous learning situations, increase the likelihood of failure expectations. This then leads to low motivation, low effort, and task-avoidant or task-irrelevant behaviour in later learning situations.

Parents' teaching of mathematics to their children is assumed to have an impact on children's mathematical skills (Blevins-Knabe & Musun-Miller, 1996; LeFevre, Clarke, & Stringer, 2002). There is also research showing that behavioural interactions of parents and children while they are working together on tasks are related to children's achievement motivation and behaviours (Hokoda & Fincham, 1995; Salonen, Lepola, & Vauras, 2007). Supportive home environment and parents' involvement can benefit the children both in the form of improved skills, and in the form of improved motivation and achievement behaviours.

Aims

The aims of this study were to examine (1) how children's task-avoidant behaviour and mathematical skills develop reciprocally and simultaneously, and (2) to examine how parents' level of education and their teaching of mathematics to their children relate to the development of skills and task-avoidant behaviours of their children.

Methods

A total of 217 children (105 girls and 112 boys) were tested for their mathematical skills in kindergarten and Grades 1 and 2. Children's task-avoidant behaviour in learning situations was rated by their teachers. Parents' educational level was assessed in the middle of the kindergarten year. Parents also reported how frequently they had taught mathematics to their children during kindergarten and Grade 1. Structural equation modelling was used to examine the relationships between these variables. Separate models were constructed for mothers and fathers, and multi-sample procedures were used to examine differences between girls and boys.

Findings

The results showed, first, that there was a reciprocal relationship between mathematical skills and task-avoidant behaviour from kindergarten till Grade 2. On one hand, task-avoidant behaviour was related to lower skills in mathematics in the subsequent time point, and on the other hand, low skills were related to more task-avoidant behaviour in the subsequent time point. Secondly, mothers' high level of education was predictive of children's good performance in mathematics. Mothers' teaching of mathematics in kindergarten enhanced their children's skills in kindergarten, but in Grade 1 mothers' teaching no longer had benefits for the development of children's skills. Fathers' high level of education also predicted children's good performance in mathematics, whereas fathers' teaching of mathematics in kindergarten and Grade 1 was related to their children's lower skills. Both mothers and fathers adjusted their teaching according to the children's skill level: The lower the child's skills in kindergarten were, the more the parents taught their child during Grade 1. Fathers also reacted to the avoidant behaviour of their sons: The more task avoidance boys showed in kindergarten, the more their fathers taught them in Grade 1.

Theoretical and educational significance

The findings of this study support the assumption of a cumulative cycle in the development of mathematical skills and task-avoidant behaviour: Task-avoidant behaviour is a risk of difficulties in mathematics, which can further lead to more task avoidance. Attention should be paid to how children interpret their performance in learning situations, because negative learning experiences are likely to lead to low efficacy beliefs and failure expectations, which further results in more task-avoidant behaviour and low effort. Parents' role in promoting children's learning of mathematical skills and their achievement motivation seems somewhat controversial. Parents evidently try to help when their children are facing difficulties in learning, but this help does not directly show in the children's performance. Instead of direct teaching of mathematical skills, children might benefit more from their parents' support of interest and motivation in learning of mathematics. Parents' personal attitudes and interest can help the children in developing and maintaining their motivation towards mathematics despite the difficulties they may face.

Early mathematical cognitive development in situations of play and exploration

Rose Vogel, Goethe-University Frankfurt / Main, Germany; Birgit Brandt, Goethe Universität Frankfurt, Germany; Gotz Krummheuer, Institut für Didaktik der Mathematik und der Infor, Germany; Melanie Huth, Goethe-University Frankfurt/Main, Germany; Anna-Marietha Hummer, Goethe-Universität Frankfurt a.M., Germany; Ergi Acar, Goethe-University Frankfurt/Main, Germany

Introduction

In the first three years the long-term study erStMaL (early Steps in Mathematics Learning) focused its research interests on children between the ages 3;6 and their entry into primary school. The overarching goal is to develop a theory of mathematics education concerning children's development of mathematical thinking between the ages four and ten. Particular attention is paid to the developmental stepping-stones of children acquiring mathematical knowledge in German as their second language. With regard to the international discussion in mathematics education an interdisciplinary theoretical framework is chosen. This framework integrates psychological theories of cognitive development, social-constructivist, cultural-psychological, linguistic and semiotic theoretical approaches. From a mathematical perspective an isolated description of separated mathematical domains, such as arithmetic or spatial thinking, is insufficient. Hence for a more extensive description the following mathematical domains were chosen for the erStMaL study: Numbers and Operations, Geometry, Measurement, Pattern and Structure, Data Analysis and Combinatorics (Ginsburg et al. 2004).

Aims

Within the symposium the following aims are central:

What are the multimodal contexts (relationships between spoken language, gesture, actions with material and inscriptions), which appear in mathematical discourses with children?

In kindergarten which concepts of folk pedagogy (Olson & Bruner 1996) become apparent in mathematical situations of play designed by kindergarten teachers?

Methodology

The qualitative study is carried out in 12 day-care centres within urban areas and surrounding. Chosen with respect to socio-economic factors the participating day-care centres show a great variety concerning this matter. Until now 178 children have participated in the study; thereof 120 children are observed at every data collection points within the longitudinal design. 55% of the children learn German as their second language when they enter kindergarten or even earlier. Data collection takes place twice a year and is carried out in the familiar environment of the day-care centres. The settings' central points are the mathematical situations of play and exploration, which especially were developed for data collection in the erStMaL study. Specially trained members of the project's staff carry out these situations. Thriftily placed stimuli in spoken language and through gestures follow the aim to encourage the participating children to act and argue mathematically in the chosen mathematical domain.

Furthermore the kindergarten teachers of the participating day-care centres get the order to design a mathematical situation of play and exploration, which might be interesting for the children.

On the one hand the video data emerging from these situations is analysed with videographic methods (Vogel & Reimann appears 2011) and with interaction and participation analysis on the other hand (Krummheuer 2007).

Results

According to the view, that gesture and speech form a single integrated system (cf. Goldin-Meadow 2003) the previous results show a bridging function of gesture concerning the development of a mathematical terminology as well as concerning the accessibility to the ideas of one's conversational partners (Vogel & Huth 2010). In the same way differences in the modes of expression indicate a possible perspective expansion or rather initiating "conceptual changes" (Huth 2010).

Regarding the situations designed by the kindergarten teachers with their own play and learning material the analysis on the one hand shows the width of the concepts of folk pedagogy in these mathematical situations. On the other hand a professional focus on mathematical aspects within the situations shows the praxis of doing mathematics that is integrated into the praxis of teaching and learning mathematics (Brandt & Tiedemann appears 2011).

Theoretical and educational significance

The previous results form a good basis for the development of a multi-perspective theory of mathematics education concerning early mathematical thinking. The theory exceeds the restriction to one special mathematical domain (arithmetic) and takes the implications of linguistic and cultural diversity as well as multimodal ways of expression into consideration. At the same time the potential of the mathematical situations of play and exploration as an instrument to collect data becomes clear.

Empirically grounded the professional aspects of concepts of folk pedagogy in institutionalised adult-child-interactions (kindergarten and pre-school age) provide a basis for the development of a training and advanced training concept. Such a concept sensitises kindergarten teachers to the relationships between action with material in co-constructivist interaction processes and the associated possibility of professional learning processes.

This research was funded by the Hessian initiative for the development of scientific.

Games fostering mathematics in kindergarten

Bernhard Hauser, Pädagogische Hochschule SG, Switzerland; Karin Rechsteiner, Pädagogische Hochschule St. Gallen, Switzerland; Rita Stebler, University of Zurich, Switzerland; Franziska Vogt, Pädagogische Hochschule des Kantons St. Gallen, Switzerland

In this intervention study, two approaches to fostering early mathematics are implemented in 35 Swiss Kindergarten: a training program (Krajewski et al 2007) and a newly developed play-based approach are compared with the learning outcomes of a control group. The training program and the play-based early mathematics cover identical learning goals on counting, quantities and numbers and require 24 units of half an hour over 8 weeks. 12 teachers implemented the training program with their class, 11 teachers the play-based early mathematics. Pre- and Post-tests (Moser & Berweger 2009) measuring the numeracy skills of the six years old children show a significant learning gain for the play-based approach compared with the control group, but no significance in the learning outcome of the training program. 47 videographed sequences of children playing the specifically selected and developed games reveal the ways in which a play-based approach can foster mathematical learning. Interviews with the teachers explore the potential and challenges of fostering mathematics in kindergarten – in a context of a controversy over the role of instructional learning in early childhood education.

Introduction

Precursory skills in mathematics are of great importance for future competence (Moser & Bayer 2010). Within early childhood education, foundations for numeracy skills are laid with children exploring quantities, counting and numbers. In order to enhance opportunities for all children, early childhood education needs to foster the acquisition of such precursory skills. Currently, the competence gap at entry into state education of four or five years old children in relation to their home learning environment is not tackled by educators. More effort is needed to enhance mathematics education in early childhood to ensure basic numerical skills for acquiring a quantity-number concept and for grasping number relationships for all children.

For young children, learning through play is essential (Golinkoff 2010; Hauser, 2005). Traditionally, the pedagogy of kindergarten centered on play. However, more recently, several highly structured training programs relying on teacher-directed instruction of the whole group have been implemented in many Swiss kindergartens. The training

program Mengen zählen Zahlen [Quantities, counting and numbers] had significant effects in a study in German kindergartens (Krajewski et al. 2008). Play-based approaches however, have not been yet systematically developed.

Aims

This research project aims at developing a play-based approach to foster mathematics in kindergarten and to compare the effectiveness on mathematical learning outcomes of the play-based approach with a training programme and with a control group.

Methodology

For this project, a play-based approach to early mathematics has been developed. Krajewski's model of mathematical competency development provides the theoretical background of the play-based approach. The play-based approach therefore addresses the same learning goals on counting, quantities and numbers as the training program. Duration has also been controlled: as the training programme has been laid out for 24 units of half an hour over 8 weeks, the play-based approach was set for the same time-frame. After a piloting phase of two months in three kindergartens, a set of twelve games (existing and newly developed) were included in the play-based approach.

For each of the intervention group and for the control group, 12 kindergarten teachers were randomly recruited to take part. Pre-tests included a numeracy test (Moser & Berweger 2007), a cognitive ability test (Moser & Berweger 2004) and a parent's questionnaire on the home learning environment.

Following pre-tests, teachers of the two intervention groups received two days of in-service training. They implemented the training program and the play-based early mathematics in their class. During implementation, two half day teachers' meetings ensured high quality of implementation. Both intervention groups were visited and equally accompanied and a session in each class was video graphed.

After the intervention, teachers were interviewed by an independent researcher and gave their feedback in a questionnaire. Children were tested again using the same numeracy test.

Results

The analysis is based on 324 children in 35 classes. The three groups do not differ with regards to cognitive abilities (ANOVA: $F = 0.652$, $df = 2$, $p = 0.522$) nor with regards to their pre-test numeracy skills (ANOVA: $F = 1.988$, $df = 2$, $p = 0.139$). Learning outcomes of the three groups differ: The two factor analysis of variance with repeated measure indicates a significant interaction effect (time * group: $F = 4.04$, $df = 2$, $p = 0.019$, $\eta^2 = 0.025$ partial η^2). Results from the Scheffé-Test reveal a significant effect between the play-based group and the control group (Delta Mean = -3.33; SD = 1.18, $p = 0.01$) but no significant differences between training and control (Delta Mean = -1.03; SD = 1.11, $p = 0.326$) nor between play-based and training (Delta Mean = -2.03; SD = 1.21, $p = 0.084$). It can be concluded, that the play-based early mathematics is effective in fostering mathematical skills, whereas the training program did not show the expected results.

More detailed analysis on subtests as well as an analysis examining the effects of the interventions for children with high and with low levels of skills at pretest will be presented. Also, the analysis of the qualitative data (video study and interview) will provide an understanding of these effects.

Theoretical and educational significance

Based on the results of this research project, it can be concluded, that a play-based approach, carefully tuned to mathematical development, implemented in a limited choice setting is at least as successful in terms of learning outcome as a training program in whole-group teaching and more effective than the traditional fostering of precursory skills in kindergarten. The play-based approach might also be more compatible with the pedagogy of kindergarten and possibly meets the interests of children better than a teacher directed whole class program. The findings of this research contribute to the debate on the role of play for early childhood education. Teaching in the classroom can benefit from a deeper understanding of the potential of play for early mathematics. In addition, the results are also relevant for policy development.

This research is funded by the Swiss National Science Foundation.

SYMPOSIUM

Brain mechanisms of arithmetic strategies: Implications for education?

Chairperson: Roland H. Grabner, Swiss Federal Institute of Technology (ETH) Zurich, Switzerland

Organiser: Roland H. Grabner, Swiss Federal Institute of Technology (ETH) Zurich, Switzerland

Discussant: Kerry Lee, National Institute of Education, Singapore

Arithmetic strategies have been a major focus of research on mathematics education. There is a vast amount of evidence from behavioral studies that children and adults apply various strategies to solve arithmetic problems and that the successful acquisition of arithmetic skills is typically accompanied by cognitive changes towards more effective and efficient problem-solving strategies. Building upon these findings, cognitive neuroscience studies have recently begun to investigate the brain correlates of these strategies. In this symposium, three studies are presented which not only show how the use of different strategies is reflected in brain activity but which also illustrate ways of how the application of neuroimaging and neurophysiological methods can yield incremental insights to educational theory and practice. An electroencephalography (EEG) study on procedural and retrieval strategies in simple arithmetic provided first neurophysiological evidence for the validity of verbal strategy self-reports which have been controversially discussed in the educational literature. Using functional magnetic resonance imaging (fMRI), a relationship between brain activity and strategy choice in multi-digit arithmetic was found which may shed light on why students persist in using sub-optimal strategies despite being taught more efficient ones. Finally, fMRI data is presented showing that verbal and visual cognitive styles do not influence the engagement of brain areas specialized for number processing, which may explain previous findings of a low correlation between cognitive style and arithmetic performance. The discussion of the symposium will focus on the potential and limitations of applying cognitive neuroscientific methods in educational research on arithmetic strategies.

EEG correlates of arithmetic strategies: Comparing self-reports with the problem size approach

Roland H. Grabner, Swiss Federal Institute of Technology (ETH) Zurich, Switzerland; Bert De Smedt, University of Leuven, Belgium

Research on mathematics education has shown that arithmetic problems (e.g., $6 + 2 =$) are solved with various strategies such as fact retrieval (retrieving the correct solution from memory) or procedural strategies which involve counting or transformation. The applied strategies can be either inferred from the size of the presented problems or from trial-by-trial verbal strategy self-reports. The validity of these self-reports, however, has been repeatedly questioned. The aim of the present electroencephalography (EEG) study was to gain further insights into the brain correlates of arithmetic strategies by applying both research approaches (problem size manipulation and trial-by-trial verbal strategy self-reports) and to evaluate whether the neurophysiological result patterns from both research approaches converge. Twenty adults solved small and large addition and subtraction problems and they indicated the applied strategy after solving each problem. Analysis of event-related (de-) synchronization (ERS/ERD) in theta and alpha frequencies revealed a high convergence of both the problem size approach and the strategy self-reports. Fact retrieval was accompanied by higher left-hemispheric theta ERS, whereas procedural strategies were reflected in stronger widespread ERD in the lower alpha band. These findings provide neurophysiological evidence for the validity of verbal strategy reports and pave the way for the development of neurophysiological indices of problem-solving strategies in arithmetic.

There has been a long tradition of research on mathematics education showing that children and adults use different strategies to solve arithmetic problems. Neuroimaging and neurophysiological studies have recently begun to investigate the brain correlates of these strategies by manipulating the size of the presented problems.

This research approach is based on the assumption that small problems are mainly solved by fact retrieval from memory, whereas in large problems calculation procedures such as transformation or counting are typically more frequently used. In contrast to the problem size manipulation, many behavioral studies rely on verbal strategy self-reports to infer the applied arithmetic strategies, that is, participants have to indicate on a trial-by-trial basis how they solved each problem. These studies have revealed that individuals use different strategies in problems of a given size and that the strategies may vary from trial to trial. Even though this introspective research approach appears to be a more direct way to assess individuals' strategy use, its validity has been repeatedly questioned. In addition, there exists no neuroimaging or neurophysiological study that has used this approach to infer the brain correlates of arithmetic strategies. The aim of the present electroencephalography (EEG) study is to gain further insights into the brain correlates of arithmetic strategies by applying both research approaches (trial-by-trial verbal strategy reports and problem size manipulation) and to evaluate whether the neurophysiological result patterns from both methods converge. Twenty adult students were presented with addition and subtraction problems that have a high probability of retrieval (small problems) or procedural (large problems) strategy use. Retrieval problems were small problems with sums or minuends ≤ 10 , which showed high frequencies of retrieval use in adults. Procedural problems had sums or minuends between 11 and 35 and required carrying/borrowing. After solving each problem, participants were required to indicate whether they solved the problem by using fact retrieval, the application of a procedure or any other strategy.

The data were analyzed following the problem size approach and strategy approach. Specifically, we compared the behavioral and EEG data of small vs. large problems and of problems solved with retrieval vs. procedural strategies. In the EEG analysis, we focused on event-related (de-)synchronization (ERS/ERD), as this measure not only reflects the dynamics of functional network formation during cognitive processing but has also turned out to be sensitive to arithmetic problem solving. The behavioural data showed a high percentage of retrieval strategy use in small problems (about 90 %) and of procedural strategy use in large problems (about 75 %). As expected, small and retrieval strategy problems were solved significantly faster and more accurately than large and procedural strategy problems. Analysis of ERS/ERD patterns in the theta (3-6 Hz) and two alpha frequency bands (lower alpha: 8-10 Hz; upper alpha: 10-13 Hz) revealed a high convergence of both research approaches. Irrespective of the method, fact retrieval was accompanied by higher left-hemispheric theta ERS, whereas the application of procedural strategies was reflected in higher widespread ERD in the lower alpha band. In the upper alpha band, however, only the distinction based on the verbal strategy reports yielded differential activation patterns. Reported procedural (compared to retrieval) strategies elicited a higher ERD in the parietooccipital cortex bilaterally.

The theoretical and educational significance of the present findings are twofold. First, this study has revealed that fact retrieval and procedural strategies in mental arithmetic are accompanied by distinct neurophysiological patterns in the theta and alpha frequency bands. This finding does not only provide further insights into the brain correlates of arithmetic strategies but may also represent a potential starting point for the development of EEG indices of different problem solving strategies. These indices could, in future, be used in developmental and learning studies. Second, the high convergence of the EEG result patterns from the verbal strategy report and problem size approach suggests that both methods are appropriate instruments to capture arithmetic strategies. In particular, the present study provides the first neurophysiological evidence for the validity of verbal strategy reports which have been controversially discussed in the behavioural literature.

The finding that only strategy report data but not problem size manipulation was reflected in upper alpha ERD even suggests that the introspective approach is more powerful in detecting differences between arithmetic strategies at the neural level. In sum, the present study illustrates how neuroscientific investigations of arithmetic strategies can add to a more detailed understanding of how mathematical thinking and learning takes place.

Imaging reordered calculation strategies

Miriam Rosenberg-Lee, Stanford University School of Medicine, United States; Marsha Lovett, Carnegie Mellon University, United States; John Anderson, Carnegie Mellon University, United States

Most imaging studies of strategy variation have contrasted strategies which would be expected to have different neural substrates, such as calculation and retrieval. However, strategies that involve reordering calculation steps (and hence the same brain regions) may be of particular interest to educators: more efficient strategy use can signal

conceptual understanding. Here, we examined cortical activation as a function of two different calculation strategies for mentally solving multi-digit multiplication problems. The School strategy, equivalent to long multiplication, involves working from right to left. The Expert strategy, used by "lightning" mental calculators, proceeds from left to right. The two strategies require essentially the same calculations, but differ in that the School strategy incurs greater demands on working memory. Participants were slower and less accurate when using the School strategy, and had significantly greater activity in areas involved in attentional aspects of number processing (dorsal superior parietal lobule, SPL) and mental representation (ventral SPL), but not in a numerical magnitude area (intraparietal sulcus) or a semantic memory retrieval area (inferior frontal gyrus). A computational model of the task successfully predicted BOLD responses in parietal and frontal areas. In a follow-up session (outside the scanner), participants were allowed to select between the strategies. Surprisingly, participants did not exclusively use the less taxing Expert strategy; instead they favoured the strategy that had produced the least activity in the SPL, suggesting that students may persist in using less "optimal" strategies because they require less mental effort.

Extensive behavioural research into mathematical cognition suggests that children and adult use a wide variety of strategies when solving arithmetic problems. A growing awareness of strategy variation has led to imaging studies that examine the neural activation difference between calculation and retrieval strategies. While these strategies likely engage different brain areas, another class of strategy variation – reordering calculation steps – would not be expected to activate different brain regions. This form of strategy variation may be of particular interest to educators because it can signal conceptual understanding. This presentation focuses on the neural underpinnings of these so-called reordered calculation strategies, featuring two experiments where participants mentally solved multi-digit multiplication problems, such as 53746×8 . Using functional magnetic resonance imaging (fMRI) we established that these strategies differentially activate the same brain areas, and found that neural activity predicted participants' strategy choices. We also used cognitive modelling to disentangle the effects of strategy in brain areas relevant to numerical and mathematical cognition. We studied two multiplication strategies that differed in the order in which individual multiplication steps were performed. The "School" strategy, equivalent to long multiplication without pen and paper, involved working from right-to-left. The "Expert" strategy, used by some "lightning" mental calculators, proceeds from left-to-right, so that the largest place digit(s) of the product is calculated first. The two strategies require essentially the same set of calculations but in different orders. Responses were output largest digit first (as if spoken or entered into a calculator). As a consequence in the School strategy all calculations had to be completed before outputting could begin, producing a rapid sequence of key presses at the end of the trial. In contrast, in the Expert strategy, digits could be output as they were calculated, producing intermittent key presses throughout the trial. Thus, each strategy has a "behavioural signature" that was used to deduce which strategy participants were using.

The two strategies involve performing equivalent cognitive processes (retrieving multiplication facts, transforming internal representations, outputting responses), thus engaging the same brain areas. However, another important consequence of the "largest digit first" output constraint is that the working memory demands differ between the strategies. In the Expert strategy, participants output their responses as they go, reducing the amount of information they have to keep in mind; in the School strategy, they must retain all the calculated digits until the end of the trial, increasing the working memory demand. Thus, the two strategies should differentially engage brain areas that are sensitive to working memory load. In the first study, 15 participants solved 3- and 5-digit by 1-digit multiplication problems, while brain activity was measured using fMRI. Behaviourally, the Expert strategy produced faster and more accurate performance, particularly for the 5-digit problems. Participants' compliance in using the instructed strategy was confirmed by their pattern of key presses. We investigated two parietal regions implicated in numerical cognition: a dorsal superior parietal lobule (SPL) region and the intraparietal sulcus (IPS). We also considered two regions implicated in complex problem solving: a ventral SPL region and the inferior frontal gyrus (IFG). While all these areas were robustly activated in the task, only the dorsal and ventral SPL regions had greater activity for the School strategy.

A computational model revealed that activity in the IFG was consistent with the retrieval demands of the task, whereas activity in the ventral SPL matched the maintenance and transformation demands of the task. Interestingly, activity in the IPS and the dorsal SPL was consistent with a combination of visual and transformation processing. Thus, reorder strategy variation helped elucidate the function of brain regions involved in mathematical cognition. The second study was a behavioural follow up session using the choice/no-choice paradigm to investigate the relationship between performance, neural activity and strategy choice. Thirteen participants from the first experiment returned to repeat the in-scanner task of solving problems using an instructed strategy and then were allowed to use either strategy to solve the problems. Participants' self-reports of strategy use were confirmed using the pattern of key presses, and their performance inside and outside the scanner did not differ. When participants were allowed to pick a strategy, we predicted that most subjects should prefer the Expert strategy, as it requires less information to be maintained in memory and was faster on larger problems. Consistent with this prediction, about half of the

participants chose the Expert strategy exclusively. For these participants, activity in the SPL (measured during the study above) was lower for the Expert strategy than for the School strategy, suggesting their choice minimized mental effort. For the participants who chose both the School and Expert strategy, there was greater SPL activity for the Expert strategy, even for those 5-digit problems that were solved more quickly by this method. Thus participants chose strategies that produced the least neural activity, even when these strategies were slower.

This result sheds light on why students sometimes persist in using well-learned, but mediocre strategies over more efficient ones. Students may choose strategies based on their mental effort rather than objective measures, suggesting a link between solvers' subjective experience of difficulty and choice behaviour that would not be apparent without neuroimaging.

Different cognitive styles - different brains? The impact of cognitive style on arithmetic

Anja Ischebeck, University of Graz, Austria

Some people report that they mentally imagine an arithmetic problem visually whereas others report to repeat problems or parts of it verbally in their mind. Especially in education, a considerable amount of research has been devoted to the possible impact of an individual's cognitive style on arithmetic. However, although individuals consistently report habitual differences in cognition such as verbal or visual cognitive style, clear evidence of an impact on performance was comparatively scarce. At present, functional imaging offers yet another window to shed light on the elusive relationship between performance and individual differences such as different cognitive styles. In two fMRI studies we investigated whether differences in cognitive style (verbalizer, visualizer) influenced brain activation during arithmetic problem solving. Simple multiplication and subtraction problems were presented to forty-two participants reporting very different degrees of verbalizing or visualizing during calculation. We observed that the verbal cognitive style modulated brain activation in brain areas related to language and auditory processing, such as the supramarginal gyrus, the rolandic operculum, and Heschl's gyrus. No modulation was observed, however, in brain areas involved specifically in number processing, such as the intraparietal sulcus, bilaterally, or the left angular gyrus. These results suggest that the brain areas subserving number processing work independently from stimulus modality. Furthermore, the limited impact of cognitive style to more general aspects of sensory processing might explain the low correlation between cognitive style and behavioral performance in arithmetic.

Cognitive styles have a long history of research in mathematics education, based on the assumption that a better understanding of cognitive preferences can help develop training programs that are optimal on an individual basis. Evidence relating different cognitive styles to clear performance differences in arithmetic, however, is comparatively scarce. In the present study we investigated whether different cognitive styles (verbalizer / visualizer) modulated activation in brain areas involved in number processing. The intraparietal sulcus (IPS) is assumed to host an amodal representation of quantity, which has been referred to as the 'mental number line'. Another brain area important for arithmetic problem solving is the left angular gyrus (AG), which is assumed to support arithmetic fact retrieval, such as the multiplications tables. To assess an individual's verbal or visual cognitive style in arithmetic problem solving, a short questionnaire, the cognitive style in arithmetic questionnaire (CSAQ), was developed and tested in a preliminary investigation with 100 participants. In two fMRI experiments with forty-two participants in total, the impact of cognitive style score on brain activation patterns was evaluated. The first fMRI session investigated a possible impact of cognitive style on different operations, that is, multiplication and subtraction. 15 simple subtraction problems (e.g. $21 - 7$) and 15 multiplication problems (e.g. 3×4) were presented four times each in an event-related design. The second fMRI session investigated a possible impact of cognitive style on different number formats, that is, Arabic digits and number words. The same 15 single-digit multiplication problems were used. In total, 30 multiplication problems ($15 + 15$, order of operands reversed) were presented as Arabic digits (e.g., 3×4) or with number words (e.g. three times four) in an event-related design. In both sessions, the participant's task within the scanner was to select the correct calculation result out of two alternatives.

To investigate a possible relation between cognitive style and intelligence, participants were also asked to complete nine subtests of the intelligence test I-S-T 2000 R to assess verbal, numerical and figural-spatial intelligence. There was also no correlation between cognitive style and verbal, numerical or figural-spatial intelligence. For the fMRI measurement, a 3 T Siemens Tim Trio scanner was used with a Siemens-issued 32-channel bird-cage headcoil. For both fMRI sessions, the impact of cognitive style on brain activation was assessed. The ROIs to investigate the impact of cognitive style on number processing were the left and right AG and the left and right IPS. The ROIs to investigate the impact of cognitive style on verbal and visual processing were the left fusiform gyrus, the supramarginal gyrus, Broca's area, Heschl's gyrus, the Rolandic operculum, and the inferior occipital gyrus. The results showed that verbalizers activate brain areas involved in language and auditory processing more strongly than visualizers. For visualizers, no brain area was observed to be more activated than for verbalizers.

These results suggest that differences in cognitive style reflect differences with regard to the demand on or employment of modularity specific processing resources. No modulation of brain activation was observed, however, for the brain areas involved in number processing, namely, the IPS and the AG. This result suggests that the brain areas involved in number processing operate on a modularity independent and abstract level. Overall, cognitive style was not observed to wield a great influence on brain activation during calculation, maybe with the exception of relatively low-level modality-specific stages of processing. Our results suggest that an individual's assessment of their cognitive style is based on actual differences of preference for a specific processing modality. However, different cognitive styles do not seem to have consequences for cognitive abilities that depend on a modality-independent or abstract representation, such as arithmetic. It can be concluded that there is no true need to adapt instruction in arithmetic to an individual's cognitive style.

SYMPOSIUM

Working memory and educational achievement in children with intellectual/developmental disabilities

Chairperson: Henrik Danielsson, The Swedish Institute for Disability Research, Sweden

Organiser: Lucy Henry, London South Bank University, United Kingdom

Discussant: Claudia Maehler, Institute of Psychology, Germany

The relationships between working memory and educational achievement have been extensively investigated in typical children. However, such research is only just beginning in children with intellectual disabilities (ID) and specific language impairment (SLI), despite their vulnerability in terms of academic underachievement. This symposium will address two important questions: (1) are the working memory weaknesses characteristic of children with ID and SLI directly related to their performance on measures educational achievement?; and (2) what types of interventions can we offer to improve educational achievement in these populations?

In the first two papers, relationships between the three main components of working memory (phonological short-term memory, visuospatial short-term memory, executive-loaded working memory) and educational achievement will be examined. In paper 1, evidence is reported in relation to children with ID, that phonological short-term memory is linked to spelling; whereas executive-loaded working memory is related to mathematics and reading. In paper 2, evidence is reported in relation to children/young people with SLI, that stronger phonological short-term memory is linked with better reading; yet stronger visuospatial skills seem to depress performance. In the final paper, the effectiveness of targeted mathematics training on both working memory and arithmetical skills is assessed for children with ID.

The findings from all of the studies underline the importance of distinguishing different types of working memory ability and examining their independent relationships with academic achievement. In this way, new interventions that really work for children with specific types of intellectual and developmental disabilities can be developed.

Working memory and school achievement in children with mild to borderline intellectual disabilities

Sebastian Poloczek, Psychology (Psychologie), Germany; Gerhard Buettner, University of Frankfurt, Germany;

Marcus Hasselhorn, DIPF, Germany

In typically developing children working memory is linked to school achievement. The aim of the study was to examine whether and how measures of working memory are related to spelling, reading and calculating in children with intellectual disabilities (ID) and if these relationships vary with the difficulty level or executive load of the reading and calculating tasks. A selection of school achievement subtests and a battery of working memory measures were administered to 49 9- to 11-year-old children with mild to borderline intellectual disabilities. A mental age matched sample of 49 6- to 8-year-old typically developing children was also assessed. The indicator for the phonological short-term memory (PSTM) accounted for the most variance in spelling in both groups, while the prediction pattern for reading and calculating differed between groups. For children with ID the visuospatial working memory measures were most predictive for reading comprehension and calculating skills for tasks with lower and higher executive load. In contrast, in the group of typically developing children PSTM was the only significant predictor for reading, while calculating was predicted by the phonological working memory measures, in each case irrespective of the task difficulty. The results will be discussed with reference to the few previous studies on the topic and possible explanations for the differences in the prediction pattern between groups will be addressed.

Aims

There is extensive evidence that working memory measures are linked to reading, writing and mathematics in typically developing children (e.g. Alloway, Gathercole, Adams, Willis, Eaglen & Lamont, 2005) and that working memory components are impaired in children with specific reading or arithmetic learning disabilities (e.g. Swanson, Zheng & Jerman, 2009; McLean & Hitch, 1999). Besides, there is also ample evidence that working memory of children with intellectual disabilities (ID) is impaired in comparison to typically developing peers and that their phonological short-term memory even might be impaired in comparison to younger children matched for mental age (e.g. Schuchhardt, Gebhardt & Mähler, 2010; Van der Molen, Van Luit, Jongmans & Van der Molen, 2009). However, there are only a few studies on the relationships between working memory components and school achievement in people with ID and results vary between studies. The aim of the current study was to examine whether and how measures of working memory are related to spelling, reading and calculating in children with ID and if these relationships vary with the difficulty level or executive load of the reading tasks (word comprehension vs. sentence comprehension) and the mathematical tasks (addition and subtraction up to 10 vs. calculations crossing the 10).

Methodology

Participants

The final sample consists of 49 children with mild to borderline intellectual disabilities (ID) (mean IQ=72,4; Range 58–84) of non-specific aetiology attending special schools in Hesse / Germany with an age between 9;7 and 11;9 years. For the mental age (MA) control group we recruited 49 children from first grades in mainstream elementary schools (age range 6;7–8;3), who were matched for intelligence test raw scores and who had to obtain an IQ of at least 85 (mean IQ=105,9; Range 88–123). To be included, children of both groups had to be able to at least read and write simple words and solve some addition tasks.

Procedure

The ability to read, spell and calculate was assessed with subtests of 3 German school achievement tests suitable for first graders. To demonstrate their reading abilities children were asked to mark words corresponding to pictures (word comprehension) and to mark words fitting into a sentence (sentence comprehension; Lenhard & Schneider, 2006). To assess spelling a simple story consisting of 29 words was dictated word for word (Stock & Schneider, 2008). In 4 arithmetic subtests the participants were asked to add or subtract either in the number range up to 10 or up to 20 (Grube, Weberstock, Stuff & Hasselhorn, 2010).

Most working memory tasks were presented with the computerized German Working Memory Test Battery for Children (Hasselhorn et al., 2011). Word span and digit span scores were averaged to derive an indicator for phonological short-term memory (PSTM). Also, phonological working memory tasks with central executive load (PWM) digit backwards span and a complex span (judging whether objects are edible and remembering their names) were administered. Corsi span served as indicator for the visuospatial short-term memory (VSSTM). In order to also test visuospatial working memory with central executive load (VSWM) we created computerized corsi backwards and odd one out task with the same adaptive testing protocol as in the other memory tasks.

Findings

Stepwise regressions were used to examine the relative contributions of the different working memory indicators to the spelling, reading and calculating skills in each group. In both groups the only significant predictor for spelling was the phonological STM indicator (ID: $b=.42$, $p=.003$; MA: $b=.46$, $p=.001$). In the ID group reading was predicted by the visuospatial WM indicator (word comprehension: $b=.44$, $p=.002$, sentence comprehension: $b=.42$, $p=.003$), while the other indicators could not for additional variance. In contrast in the MA control group of typically developing children only PSTM was predictive of reading skills (word comprehension: $b=.51$, $p=.30$ - $.40$, $p=.03$ - $.005$). In two subtests (addition crossing 10 and subtraction up to 10) the phonological STM accounted for additional variance (ID group ($b=.33$ & $.35$, $p=.02$ & $.01$).

Theoretical and educational significance of the research

In accordance with two out of three previous studies (Henry & Winfield, 2010; Numminem et al., 2000) phonological STM seems to be important in the development of spelling skills in children with ID. Our study adds evidence that working memory plays some role in reading development of children with ID. However, from the existing studies no clear picture emerges which working memory component is most important in learning to read.

No evidence was found to support the assumption that working memory tasks with central executive load are more important in explaining reading comprehension or calculation skills measured with higher executive load than in predicting these skills measured with analogue tasks with lower load.

As in the studies of Alloway and Temple (2007), Henry and Winfield (2010) and Numminem and colleagues (2000) central executive loaded working memory measures were related to number and calculation skills. By separating phonological and visuospatial WM the prediction pattern differed between typically developing children (PWM most important) and children with ID (VSWM most important). One explanation for this difference might be that in special schools illustrations and visualizations of math problems are more important in teaching to calculate. A related explanation is that children with ID might use different strategies than typically developing children to solve the calculations. However, these explanations are speculative and the differences in the prediction pattern have to be interpreted cautiously. On the one hand the phonological and visuospatial WM measures might work differently in the ID and the MA group. On the other hand, the difference was just observed in one sample of moderate size ($N = 2 \times 49$) even though this sample size is relatively large for a study involving children with ID.

Working memory and reading achievement in children/young people with specific language impairment

Lucy Henry, London South Bank University, United Kingdom; David Messer, The Open University, United Kingdom; Gilly Nash, London South Bank University, United Kingdom

The relationships between working memory and reading achievement were assessed in age-matched samples of 51 children/young people with and without specific language impairment (SLI). For those with SLI, reading skills were significantly related to phonological short-term memory (the ability to passively hold verbal information in mind for short periods of time). Word reading, as opposed to nonword reading, was also negatively related to visuospatial short-term memory, suggesting that those with better visuospatial storage skills may have been using visual strategies for reading real words that hampered their overall reading progress. In children with typical development, executive-loaded working memory (tasks requiring concurrent processing and storage) related to both word and nonword reading achievement. Educationally, these findings suggest that passive phonological storage is crucial for reading in children/young people with significant language difficulties; whereas typical children rely more on executive working memory skills.

Aims

Children and young people with specific language impairment (SLI) have significant difficulties with language in the absence of an obvious cause, yet generally have non-verbal abilities in the average range. Many individuals with SLI also have significant difficulties with literacy.

The purpose of the current research was to examine whether literacy problems in children with SLI were related to their difficulties with working memory. The working memory model (Baddeley, 2000), which incorporates passive phonological and visuospatial short-term memory components, as well as active 'executive-loaded' working memory, was used as a theoretical background for the work.

There is extensive evidence that those with SLI have marked difficulties with phonological short-term memory (see Estes et al., 2007, for a meta-analysis). Similarly, executive-loaded working memory abilities, whether for verbal or visuospatial materials, are weak in this population (Ellis-Weismer et al., 1999; Marton, 2008). By contrast, visuospatial short-term memory appears to be relatively unimpaired (Archibald & Gathercole, 2006).

We predicted that reading achievement would be related to phonological short-term memory and executive-loaded working memory in those with SLI, reflecting their working memory difficulties. By contrast, we predicted that the most important predictor of reading in typical children would be executive-loaded working memory, based on previous literature (Leather & Henry, 1994; St Clair-Thompson & Gathercole, 2006; Swanson, 2008). Using regression analyses, the extent to which different measures of working memory accounted for variance in reading achievement over and above the contributions made by non-verbal and verbal ability was assessed in each sample.

Methodology

51 children and young people with SLI were recruited via Speech and Language Therapists from primary and secondary schools in London. They were between 8 and 14 years of age (mean 11.5 years) with significant language difficulties as measured by a well-established battery of language functioning (Clinical Evaluation of Language Fundamentals, Version 4; CELF-IV, UK, Semel, Wiig, & Secord, 2006). Included participants had non-verbal abilities that were no more than one standard deviation below the mean (British Abilities Scale II Matrices subtest); and language scores that were one standard deviation or more below the mean on at least two out of four subtests from the CELF-4. Typical participants were of the same age with no weak language scores and similar non-verbal abilities. Working memory was assessed using subtests from the Working Memory Test Battery for Children (WMTB-C, Pickering & Gathercole, 2001) and odd one out span (Henry, 2001). The measure of phonological short-term memory represented averaged z-scores from Word List Recall and Nonword List Recall; the measure of visuospatial short-term

memory was Block Recall (z-scores); and the measure of executive-loaded working memory was the averaged z-scores from Listening Recall and odd one out span.

Reading was assessed using the Test Of Word Reading Efficiency (TOWRE, Torgesen, Wagner, & Rashotte, 1999), which provides standardised measures of word and nonword reading.

Findings

Hierarchical multiple regressions were used to assess whether the working memory variables were good predictors of word and nonword reading, after IQ had been controlled. In all regressions, IQ (verbal or non-verbal) was entered at step 1; and at step 2 the three working memory variables were entered in a block. Standardised scores for word and nonword reading, rather than raw scores, were used to control for the effects of age.

Initial exploratory regressions indicated that executive-loaded working memory was never a significant predictor of reading for children/young people with SLI. Therefore, final regression models included only phonological short-term memory and visuospatial short-term memory. Exploratory regressions for the typical group indicated that executive-loaded working memory was the only significant working memory predictor, therefore final regression models did not include the other working memory variables.

Regressions

Word reading. (1) SLI: Verbal IQ, phonological short-term memory and visuospatial short-term memory were significant predictors of word reading. The contribution of phonological short-term memory was positive; those who had higher scores were better readers. The contribution of visuospatial short-term memory was negative; those with better scores were weaker readers. (2) Typical development: The only significant predictor of word reading was executive-loaded working memory.

Nonword reading. (1) SLI: Phonological short-term memory and verbal IQ were significant predictors of nonword reading. (2) Typical development: Executive-loaded working memory and verbal IQ were significant predictors of nonword reading.

The working memory variables accounted for between 11 and 21% of the variance in reading in all regressions.

Theoretical and Educational Significance of the Research

Children and young people with SLI have known difficulties with phonological short-term memory (Estes et al., 2007) and the current findings suggest that these difficulties are related to reading achievement. Those with weaker phonological short-term memory made less progress with respect to reading words and nonwords.

Although children and young people with SLI also have difficulties in relation to executive-loaded working memory (Ellis-Weismer et al., 1999), this aspect of working memory was not related to their word and nonword reading achievement. By contrast, typical children showed the expected relationships between executive-loaded working memory. It would appear, therefore, that passive phonological storage (phonological short-term memory) is more important for reading in those with SLI than the ability to concurrently process and store information (executive-loaded working memory).

The negative impact of visuospatial short-term memory on real word reading performance was surprising. This indicated that children and young people with SLI who had better visuospatial storage abilities made less progress in reading real words. This may have been because these individuals were attempting to make the most of their visuospatial strengths by reading words using visual strategies, and this may hold back their progress in phonological decoding. These relationships were not significant for nonword reading, suggesting that children and young people with SLI are less likely to use such visual strategies when attempting to read unknown nonwords, probably because they realise these items are not in their sight vocabularies. These findings have implications for teaching methods, suggesting that over-reliance on visual decoding strategies may not be helpful for children and young people with SLI.

Arithmetic practice and its influence on arithmetic skills and working memory in children with ID

Mariet van der Molen, VU University Amsterdam, Netherlands; Brenda Jansen, University of Amsterdam, Netherlands; Eva de Lange, University of Amsterdam, Netherlands

The aim of the present study was to see whether a five-week basic arithmetic practice with the Math Garden (Straatemeier, Jansen, Klinkenberg, & Van der Maas, 2010; see www.rekentuin.nl) leads to better arithmetic abilities, short-term memory and working memory in pupils with mild to borderline intellectual disabilities (M-BID).

Furthermore, the relationship between working memory and short-term memory on the one hand and arithmetic abilities on the other hand was investigated.

In total, 60 children with M-BID within special education were tested with a battery of tasks measuring fluid intelligence, arithmetic, short-term memory and working memory. Thirty of these children were then randomly assigned to the experimental group and practiced basic arithmetic abilities (addition, subtraction, multiplication and division) during five weeks with the computerized program Math Garden. After this period, both the experimental group and waiting list control group were tested again with the same battery but without the task for fluid intelligence.

Results are explained in terms of effectiveness of the program on arithmetic abilities, short-term memory and working memory in pupils with M-BID. Furthermore, the relationship between arithmetic and both working memory and short-term memory in children with M-BID are discussed.

Aims

Pupils with mild to borderline intellectual disabilities (M-BID) within special education show more problems with arithmetic than their typically developing peers within regular education. This difference can easily be explained by the lower intelligence level of the M-BID group. However, it is suggested that this difference is also related to the total amount of arithmetic lessons (Van Lieshout, 2001), which is lower within special education. The first aim of the current study was to see whether children with M-BID perform better on arithmetic tasks after a five-week period of practicing with the Maths Garden, a web-based method in which the four main operations are practiced; addition, subtraction, multiplication and division (Straatemeier, Jansen, Klinkenberg, & Van der Maas, 2010; see www.rekentu.nl). Kroesbergen and Van Luit (2003) showed with their meta-analysis that the effect size of arithmetic interventions for children with M-BID is rather large (.80). Especially interventions focussing on the main operations were effective. Therefore, we expected the Maths Garden to be effective for children with M-BID.

Children with M-BID also show a weak working memory, often weaker than is expected on the basis of their mental age (e.g. Henry, 2001; Schuchardt, Gebhardt & Maehler, 2010; Van der Molen, Van Luit, Jongmans, & Van der Molen, 2009). Working memory, the ability to simultaneously store and manipulate information, is considered a central construct within cognitive psychology and plays an important role in scholastic abilities like arithmetic (e.g. Shah & Miyake, 1999). Several studies have shown that working memory and visuo-spatial short-term memory strongly correlate with arithmetic abilities in typically developing children (e.g. Bull, Espy, & Wiebe, 2008; Holmes & Adams, 2006). It is not known if this relationship also holds for children with M-BID. The second aim of the current study was to see if arithmetic abilities and visuo-spatial short-term memory and working memory are correlated constructs in children with M-BID. A recent study on working memory training in children with M-BID revealed that the training led to higher scores on an arithmetic task (Van der Molen, Van Luit, Van der Molen, Klugkist, & Jongmans, 2010), therefore it was expected that also within this population at least working memory and arithmetic are related.

Finally, we explored if practicing with the Maths Garden also leads to increased working memory capacity in the children with M-BID. A study with normal aged people revealed that practicing arithmetic problems lead to improvements in cognitive functioning, including working memory (Uchida & Kawashima, 2008).

Methodology

Sixty children (age 12-14 years) with M-BID attending special education participated in this study, 30 within the experimental group and 30 within the control group. All children were tested with several tasks measuring arithmetic, working memory, short-term memory and fluid intelligence.

The children who were randomly assigned to the Maths Garden then practiced in 4 sessions per week of 15 minutes each, during five weeks with this web-based program. The Maths Garden is computer adaptive; the difficulty of the sums offered is adaptive to the child's abilities, based on reaction time and accuracy of each sum. On average, the children have a probability of 75% to make the sum correct within the time limit. The control group children got the opportunity to practice with the Maths Garden after the study was finished (waiting list control group).

Findings

Results will be explained in terms of effectiveness of the Maths Garden for arithmetic, working memory and visuo-spatial working memory. This was done by use of repeated measures ANOVA's. Furthermore, multiple regression analysis was used to give insight in how the different constructs are related.

Theoretical and educational significance

First of all, this study gives insight in the usefulness of the computerized program Maths Garden in increasing basic arithmetic abilities of children with M-BID. When proven effective, it could easily be implemented in the school context.

Furthermore, this study adds to the current understanding of the relationship between working memory / short-term memory and arithmetic in children with M-BID. Also, an increase in working memory / short-term memory capacity after following the program would mean that there is a reciprocal relationship between both constructs. This leads to new ideas about the working memory delays observed in this population (e.g. Schuchardt et al., 2010): not only does a weak working memory lead to weak scholastic abilities, also little scholastic practicing might lead to a weak working memory.

SYMPOSIUM

Interactive Problem Solving and Test Context: Current Issues from PISA 2003 to 2012

Chairperson: Jens Fleischer, University of Duisburg-Essen, Germany

Organiser: Detlev Leutner, Duisburg-Essen University, Germany

Jens Fleischer, University of Duisburg-Essen, Germany

Discussant: Romain Martin, University of Luxembourg, Luxembourg

In PISA 2003, problem-solving competency was assessed using a paper-and-pencil test format. In PISA 2012, a technology-based assessment (TBA) format will be used. This TBA format allows new ways of measuring problem-solving competency, using problems within an everyday context and focusing on interactive and dynamic aspects of the problem-solving process, e.g., problem-solving strategies. In the first paper, a generic model for the assessment of problem-solving competencies in dynamic problem situations (MicroDyn) is introduced and evaluated with respect to its psychometric properties based on a German sample. In the second paper, this model is evaluated in a Hungarian sample with a specific focus on item difficulty and background variables like motivation and ICT attitudes and ICT experience. Using problem-solving items from PISA 2003, the third paper focuses on test context as a further background variable that affects problem-solving assessment. The results of the three papers demonstrate that there is a significant development in problem-solving research, the results of which can be used to improve the assessment of problem-solving competency from PISA 2003 to PISA 2012.

Interactive Problem Solving: Just Intelligence or More than That – Some Empirical Answers

Sascha Wustenberg, University of Heidelberg, Germany; Samuel Greiff, University of Heidelberg, Germany; Joachim Funke, Psychology Department, Germany

Interactive problem solving (the terms interactive and complex problem solving are interchangeable) is commonly seen as a key qualification for success in life and therefore receives interest from international large-scale assessments like PISA and PIAAC. This growing interest increases the need for efficient assessment procedures.

As a possible measurement device we present MicroDYN, a new approach bringing together a formalized item pool and Dörner's Theory of Operational Intelligence (1986). Three facets to measure interactive problem solving competency in dynamic systems are theoretically derived and empirically evaluated.

Additionally, first empirical data to check psychometric properties (i.e., internal structure) and construct validity (i.e., relation to IQ and school grade) of the theoretically derived indicators are presented. By this, MicroDYN allows, for the first time, a psychometrically sound evaluation of a measurement device of problem solving ability and shows the importance of the captured multi-dimensional construct in the assessment of school achievement. Implications and further steps on the road to competency levels are critically outlined.

Interactive problem solving within dynamic systems has been an area of major interest in experimental research over the last decades (Funke & Frensch, 2007). Little research, however, has been conducted about interactive problem solving in the context of individual differences. However, embedded in the recent appearance of large-scale assessments like PISA or PIAAC, cross-curricular competencies such as interactive problem solving have been discovered as valuable aspects of school achievement. Despite the awakening interest in individual differences, there is still a substantial lack of well-scrutinized testing devices and almost nothing is known about their validity.

We propose a new approach taking into account a formalized item pool: The MicroDYN-approach (Greiff & Funke, 2008, in press). It provides an infinite number of items based on a mathematical formalism. Each item represents a

"system" and asks participants to detect causal relations between two sets of variables (exogenous and endogenous) and to control the system. We suggest that many everyday situations can be modeled by MicroDYN systems since advanced skills in strategic planning, internal model building and system control are crucial in the specified situations as well as tested within the MicroDYN framework. Participants face several items on the computer, each lasting about 6 minutes. The items are minimally but sufficiently complex in terms of the number of variables and their interconnections. Each item is processed in three stages: Stage 1, exploration phase: Participants can freely explore the system for some minutes. They are asked to become acquainted with the system and to learn how it works. No restrictions or goals are presented at this time. Stage 2, drawing the mental model: Simultaneously (or subsequently) to their exploration, participants are asked to draw the connections between variables as they suppose. Stage 3, control phase: Participants are asked to reach given target values on the endogenous variables by entering adequate values for the exogenous variables. During this phase, the practical application of the acquired knowledge is assessed. MicroDYN is linked to Dörner's theory of Operational Intelligence (1986). In his theory, Dörner names five characteristics of "problems": intransparency, interconnectedness, dynamics, complexity, and polytely. These characteristics correspond to five requirements on side of the problem solver: information retrieval, model building, forecasting, reduction of information, and evaluation. In MicroDYN, information retrieval is captured in Stage 1, the exploration phase, by evaluating use of strategy. Furthermore, the mental model drawn in stage 2 indicates model building as the second requirement sensu Dörner, while forecasting, the third requirement, is measured during the control phase (Stage 3). The two remaining facets are currently under development.

This paper focuses on two empirical questions:

- (1) Do the three theoretically distinguished dimensions show up empirically?
- (2) How do the MicroDYN-facets relate to other constructs, i.e. intelligence (measured by the APM) and final school grade. More specifically, does MicroDYN predict school grade beyond intelligence?

To elaborate on these questions data of $n = 121$ university students was available.

Ad (1): Empirically, the assumed 3-dimensional model had a substantial better fit ($\chi^2 = 55.75$, $df = 36$, $p = .02$, RMSEA = .06; WLSMV-estimator for this and all subsequent models) than a 1-dimensional model ($\chi^2 = 64.19$, $df = 34$, p information retrieval and model building were almost identical (latent $r = .95$, p information retrieval/model building and the second dimension forecasting fitted the data well ($\chi^2 = 55.31$, $df = 36$, $p = .02$, RMSEA = .06) and not worse than the original 3-dimensional model (χ^2 -difference 1.99, $df = 2$, $p > .05$). Additionally, this model with two dimensions fitted the data significantly better than a 1-dimensional model (χ^2 -difference 11.63, $df = 1$, p communalities in the final model were generally high and almost universally above .40. Reliability estimates were satisfactory (information retrieval/model building Cronbachs' $\alpha = .88$, forecasting Cronbachs' $\alpha = .90$). The two dimensions correlated latently with .85 (p

In summary, the three dimensions derived theoretically did not show up clearly because students who retrieved information well could obviously transfer this information into an adequate model. This might be true for the available data consisting of highly selected university students and might not hold for more heterogeneous samples where this transfer is likely to be more erroneous.

Ad (2): Additionally, we checked construct validity by comparing the subjects' results on the two facets information retrieval/model building and forecasting with their final school grade and intelligence. When entering the two MicroDYN-dimensions and IQ as simultaneous predictors of school grade, only information retrieval/model building showed a statistically significant relation to school grade (path coefficient .42, $R^2 = .18$, p The overall model fit was good ($\chi^2 = 43.63$, $df = 37$, $p > .21$, RMSEA = .03). When entering IQ as the first predictor and the two MicroDYN-dimensions as the second block in a latent stepwise regression analysis, IQ predicted school grade significantly (path coefficient .29, $R^2 = .09$, p information retrieval/model building explained considerable variance beyond intelligence (path coefficient .30, $R^2 = .09$, p Forecasting showed no significant relations with the criterion. The overall model fit was good ($\chi^2 = 44.04$, $df = 37$, $p > .19$, RMSEA = .04).

In summary, model building predicted final school grade better than intelligence and explained variance above and beyond intelligence – thus emphasising the potential of interactive problem solving not only theoretically but for the first time also empirically. Appropriate criteria predicted by the procedural aspect of forecasting are yet to be found.

If – at least in the long run – interactive problem solving can be classified and established as a valid construct it might be relevant in virtually all areas involving prediction or explanation of cognitive performance. In the context of educational large-scale assessments, the diagnostics of a cross-curricular competence like interactive problem solving yields important additional information for ability assessment. Encouraging empirical results are presented in this paper.

Measuring adults' dynamic problem solving competency

Krisztina R. Toth, German Institute for International Educational Research, Germany; gyongyver Molnar, University of Szeged Institute of Education, Hungary; Sascha Wustenberg, University of Heidelberg, Germany; Samuel Greiff, University of Heidelberg, Germany; Beno Csapo, University of Szeged, Hungary

Compared to traditional paper-and-pencil testing, technology-based assessment (TBA) offers the possibility to measure new constructs e.g. by using rich stimulus materials during testing. One example for the innovative use of TBA is the MicroDYN approach that measures dynamic problem solving (DPS). It integrates several advantages of computerized testing: it accomplishes a testing system involving everyday situation tasks, in which variables influence one or more outcomes, and provides the opportunity to assess dynamics. The user thereby has to interact with a system. In this paper we present the results of a first pilot study that measures adults' DPS competences in Hungary. Our aims are to (1) describe the internal structure of adults' competency level in DPS; (2) to identify item characteristics affecting item difficulty and (3) to depict relationships between DPS and a background data set (consisting of motivation, ICT-related variables). The MicroDYN test was composed of 8 complex and dynamic items. Results indicate that the internal structure of adults' competency level could be best described with a two dimensional model (two facets: model building and forecasting). The examination of item level characteristics identified the quality of effects as a responsible factor for item difficulty. Based on background variables, adults' DPS competency did not show significant relationships with ICT related variables, self efficacy and some of the measured motivational aspects. However, higher DPS-scores were generally associated with success orientation and job qualification.

Conceptual background

Existing models of assessment are typically inappropriate to measure complex and technology-associated competencies. However, these are becoming increasingly important in the 21st century and some of them might be captured more adequately in technology-based assessment (TBA). Consequently, the use of TBA in educational settings is now considerably more widespread than it was only a few years ago (see Csapo, Latour, Bennett, Ainley, & Law, 2010). Advantages of TBA are versatile, e.g., online item generation (CAT), automatic scoring and data processing, direct feedback and increased assessment speed. It is also possible to link rich stimulus material to conventional test item formats. All this enhances the measurement of traditional constructs (e.g. static problem solving in rich technology environments, see Bennett, Persky, Weiss & Jenkins, 2007) and enables the measurement of new constructs such as dynamic problem solving (Greiff & Funke, 2009).

Aims of this paper

Administering technology-based tests where participants meet a dynamically changing environment in educational context poses several challenges. The purpose of this paper is to study adults' DPS competencies and its underlying internal structure in Hungary. In this paper we (1) describe the internal structure of adults' competency in DPS; (2) characterize which item characteristics have an impact on item difficulty and (3) examine the correlation between DPS and several background variables (e.g., motivation, ICT-literacy).

Methods

The sample was drawn from high-school teachers ($n=86$) and students ($n=27$) with a mean age of $M=42.57$ ($SD=8.88$) and $M=21.04$ ($SD=1.87$) respectively. The instrument was developed within the MicroDYN approach (Greiff & Funke, 2009) and consisted of 8 items that were delivered fully computer-based. The MicroDYN-approach is strongly connected to Dörner's Theory of Operational Intelligence (Dörner, 1986) and captures three different facets of DPS: information retrieval (i.e., use of strategy), model building (i.e., correctness of mental model) and forecasting (i.e., controlling a system). In each item, participants first freely explore a dynamic system (facet 1: information retrieval). The adequate use of strategy is assessed here. Subsequently they draw the connections between variables as they suppose (facet 2: model building). This assesses acquired declarative knowledge. Finally, participants have to reach given target system values by entering adequate values into the system (facet 3: forecasting). During this phase, the participant has to apply the knowledge gained, which is a procedural aspect of problem solving competency (facet 3: forecasting).

A detailed task analysis was performed to determine item characteristics which potentially predict item difficulty. Furthermore, we also considered background variables such as motivation and ICT-related variables as predictors of performance in MicroDYN. The data was collected with the TAO platform.

Educational and scientific importance

While most TBA applications use only static items and conventional item formats, dynamic items and assessing characteristics of the problem-solving process (e.g., use of strategy) enable one to use the full potential of TBA. By

applying the dynamic assessment approach we measure skills and competencies that fit the requirements of the dynamically changing world. The paper outlines the results of a first pilot study of dynamic testing in Hungary.

Results and Discussion

The general fit of the theoretically assumed 3-dimensional model ($\chi^2=80.34$, $df=39$, $p=44.09$, $df=32$, $p>.07$, CFI=.96, TLI=.96, RMSEA=.05). Thus, each examinee was assessed with two individual scores, one on each facet. The average item difficulty was .20 ($SD=.19$) for model building and .19 ($SD=.23$) for forecasting, disclosing both facets as equally difficult with more variance in the procedural aspect of forecasting. Furthermore, results indicated high individual differences between test takers, while teachers' and students' achievements did not differ significantly on a group level.

Results indicated higher probability of drawing the correct mental model if direct effects (i.e., direct connections between input and output variables) were present in the items while indirect effects (i.e., true dynamics, the system changes by itself) increased difficulty considerably. Other item characteristics (e.g., number of connections, system size) were not varied systematically making it impossible to estimate their influence on item difficulty at this point. Further research needs to shed light on this important research question.

How is DPS related to motivation and self-efficacy? The latter was, unexpectedly, not associated with DPS performance. Additionally, four motivational factors were measured. Out of these four (anxiety, challenge, interest, expected success), only expected success was related to model building ($r = .26$, $p = .05$). However, the level of teacher qualification was found to be significantly related to DPS-scores ($r = .33$, p

In sum, DPS was not as strongly related to background variables as expected. This might be due to limited variance in motivation and ICT-variables. Evident was the relation between DPS and level of qualification emphasizing the importance of DPS as a cognitive construct. Studies with MicroDYN have been largely conducted in Germany and in English-speaking countries where 2-dimensional solutions are generally supported by the data. This was shown for the first time in Hungary in this study suggesting a cross-European comparability of DPS-scores.

Effects of test context on students' achievements in mathematics and problem solving

Jens Fleischer, University of Duisburg-Essen, Germany; Joachim Wirth, Ruhr-University Bochum, Germany; Detlev Leutner, Duisburg-Essen University, Germany

Despite strong theoretical and empirical relations between mathematics and problem solving, results from the PISA study 2003 show considerable differences between students' mean performance in both competencies, in many countries in favour of problem solving. This difference can be seen as an indication that students have cognitive potentials which have not been used sufficiently in school. Based on data from 515 students, we examined effects of test context and moderator effects by motivational and emotional factors that might hinder students in using their cognitive potential when working on mathematical tasks. A mathematics test and a problem solving test were embedded both within a mathematical and a problem solving context. Results show that students' achievements under the mathematical context condition are lower than under the problem solving context condition both for the mathematics and the problem solving test. This effect is especially pronounced among students with low mathematical self-concept, high mathematics test anxiety and low mathematical self-efficacy (last mentioned only for the mathematics test). The difference found in PISA 2003 might partly be explained by these results.

SYMPOSIUM

Extension of number concept: developmental trajectories of number sense

Chairperson: Erno Lehtinen, University of Turku, Finland

Organiser: Erno Lehtinen, University of Turku, Finland

Minna M Hannula-Sormunen, University of Turku, Finland

Discussant: Minna M Hannula-Sormunen, University of Turku, Finland

Students' difficulties learning fractions and decimal numbers are widely reported by mathematics teachers and researchers on mathematics learning. Many innovative teaching methods, including different metaphors, models and representations have been developed to support students' learning. However, the fraction concept continues to be one of the most challenging mathematical topics for elementary and middle school children. The learning of rational numbers is a complex process and better understanding of this complexity requires that the extensions of number concept are analyzed in a broader context of the development of number sense.

The aim of the symposium is to explore if the conceptual change approach and research on learning trajectories from earlier conceptions of numbers to rational numbers provide us with __ better theoretical and methodological tools to analyze these difficulties and developmental processes that underlie students' learning of rational numbers.

The papers of this symposium connect the learning of rational numbers to basic research on the nature of the mental number line that underlies children's number sense and to the emerging proportional thinking among younger children. These approaches are then connected to the analysis of intermediate states of understanding during the learning trajectory from natural to rational numbers.

Mental Number Line, Number Line Estimation, and Mathematical Achievement: Their Interrelations in Gr

Jennifer Paetsch, Freie Universitat Berlin, Germany; Michael Schneider, ETH Zurich, Switzerland; Roland Grabner, ETH Zurich, Switzerland

As indicated by the distance effect and the SNARC (Spatial-Numerical Association of Response Codes) effect, natural numbers are mentally represented on a number line. Purportedly, this number line underlies children's number sense which supports the acquisition of more advanced mathematical competencies. In three studies with a total of 429 fifth- and sixth-graders we compared the influences of each child's distance effect, SNARC effect, conceptual knowledge about decimal fractions, and numerical intelligence on mathematical school achievement. Additionally, we tested using decimal fractions whether number line estimation competence mediates the influence of the internal number line. In all, the results, found with path models, revealed that domain-specific conceptual knowledge, numerical intelligence, and number line estimation each were good predictors of achievement, while distance and SNARC effects were virtually unrelated to all other variables. Individual differences in the use of the internal number line, as assessed by these two effects, seem to be of little importance when it comes to the acquisition of the content of fifth- and sixth-grade mathematics lessons. The results instead highlight the importance of conceptual understanding and estimation competence for the acquisition of more advanced mathematical competencies.

Theoretical background

Mathematical competence comprises a wide variety of different cognitive skills and processes. Some elementary mathematical skills such as the discrimination of numerosity or arithmetic computations with small sets of objects are already observed in infants (Wynn, 1992) which has been interpreted as evidence that the human brain is endowed with an innate number sense (Dehaene, 1997). In this context, number sense refers to the fundamental "ability to mentally represent and manipulate numerosities on a mental 'number line'" (Dehaene, 2001, p. 17). Numbers are regarded to be represented in an analogical format on this mental number line, allowing for an automatic and efficient processing of numerical quantities (cf. Newcombe, 2002).

Empirical evidence of a link between the mental number line and higher-order mathematical competence is sparse and inconclusive. How the fundamental ability to represent and manipulate numerical information on the mental number line is related to mathematical knowledge and intelligence, and whether this basic capacity can explain individual differences in mathematical competence beyond these two well-established variables has not yet been investigated. The aim of the present investigation is to provide first insights into the relationship between the mental number line, conceptual knowledge, intelligence, and mathematical achievement in school. While it has already been shown that the mental number line influences children's early abilities to understand and operate on whole numbers (Gilmore, McCarthy, & Spelke, 2007), we focused on its influence on competencies, which are just a step further advanced. We investigated fifth- and sixth-graders' knowledge about decimal fractions, since this topic is taught

shortly after whole-number arithmetic in many countries. Three empirical studies are reported in which the relations between the aforementioned variables were investigated using path analyses.

Study 1

In Study 1, a parsimonious design was administered to provide first data on the relation between the mental number line, conceptual knowledge, and mathematical school achievement. Individual differences in reliance on the mental number line are operationalized by means of the distance effect size. If the mental number line is related to mathematical achievement, a significant correlation between the size of the distance effect and the mathematics mark should emerge. In addition to these three variables, the performance in an external number line test was included as variable that potentially moderates the influence of knowledge and mental number line on the mathematics mark.

The sample comprised 115 fifth-graders. We measured distance effect, conceptual knowledge about decimal fractions, number line estimation accuracy (of decimal fractions), number line estimation speed, and mathematics marks in a session that lasted about 70 minutes per child.

Study 1 provided no evidence of a relation between mental number line and mathematical achievement. However, mental number line was only measured in terms of the distance effect.

Study 2

In Study 2, the SNARC effect was introduced as an alternative measure for the mental number line. We used the same procedure as in Study 1, with $N = 110$ volunteering fifth-graders. Neither the distance effect nor the SNARC effect is significantly correlated with mathematics mark. There is only a small correlation between distance effect and number line estimation accuracy. In addition, distance effect and SNARC effect are significantly, yet weakly correlated. Based on the inter-correlations and our theoretical expectations, we specified the model shown in Figure 1. This model has an excellent fit to the data ($\chi^2 = 2.246$, $df = 5$, $p = .814$, $CFI = 1.000$, $RMSEA = 0.000$).

Study 3

Studies 1 and 2 revealed that conceptual knowledge is strongly related to mathematical achievement at school, whereas distance effect and SNARC effect are not. The participants' numerical intelligence was introduced as additional predictor in Study 3. Since competence in using external numerical representations may also transfer to more complex representations such as coordinate systems, an additional graph test was administered.

Participants were $N = 204$ volunteers from the fifth and sixth grades. We assessed children's conceptual knowledge about decimal fractions and their accuracy on the number line estimation task at three measurement points. At time 3 we additionally measured the distance effect, the SNARC effect, a graph test, and intelligence using the same method as in Study 1 and Study 2.

Based on the inter-correlations and our theoretical expectations, we specified the model shown in Figure 2. Most indices show a good fit of the model to the data ($\chi^2 = 17.269$, $df = 11$, $p = .100$, $CFI = 0.980$, $RMSEA = 0.053$).

Discussion

During the last two decades, researchers have claimed that the mental number line is not only important for the representation of numerical quantities, but also for mathematical competencies in general (Case & Okamoto, 1996). Dehaene (2001, p. 16) postulated "that higher-level cultural developments in arithmetic emerge through the establishment of linkages between this core analogical representation (the 'number line') and other verbal and visual representations of number notations". While this seems to be the case for elementary arithmetic (Gilmore, McCarthy, & Spelke, 2007), our results show that the limits of this claim are reached when it comes to the content of fifth- and sixth-grade mathematics classes. Using tasks from the domain of decimal fractions, we showed that in this age group, the influence of the mental number line on school achievement is negligible when compared with the influences of conceptual knowledge and numerical intelligence.

Spontaneous Focusing on Relations in 5-8 year old Children

Jake McMullen, University of Turku, Finland; Minna M Hannula-Sormunen, University of Turku, Finland; Erno Lehtinen, University of Turku, Finland

A child's tendency to spontaneously focus on numerosity (SFON) is a domain-specific predictor of mathematical development. Proportional reasoning can be seen as the basis for the later understanding of rational numbers and fractions. A basic understanding of proportional relations has been found in children as young as the age of four. In the present study we examine children's spontaneous focus in two tasks that can be attended to in a number of ways, including proportional relations, numerosity, or non-mathematical aspects. Video-recordings were collected from 86 children, ages 5 to 8, solving these two tasks. Children were found to differ in their tendency to spontaneously focus on proportional relations (SFOR) in these tasks. SFOR is defined as a person's spontaneous (i.e. undirected) focusing of attention on quantitative relations and the use of these relations in reasoning. On both tasks Grade-one children were significantly more likely to SFOR than both day-care and kindergarten children. This suggests that SFOR tendencies begin to develop around age 7, indicating that proportional relations become more salient with age.

Background

A child's tendency to spontaneously focus on numerosity (SFON) is domain-specific predictor of mathematical development (Hannula & Lehtinen, 2005; Hannula, Lepola, & Lehtinen, 2010). These findings indicate that children who more often spontaneously attend to exact number in their environment acquire from a greater amount of practice with enumeration. However, this self-initiated practice in enumeration may be only one aspect of the role of spontaneous focusing in mathematical skills development. As more advanced mathematical concepts, such as mathematical relations, become more relevant, children may similarly benefit from a tendency to spontaneously focus on relational aspects of their environment.

Proportional reasoning can be seen as the basis for the later development of rational number and fraction skills (Resnick, 1992) and a basic understanding of proportional relations may be seen in children as young as the age of four (Mix, Levine, & Huttenlocher, 1999). However, numerosity appears to become more salient than proportionality to children's thinking around the age of 5 (Sophian, Harley, & Manos, 1995) and continues even till the age of 9 (Boyer, Levine & Huttenlocher, 2008). The possible influence of spontaneous focusing processes on these developmental patterns warrants investigation. We therefore ask: (1) What are the age related differences in the tendency to spontaneously focus on proportional relations (SFOR) in tasks that require children to choose the most relevant aspect of the tasks?

Method

Data Collection

86 Finnish-speaking children, ages from 5 to 8 years ($M = 6;8$; $SD = 1.0$), with no diagnosed learning impairments participated in a series of video-recorded tasks over two 30-minute sessions with a trained experimenter. Children were given sufficient breaks during the testing and the ethical guidelines were followed. The tasks included measures of children's tendency to spontaneously focus on numerosity and proportional relations. Children were split into three age-groups based on their placement in kindergarten ($N = 31$; $MAGE = 5;6$), pre-school ($N = 27$; $MAGE = 6;9$), or first grade ($N = 28$; $MAGE = 7;9$).

Tasks

Two tasks were created from SFON tasks (Hannula & Lehtinen, 2005) to examine children's spontaneous focus on proportional relations. In both tasks children 'feed' stuffed animals with either different proportional sliced pieces of bread (see Figure 1) or different proportional sized spoons of rice. The tasks were introduced to the participants without any mention of the quantitative nature of the tasks; no mention of amount, relations in size, or number aspects were made during the experiment.

Based on video-recordings participants were scored as spontaneously focusing on proportional relations if they were able to give the same amount (i.e. the same proportion) of bread or rice as the experimenter gave, or make any mention of proportional relations. Participants were scored as spontaneously focusing on numerosity if they gave the same number of pieces of bread or spoonfuls of rice as the experimenter, or offer any other evidence of enumeration (e.g. counting, number words). If the child gave no evidence of focusing on relational or numerical aspects, they were scored as focusing on non-mathematical aspects. Children were scored for each trial based on the most complex aspect on which they focused, with proportional relations being the most complex, then numerosity, and finally non-mathematical aspects.

Results

12 (14%) participants focused on proportional relations on the majority of the trials for the bread task and 9 (11%) did so for the rice task. 55 (64%) participants focused on numerosity on the majority of the trials for both tasks. One-way ANOVA analyses were used to test age related differences in participants' spontaneous focus. For the bread task (Figure 2) significant main effects were found for the frequency of SFOR, $F(2,83)=7.85, p=0.001$. For the rice task (Figure 3), significant main effects were found for SFOR, $F(2,83)=4.40, p<0.05$ and focus on non-mathematical aspects, $F(2,83)=9.86, p<0.001$. Tukey post-hoc comparisons revealed that on both the bread and rice tasks Grade-one children had significantly higher SFOR scores than day-care and kindergarten children (Bread: $ps<0.01$; Rice: $ps<0.05$). On the rice task kindergarten children were more likely to focus on non-mathematical aspects than day-care and Grade-one children ($ps<0.01$).

Conclusions

SFOR is defined as a person's spontaneous (i.e. undirected) focusing of attention on quantitative relations and the use of these relations in reasoning. Age related differences were found that suggest that SFOR tendencies begin to develop around age 7. While whole-number knowledge has been shown to be both a promoter and an inhibitor of rational number development (Boyer et al., 2008), more detailed knowledge is needed about the learning trajectories of the relation of whole and rational numbers. The confounding influence of whole-number reasoning on the development of proportional reasoning may be partially explained by attentional processes. The significant increase in the tendency to SFOR between the age of 6 and 7 indicates that proportional relations become more salient with age. Rational number learning is based on experience with informal proportional reasoning (Resnick, 1992). Those who begin to SFOR with greater frequency may gain more, and more varied, valuable practice with relational reasoning better equipping them for formal fraction learning. The precise role of SFOR in the development of mathematical skills must be further investigated in order to truly assess these claims.

Greek and Flemish students' conceptual difficulties in the shift from (discrete) natural to (dense)

Xenia Vamvakoussi, , Greece; Lieve Nertebs, University of Leuven, Belgium; Konstantinos P. Christou, University of Crete, Greece; Wim Van Dooren, K.U. Leuven, Belgium

The framework theory approach to conceptual change hypothesizes that in the shift from natural to rational numbers, overcoming the idea that numbers are discrete is gradual, and that certain intermediate states of understanding will appear in students. Previous studies with Greek participants pointed to such intermediate states of understanding of the number of numbers in an interval, wherein the type of the interval end points (i.e., natural numbers, decimals, or fractions) affects students' judgments. One could argue, however, that these results are the product of instruction within a specific educational system. We report a cross-cultural comparison study with Greek and Flemish 9th graders who solved a test targeting the infinity of numbers in an interval. It should be noted that Greek students are consistently ranked below the average in mathematical tasks in PISA, whereas Flemish students are consistently ranked among the best performing students worldwide. Thus, one could expect that Flemish students would outperform their Greek peers in our research tasks. From the perspective of the framework theory approach to conceptual change, one would nevertheless expect that similar intermediate levels of understanding of density would be traced in Flemish students as well.

As expected, Flemish students outperformed their Greek peers. More importantly, a cluster analysis of students' responses showed intermediate levels of understanding that were very similar for Greek and Flemish students. These results point to specific conceptual difficulties involved in the shift from natural to rational numbers, and raise some questions regarding rational number instruction in both countries.

It is widely documented that the density property of rational numbers is difficult for students to grasp. Vamvakoussi and Vosniadou (2010) investigated secondary students' understanding of density from the perspective of the framework theory approach to conceptual change (Vosniadou, Vamvakoussi, & Skopeliti, 2008). Based on this theoretical framework, they hypothesized that, in addition to students who answer consistently that there are infinitely many numbers in any interval and those who invariably believe that there is a finite number of intermediates, there are students at intermediate levels of understanding. Indeed, they found a considerable number of students who answered that there are infinitely many intermediates in some, but not all cases. These students, however, did not just provide answers randomly. Specifically, their judgements were largely affected by the type of the interval endpoints, (i.e. natural numbers, decimals, or fractions). For example, a student would answer that there are infinitely many numbers between 0.2 and 0.3, but no numbers between $1/2$ and $1/3$.

Because Vamvakoussi and Vosniadou (2010) make a rather general claim about the processes of learning counter-intuitive concepts in science and mathematics, a cross-cultural comparison is theoretically interesting. In the event that different populations do not appear to face similar difficulties with respect to the dense ordering of rational numbers, or do not show comparable intermediate states, one could argue that the results of Vamvakoussi and Vosniadou are merely a product of instruction, in the context of a particular educational system. Similarly, if students from other populations were found to either succeed or fail across all number types, or make random mistakes, then not only the generality of Vamvakoussi and Vosniadou's findings but also the assumptions of the framework theory of conceptual change would become questionable.

Using the method and instrument reported in Vamvakoussi and Vosniadou (2010), we conducted a cross-cultural comparison study with a Greek and Flemish sample of 9th graders. Belgium and Greece participated in the Programme for International Student Assessment (PISA) for 9th graders in 2000, 2003, and 2006. Greek students were consistently ranked below the OECD average in mathematical tasks, whereas Flemish students were consistently ranked among the best performing students worldwide. Thus, one could expect that a representative sample of Flemish students would perform better than the Greek ones in the tasks used by Vamvakoussi and Vosniadou. From the perspective of the framework theory approach to conceptual change, one would nevertheless expect that Flemish students would be at similar intermediate levels of understanding of the infinity of numbers in an interval.

The participants of the study were 84 Greek and 111 Flemish 9th graders. According to the mathematics curricula in both countries, 9th graders have in principle all knowledge necessary to deal with the research tasks correctly.

The items we used came from the questionnaire developed by Vamvakoussi and Vosniadou (2010). There were 10 multiple-choice items that presented students with pairs of pseudo-successive numbers, such as .005 and .006, or $1/3$ and $2/3$, asking how many numbers there are in between. The type of the interval endpoints was varied across natural numbers, decimals, and fractions. The answering alternatives were as follows: a) There is no other number, b) there is a finite number of decimals, c) there is a finite number of fractions, d) there are infinitely many decimals, e) there are infinitely many fractions.

Flemish students outperformed, as expected, their Greek peers. However, there was a significant effect of the interval endpoints on students' judgments for both nationalities. Specifically, Flemish as well as Greek students performed better in the case of natural numbers; their performance decreased in the case of decimals and was lowest in the case of fractions. A cluster analysis yielded four distinct individual student profiles. More specifically, 36 students (17.0%) answered that there is a finite number of intermediates across all types of numbers. Fifty-six students (27.4%) answered that there are infinitely many numbers between natural numbers, but a finite number between decimals and also fractions. Fifty-eight students (27.4%) answered that there are infinitely many intermediates across all types of numbers, but were reluctant to accept that there can decimals between fractions and vice versa. Finally, 62 students (29.3%) answered that there are infinitely many numbers, of different symbolic representations, across all number types. Compared to their Greek peers, Flemish students were found more frequently in the last, more "sophisticated", category (21.4% and 34.4%, respectively); and less frequently in the first, more "naïve", category (21.4% and 14.1%, respectively).

However, a similar –and more importantly, considerable– percent of students from both countries was found in the two intermediate categories (52.8% Greek, 51.6% Flemish).

These results are in line with the findings of the Vamvakoussi & Vosniadou (2010) study. In a more general fashion, they are in line with the predictions of the framework theory approach to conceptual change and thus provide support for this theoretical position.

On the other hand, these results raise some interesting questions about rational number instruction in both countries. The Flemish students, ranked among the best performing students in mathematics worldwide, appeared to face the same conceptual difficulties with the rational number concept as the Greek students. We suggest that these difficulties are, to a large extent, the product of an “enrichment” view on learning, reflected in the mathematics curricula of both countries, which do not address the problems of conceptual change in the transition from natural to rational numbers.

SYMPOSIUM

Teacher thinking about Learning and Teaching

Chairperson: Natalia Schlichter, Georg-August-University of Gottingen, Germany, Germany

Organiser: Natalia Schlichter, Georg-August-University of Gottingen, Germany, Germany

Matthias Nuckles, University of Freiburg, Germany

Discussant: Lin Norton, Liverpool Hope University, United Kingdom

Teachers' thinking has become a topic of interest in educational research. This interest is rooted in the belief that the way teachers plan classroom activities depends on their conceptions about learning and teaching. Indeed, there is growing consensus that teachers' thinking influences their teaching practices and this in turn affects the learning outcomes of their students. However, although considerable scientific effort has been made since Pajares' state of the art review in 1992, teachers' beliefs about learning and teaching still remain – to put it in Pajares' words – a ‘messy construct’. Theoretically, empirical research on teacher beliefs has naturally been inspired by scientific conceptions of learning and teaching. Accordingly, the distinction between a knowledge transmission and knowledge construction view of learning is reminiscent of the shift from early cognitivism to the modern constructivist paradigm. Current empirical research further suggests that there are more than two opposing views (Pratt, 2002). Hence, analogous to the socio-cultural shift in educational research, “learning as participation” (Sfard, 1998) might also constitute an important dimension in research on teacher beliefs. Thus, in this symposium, current research projects on teacher beliefs from Germany, China and Spain will be presented and the similarities and differences between their underlying theoretical assumptions and their empirical results will be explored.

Teachers' Thinking at the University Stage

Marcos Iglesias, University of Alicante, Spain; Ines Lozano, University of Alicante, Spain; Vicente Corrasco, University of Alicante, Spain; Maria A. Martinez, Universidad de Alicante, Spain

In this study, situated in the framework of a wider research on the academic staff thinking, the authors examine the teaching conceptions, visions and inner culture of a cohort of teaching assistants, members of diverse faculties of Alicante's University. The cohort studied is inclusive of 60 participants, male and female in the same proportion, in the fields of: sciences, health sciences, social sciences, law studies, technology, education, arts and humanities. The data were obtained through open, semi-structured oral interviews that were translated in a written form and processed with the support of the Aquad software for qualitative studies. In the first place, the authors identified significance units, that posterior were classified in coda and metacoda. The results inform about multiple dimensions of assistants thinking. Singularly, the data indicate that these professionals assume that in the constitution of their professional identity their vocational inclination and their motivation force to teaching are key points and, also that they feel their teaching identity stronger than their research claim. Furthermore, they explicit a social compromise as their lighthouse academic. On the other hand, they manifest a considerable degree of anxiety about their possible professional career. Ulterior, they are conscious that their efforts to improve teaching will be not rewarded, due that promotion, here and now, is only dependent on the research capital obtained.

Aim of the study

In this study, situated in the framework of a wider research on the academic staff thinking, the authors examine the teaching conceptions, visions and inner culture of a cohort of teaching assistants, members of diverse faculties of Alicante's University. The cohort studied is inclusive of sixty participants, male and female in the same proportion, in

the fields of: sciences, health sciences, social sciences, law studies, technology, education, arts and humanities. In the Spanish universities, the assistants have a pre or post doctoral contract that entitles them with teaching responsibilities. In some way, they are the source of the future staff community.

Theoretical background

The theoretical framework is focus on the perspectives, tendencies and methodological problematic of the teachers' thinking theories considering, also, the new hypothesis about the social mind and brain (Dunbar & Schultz, 2007; Rizzolatti & Sinigaglia, 2006). This hypothesis can open a light in our knowledge of the emotional dimension in teaching and learning.

We precise answer, with a new teaching model, the new role of the universities in the deep and complex social transformations context, mainly given the current blur of equity and solidarity values (Sennett, 2006; Silverstone, 2007; Zizek, 2006). Promote the teacher thinking is indispensable for the professional identity constitution if we want overcome the fall of the intellectual compromise and the emotional disaffection between the teachers' community (Altbach, 2003; Burge, 2007).

Methodology

The data were obtained through open, semi-structured oral interviews that were translated in a written form and processed with the support of specific software for qualitative studies. The data analysis process was performed using the AQUAD software program (Huber & Gurter, 2003) in its 6.8.2.2 version. The main characteristic of this software is its capacity both to categorise the data and to bring them together by codes mutually relating and crossing categories. The metacode, according with the emergent thematic in the participants narratives, are concentrated, ones around their teaching functions as the reflections about curricula program, teaching practice, students assessment, the articulation of the CIT, the student-teacher relations, or the teachers coordination; and others around the academic staff problems, needs, and perspectives. In the theme of professional identity, the research has identified significance units that were classified in code and diverse subcode, depending on how participants see them self as: alumni, disciple of a mentor, a calling person, a novice researcher, a teacher, or a social driving person.

In our view, the information obtained comes from the natural 'scenery' in which the participants are working. Then, the narrative data collected in the questionnaires become essential referents for qualitative research because one cannot construct a professional identity outside the professional culture (Errante, 2000).

Results

The results inform about multiple dimensions of assistants' thinking. Singularly, the data indicate that these professionals assume that in the constitution of their professional identity the key points are their vocational inclination (33.33%) and their motivational force to teaching (34.62%) and, even some participants feel their teaching identity stronger than their research claim (8.97%). Furthermore, they explicit a social compromise as their lighthouse academic. On the other hand, more the 23.08% manifest a considerable degree of anxiety about their possible professional career. Lastly, they are conscious that their efforts to improve teaching will be not rewarded, due that promotion, here and now, is only dependent on the research capital obtained.

Educational significance

The conceptions of learning and teaching that underlie the classroom practices could come in confluence or in confrontation with the innovative proposals of change that the Higher Education reforms are demanded (Henkel & Vabo, 2006). In an educative model that is not prepared to meet the complexity, diversity and uncertainty of the XXI century context, we must start with a deep analysis of teacher's visions and believing (Welch, 2007). The results of this research give us a deeper understanding of the voices that in the future will conform the Higher Education community.

Beliefs at Different Stages of Teacher Education and with Different Levels of Teaching Experience

Natalia Schlichter, Georg-August-University of Göttingen, Germany, Germany; Rainer Watermann, University of Göttingen, Germany; Matthias Nuckles, University of Freiburg, Germany

Teachers' beliefs about learning and teaching play a significant role in classroom activities. Recent research identifies several beliefs with a focus on transmission and construction, while others like participation and nurturing are still neglected. The present study investigated how many and which beliefs could be found in teachers and whether they are associated with different stages of teacher education and different levels of teaching experience. The 50 interviewees were student-teachers at the (a) beginning, (b) middle, and (c) end of their studies, as well as teachers, both (d) beginning, and (e) experienced. Content analysis identified four distinct beliefs of which transmission was the prevalent one compared with the other beliefs. Furthermore, different beliefs were prominent at different stages of studies and levels of teaching experience. For example, more sophisticated beliefs such as knowledge construction and participation seemed to be relatively prominent in the middle of studies, whereby with growing professional experience less sophisticated beliefs such as transmission became dominant. Evidently, teacher beliefs are associated with teacher education and teaching experience. Hence, they may act as the agency of belief change. Suggestions for teacher education and professional development will be made.

Teachers' beliefs are assumptions about the learner, the teacher, the learning and teaching process and classroom management. They influence teachers' practices and this in turn affects the learning of their students (Fang, 1996). Therefore the aim of our study was to investigate self-reflected beliefs about learning and teaching.

Recent research differentiates between several beliefs: teaching as the transmission of knowledge from the teacher to the learner, learning as the cognitive construction of knowledge influenced by the prior knowledge. Current research often focuses on transmission and construction. In contrast, learning as a process of becoming a member of a community according to participation (Lave & Wenger, 1991; Sfard, 1998) or fostering students' self-efficacy according to nurturing (Pratt, 2002) have rarely been studied. Therefore our first research question focused on how many and which beliefs could be found in the interviews. We expected to find more distinct beliefs than merely transmission and construction.

Our second research question focused on different stages of teacher education and different levels of teaching experience. We were interested whether beliefs would differentiate across different stages and levels. According to Pajares (1992), beliefs do not change easily or rapidly, because they are at the core of our world views. However, there are some studies which provide evidence for changing beliefs (Martínez, Saulea & Huber, 2001).

Methodology

The sample (N = 50) consisted of student-teachers (mean age = 23.73; SD = 4.34) (a) at the beginning, (b) in the middle, (c) at the end of their studies, (d) beginning (M = 28.4; SD = 3.37), and (e) experienced teachers (M = 48.8; SD = 8.40).

Interviewees were asked to draw and explain a picture describing their ideas of learning and teaching. On the basis of these explanations we asked some clarifying questions, such as the role of teacher in the learning process. The interviews were divided into single segments (i.e. statements or idea units), which were assigned by their contents to subcategories and then to more comprehensive categories.

Example for a segment:

... It was always helpful when a text was written on the black board for copy//

This coding process was performed by two raters, who were trained for this procedure. The inter-rater reliability as determined by Cohen's Kappa was good ($\kappa = 0.82$).

Results

In our content analysis, four beliefs were identified: transmission, construction, participation and nurturing. The dominant belief, determined as the belief which had a value one standard deviation above the personal mean, was calculated for each participant. 32 were found to hold one dominant belief. Accordingly, transmission was dominant in twelve, participation in eight, construction in six and nurturing in six participants.

The second research question concerned different stages of teacher education and levels of teaching experience. We used the percentages of the single segments as they represent the personal preference of interviewees.

As the Figure 1 shows, transmission was highest in student-teachers at the beginning of their studies; it decreased in the middle and end of their studies and increased once again in practicing teachers with growing experience. Construction and participation, however, were relatively low at the beginning of their studies, then became quite pronounced during their studies, but lost their prominence in practicing teachers, depending on the levels of experience. Nurturing was relatively prominent at the beginning, lower during the studies, and stronger with growing professional experience.

To examine the statistical significance of these trends, we computed contrast tests for each belief. The test of the observed trend for construction (-3 1 1.5 1 -0.5) proved to be significant, $F(1, 45) = 18.75$, $p < .05$. The test of the trend for participation (-1.5 1.5 0.5 0 -0.5) was significant, $F(1, 45) = 4.21$, $p < .05$, and the test of the trend for nurturing (2 -2 -2 1 1) reached statistical significance, $F(1, 45) = 9.00$, $p < .05$. The trend test for transmission was not significant. Evidently, there were different patterns of beliefs depending on stages of teacher education and levels of experience.

Discussion

Investigating teachers' beliefs regarding different stages of studies and levels of experience, we found four distinct beliefs. The most traditional of these – transmission – was prevalent in our sample compared with the other beliefs.

Our study supports the findings of previous research that found changes in teachers' beliefs (Martínez, Saulea & Huber, 2001). We also found that different beliefs were prominent at different stages of studies and levels of teaching experience. For example, more sophisticated beliefs such as knowledge construction and participation seemed to be of relative low importance for student-teachers at the beginning of their studies, but gained greater attention during the studies as a result of academic instruction. Nevertheless, with growing professional experience, this trend was completely reversed, and less sophisticated beliefs such as transmission once again became dominant. It can be assumed that academic teacher education (in typical German universities such as the University of Göttingen) has no sustainable effect on teachers' beliefs about teaching and learning. Therefore teacher professional development should provide opportunities for practicing teachers to connect to current research and to scrutinize their own beliefs about teaching and learning.

Student Teachers' Epistemological Beliefs and Conceptions of Learning and Teaching

May CHENG, University of Oxford, United Kingdom; Angel K. Y. Wong, Hong Kong Institute of Education, China

This paper reports on a study involving 197 preservice teachers in the final year of a 4-year BEd programme in Hong Kong. The aim of the study is to capture student-teachers' epistemological beliefs, conceptions of teaching and learning, and the perceived influence of teaching and learning experience. The Pearson correlations of all the factors extracted from the three questionnaires found that four out of five factors of the perceived influence of teaching and learning experience are significantly correlated with their espousal of constructivist conception of teaching and learning. Both the formal and the informal curriculum of the BEd programme, the field experience, and the overseas learning experience which forms part of the programme are all positively related to the student-teachers' support of a constructivist conception of teaching and learning. With regard to the epistemological belief that effort is needed to acquire knowledge, the formal learning experiences at both tertiary and pre-tertiary levels have a role to play. Implications for the design of teacher education programmes are identified drawing on the findings. Apart from ensuring the quality of the formal learning experiences in a teacher education programme, the informal experiences and pre-tertiary are significant. While there are attempts to influence the student-teachers' conception of learning and teaching, teacher educators need to be aware of the changes of their epistemological beliefs during the programme.

Data were collected from 197 year 4 students in a Bachelor of Education (BEd) programme at the Hong Kong Institute of Education. Respondent were asked to complete the Epistemological Beliefs Questionnaire (EBQ), Conceptions of Teaching and Learning Questionnaire (CTLQ) (both by Chan & Elliot, 2002) and the newly developed Perceived Influence of Teaching and Learning Experience on these beliefs and conceptions (PITL). Principal axis extraction and

oblimin rotation were used to extract factors. Using a minimum Eigenvalue of 1 as criterion, a four-factor and two-factor model are identified for EBQ and CTLQ respectively, which replicate earlier-results of Chan and Elliot (2002) and Wong et al. (2009). The four EB factors are innate ability (INA), learning effort (LEP), authority of knowledge (AUK) and certainty of knowledge (CEK). With respect to the CLT, a constructivist teaching and learning conception (CONS) and a traditional one (TRAD) were extracted.

The 18 components of the newly developed scale of ITLE can be factorized into six factors that account for 69.57% of the total variance. This percentage is commonly considered to be a satisfactory solution in the social sciences. All the item loadings are over or very close to .40, which are considered significant with the current sample size (See Table 1). The factors are labelled as follow: factor 1: "core components in the formal curriculum of the BEd programme (FORM)", factor 2: "field experience (FIELD)", factor 3: "non-local learning experience (N-LOC)", factor 4: "informal and hidden curriculum of the BEd programme (INFORM)", factor 5: "pre-tertiary learning experience (PRE-TER)", and factor 6: "other experience" (OTHER). The Cronbach alphas of these factors, except that of "other experience", range from acceptable (.54) to very good (.91) (See Table 2). The low alpha of factor 6 (.34) indicates low reliability and it wouldn't be further analyzed.

The Pearson correlations of all the factors are reported in Table 2. The grey area reports the correlations among the sub-scales of EB, CLT, and PITLE. It is found that four out of five factors of the perceived influence of teaching and learning experience are significantly correlated with their espousal of constructivist conception of teaching and learning. Both formal and the informal curriculum of the BEd programme, the field experience that students have gone through, and the experience that they have gained in their overseas learning are all positively related to their support of constructivist conception of teaching and learning. The prime role played by the teacher education programme in shaping this conception is also indirectly indicated by the insignificant correlation of the constructivist conception with their pre-tertiary educational experience. On the contrary, the way these pre-service teachers thought about traditional way of teaching and learning is related to neither the educational experience in the teacher education programme nor the earlier schooling. With regard to the belief that effort is needed to acquire knowledge, both tertiary and pre-tertiary experiences have a role to play. But it is the "regular" learning experience, be it the learning of knowledge in the formal curriculum or the teachers associated with such learning in the informal curriculum, that counted. Practical experience in learning to teach in schools and immersion or exchange experience are not associated with this belief. The belief in teachers as authority in knowledge shows a significant positive, though a bit weaker, relationship with the formal curriculum. It seems that students still regard their teachers as an authority figure in their learning of academic content.

Table 1 Pattern matrix reported by exploratory factor analysis for perceived influence of teaching and learning experience of BEd students (n=197)

PANEL DISCUSSION

Research on discursive teaching and learning: What have we learned and where are we heading next?

Chairperson: Christa Asterhan, Hebrew University of Jerusalem, Israel

Organiser: Christa Asterhan, Hebrew University of Jerusalem, Israel

Discussant: Lauren B. Resnick, University of Pittsburgh, United States

For the last 25 years or so there has been rising interest among scholars from a variety of disciplines in the role of dialogue and discussion in learning. The different research strands that have developed over the years have traditionally focused on different social situations and are rooted in different research disciplines. Each of them is characterized by a particular set of theoretical assumptions and research paradigms and by a focus on different aspects of both learning and of dialogue. Even though the research and theory development within each of these strands has been very productive, the extent of communication and collaboration across the strands has been rather limited. The overall aim of this discussion panel is then to practice what we, as proponents of discursive techniques for learning and instruction, preach, namely to initiate a multi-disciplinary, productive dialogue among experts from the different research traditions. We will look back to evaluate what has been accomplished and identify what thus far has remained unexplored, both within as well as across the specific research strands. Based on these insights, we will

then outline future directions in research on discursive learning and teaching, discuss the potential benefits and pitfalls of a multi-disciplinary approach, and explore the promise of novel technologies in future research and applications.

Time, talk and learning

Karen Littleton, Open University, United Kingdom

In my contribution to this panel discussion I wish to argue that the relationship between time, talk and learning is intrinsically important to classroom education, and deserves more attention by those engaged in educational research and practice. The coherence of educational experience is dependent on talk amongst participants, and so analyses of the ways that their continuing shared experience is represented and the ways that talk itself develops and coheres over an extended period are required if we are to understand the dialogic process of teaching-and-learning. I will suggest that as educational researchers, we need to understand more about the temporal processes and outcomes of educational dialogues, because only then will we be able to help teachers to see how the precious resource of the time spent with their students can be used to best effect.

In my contribution to the panel discussion I wish to argue that the relationship between time, talk and learning is intrinsically important to classroom education, and deserves more attention by those engaged in educational research and practice. The coherence of educational experience is dependent on talk amongst participants, and so analyses of the ways that their continuing shared experience is represented and the ways that talk itself develops and coheres over an extended period are required if we are to understand the dialogic process of teaching-and-learning.

In broader terms, a sociocultural perspective provides an appropriate theoretical base for developing a more temporally-sensitive understanding of teaching and learning – with concepts such as reflexivity, intertextuality and the Intermental Development Zone highlighting the dialogic, dynamic, self-contextualizing nature of classroom talk (see Mercer and Littleton, 2007). But stronger conceptual links need to be built between the different levels of human activity identified by sociocultural theory - the cultural, the psychological and the social – so that we do not treat the cultural context of educational activity as static and given but explain how it is constituted, renewed and transformed in and through the creative activities of people in conversation and embodied in the products of joint intellectual endeavour. In other words we need to take account of what Lemke (2001, p. 25) has called the multiple timescales of human social activity, development and learning, so that we are ...'as willing to look at biography and history as at situations and moments, as methodologically and theoretically prepared to study institutions and communities as to study students and classrooms.'

Methodologically, there is no doubt that we need better ways of analysing classroom talk as a continuing, social mode of thinking, which represent the ways in which the joint construction of knowledge is negotiated, contested, resourced and achieved over time. Talk which mediates continuing joint intellectual activity poses a considerable methodological challenge for a discourse analyst because of its reflexivity. Every conversational interaction has a historical aspect and a dynamic aspect. Historically, the interaction is located within a particular institutional and cultural context, and speakers' relationships also have local and more specific histories. Speakers may invoke any knowledge from the past experience of all those interacting, whether gained separately or jointly. The dynamic aspect refers to the fact that talk is inherently reflexive: its contextual base is in a constant state of flux, as immediate shared experiences and corresponding conversational content provide the resources for building future conversational context. A key problem for researchers concerned with explaining how talk is used for the joint construction of knowledge (or, indeed, with understanding how conversational communication functions at all) is understanding how speakers build contextual foundations within and for their talk.

We can only do this in a partial, limited fashion, by sampling their discourse over time and by drawing in our analysis on any resources of common knowledge we share with the speakers. Understanding the creation of shared knowledge over extended periods of time will bring with it many other challenges for researchers. For example, as learners establish a shared history and develop common knowledge, the need to be verbally explicit about their work declines. For the participants in a collaboration, this is undoubtedly an asset. For researchers of productive interaction, however, this backgrounding is an analytic challenge. But however difficult it may be to find solutions, the problems cannot be avoided. We need to find ways of representing how the joint construction of knowledge is achieved by participants over time, because the process of teaching-and-learning depends on the development of a foundation of common knowledge.

Temporal analyses can help us see how students' ideas change through the extended process of interaction with a teacher and each other and how new concepts, ways of using language and ways of solving problems are

appropriated. Analytic methods which do not recognize or deal with the temporal development of talk, its reflexivity and cohesive nature over longer timescales than one episode or lesson will inevitably fail to capture the essence of the educational process. Methods for analysing discourse in which the analyst only attends to the relationship between contributions made by participants in one recorded conversation, without applying available information about previous related interactions and historically contextual knowledge shared by participants (as seems to have been advocated by some conversation analysts) would simply not work. Other researchers making functional analyses of language in institutional settings, including those outside education, have made this point. The use of coding schemes in which utterances with the same syntactic form and/or explicit content are taken to have the same pragmatic or semantic value, regardless of their location in the temporal sequence of communication, would also be inappropriate for addressing the kinds of questions with which I am concerned. Rather than trying, in the interests of objectivity, to distance ourselves as analysts from the perspectives of those inside in the long conversations of teaching and learning, I suggest that we should rather try to share those perspectives. As Roth (2001) says, in advocating the dual role of teacher-researcher, knowing a school culture from the inside allows researchers to appropriate participants' competence systems and so enables a richer interpretation of observed language and events.

Teachers use talk to sow seeds from which, in time, may grow the understanding of their students. Dialogues with teachers, and with their fellows, enable students to consolidate and develop their understanding over time, so that they can build new understanding upon the foundations of past experience. As educational researchers, we need to understand more about the temporal processes and outcomes of educational dialogues, because only then will we be able to help teachers to see how the precious resource of the time spent with their students can be used to best effect.

Towards Monitoring Classroom Interactions Through Speech Processing

Carolyn Rose, Carnegie Mellon University, United States

This presentation reports on an effort conducted over the past 5 years to formalize and computationally model a construct that has been called "transactivity" in discourse, beginning with analysis of synchronous and asynchronous on-line discussions and then extended to the case of discussion in classrooms. Transactive contributions are arguments constructed in such a way as to explicitly display the speaker's reasoning processes while referencing, sometimes described as "operating on", the previously expressed reasoning of self or others. A body of work in the collaborative learning community supports its value as a property of discussions for learning. Ideas related to effective patterns of discussion in classroom contexts have evolved within their own separate history from that of the community of researchers studying analysis of collaborative learning interactions. At the same time, a growing subcommunity of the classroom discourse community has focused on facilitation strategies for group discussions that have very similar motivations relating to encouraging children to articulate their reasoning and to listen to and respond to the reasoning of others transactively. One goal of our formalization has been to work towards automating analysis of transactivity in discussions in multiple contexts for supporting research in the role of discussion for learning, for stimulating enhanced learning experiences through support of productive discussions, and for supporting teacher reflection on their own teaching practices. In this presentation, I will discuss the process of developing this formalization, both from a conceptual and technical perspective as well as exploring the many caveats and considerations from a methodological perspective.

This presentation reports on an effort conducted over the past 5 years to formalize and computationally model a construct that has been called "transactivity" in discourse, beginning with analysis of synchronous and asynchronous on-line discussions and then extended to the case of discussion in classrooms. Transactive contributions are arguments constructed in such a way as to explicitly display the speaker's reasoning processes while referencing, sometimes described as "operating on", the previously expressed reasoning of self or others. A body of work in the collaborative learning community supports its value as a property of discussions for learning. Ideas related to effective patterns of discussion in classroom contexts have evolved within their own separate history from that of the community of researchers studying analysis of collaborative learning interactions. At the same time, a growing subcommunity of the classroom discourse community has focused on facilitation strategies for group discussions that have very similar motivations relating to encouraging children to articulate their reasoning and to listen to and respond to the reasoning of others transactively. One goal of our formalization has been to work towards automating analysis of transactivity in discussions in multiple contexts for supporting research in the role of discussion for learning, for stimulating enhanced learning experiences through support of productive discussions, and for supporting teacher reflection on their own teaching practices. Automatic analysis of discussion logs from studies of computer supported collaborative learning has become more prevalent as technology for machine learning and text mining have become more powerful and usable. We have extended this effort to analysis of

transcripts of whole group classroom discussions. Results from an evaluation of this technology applied to transcripts from 3 class periods of middle school math demonstrate promising results, specifically Cohen's Kappa of .69 in comparison with human annotators for identifying transactive contributions and .68 for identifying which prior utterance a transactive contribution relates to.

Much work has already been invested in fruitful applications of automatic analysis technology in the area of computer supported collaborative learning. The work presented in this presentation points towards a new line of research applying this technology in a classroom context. One potential application of this technology could be for use in teacher professional development, by supporting instructors in reflecting on how their classroom interactions with students have proceeded and how the students are progressing in terms of striving towards articulations of transactive expressions of their reasoning. In support of the students themselves, such technology could be used to track development of a student's argumentation and articulation skills over time. Finally, eventually it may be possible for such technology to provide real time feedback to instructors or students during group discussions in order to stimulate higher levels of transactivity within the discussions. In addition to these practical applications, one can imagine that such technology also holds the potential to speed up the science of investigating the role of patterns of conversational behaviour in stimulating valuable social and cognitive processes within classroom contexts. We are beginning to apply this technology to speech recordings. Being able to achieve reliable detection of these types of conversational events from speech recordings is necessary before this technology will be able to be used in a classroom setting in real time.

Our current work on speech processing focuses on recordings from small group discussions. Simple pitch related prosodic features that have been predictive of a variety of affect related variables in other speech processing work have not proven very predictive of transactivity. However, based on the connection between transactivity and social constructs such as solidarity, trust, and respect, we expect to see correlations between the occurrence of transactivity and features that indicate stylistic convergence between speakers. Thus, we are investigating how to operationalize the notion of style convergence from a technical perspective. In this presentation, I will discuss our progress towards developing a formalization of transactivity in classroom discussions, both from a conceptual and technical perspective as well as exploring the many caveats and considerations from a methodological perspective.

Promoting Collaborative Dialogue in the Classroom

Robyn Gillies, The University of Queensland, Australia

Although it is well acknowledged that students benefit from interacting with others, it is only in recent years that research has begun to examine the role that teachers play in promoting collaborative dialogue in the classroom. This is a concern because there is no doubt that teachers play a key role in inducting children into ways of thinking and learning by making explicit how to express ideas, seek help, contest opposing positions, and reason cogently. This paper reports on two studies undertaken by the author that illustrate the difference between teachers' and students' discourses during cooperative and small-group instruction (Study 1) and the additive benefits students derive when their teachers are trained to use specific linguistic tools to enhance students' thinking and learning during cooperative learning (Study 2). The findings from these two studies provide clear support for the importance of explicitly teaching students how to dialogue together if they, in turn, are to use these dialogic strategies to generate new understandings and learn during their cooperative, small group discussions.

Cooperative learning is widely accepted as a pedagogical practice that can be employed in classrooms to stimulate students' interest in learning through collaborative interaction with their peers. When children work cooperatively, they learn to listen to what others have to say, give and receive help, discuss different ideas, and, in so doing, they learn to develop mutual understandings of the topic at hand. In fact, talk is so important that it is now recognised as more than a means of sharing thoughts. It is also a social mode of thinking and a tool for the joint construction of knowledge and new learning (Mercer, 1996). Students who cooperate show increased participation in group discussions, engage in more useful help-giving behaviours, and demonstrate more sophisticated levels of discourse than students who do not work cooperatively with their peers (Gillies, 2003; 2004). The result is that children who work cooperatively tend to perform better academically (Johnson & Johnson, 2002), and are more motivated to achieve than children who have not had these experiences (Johnson & Johnson, 2008).

However, while cooperative learning provides opportunities for students to dialogue, concern has been expressed about the quality of the discourse that often emerges if students are left to engage in discussions without training in how to interact with others. Meloth and Deering (1999) found that task-related talk about facts, concepts, and strategies only appear with low frequency when left to emerge as a by-product of cooperative learning while Chinn et al. (2000) found that children only used high quality discourse when they were required to discuss reasons for their

answers. Similarly Rojas-Drummond and Mercer (2003) reported that although children do not initially use talk to explore and investigate issues when they work collaboratively together, they can be taught to do so and this has a positive effect on their thinking and reasoning. In short, Meloth and Deering, Chin et al., and Rojas-Drummond and Mercer believe that direct intervention by teachers to facilitate discussions is warranted if children are to learn to dialogue effectively with each other.

The teacher's role in promoting collaborative discourse

Although the benefits of children's discussion in cooperating groups is acknowledged (King, 2002; Gillies, 2003), little research has examined the role teachers play in promoting interaction among students. This is a concern because there is no doubt that teachers play a critical role in inducting children into ways of thinking and learning by making explicit how to express ideas, seek help, contest opposing positions, and reason cogently, and to do so in socially appropriate ways. Given the widespread benefits attributed to cooperative learning, neglecting to document the role of the teacher is unusual. This may have happened because teachers have been encouraged to act as facilitators encouraging children to use each other as a resource rather than rely on outside help (Hertz-Lazarowitz & Shachar, 1990) so the focus has been on the benefits that accrue to children from interacting with others (Webb & Farivar, 1999) rather than the role teachers play in the learning process.

In the first study, Gillies (2006) reports on the different discourses used by high school teachers who implemented cooperative learning in their classrooms in contrast to teachers who implement small-group work only. The results show that the teachers in the cooperative condition used more mediated-learning interactions such as paraphrasing to assist understanding, prompting to scaffold learning, and mediating learning between students to encourage engagement about a topic under discussion. Comments such as the following are typical of the mediated-learning interactions the teachers used: You seem to be saying...(paraphrases the student's comments to elicit clarity); Maybe if you consider this....(prompting); and, Perhaps you could consider trying to see if his (students) idea may work (mediating learning between students). Interestingly, the students in these teachers' classrooms appropriated many of these dialogic interactions and recorded nearly twice as many elaborations and task-related interactions, interactions that promote learning, as their peers in the group-work only groups.

In the second study, Gillies and Haynes (2010) built on the previous study by seeking to determine whether teachers who receive training in explicit questioning strategies demonstrate more dialogic interactions that mediate students' learning than teachers who have not received such training. The study also sought to determine whether students who participate in such training demonstrate more explanatory behaviour than their untrained peers. The results show that the teachers who receive training in explicit questioning used significantly more mediated-learning discourse than their peers in the cooperative condition. Furthermore, the children in these teachers' classes engaged in more elaboration and received significantly higher scores on the follow-up reasoning and problem-solving tasks. Implications for both these studies will be discussed

How to talk about talking classrooms

Anna Sfard, University of Haifa, Israel

These days, students' active engagement in conversations on topics of their study is believed to be highly beneficial to their learning. However, corroborating the principle of "conversational learning" with empirical evidence is not a straightforward matter. When taken together, the relevant classroom studies are bringing a mixed message about merits of the talking classrooms. In this talk I wish to claim that one of the reasons for our inability, so far, to combine the results of multiple studies into a clear, if complex, message about advantages and pitfalls of learning-through-conversation is the lack of a language in which to express and summarize the multifarious findings. The first thing we need in order to make our research on learning-through-conversation truly useful is to present the inner workings of our respective research discourses as clearly as possible. Above all, we need to be explicit about the way we use the basic terms such as learning and discourse. As it turns out, however, these words are rarely given the attention they deserve. In this talk, after presenting the spectrum of possibilities for the conceptualization of the relation between communication and learning, I will present my own research discourse in which thinking is considered as a special case of communicational activity and learning of school subjects, such as mathematics or physics, becomes the activity of individualizing (gaining agency over) specialized, historically established forms of discourses.

These days, students' active engagement in conversations on topics of their study is believed to be highly beneficial to their learning. The use of the verb believe rather than know in this last sentence is not accidental. Although learning-by-talking quickly becomes the leading classroom practice, the benefits of the discourse-intense classroom cannot be

taken for granted. True, the study of dialogical learning occupies the centre scene in the current educational research and has already produced a wealth of relevant findings. As it turns out, however, corroborating the principle of "conversational learning" with empirical evidence is not a straightforward matter. When taken together, the relevant classroom studies are bringing a mixed message about merits of the talking classrooms. Whereas many of them justify the enthusiasm with which the idea is promoted by its numerous advocates, other voices can be heard as well, claiming that it has been largely oversimplified and will require much additional refining to be turned into a truly helpful pedagogical principle. The findings collected so far are not just ambiguous – they often appear to be ridden with inner contradictions.

In this talk I wish to claim that one of the reasons for our inability, so far, to combine the results of multiple studies into a clear, if complex, message about advantages and pitfalls of learning-through-conversation is the lack of a language in which to express and summarize the multifarious findings. As stated by Christa Asterhan in her invitation to this panel, "the research involving discussion-based teaching and learning is being conducted by investigators from multiple theoretical perspectives, uses varied methodologies and analyzes different aspects of both learning and of dialogue." This multiplicity of perspectives is, of course, a healthy phenomenon and any attempt at conceptual or methodological unification would bring more damage than benefits. This said, conceptual and methodological freedom must not be confused with the exemption from an explicit theoretical commitment by the researcher. Indeed, if we are to benefit from the collective wisdom of research on learning-through-conversation, the person committed to making a useful contribution cannot just talk in her own language; to be properly understood by others, she has to be explicit about the way she uses words and about the foundational assumptions implied in these words' definitions. While always important, in our times of discursive pluralism this principle of conceptual accountability becomes *conditio sine qua non*. Indeed, a person who wished to build on research already done has to be able to become, if only temporarily, a participant of other researchers' discourses. Only when endowed with keys to these other researchers' unfamiliar uses of familiar words will she be able to engage in the task of compiling their multiple stories into a consistent narrative, which she then may try to take a few steps further.

In short, the first thing we need in order to make our research on learning-through-conversation truly useful is to present the inner workings of our respective research discourses as clearly as possible. Above all, we need to be explicit about the way we use basic terms such as learning and discourse. As it turns out, however, these words are rarely given the attention they deserve. Even more worrying is the fact that the central question of the relation between communicating and learning, and even more fundamentally, between communication and thinking, is rarely addressed by researchers in a direct manner. At a closer look, a variety of answers seem to be underlying diverse research efforts. These answers are spanning a wide range of possibilities, delineated by two extreme doctrines. On one end of the spectrum, there is the conviction that thought and communication, although interrelated and often concomitant, are distinct types of human activity, with discourse playing the secondary role of the "carrier" of one's thoughts. The other extreme is marked by Wittgenstein's denial of the primacy of thought over speech and by his rejection of the idea of "pure thought" that would preserve its identity through a variety of verbal and non-verbal expressions. This radical position is in concert with the work of Lev Vygotsky (1896 – 1934), who illustrated the inseparability of thought (or meaning) and speech by saying that conducting study of thought independently of the study of words is comparable to investigating properties of water by focusing separately on hydrogen and on oxygen. Some would even go so far as to claim that learning mathematics is tantamount to holding a dialogue on mathematical problems.

In my own research, I opt for this last, non-dualist research discourse, in which thinking is considered as a special case of communicational activity and learning of school subjects, such as mathematics or physics, becomes the activity of individualizing (gaining agency over) specialized, historically established forms of discourses. The analytic argument for the indispensability of active mathematical talk for one's learning of mathematics is right there, in the definitions themselves. As I also hope to be able to show in this brief presentation, the proposed non-dualist approach is quite effective in accounting for much of what is known today from empirical research on learning in the talking classrooms.

SYMPOSIUM

Invited SIG

Towards bilingual Europe: Studies in L1 and L2 writing

Chairperson: Gert Rijlaarsdam, University of Amsterdam, Netherlands

Organiser: Gert Rijlaarsdam, University of Amsterdam, Netherlands
Discussant: Eva Lindgren, Umea University, Sweden

In Europe, students must learn their national language of instruction and the European lingua franca, i.e. Global English, for the purposes of international communication and study. In a European context, a large network of researchers in writing try to set up collaborative work to study the relations between L1 and L2 writing processes and the relations with written products to produced knowledge for linking education in writing in L1to L2 v.v., supported by European funds. The aim is to identify the conditions for successful transfer between L1 and L2 writing strategies, and to test the effects of learning environments on the quality of writing. Cross-national studies will be set up to analyze the relationship between L1 and L2 writing processes, and their impact on the resulting text quality, by observing these processes online, using various research tools such as Inputlog (Van Waes, Leijten, & Neuwirth, 2006) and think-aloud protocols (Rijlaarsdam & Van den Bergh, 2006). Data will be collected from L1 students (French, Dutch, Flemish) writing in L1 and L2. This symposium will discuss three studies on L1-L2-writing processes, each with different angles. The aim of the symposium is to explore possibilities to set up crossnational studies, that inform instructional design.

Formulation in foreign language writing and the temporal dimension of writing processes

Rosa Manchon, Faculty of Arts, Spain

Julio Roca De Larios, Faculty of Education, Spain

This presentation will report on some of the outcomes of a programme of research into the regularities that govern cognitive activity in foreign language writing. We shall focus on the results concerning the temporal dimension of writing processes by providing (i) an overview of our general findings in this area, and (ii) a more detailed analysis of the way in which our participants' L2 proficiency level influenced the temporal dimension of formulation processes. A total of 21 Spanish EFL participants took part in the research programme. They varied in terms of educational level, L2 proficiency and previous writing experience and instruction. Two main data sources were used in the project: think-aloud protocols while writing argumentative tasks in their L1 and L2, and retrospective questionnaires. Results show (i) the various composing activities our participants engaged in did not stand an equal chance of being activated at any given time in the composing process; (ii) the dominance of formulation processes regardless of L2 proficiency level; and (iii) the proficiency-dependency of both the purported recursive nature of writing, and the amount of composition time devoted to formulation.

This presentation will report on some of the outcomes of a programme of research whose ultimate aim was theoretical in orientation: we planned our research as an inquiry into the regularities that govern cognitive activity while writing, attempting at the same time to shed light on how our writers' processes and strategies varied when they tackled writing tasks in the languages that constituted their linguistic repertoire. The development of our research project over the years led to a search for answers in two main areas: the temporal dimension of writing processes, on the one hand, and the problem-solving nature of composing activity, on the other. Regarding the former (our focus of concern in this presentation), we assumed that it was worth looking into the temporal dimension of text production in order to ascertain whether all processes are equal candidates to be activated during L2 writing, and hence equal candidates for interacting with any other. In addition, we also speculated that the time-based character of composing might be constrained by individual differences, such as level of writing ability or L2 proficiency, an issue clearly overlooked in previous L2 writing empirical research. Our research agenda, therefore, included an inquiry into the allocation of attentional resources (operationalized as the time spent on different composing activities) by focusing on the whole L2 composing activity (Roca de Larios et al., 2008), or just on one macro-writing process in L1 and L2 writing, be it formulation, i.e. text-generating activity (Roca de Larios et al. 2001, 2006) or planning (Manchôn & Roca de Larios, 2007). This presentation will provide (i) an overview of our general findings regarding the temporal distribution of writing processes, and (ii) a more detailed analysis of the way in which our participants' L2 proficiency level influenced the temporal dimension of formulation processes.

Methods

In our attempt to achieve the necessary fit between the cognitive orientation and general aims of the project and its design and implementation, two main methodological decisions were taken. First we opted for think-aloud protocols as our main data-elicitation procedure because we needed to get as close as possible to our participants' on-line processing. Second, we chose a within-writer design in the belief that this would allow us to compare across languages and within proficiency levels.

A total of 21 Spanish EFL participants took part in the research programme. They varied in terms of educational level, L2 proficiency and previous writing experience and instruction. Our writers were 7 secondary school pupils (Level 1) with a pre-intermediate level of English proficiency, 7 university students of Education (Level 2) at an intermediate proficiency level, and 7 recent graduates in English (Level 3) with an advanced command of English. All were native speakers of Spanish, with classroom exposure to English that ranged from 5 to 12 years. The three groups had received some writing guidance as part of their language courses, but no instruction specifically aimed at developing their writing skills. The more advanced participants had had both greater contact with English (as this was the medium of instruction in the last three years of their degree course) and substantially more L2 writing practice, particularly academic writing.

Two main data sources were used in the project: think-aloud protocols while writing argumentative tasks in their L1 and L2, and retrospective questionnaires. We followed standard procedures for the elicitation of protocol data with respect to the nature of the instructions and the trial run. The data analysis entailed the transcription of the participants' verbalizations, on the one hand, and the setting up of the coding schemes guiding the different studies, on the other. Regarding the latter, we followed basic principles for the analysis of protocol data suggested in the relevant literature and, in particular, the tenet that encoding must have a theoretical basis, in our case cognitive, problem-solving theories of writing. With respect to the analysis of the temporal dimension of writing processes, we decided to use the time spent on the different writing activities as percentages of total composition time in an effort to neutralize variability across informants regarding the number of processes verbalized and the time spent on the task. As for the analysis of the temporal distribution of writing activity throughout the composing process, the total amount of time spent on each writing task was divided into three equal periods.

Main results

- 1) As proficiency grows, a more balanced allocation of attentional resources to different processes can be observed.
- 2) The various composing activities our participants engaged in did not stand an equal chance of being activated at any given time in the composing process. Across languages and proficiency levels, planning episodes tended to concentrate in the first period, whereas formulation reached its peak in the second period. Revision, in contrast, gradually increased from the beginning to the end of the composition process.
- 3) This general tendency was mediated by proficiency, as seen in the statistically significant triple interaction found between proficiency, process, and period. This means that with greater competence, L2 writers appeared to be able to strategically decide what attentional resources to devote to which composing activities at any particular point in the writing process.
- 4) Regarding formulation, the lower the proficiency level, the more dominant formulation was in the writing process. Another fairly robust finding was that for all participants, regardless of their proficiency level, this process took up most of their composition time, occupying around 60% (Levels 1 and 2) to 80% (Level 1) of the total time.
- 5) We also observed that the internal structure of text-generating activity entailed the combination of episodes in which writing developed without having to tackle problems (fluent formulation), and episodes that clearly involved having to solve various kinds of problems (problem-solving formulation). Fluent formulation was more frequent than problem-solving formulation for all groups and tasks.

Explaining process differences between L1 and L2 writing:

Marion Tillema, Utrecht University, Netherlands; Huub Van den Bergh, Utrecht University, Netherlands; Gert Rijlaarsdam, University of Amsterdam, Netherlands; Ted Sanders, Utrecht University, Netherlands

Writing in a second language (L2) is more difficult than writing in a first language (L1). This is reflected by the observation that L2 writing processes often differ from L1 writing processes. Writing ability is a construct which consists of several subskills. Hayes (1996) lists a number of subskills in the long-term memory component of his model. These can be characterised as metacognitive skills (task schemas, topic knowledge, audience knowledge, genre knowledge) and linguistic knowledge. Since they are embedded in the model part labelled 'the individual', these subskills may be interpreted as learner variables. Can process differences between L1 and L2 be explained by learner variable differences? Twenty students (age=14/15) wrote four argumentative essays in Dutch (their L1) and four argumentative essays in English (their L2). Their cognitive activities during writing were registered by means of concurrent thinking aloud and keystroke logging. In addition, a number of learner variables were measured. These

were: metacognitive knowledge about process strategies, metacognitive knowledge about texts (i.e. the quality of the students' task schemas), and L1 and L2 vocabulary knowledge. L1 and L2 processes differed in terms of distributions of cognitive activities across task execution. The most notable of the observed effects will be discussed, focusing on differences between the effects of learner variables in L1 and L2 contexts. We will employ a theoretical perspective (i.e. relative contributions of each subskill) as well as an educational perspective (i.e. should L2 writing education focus on different subskills than L1 writing education?).

Even for relatively accomplished learners of a second language (L2), writing in their L2 is often more difficult than writing in their first language (L1). This is reflected by the observation that the execution of L2 writing tasks differs from the execution of L1 writing tasks. Van Weijen, Van den Bergh, Rijlaarsdam and Sanders (2008), for example, investigated L1 and L2 writing processes of undergraduate university students and found that cognitive activities, such as planning, generating ideas and text production, were differently distributed across the process of task execution in the L2 than in the L1. In addition, writers varied their writing processes more between tasks in the L1 than in the L2. How can these process differences between L1 and L2 writing be explained? We know that writing ability is a construct which consists of a number of subskills. These subskills have sometimes been identified in theoretical models. Hayes (1996), for example, lists a number of subskills in the long-term memory component of his model. The elements in this model component can be characterised as metacognitive skills (task schemas, topic knowledge, audience knowledge, genre knowledge) and linguistic knowledge. In Hayes' (1996) model, long-term memory is embedded in the model part labelled 'the individual'. Therefore, these subskills may be interpreted as learner variables, which are brought to the writing task by the writer. It seems likely that process differences between L1 and L2 can be (partly) explained by learner variable differences.

Method

Participants (N = 20) were fourteen- and fifteen-year-old students of pre-university secondary education. All participants completed eight writing assignments: they wrote four argumentative essays in Dutch (their L1) and four argumentative essays in English (their L2). Their writing processes were registered by means of concurrent thinking aloud and keystroke logging. These data were subsequently transcribed, segmented and coded by three coders, according to a coding scheme consisting of fourteen categories of cognitive activities. Examples of cognitive activities are: process planning, text planning, text production and revising. In addition, a number of learner variables were measured. Metacognitive knowledge about the writers' own writing processes were measured by means of Kieft's Writing Style Questionnaire (Kieft, Rijlaarsdam & Van den Bergh, 2008). This questionnaire measures the degree to which respondents characterise themselves as engineers (writers who generate text plans before text production) and/or sculptors (writers who use text production as a means to arrive at a text plan). The second learner variable was participants' metacognitive knowledge about texts: knowledge which the writer has about what the intended text should look like. To measure this, participants were presented with a finished argumentative essay with errors on various levels, such as spelling mistakes, wordy sentences, offensive tone and coherence mistakes. They were instructed to make all the improvements they deemed necessary. The quality of the revised texts was rated by five raters. These quality scores are an indication of the quality of their task schema. Thirdly, vocabulary knowledge was measured, both for the L1 and the L2. This was done by means of cloze tests. The distributions of various cognitive activities across task execution was modelled by means of polynomial logistic regression analysis, both for the L1 and the L2. The effect of the measured learner variables on the distributions of cognitive activities during writing was also modelled for both languages. For L2, the quality of the L1 texts (i.e. the L1 writing proficiency) was also used as a predictor variable.

Results & Conclusion

In the present study, too, differences were found between L1 and L2 in terms of distributions of various cognitive activities across task execution. In addition, process differences could be explained by learner variable differences. The higher the quality of the task schema, for example, the higher the probability that text production activities occur at the start of task execution and the lower the probability that text production activities are applied at the end of task execution. We will discuss some of the most notable of the observed effects, focusing especially on the differences between L1 and L2 contexts in terms of the size and shape of the each effect. In doing so, we will employ a theoretical perspective as well as an educational perspective. The theoretical questions are: what is the relative contribution of each of the constituent subskills and how is this different in L1 and L2? The educational perspective pertains to the identification of conditional relations between the various learner variables (do some subskills need to be mastered for other subskills to be effective?) and to the question whether the education of L2 writing should focus on different subskills than the education of L1 writing.

L1 use during L2 writing: relations between writing skill, language proficiency and text quality

Daphne van Weijen, Utrecht University, Netherlands; Huub Van den Bergh, Utrecht University, Netherlands; Gert Rijlaarsdam, University of Amsterdam, Netherlands; Marion Tillema, Utrecht University, Netherlands

This study examined the way in which second language (L2) writers use their first language (L1) to carry out cognitive activities when writing in their L2. The focus was on when L1 use occurred, whether it varied between writers and tasks, and whether L1 use was related to L1 writing skill, L2 proficiency and text quality. To answer these questions, twenty students each wrote four short argumentative essays in L1 (Dutch) and four in L2 (English) under think-aloud conditions. The writers in the study all appeared to use their L1 while writing in L2, although some did so more frequently than others, and the extent to which they did so also varied between cognitive activities. Thus L1 use did not appear to be a writer-specific characteristic. Proficient L1 writers were less likely to use their L1, and more likely to use their L2 during L2 writing than less proficient L1 writers. For L2 proficiency, no relation with L1 use could be determined. For the specific cognitive activities which were examined only the occurrence of L1 Metacomments appeared to have a negative effect on L2 text quality. For the occurrence of other cognitive activities the opposite effect was found, as they appeared to have a positive effect on L2 text quality when they occurred in L2 during L2 writing. Possible explanations for these findings and implications for teaching will be discussed.

The number of multilingual pupils in language classrooms all over Europe is rapidly increasing. This change affects the way languages and writing skills are taught at all educational levels. How should teachers respond, for example, to pupils who use their L1 while writing in their L2? Should this be encouraged or discouraged? Earlier research has shown that writers use their L1 during L2 writing for a wide variety of purposes, such as planning, generating ideas, solving linguistic problems, and as a means to prevent cognitive overload. But the effect of L1 use on L2 writing and text quality remains somewhat unclear. It can be beneficial, but not in all cases and not for all writers. This appears to depend, for example, on L2 proficiency, the type of task and topic-knowledge. Earlier studies were often based on a single task per writer, making it hard to generalize results over tasks or across languages. In addition, such studies often attempted to relate L2-proficiency to L1 use (e.g. Beare & Bourdages, 2007; Wang & Wen, 2002), instead of examining the possible effect of L1 use on text quality directly, which seems far more informative especially for educational purposes. Therefore, this study hopes to provide further insight into the role L1 use plays during L2 writing, by analyzing multiple tasks per writer. This study aims to determine to what extent specific cognitive activities occur in L1 during L2 writing. The analysis focuses on conceptual activities, which are more likely to occur in L1 during L2 writing than linguistic activities (Wang & Wen, 2002). Setting participants multiple writing assignments, helps determine whether L1 use is relatively stable within writers or whether it varies between tasks. This can also indicate whether writers are more or less inclined to use L1 while writing in L2 due to personal preferences, learner characteristics such as L1 writing skill or L2 proficiency, or due to task effects such as the topic of the assignment (see Krapels, 1990). Second, this study aims to establish more directly what the effect of L1 use is on text quality and to what extent this is influenced by the learner characteristics: L1 writing skill and L2 proficiency. This will be done by analyzing which cognitive activities occur in L1 during L2 writing and whether their occurrence correlates with text quality. Therefore, the main questions in this study are:

1. Do writers use their L1 to carry out conceptual activities while writing in L2? And if so, when?
2. To what extent does L1 use during L2 writing vary for individual writers? and
3. Is L1 use while writing in L2 related to text quality?
4. Is this relation influenced by general writing proficiency and L2 proficiency?

Method

Subjects: Twenty first year students (\approx 18 years old), wrote four short documented essays each in their L1 (Dutch) and four in their L2 (English) under think-aloud conditions. The think-aloud protocols were transcribed and coded to distinguish between eleven different cognitive activities. The assignment consisted of two parts: information concerning the writing task, and a number of quotes on the topic of the task, of which they had to integrate at least two in the text. Subjects were given thirty minutes to complete each assignment. Each session was recorded with audio and video equipment. Data & Analysis The think-aloud protocols were segmented and coded by five different

coders in L1 and six different coders in L2. Five protocols in each language were also coded by two independent coders. The interrater reliability proved satisfactory in both languages.

The quality of the L1 and L2 texts was rated twice, by two groups of five raters, one for each language. For both methods the correlation between raters proved satisfactory. The correlation between the two methods proved high in both languages, so they were summed into two general scores indicating text quality for L1 and L2. Participants were divided into two groups with high and low L1 writing skill based on the average text quality rating for their four L1 essays. They were also divided into two groups with high and low L2 proficiency based on their scores on an L2 vocabulary test.

Results & Conclusions

The writers in the study all appeared to use their L1 while writing in L2, although the extent to which they did so varied between writers, tasks and cognitive activities. Thus L1 use did not appear to be a writer-specific characteristic. Proficient L1 writers were less likely to use their L1, and more likely to use their L2 during L2 writing than less proficient L1 writers. For L2 proficiency, no relation with L1 use could be determined. For the specific cognitive activities which were examined only the occurrence of L1 Metacomments appeared to have a negative effect on L2 text quality. For the occurrence of other cognitive activities the opposite effect was found, as they appeared to have a positive effect on L2 text quality when they occurred in L2 during L2 writing. Possible explanations for these findings and implications for teaching will be discussed. Finally, it seems likely that L1 use itself does not cause a decrease in L2 text quality, but is a sign that writers are trying to overcome or prevent cognitive overload while writing in L2. If this attempt is unsuccessful, then L2 text quality is likely to suffer.

SYMPOSIUM

Invited EARLI

The Question of Research Methodology: Where next for EARLI?

Chairperson: Debra Myhill, Exeter University, United Kingdom

Organiser: Rupert Wegerif, University of Exeter, United Kingdom

Discussant: Rupert Wegerif, University of Exeter, United Kingdom

The question of what constitutes quality research in the field of Learning and Instruction is highly controversial and yet this question is seldom raised in official EARLI conferences and journals. This invited symposium, and the online debate that accompanies it, addresses this lack. It is an opportunity for self-reflection within EARLI on what counts as quality in our research. The symposium contrasts three distinct positions presented by three leading experts. Manfred Prenzel, President of the 2013 EARLI Conference, defends the importance of rigorous quantitative research studies designed to inform educational decision makers about 'what works' in education. Gert Biesta, an educational theorist, raises a number of fundamental conceptual challenges to this approach. He argues that because educational practices are constituted by values, good educational research always needs to be conducted with reference to the values that constitute such practices. Martyn Hammersley, an expert on educational research methodology, argues that there can be many types of high quality educational research serving different aims in different contexts. However, quality in research requires an academic dimension which can be threatened when the practical desire to find out 'what works' dominates. In his discussion Rupert Wegerif will relate these three talks to the question of the future direction of EARLI. Everyone is invited to participate in this debate. Do our current set of criteria for judging quality in research need challenging? Does EARLI need to change in order to remain cutting edge in a rapidly changing world?

More evidence is needed: What works and what does not work in education.

Manfred Prenzel, TUM School of Education, Germany

The idea of "evidence-based education" is sometimes associated with expectations that seem to be unreasonably high. It would not be fair, however, to criticise the approach of evidence-based education, because excessive demands have not yet been reached. For a factual dispute, the claims, the peculiarities, as well as the possibilities and limits of evidence-based education have to be analysed clearly and precisely. Evidence-based approaches could and should

show “what works.” Until now, however, the majority of educational research findings shows with high consistency and reliability “what does not work” in education. Some examples will be presented in the paper. Although this evidence about “what does not work” may be perceived as negative, it is in fact highly relevant. As will be argued, however, we have to deal with the idea of “evidence” in the educational context more carefully. For a number of relevant educational problems, we do not yet have sufficient evidence for effective treatments. For some issues, we have only provisional and fragile evidence. Frequently, we are also confronted with contradictory findings. However, for professionals as well as for researchers in education, any kind of evidence—even fragile or contradictory evidence—is helpful. The justification of evidence-based education is ultimately based on a model of rational decision. This rational model does not exclude educational relationships that are characterised by emotions, beliefs, and value-orientations. Moreover, the effects of beliefs, empathy, attitudes, or styles of interaction have to be analysed using controlled and randomised designs.

The idea of “evidence-based education” is sometimes associated with expectations that seem to be unreasonably high and unrealistic. Quite a number of stakeholders in administration and policy hope that pending decisions will win quality and legitimacy if they are based on scientifically sound evidence. At the same time, they expect that evidence-based educational practices may quickly lead to educational progress in the whole breadth of an education system. In addition, many practitioners would be happy to base their decisions on evidence at hand concerning effective educational practices. The sometimes too far-reaching hopes regarding the benefits of empirical knowledge and evidence-based approaches can be understood as a reaction to the long-standing disappointment with traditional pedagogy that has contributed little to improve the education taking place in schools and other institutions in recent decades.

Unrealistic expectations of evidence-based education inevitably lead to disappointment. It would not be fair, however, to criticise the approach of evidence-based education, because excessive demands have not yet been reached. For a factual dispute, the claims, the peculiarities, as well as the possibilities and limits of evidence-based education have to be analysed clearly and precisely. As long as there is limited evidence on interrelations between causally relevant factors (at different levels), educational processes, and multi-dimensional educational outcomes, the mere proclamation of evidence-based practices is not helpful. Evidence-based education requires a body of evidence from consequent, cumulative, and rigorous research. The use of solid designs and sound methods in educational research is relatively young and, considering the number of researchers and the resources in this field, relatively small. In this contribution, it will be shown that the number of studies that systematically examine the relations between outcomes and process or structural factors is still quite limited in many areas of educational research.

Evidence-based approaches could and should show “what works.” This is a common belief. Until now, however, the majority of educational research findings shows with high consistency and reliability “what does not work” in education. These findings attest, for example, that many students in many classrooms do not attain important educational goals, leading to increased disparities between certain groups of students. More examples will be presented in the current paper. Such evidence is unpleasant in many ways, first because it identifies problems and challenges for those who feel responsible. Additional evidence with respect to short- and long-term consequences of these problems for individuals and for society emphasises the relevance and urgency of such discrepancies between outcomes and goals.

Although this evidence about “what does not work” may be perceived as negative, it is in fact highly relevant. Such evidence points to an existing knowledge deficit—in research as well as in practice. On the other hand, there are also findings indicating that some problems do not occur under certain circumstances, showing, for example, that better results or lower disparities in schools or school systems can be achieved. Depending on the design of such studies, the findings may not reveal the crucial factors for success. At least such findings provide evidence that ambitious goals can be attained in principle and stimulate efforts to find ways for improvement: Practitioners may critically consider their own practices, alone or in professional communities, in order to discuss, reflect, change, and evaluate their approaches in continuous cycles with subsequent evaluations and reflections. This is not yet evidence-based practice, but professional action stimulated by evidence. For researchers, of course, such discrepancies (particularly between practical and attainable achievements) are the starting points to analyse systematically what works.

Hence, a theory-driven search for evidence begins that will systematically contribute to the body of evidence. As will be argued, we have to deal with the idea of “evidence” in the educational context more carefully. For a number of relevant educational problems, we do not yet have sufficient evidence for effective treatments. For some issues, we have only provisional and fragile evidence. Frequently, we are also confronted with contradictory findings. However, for professionals in education, any kind of evidence—even fragile or contradictory evidence—is helpful if they know

how to act professionally under conditions of insufficient evidence. This challenge provides important reasons to base professional teacher training on scientific studies.

The justification of evidence-based education is ultimately based on a model of rational decision and action. Rational decisions, however, are not a guarantee of success. In case of failure, rational actors do not have to blame themselves, because they tried to make decisions based on the best available knowledge and evidence.

The rational model of evidence-based education, however, does not exclude educational relationships that are characterised by emotions, beliefs, and value-orientations. Moreover, the effects of beliefs, empathy, attitudes, or styles of interaction have to be analysed using controlled and randomised designs. We also need controlled intervention studies that analyse approaches to develop such characteristics with teachers. Though such studies are quite challenging to implement, they will contribute to evidence-based approaches that really matter.

Evidence-based or value-based? The need to redefine the relationship between research and practice

Gert Biesta, University of Stirling, United Kingdom

The idea that professional practices such as education should be based upon or at least be informed by evidence continues to capture the imagination of many politicians, policy makers, practitioners and researchers. There is growing evidence of the influence of this line of thought. At the same time there is a growing body of work that has raised fundamental questions about the feasibility of the idea of evidence-based or evidence-informed practice. In this paper I make a further contribution to this discussion through an analysis of a number of assumptions that inform the discussion. I focus on the epistemological, ontological and praxeological dimensions of the discussion and in each domain identify a deficit. In the epistemological domain there is a knowledge deficit, in the ontological domain an effectiveness or efficacy deficit and in the practice domain an application deficit. Taken together these deficits not only raise some important questions about the very idea of evidence-based practice but also highlight the role of normativity, power and values. Against this background I outline the case for the idea of value-based education as an alternative for evidence-based education. As I am generally concerned about the expectations policy makers hold about what evidence can and should achieve in professional practices such as education, my contribution is primarily meant to provide educators and other professionals with arguments that can help them to resist unwarranted expectations about the role of evidence in their practices and even more so of unwarranted interventions in their practices.

The idea that professional practices such as education should be based upon or at least be informed by evidence has become influential in many countries around the world. There is, of course, something intuitively appealing about the idea that evidence should play a role in professional work. This is even more so because professions, unlike other areas of work, lay claim to the possession of specialized knowledge and skill thought to be of value to human life. This not only raises general questions about the basis for the knowledge and skills professionals deploy. Given that professional work is orientated towards human well-being, there seems to be a *prima facie* case for basing professional action on the best knowledge available.

This does not mean, however, that evidence should be the only thing that matters. The important question, therefore, is not whether or not there should be a role for evidence in professional action, but what role it should play. This at the very same time requires reflection on the question what kind of role it can play, as there is no point in having expectations about evidence that are impossible to achieve. This is particularly important in relation to the uptake of the idea of evidence-based practice by policy makers, where there is a tendency to expect far too much from evidence. This becomes deeply problematic in those cases in which it is argued that professionals should only be allowed to do those things for which there is positive research evidence available.

The idea of evidence-based practice has generated a substantial amount of discussion. While some caution about what can be expected from scientific evidence, others continue to promote research that emulates “the medical model” as the solution to many if not all problems in education. In my own contributions to the discussion I have particularly highlighted the ‘democratic deficit’ of the discussion, emphasising how a particular use of evidence threatens to replace professional judgement and the wider democratic deliberation about the aims and ends and the conduct of education. In this presentation I will revisit some aspects of this earlier discussion and will add some further dimensions to the analysis. I will present my reflections in the form of a case for value-based education as an alternative for evidence-based education. Calling the idea of value-based education an alternative, is not meant to suggest that evidence plays no role at all in value-based education but to highlight that its role is subordinate to the values that constitute practices as educational practices.

In my analysis I will focus on three aspects: epistemology, ontology and practice. In the case of epistemology I will make a distinction between representational and transactional epistemologies; in the case of ontology I will make a distinction between closed and open systems; in the case of practice I will make a distinction between application and incorporation. In all three cases I will identify a deficit. In the epistemological domain there is a knowledge deficit, in the ontological domain an effectiveness or efficacy deficit and in the practice domain an application deficit. Taken together these deficits not only raise some important questions about the very idea of evidence-based practice but also highlight the role of normativity, power and values. In the final section I will discuss the implications of these deficits for the practice of education which will lead me to my case for value-based education. I argue that the idea of value-based education can help to redefine the relationship between educational research and educational practice in a way that is fitting for the kind of practice that education is.

Can Research Tell Us What Works? On the Methods and Products of Educational Enquiry

Martyn Hammersley, UK Open University, United Kingdom

This paper begins from the idea, promoted by the evidence-based practice movement, that the task of educational research is to discover 'What works?'. It will examine the effectiveness of the randomized controlled trial, often taken as the gold standard by this movement. The argument is that there is no perfect research method, we are faced with a range of strategies with differing advantages and disadvantages, and we must make methodological decisions that trade these off against one another in ways that are most beneficial given the purposes and circumstances of each particular study. The notion of mixing or combining methods will be examined, and some of the complex issues around triangulation explored. It will be argued that mixing methods is no panacea, and that it carries the danger of leaving the methodological ideas currently underpinning qualitative and quantitative methods intact, when these need to be interrogated. In the final part of the talk the question of whether 'what works' is an appropriate focus for educational research will be considered. The way in which this notion conflates factual and normative goals and conclusions will be highlighted. It will be argued that, even when reformulated as a question about the effects of some policy or practice, it is an inappropriate task for academic, as against, practical research. The important distinction between these two kinds of enquiry will be clarified, and current threats to academic research outlined.

The starting point for this paper will be a discussion of the moves to reform educational research that began in several countries in the late 1990s, and that are continuing to one degree or another today. These relate both to the focus of enquiry, with a shift towards addressing technical questions about the effectiveness of particular policies and practices, and to the issue of what are valid research methods. One of the major factors behind the pressure for reform was the rise of the evidence-based practice movement. Its slogan was 'What works?', and educational enquiry came to be challenged by influential and powerful figures for failing to provide sufficient and reliable evidence about this. The origins of that movement lay in evidence-based medicine, which emerged in the 1980s and demanded that the treatments offered to patients must be scientifically tested to show both that they work and that they do not have serious side effects. The format for scientific testing here was randomized controlled trials synthesized through systematic reviews, the key exemplar being trials of new drugs. By this means, some medical treatments were shown to be ineffective or even harmful. This methodological model has been applied in other fields, including education, with mixed reviews; but even those advocates of the model who accept that it cannot be applied in all cases nevertheless tend to treat randomized controlled trials and systematic reviews as the gold standard. The questions that will be addressed in this paper are: whether this methodological model can be extended to the field of education in an effective way; whether it should be; and, if not, what is the alternative? The starting point will be an examination of the strengths of, but also the weaknesses and limits to, randomized controlled trials, especially when applied beyond the realm of drug trials. It will be made clear that the limitations operating on this method are by no means distinctive to the field of education. The more general theme will be that there is no perfect research method, that we are faced with a range of strategies with differing strengths and weaknesses, and that we must make methodological decisions that trade these off against one another in ways that are most advantageous given the purposes and circumstances of each particular study. Following on from this, the notion of mixing or combining methods will be examined, and some of the complex issues around triangulation explored. It will be argued that mixing methods is no panacea, and that it carries the danger that it leaves the methodological ideas currently underpinning qualitative and quantitative methods intact, when these need to be subjected to interrogation. There will be discussion here of attempts to ground mixed methods strategies in epistemological positions like pragmatism and critical realism, suggesting that this must be followed through into a fundamental reconsideration of the qualitative-quantitative divide. This needs to take in both the heterogeneity of the research strategies under each of those headings and the fact that they are designed to tackle the same tasks and face similar problems. In the final part of the paper the question of whether 'what works' is an appropriate focus for educational research, or should be its main focus, will be considered. The way in which this notion conflates factual and normative goals and conclusions will be highlighted. It will be argued that, even when reformulated as a question about the effects of some policy or practice, it is an

inappropriate task for academic, as against, practical research. The important distinction between these two kinds of enquiry will be clarified, and current threats to academic research outlined.

SYMPOSIUM

Invited SIG

Cognitive and Affective Processes in Multimedia Learning: In Memory of Dr. Roxana Moreno - Part II

Chairperson: Detlev Leutner, Duisburg-Essen University, Germany

Organiser: Roland Bruenken, Saarland University, Germany

Jan L. Plass, New York University, United States

Discussant: Detlev Leutner, Duisburg-Essen University, Germany

This invited SIG 6 symposium on Instructional Design is dedicated to Dr. Roxana Moreno, who passed away in summer 2010. Our community lost one of our most prolific researchers, highly productive scholars, and a wonderful human being who will be missed by many. With this symposium we would like to inspire more research related to Dr. Moreno's Cognitive-Affective Theory of Learning with Media (CATLM; Moreno, 2006). Therefore, seven contributions are presented that focus on cognitive and/or on affective processes in multimedia learning (De Koning, Tabbers, & Paas; Imhof, Scheiter, Gerjets, & Edelmann; Kirschner, Phielix, & Prins; Magner, Schwonke, Renkl, Aleven, & Popescu; Park, Seufert, Moreno, & Brünken; Um & Plass; van den Boom, Kirschner, & van Merriënboer). Kirschner et al. discuss self- and group awareness of cognitive and social behaviour. Magner et al. concentrate on the effects of decorative illustrations and their distracting or motivating function. Imhof et al. present different visualizations, which facilitate mental animation. Park et al. show that combined effects of different cognitive load inducing factors are not necessarily additive and how to motivate learners to make full use of their cognitive resources during learning. Um and Plass describe how experienced positive emotions facilitate cognitive processing and improve cognitive and affective outcomes. Van den Boom et al. discuss prompting to stimulate self-regulated learning competence. Finally, De Koning et al. present their results on the function of gesturing as a means to foster understanding. Detlev Leutner will be discussant for the papers presented in the symposium.

Emotional Design in Multimedia Learning

Eunjoon Rachel Um, The New York Times, United States; Jan L. Plass, New York University, United States

Can positive emotions experienced during multimedia learning facilitate cognitive processing and improve cognitive and affective outcomes? 118 college students were randomly assigned to four experimental treatment conditions created by two design factors for the induction of positive v. neutral emotions, (1) by means of a self-referencing mood induction procedure, and (2) through the emotional design of the learning material. Results showed that the emotional design of the materials can induce positive emotions in learners, and that these positive emotions improved cognitive learning outcomes, motivation, satisfaction and perception toward the materials. The study suggests that emotional design should be considered an important factor in the design of educational materials.

Background

Can positive emotions facilitate cognitive processing and improve cognitive and affective outcomes in multimedia learning? Positive emotions are attributed long lasting effects on the personal growth of individuals and their social and emotional well-being (Fredrickson, 2001). When it comes to designing educational experiences, however, little is known about how the emotional impact of learning materials on the learner may affect learning outcomes. There are two competing hypotheses for the effect of positive emotions on cognition. The facilitation hypothesis suggests that positive moods facilitate performance on divergent, creative problem solving tasks (Isen & Baron, 1991; Erez & Isen, 2002; Konradt et al., 2003). In contrast, the suppression hypothesis suggests that moods can take extra-task processing or task-irrelevant processing and will have a negative effect on reasoning (Oaksford, Morris, Grainger, & Williams, 1996). We aim to investigate whether positive emotions in multimedia learning environments facilitate or suppress cognitive processes and, as a result, learning. Our approach to induce positive emotion in multimedia learning uses manipulations that (1) do not add significant amounts of new information to the material, and (2) use established effects that have been empirically validated in their impact on learners' positive emotions. These effects include the use of specific color combinations, anthropomorphism, and the baby face bias - we refer to the combined application of all three visual design effects as positive emotional design. We are interested in how the induction of positive emotions during learning, through the positive emotional design of learning materials would affect learning outcomes compared to an induction of positive emotions before a learning task, through a mood induction procedure.

Method and Design

Participants were 118 students at a private university in the US (79 female, $M=4.9$, $SD=6.4$ yrs.), randomly assigned to one of the four treatment conditions in this factorial design. Factors were the external induction of positive emotions by means of a self-referencing Mood Induction procedure (positive or neutral emotions) (Seibert & Ellis, 1991), and the internal induction of positive emotions by means of the Emotional Design of the learning materials (positive or neutral design). Multimedia learning material was a seven-minute computer-based lesson covering the topic "How immunization works". To manipulate affect, there were two design versions; the neutral emotional design was developed in monochromatic gray-scale, the positive emotional design was a revised version of the neutral design that applied established effects to induce positive emotions without changing the learning content of the materials by using the visual design; color combination, anthropomorphism, and baby-face bias (Figure 1): (see Appendix)Figure 1. Screen shots of multimedia learning materials: Neutral Design (left) and Positive Design (right)As a manipulation check of mood induction, the Positive Affect Scale (PAS) from the Positive and Negative Affect Schedule (PANAS; Watson, Clark, & Tellegen, 1998) was used. Participants first received an introduction and then completed a background questionnaire. Then, twenty-five statements of either the positive or the neutral mood induction were displayed, followed by the first PAS as manipulation check. Next, the multimedia instruction with either neutral or positive design of the material was presented to study for 15 minutes. Participants were given 25 minutes to complete the second PAS, comprehension and transfer tests, and other motivation and interest measures.

Results

Manipulations check revealed that the mood induction had the intended effect. A 2x2 ANOVA on comprehension test scores with Emotional Design and Mood Induction as between-subject factors revealed a significant main effect for Emotional Design, $F(3,114)=11.57$, $MSE=90.58$, pA 2x2 ANOVA on transfer test scores with Emotional Design and Mood Induction as between-subject factors revealed significant main effects for Mood Induction, $F(3,114)=12.25$, $MSE=314.80$, $pConclusionResults$ showed that learners who studied materials designed to induce positive emotions had better comprehension than learners who received the neutral design. In addition, both methods of inducing positive emotions externally, before learning, and internally, using materials designed to induce positive emotions, increased participants' transfer test performance. Results support the facilitation hypothesis that a positive emotional state serves as an effective retrieval cue for other positive materials and demonstrate that positive learning effects can be obtained by applying emotional design principles to the design of multimedia learning environments.

Learning about locomotion patterns with static-simultaneous visualizations and motion-indicators

Birgit Karoline Imhof, Knowledge Media Research Center, Germany; Katharina Scheiter, Knowledge Media Research Center, Germany; Peter Gerjets, University of Tuebingen, Germany; Jorg Edelman, Knowledge Media Center, Germany

The ability to self-regulate one's own learning is considered beneficial for learning and a prerequisite for lifelong learning, especially in non-formal and informal settings. Reflection on one's own learning experiences, in turn, is important for developing this self-regulated learning competence (SRLC). Prompting learners so as to stimulate their reflection can be effective for eliciting the desired reflections. Evocative feedback is seen as a means to intensify reflective activities. Students working together on a task in an electronic discussion group were stimulated to reflect on their own learning, provide feedback on each others reflections, and co-reflect on relevant aspects of these reflections. The effects of "instruction on how to provide feedback (feedback instruction)" and "guidance and support by a tutor in the discussion group (tutor moderation)" on the reflective activities, resulting SRLC development, and learning outcomes were investigated. Preliminary results show that in conditions with feedback instruction and tutor moderation reflective activities were more intensive than without feedback instruction and tutor moderation. The

groups differed significantly in their development on certain aspects of SRLC - as measured by MSLQ - as well as on the learning outcomes. A main effect on the MSLQ External goal orientation scale was found for "instruction on how to provide feedback". An interaction effect was found for the MSLQ Peer learning scale. Concerning learning outcomes, conditions with feedback instruction outperformed conditions without feedback instruction. No learning effect was found for tutor moderation.

Background

Self-regulated learning (SRL) refers to those learning processes where the learner orchestrates his/her own learning. The ability to self-regulate one's own learning (i.e., SRL-competence; SRLC) is an important factor in making learning more effective, efficient, and satisfactory and is a prerequisite for lifelong learning, not only in the formal setting, but also in informal and non-formal settings. Reflective activities are essential to acquiring SRLC (Ertmer & Newby, 1996; Nýckles, Hýbner, & Renkl, 2009; Van Velzen, 2002). Reflective activities, however, often need to be evoked. Several authors have claimed that prompts embedded in instruction are well suited for evoking reflection (Berthold, Nýckles, & Renkl, 2007; Kauffman, Ge, Xie, & Chen, 2008; Sobrol, 2000; Stark & Krause, 2009). Although reflection prompts in the form of assignments elicit the desired reflections, Van den Boom, Paas, Van Merriënboer, and Van Gog (2004) found that reflection prompts alone did not evoke the intended depth of reflection. Their results showed that reflection was more effective for developing SRLC when additional feedback on the reflection was provided which is in line with findings that the impact of reflection can be affected by external feedback (Butler & Winne, 1995; Kluger & DeNisi, 1996). Van den Boom, Paas, and Van Merriënboer (2007) found that reflection in combination with external feedback provided by a tutor positively influenced the development of SRLC. Since tutor capacity is expensive, especially as student numbers increase, they also investigated whether this positive influence could be found when feedback was provided by peers. They found, unfortunately, that students were not likely to spontaneously act as feedback providers or co-reflectors.

Aim

To determine how peer feedback and co-reflection can be stimulated in order to intensify reflective activities of students working in an electronic learning environment.

Methodology

An experiment was conducted to determine whether - and if so how - (1) instruction on how to provide feedback (feedback instruction, INS) and providing tutor guidance and support in a discussion group (tutor moderation, MOD) can affect and improve students' reflective activities, and (2) resulting reflective activities affect both self-regulated competence development and learning outcomes. Students enrolled in a university level distance education course (N=45), working together for several months on learning tasks in an electronic discussion group, were stimulated to reflect on their own learning. In all conditions, students were prompted to reflect and to provide feedback on each other's reflections and co-reflect on relevant aspects of these reflections. For the experiment, 11 reflection prompts were presented to the students as assignments in the learning tasks.

The participants were randomly assigned to one of four conditions resulting in the following division of participants over the conditions: see Appendix A, Table 1. Effects of feedback instruction and tutor support on reflective activities, SRLC development, and learning outcomes were investigated. The development of SRLC was measured via difference scores on pretest and posttest with the Motivated Strategies for Learning Questionnaire (MSLQ; Pintrich, Smith, Garcia, & McKeachie, 1991). Learning outcomes were determined via the regular course exam.

Findings

Preliminary results show that the groups differed significantly in SRLC development and learning outcomes. In the INS+ and MOD+ conditions, reflective activities were more intensive than in the INS-MOD- condition. Chi square tests revealed that the four groups differed significantly on total number of messages in the discussions ($\chi^2(1, N = 1230) = 4.11$, p MANOVA on the MSLQ difference-scores showed a main effect of INS on Extrinsic goal orientation (EGO), $F(1, 41) = 10.82$, $MSE = 0.67$, p ANOVA revealed a main effect of INS on learning outcomes, $F(1, 41) = 5.07$, $MSE = 1.81$, p Theoretical and educational significance. This study showed that an intervention using feedback instruction and tutor support in an electronic discussion group differentially affected the intensity of reflective activities. The impact of the reflections on learning outcomes was considerable. Only a minor effect was found on SRLC development. Prompting learners to reflect still seems to be a promising way to stimulate SRLC development, especially if it is combined with instructions on how to provide feedback to reflections of peer students. With that, we recommend concentrating on one or a limited number of aspects of SRLC realize a focus of control. The role of tutor support and the interaction of the tutor support and feedback instruction need to be reconsidered. Concerning educational significance, we advise cautious experimental implementation of strictly

directed feedback instructions to stimulate collaborative reflective activities and co-reflection which proved beneficial for learning. References see Appendix B

Hands in the air: Gesturing as a means to foster understanding of an animation about lightning

Bjorn de Koning, Erasmus University Rotterdam, Netherlands; Huib Tabbers, Erasmus University Rotterdam, Netherlands; Fred Paas, Erasmus University Rotterdam, Netherlands

Recent research indicates that dynamic visualizations involving human motor actions (e.g., origami folding) are more effective for learning than equivalent static visualizations, suggesting that cognitive processing is facilitated if the learning task is related to human movement. Using theories of embodied cognition and cognitive load, the present study shows for the first time that calling upon human movement in dynamic visualizations showing other (non-motor) types of knowledge also enhances learning. In two experiments, participants observed an animation about lightning formation while expressing the depicted information in gesture (i.e., manually following the movements in the animation), by observing an on-screen hand expressing the information in gesture, or without any gesturing. Interestingly, observing on-screen gestures, but not actual gestures made by participants, lead to better learning than observing the animation without gestures. These results suggest that motor experiences during learning, which have been considered to play an important role in observational learning of procedural-motor tasks, can also significantly improve people's understanding of (dynamic) systems or processes teaching more conceptual and non-motor knowledge.

Dynamic visualizations, such as animation and video, visualize processes that are dynamic in nature by explicitly showing the changes in the depicted system or procedure. Therefore, they are assumed to avoid more effort demanding dynamic inferences about the subject matter that are required in static visualizations (Hegarty et al., 2003). However, there is little evidence that animations are superior to static graphics for learning about mechanical or technical systems (Tversky et al., 2002). According to several researchers, ineffective learning from these animations is due to high working memory load caused by transient information (Van Gog et al., 2009). Nevertheless, the effectiveness of animations over static graphics in procedural learning (i.e., human motor skills) was supported in several studies (Ayres et al., 2009; Wong et al., 2009). The results of these studies tend to support the claim that the high working memory demands created by transitory information in animations is less of a problem if the learning focus is related to human movement, because of the 'mirror-neuron system' (Van Gog et al., 2009). Mirror neurons are neurons in the human motor system, which are activated both when people act and by observing motor actions made by others (for a review see Rizzolatti & Craighero, 2004). That is, the same cortical circuits that are involved in executing an action oneself, also respond to observing someone else executing the action. Moreover, this seems to prime the execution of similar actions, which suggests that the mirror-neuron system mediates imitation by preparing the brain for execution of the same action (e.g., Iacoboni et al., 1999). Hence, asking learners to observe an animation to learn a motor skill may not place an excessive burden on working memory resources.

Based on the theoretical framework of embodied cognition, in the present study, it is proposed that it might be effective for learning to call upon human movement also in animations showing other (i.e., non-motor) types of knowledge. Embodied theories of cognition assume that all aspects of human cognition such as ideas, thoughts, and concepts are shaped by the human body, such as perceptual and motor systems. That is, mental representations are formed using sensorimotor systems ordinarily used to control motor behavior and to perceive the world around us and thereby are grounded in perception and action, rather than being reducible to abstract symbols (Barsalou, 1999). One specific type of sensorimotor experience that has been shown to be effective for learning non-motor knowledge (i.e., math) and reducing cognitive load is expressing information in gesture or observing someone else who expresses information in gesture (e.g., Goldin-Meadow et al., 2001; Singer & Goldin-Meadow, 2005). We conducted two experiments that examined how gestures influence learning from an animation in a non-motor domain. The animation studied was a redesign of the animation about lightning formation originally developed by Moreno and Mayer (1998). In Experiment 1, there were two versions of the animation: an arrow-version and a hand-version. In the arrow-version, a moving arrow was added to the display that followed the main movements in the animation. In the hand-version, the arrow was replaced by a picture of a forearm of the same size. A control group of 25 participants studied the arrow-version, a self-gesture group of 25 participants studied the arrow-version while following the arrow with their hand, and an on-screen agent group of 25 participants studied the hand-version. Results revealed that participants in the on-screen agent condition performed better than the other groups on retention and transfer tests. No differences were found between the self-gesture and the control conditions, although from the gesturing literature actually making gestures should lead to the strongest learning benefits. Some likely explanations for the latter result are that 1) by placing one's hand before the screen in order to follow the arrow may have reduced the visibility of the presentation, 2) instructing participants to manually follow the arrow may have distracted learners from the core learning task because they allocated (too) much attention to the arrow.

The aim of Experiment 2 was therefore to further investigate the influence of self-gesturing on learning using a more natural and less interfering way of manually following the movements in the animation. The same animation as in Experiment 1 was used but it was presented without arrows or on-screen hands. In one group, participants were instructed to move magnets on a board placed before them in congruence with the animation's movements. This group was compared to a group who just studied the animation without making any human movements during animation study. To exclude the possibility that the act of gesturing itself and not the type of gesture (i.e., congruent or incongruent) results in better learning, we also included a third group in which participants were instructed to make gestures in a way that is incongruent with the movements in the animation (i.e., continuously rotating the hands). Experiment 2 showed that there was no significant difference in the retention and transfer performance between the three groups. This suggests that despite a more intuitive gesturing approach, coordinating one's movements with the animation's movements and trying to understand a multimedia presentation may be a too complex task for learners.

In conclusion, our experiments indicate that human action, which has been considered to play an important role in observational learning of procedural-motor tasks (Van Gog et al., 2009), can also significantly improve people's understanding of (dynamic) processes that usually have no direct relation to people's actions or bodies. Especially, observed manual gestures integrated in the animation fostered learning, which is consistent with text comprehension research (Marley et al., 2010). From an embodied cognition perspective, designing animations depicting non-human movements in ways that align with how mental representations are formed (i.e., through perceptual and motor experience), may help people understand those movements more easily.

SYMPOSIUM

Unravelling cognitive obstacles in interpreting external representations of data

Chairperson: Wolfgang Schnotz, University of Landau, Germany

Organiser: Wim Van Dooren, K.U. Leuven, Belgium

Discussant: Wolfgang Schnotz, University of Landau, Germany

Graphical displays of statistical data play an important role in an information society as a tool of communication and inference. Education therefore needs to prepare students to deal with information offered in tables and graphs. Consequently, the ability to understand quantitative phenomena and data presented in a graphical way, or shortly graphicacy (Wainer, 1992), is a common requirement in the curricula of primary and secondary education. Although most of the corresponding attainment targets are found in the field of mathematics, graphicacy can be considered as a domain-exceeding skill. The importance attached to tables and graphs in education can also be inferred from the fact that international assessments such as Trends in International Mathematics and Science Study (Mullis et al., 2005) and the Programme for International Student Assessment (OECD, 2009) frequently include tables and graphs in their test questions.

Notwithstanding the curricular importance adhered to external data representations, systematic research about the way in which students interpret these representations – and the difficulties they encounter in doing so – is rather scarce and very often anecdotal.

This symposium brings together three studies that systematically aimed at unraveling the cognitive obstacles that students encounter when they interpret external representations of statistical data. Each paper offers a theoretical perspective on this topic, and discusses the educational implications of the research findings

Students' cognitive difficulties in interpreting tables and bar graphs

Eduardo Marti, University of Barcelona, Spain; Merce Garcia-Mila, University of Barcelona, Spain; Fernando Gabucio, University of Barcelona, Spain; Sandra Gilabert, University of Barcelona, Spain

Fostering documental literacy is an important challenge in compulsory education. Tables and graphs are frequently used formats for presenting data, but there is scarce research devoted to middle school student's learning to interpret these formats. Some research (most of which focusses on adult participants) has shown that the processing required to interpret a table or a graph can be performed at different levels (Postigo & Pozo, 2000; Friel, Curcio & Bright, 2001). In the present study we analyzed primary and secondary students' degree of understanding of a double entry table and a bar graph. Our results show only a rather low level of understanding, but more importantly, little progress across educational levels. We identified some specific cognitive difficulties that can explain the students' low performance in deeply understanding tables and graphs (cross organization of data, dissociation of variables, figurative obstacles, meaning of intervals and prior knowledge). Some educational implications are discussed.

An important goal in the compulsory curriculum is to foster documental literacy, understood as the ability to identify and use information presented in various formats such as tables and graphs (Murray, Kirch, & Jenkins, 1997). This is not only important in academic and scientific tasks (Latour, 1987; Lemke, 1998) but also to function in our everyday activities. This challenge contrasts with the scarce research devoted to middle school students' learning to interpret tables and graphs. Most studies analyze adults' performance (Barquero, Schnotz, & Reuter, 2000; Leinhardt, Zaslavsky, & Stein, 1990) and those studies that involve children and adolescents mainly focus on graph interpretation. Among those studies that investigate the interpretation of graphs, we take as a reference for the present research the levels of understanding proposed by Friel, Curcio, and Bright (2001) and Postigo and Pozo, (2000). These studies explore the degree of processing involved in interpreting graphs. Friel et al. (2001) proposed the following processing categories: "read the data", "read between the data", and "read beyond the data". We take these as a starting point to understand middle school students' difficulties when they are asked to interpret graphs and tables. The objectives of our study are to analyze primary and secondary students' expertise on table and bar-graph interpretation and changes in this level of expertise over educational levels. We also wanted to test whether different levels of interpretation are present in the students' answers and to identify the main cognitive difficulties in interpreting a table and a bar graph. Method Two hundred students from a public school participated in the study: 43 5th graders (mean age= 10;8), 69 6th graders (mean age= 11;9), 43 7th graders (mean age = 13;0) and 42 8th graders (14;1). Two multiple-choice questionnaires (12 items each) were designed to evaluate the level of understanding of a table (double entry table of frequencies, see Figure 1) and a graph (bar graph, see Figure 2)

All students were asked to individually answer both questionnaires in their classroom. The order (Table - Graph) was counterbalanced in each grade level.

Items were categorized according to different levels of complexity as follows. Three of them correspond to the categories proposed by Friel et al.(2001). We added a new one (basic questions) to attend conventional and basic aspect of representations.

Level 1. Basic questions

Basic conventions of the representations; i.e. to know what is represented in the graph axis or in the table cells.

Level 2. Reading data

Extracting pieces of information that are directly present.

Level 3. Reading between data

Inferring data that are not directly available.

Level 4. Reading beyond data

To be able to relate global trends of data with other knowledge; i.e. to understand why bars are higher in the middle of the graph than in the extremes.

To analyze the main difficulties students presented in understanding the table and the graph in more detail, we interviewed 8 students of the same school (2 students in each grade). In these interviews, we presented the same table and graph with the corresponding questionnaires. For each answer, the interviewer asked the student for an explanation of his/her choice.

Results

Globally, the students showed a rather low level of understanding: for the table, mean of correct responses = 6.95 (standard deviation = 2.09) and for the graph, mean = 6.69 (standard deviation = 2.21).

Looking more closely at the data for the different groups, there were significant differences between age groups: $\chi^2(3) = 20.4$, $p = .001$ for the Table and $\chi^2(3) = 9.438$; $p = .024$ for the Graph. When the four groups were compared, only 5th graders showed a significantly lower mean compared to the other groups in both questionnaires, which was only due to the items that refer to "reading data".

Items theoretically classified as "reading data" (level 2) were the easiest, followed by "reading between data" (level 3) and followed by items of "reading beyond data" (level 4). The only non-expected result was that two items of "basic questions" were more difficult than items of direct lecture.

The qualitative analysis of the interview data enabled us to identify some of the following cognitive challenges the students encountered in the task:

a) Cross organization of data. To understand that each frequency is related to a particular value of gender variable and weight variable.

- b) Dissociation of variables. To understand that each variable is represented differently.
- c) Overcome figurative obstacles. To be able to avoid quick judgments only based in salient aspects of the figure (for example, height of bars).
- d) Meaning of intervals. To understand that the variable weight include ordered intervals that can be integrated (for example for knowing how many students weight less than 35 kg it is necessary to add the frequencies corresponding to two intervals).
- e) Questioning prior knowledge. To be able to accept that data can contradict previous ideas

Discussion and Educational Implications

According our results, the degree of middle school students' understanding of straightforward and common formats of data representation (a table of frequencies and a bar graph with two variables) was not very high. More importantly, we found little progress from 5th to 8th graders. The only exception was the progress from 5th to 6th grade in the most elementary level of interpreting: the ability to directly read data. The other levels of understanding were lower and did not show any progress over the four educational levels.

Some specific cognitive difficulties seem to be the cause of this low level of expertise. Our results lead to a some educational considerations: a) The need to explicitly instruct the specific features of tables and graphs formats (their conventions, their uses, their diversity); b) The importance of working out the main cognitive obstacles through tasks that not only require the specific use tables and graph but also need a metacognitive approach (to be able to know the main conventions of each format and their specific function).

The misinterpretation of space and direction in external representations for data distributions

Stephanie Lem, K.U.Leuven, Belgium; Patrick Onghena, Katholieke Universiteit Leuven, Belgium; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium; Wim Van Dooren, K.U. Leuven, Belgium

External representations are needed when learning or solving problems about distributions of statistical data. Well-known and widely used examples of these representations are histograms, box plots, and descriptive statistics. Besides some anecdotal evidence, not much is known about the way people interpret and use these representations. In this study we asked 125 university students to solve tasks that were specifically constructed to test for misinterpretations concerning the use of space and direction in graphs in which the distribution of one variable is represented (Tversky, 1997). Overall, performance was relatively low. We were able to detect four misinterpretations that can be accounted for by means of Tversky's design principles. This suggests that we can probably assign these interpretation difficulties at least also to the design of the representations and not only to a lack of knowledge or skill of the students. Implications for research and teaching are discussed.

Reasoning about data distributions is an important part of data description and thus of data analysis (Moore, 1990). In addition, understanding data distributions is believed to help understanding theoretical and sampling distributions (Meletiou & Lee, 2002). When interpreting the distributions of statistical data, external representations are necessary. Various representations are available and widely used in education, like histograms and box plots. There is some (mostly anecdotal) evidence concerning difficulties students have interpreting these representations, especially concerning histograms (e.g., delMas, Garfield, & Ooms, 2005; Meletiou & Lee, 2002) and box plots (Bakker, Biehler, & Konold, 2004). The present study aimed at studying these difficulties in a more systematic way by having 125 university students solve tasks specifically designed to detect possible systematic misinterpretations of these representations. The tasks were constructed based on a pilot study and the graph design principles of Tversky (1997).

Tversky's cognitive design principles

Tversky (1997) proposed two important design principles that are based on the way people interact with their environment. First, space in a graph should be used in a natural way. This means that proximity of elements in a graph should correspond to proximity of a property of the represented variable, like value, frequency, or time. The same holds for the area in a graph. Second, people tend to focus more on the vertical than on the horizontal dimension of a graph. In the vertical dimension, the top is naturally better than the bottom: We grow in a vertical direction, if you make a pile of objects the pile will get higher, and so on. This means that we tend to associate higher with "more" or "better".

Tversky's principles about the use of space and direction in graphs can be applied to external representations for data distributions to explain (and maybe even predict) how people interpret these representations. For example, when looking at a histogram or box plot, people will tend to focus at the height of the elements they see. This is relevant for the bars in a histogram, but the height of the box in a (horizontal) box plot is not at all relevant. This way we could, for

instance, predict that when interpreting a box plot, it is not unlikely that students will make mistakes by trying to take the vertical dimension into account.

Method

125 university students (first year Educational Sciences) participated in our study in return for course credit. Participants had all completed the same introductory statistics course covering descriptive statistics and graphical representations, among other topics, at the time of the study. In this paper, we will focus on five tasks from a larger paper and pencil test. These tasks were specifically constructed to systematically detect misinterpretations that were encountered in a pilot study with another group of students and that can be explained by Tversky's principles. Although most of these misinterpretations are specific for certain representations, we randomly varied the representation that accompanied a task between students: histograms, box plots, and descriptive statistics. By doing so, we would be able to see whether a specific misinterpretation was due to a certain representation or due to the task (and the involved statistical concept) itself.

Results

On average, students solved 2.03 out of five tasks correctly. Four systematically occurring misinterpretations were detected. First, when using a grouped histogram or a box plot, students did not take into account that these representations only provide a summary of the data, disguising the exact data: They believed they could see in the graph whether a specific observation was made (Figure 1A). Second, students took the height of the bars in histograms into account to compare the means of two histograms, by stating that the histogram with the highest (modal) bar also has the highest mean, while it is of course the position and overall shape of the distribution that determines the mean (Figure 1B). Third, students thought that Quartile 1, or the beginning of the box in a box plot, was the lowest observed value, thus ignoring the 50% data which is located in the whiskers (Figure 1C). Fourth, again concerning box plots, students mistakenly thought that the area of the box represents the number or proportion of observations that are located in that interval, while in fact each part of a box plot represents 25% of the data (Figure 1D). All these misinterpretations can be accounted for by Tversky's (1997) design principles, as is explained in Figure 1.

Discussion

Our results show that students have various difficulties interpreting representations for data distributions. The design principles of Tversky (1997) can help to explain why these students misinterpreted the representations. Students focused for instance on the height of the bars in histograms instead of taking also the horizontal spread into account or they tried to interpret the area of the box in a box plot. This suggests that the problem with the interpretation of these representations is not (exclusively) caused by a lack of knowledge or experience with these representations, but (also) by the general design of these representations.

For research, these results have various implications. First, when studying students' distributional reasoning, representation is a crucial factor to take into account, because any study would unavoidable rely on some representations. Second, also in other domains of statistical reasoning many representations are used, which makes it interesting to study the occurrence of misinterpretations of these representations too. Third, more effort must be put into studying where these misinterpretations come from and how they can be prevented and remediated.

For education it is also important to know how students interpret representations of data distributions as this gives teachers the opportunity to diagnose, prevent, and remediate possible problems. A fruitful approach might be to use multiple representations of the same data distributions, and to confront the conclusions that are suggested on the basis of one representation with those in another representation, in order to directly address the misinterpretations.

Difficulties in using different representations in laboratory data analysis

Comprehension of Text and Graphics, Mathematics Education, Science Education

Ida Kukliansky, Ruppin Academic Center, Israel

Haim Eshach, Ben Gurion University of the Negev, Israel

The interpretation of data and graphs is a central practice in science. Therefore an important skill needed in the university physics laboratory is the ability to process data obtained from experiments. This study aims to show students' difficulties while dealing with multiple representations of data received from physics laboratory experiments. On one hand there are a lot of benefits in using multiple representations, on the other hand it may pose a serious challenge for learners. 77 university students participated in this study. The findings show that students have significant difficulties in translating information from one representation to another (for example, visual and analytical), and in dealing simultaneously with three different visual representations.

Introduction Given that data obtained from experiments in the physics laboratory need to be processed, the interpretation of data and construction and interpretation of graphs are central practices in science (Bowen & Roth, 2005). According to Bowen & Roth (2005, p. 1064), "physical phenomena are translated through consecutive inscriptions that may include, in increasing order of complexity, such re-representations as maps, lists, tables, totals, means, graphs and equations". In addition, in the process of developing theories, scientists also manipulate data translating one representation into another. Many studies highlight the benefits learners may reap from using multiple representations. For example, Ainsworth (1999) argued that a known representation may help understanding an unknown representation and that representations may complement each other. On the other hand, working within a multi-representational learning environment may pose a challenge to learners, since it requires: 1) understanding the syntax of each of the representations, 2) understanding which part of the topic is being represented, 3) identifying partial correspondence between representations, and 4) translating between representations by finding the similarities and differences in the two systems of representation (van der Meij & de Jong, 2006). This study aims to show the student's difficulties while dealing with multiple representations of data received from physics laboratory experiments.

Method The participants were 77 students: 28 first-year engineering college students, 24 first-year physics university students and 25 university students, having a bachelor's degree, participants of physics teaching certificate program. All of them filled out the questionnaire at the end of their physics laboratory class. The "data analysis" questionnaire, which was developed for our previous study, was used (Eshach & Kukliansky, 2007). It included 20 multiple choice questions referring to different parts of an experiment on Newton's second law. The questionnaire was evaluated by five experts and showed Alpha Cronbach of 0.69.

Results The results showed that the participants had difficulties translating from one representation to another and dealing simultaneously with several representations as we will exemplarily show here. About one fifth of the participants wrongly chose a linear graph instead of a parabolic one describing a cart's movement with constant acceleration on a straight line. About one fourth of the participants experienced difficulties in questions requiring reading of kinematics graphs, where visually represented information needed to be translated to a numerical representation. For example, difficulties were incurred calculating the distance traveled by the cart during a time interval specified by two time points. Another example (Figure 1) where students had to deal simultaneously with three different visual representations was a graph containing 1) a scatter plot describing the results of the experiment's measurements, 2) the regression line calculated and drawn between the points, and 3) the calculated error bar, marked around each point. The participants were asked whether, when applying the regression line, the two relatively distant points A and B needed to be taken into account. Over 70% of the participants chose the wrong options. The correct answer is that the point within the error bar needs to be included, while the one outside the error bar must be re-measured. It seems that students had difficulty to deal simultaneously with three graphical representations and considered only two of them – the scatter plot and the regression line – disregarding the error bar.

Discussion A possible explanation for choosing the linear graphs instead of the parabolic one is that the participants were influenced by the movement which took place on a straight line, and consequently, chose a graph which included straight lines. This attests to students' difficulties in translating information from one representation to another. The difficulties revealed in the questions requiring reading of kinematics graphs where visually represented information needed to be translated to a numerical representation fit the results of other studies in the domain of kinematics graphs, for example Forster (2004). The interpretation of a graph as being a kind of a picture might be due to students' difficulty to „translate“ the distance-time graph to the real life, and instead making parallels between the cart's height and the graph's height. Also, the difficulty to extract the acceleration from a graph describing distance as a function of time stems, probably, from the difficulty to extract a numerical value from a visual representation. In addition, the difficulty to choose a graph, which best describes the distance of the cart traveled during the experiment as a function of time, probably stems from the difficulty of conducting a number of sequential translations which this task demands: translating the distance traveled by the cart as a function of time to an analytical representation – a formula – and then translating it again from the formula to the description of the correct graph as described in Figure 2. The cognitive challenge students face when processing laboratory data (e.g. manipulating raw data, simultaneously representing them in a variety of forms, moving from one representation to another) may explain the difficulties identified in this study which also concur with other studies conducted regarding the handling of several representations simultaneously (Arcavi, 2003). The cognitive barriers in handling with multiple representations have to be taken into consideration when teaching in university laboratories.

SYMPOSIUM

Research on Current Reforms in Teacher Education: Finland, Norway, and Germany

Chairperson: Johannes Bauer, TU Munchen, Germany

Organiser: Johannes Bauer, TU Munchen, Germany

Discussant: Kurt Reusser, University of Zurich, Switzerland

The Bologna-Process of higher education reform has brought an era of tremendous change in higher education structures and processes, including teacher education. The resulting variability in study forms and structures can be interpreted as a natural experiment and comes with great chances for research. Specifically, there is an urgent need for more evidence about the implementation of new study structures, innovations, and about the effects of different approaches to teacher education on prospective teachers' professional development. The aim of this symposium is to bring together empirical studies that take a comparative research perspective on innovations and reforms in teacher education. For this purpose, the symposium focuses particularly on the Scandinavian and German-speaking countries. The Scandinavian countries are renowned for their teacher education. In the German-speaking countries, there is currently a growing interest in exploring new ways of teacher education and in expanding teacher education research. By bringing together the described perspectives, the symposium creates synergies for teacher education policy and practice, as well as for further comparative research on teacher education and higher education in general. These synergies include, firstly, the provision of in-depth knowledge about current forms of, and reforms in, teacher education. Secondly, the symposium contributes evidence about the potential effects of different forms of teacher education and provides a stage for advancing new research questions and study designs.

Practice Architectures of Teacher Induction in Finland

Paivi Tynjala, University of Jyväskylä, Finland; Hannu Heikkinen, University of Jyväskylä, Finland

This study leans on the Finnish reform of the induction phase of teacher education. The national initiative to develop mentoring includes all the teacher education departments of universities and vocational teacher education institutions in Finland. The aim is to implement and further develop an innovation in supporting newly qualified teachers: peer group mentoring. Internationally, this approach is unique. The peer group mentoring model reflects the Finnish approach to educational reform, with a high level of teacher autonomy. The opposite of many mentoring programmes internationally, no elements of assessment, standardisation, or control are involved. Instead, working in a peer-mentoring group offers opportunities to learn together in a supportive environment, promoting time for collaboration and reflection. The model is built on a culture of responsibility and trust that values teachers' professional autonomy. The main aim of this presentation is to study the Finnish reform of induction within the theoretical framework of "practice architectures" (Kemmis & Grootenboer, 2008; Schatzki, 2002). Based on a nation-wide empirical data, it was found that peer group mentoring strengthens the agency of young teachers and supports their professional identity as autonomous teachers.

Aims

The objective of the project Practice Architectures of Teacher Induction (PATI) is to examine the Finnish peer group mentoring model as an innovative form of supporting newly qualified teachers, in contrast to the practice architectures of teacher induction internationally. The main aim is—in line with the European initiatives—to promote a lifelong continuum of teachers' professional development. The common European and global aim is to create conditions that might reverse feelings that contribute to teachers leaving the profession, particularly the feeling of lack of professional autonomy.

The project is based on long-term research on teacher induction at the national and international levels. At the national level, this plan leans on research and development work that has been carried out since the beginning of the century, coordinated by the Finnish Institute for Educational Research (FIER). As a result of this work, a new approach to induction, peer group mentoring model (*vertaisryhmämentorointi*), has been developed and will be disseminated nationally throughout Finland. The project is historical in two ways. Firstly, it has achieved a nation-wide consortium, including all the teacher education departments of universities and vocational teacher education institutions in Finland. Secondly, it marks the first time support for newly qualified teachers is financed so strongly at a national level (www.osaavaverme.fi). Contrary to many of the mentoring programmes world-wide, no elements of assessment, standardisation, or control are involved. Why does Finland seem to end up with such different solutions in comparison to other countries? One of the main aims of this research project is to answer this question. The main research question of this project is the following: How are the practice architectures of teacher induction reform in Finland

constituted within the national and international practice architectures of education and within the global practice architecture of the Global Education Reform Movement (GERM)?

Methodology

Methodologically, the project utilises mixed method research designs, including quantitative data collection and qualitative inquiry. We utilise material that has been collected through a nationwide quantitative enquiry in Finland, the Osaava Verme project. At the international level, the project is rooted in long-standing comparative research within European countries and Australia. The international network NQT-COME has worked with comparative studies on teacher induction since 2005. The Australian contact, since 1995, is Professor Stephen Kemmis (Charles Sturt University). Recently, Stephen Kemmis has been working with the theory of practice architectures. The main aim of this research project is to study teacher induction within this theoretical framework of practice architectures. This research approach can be described as a 'philosophical-empirical enquiry', drawing on contemporary practice philosophy and theory on the one hand, and on the other, exploring the ways that practices develop and are held in place, both in terms of the agency and actions of individuals, and in terms of the cultural-discursive, material-economic, and social-political enabling preconditions that make these practices possible.

Findings

The data shows that peer group mentoring strengthens the agency of young teachers and supports their professional identity as autonomous teachers. The model reflects the Finnish approach to educational reform, with a high level of teacher autonomy. Working in a peer-mentoring group offers opportunities for both new and experienced teachers to learn together in a supportive environment that promotes time for collaboration and reflection. Thus, it is in line with the general pedagogical trends in Finland that emphasise the social construction of knowledge (Heikkinen, Jokinen & Tynjälä, 2010; 2011). At the macro level, we view the Finnish model in the context of a (post-) welfare state, drawing on a Nordic tradition of democracy, and being challenged by neo-liberalist trends. Generally speaking, the Finnish education system has remained quite unreceptive to what is often called the global education reform movement (GERM), which has been adopted as an official agenda or accepted as educational orthodoxy within many education reforms throughout the world, including the USA, the UK, and Germany (Sahlberg, 2010).

Theoretical and educational significance of the research

The scientific impact of this project is a new theoretical understanding of teacher education and induction, based on the theoretical and philosophical literature of practice architectures. The induction phase of a teaching career is understood in the light of the macro and micro level practice architectures locally, nationally and globally. In terms of societal impact, the project will develop better methods to support teachers early in their careers. The results are directly applicable and feasible to all the teacher education institutions, and the results will be disseminated through articles, books and conference presentations. Among the potential end-users, there will be teacher educators, educational administrators, teachers and personnel in schools and educational institutions at various levels of their careers.

The Bologna Reforms in German Teacher Education: A Comparison of Current Study Structures

Johannes Bauer, TU Munchen, Germany; Uta Diercks, Leibniz Institute for Science and Mathematics Education, Germany; Manfred Prenzel, TUM School of Education, Germany

In the present study, we aimed to systematically compare the study structures that are offered by current study programmes in German teacher education. German teacher education is currently characterized by diverse reforms of

study programs as a result of the Bologna-Process of higher education reform. The present study is part of a large-scale longitudinal research project that compares preservice teachers' professional development between different teacher education programs in Germany. Specifically, we aimed to describe the heterogeneity in typical study conceptions in secondary school teacher education on the level of the organization of study components. Furthermore, we evaluated the validity of the denomination of study programs as being profession-oriented versus polyvalent (i.e., aiming at a broad qualification and requiring a late decision for becoming a teacher) in the Bachelor phase. For this purpose, we systematically collected portfolios of documents related to teacher education programs from thirteen German universities. Theory driven content analysis focused on the relative distribution of subject-related, educational, and practical study components over the timeline of a course of study. As expected, the findings revealed a great degree of heterogeneity in the study programs, even between universities within the same federal states. In concordance with current observations, we found that the denomination of study programs as profession-oriented versus polyvalent is often invalid. Most programs, even when espoused to be polyvalent, require an early decision to become a teacher.

Aims

The Bologna-Process of higher education reform poses significant challenges to the reform of study structures (Maassen & Olsen, 2007; Teichler, 2007), which also concern teacher education. In this context, German teacher education is currently characterized by a huge diversity of reform strategies. While some federal states and universities stick to traditional state-examination programs (many in a modularized form), others have introduced Bachelor-Master programs (BA-MA) on an experimental or permanent basis (Terhart et al., 2010). Within the BA-MA programs, there is additional diversity. Some study programs are denominated profession-oriented, that is, they start with courses both in the subjects and in education. Others espouse a so-called polyvalent approach, aiming at a broad qualification in the subjects during the Bachelor-phase. Polyvalent programs are supposed to allow access to a variety of Masters programs next to the teacher-specific Master of Education.

In contrast to the plethora of new study concepts and programs, there is a lack of evidence about their implementation and their differential impact on prospective teachers' professional development. The present study is part of a large-scale longitudinal research project (PaLea) that compares preservice teachers' professional development between different teacher education programs in Germany. For this purpose, firstly, we analyze and compare study structures on a systematic and theory-driven basis; secondly, we investigate a panel of students in order to assess the impact of specific study concepts on students' professional development. The analyses presented here focus on the first strand of inquiry. Specifically, we aim at answering two research questions: (1) How can we capture and estimate the heterogeneity of typical study concepts on the level of the organization of study components? (2) How valid is of the denomination of programs as profession-oriented versus polyvalent? For the sake of reducing complexity, we focus only on secondary teacher education for the academic track here (i.e., the German Gymnasium).

Methodology

The sample for the present study consists of 13 purposefully selected universities that represent all current types of study programs. The design involves a mixed-methods-approach, combining expert-survey and -interviews with a portfolio technique. The portfolios comprise relevant internal and public documents that are related to the investigated teacher education programs (e.g., study and examination regulations, module descriptions, and accreditation applications).

The gathered documents were content analysed with a focus on the relative distribution of subject-related, educational, and practical study components over the timeline of a course of study. To answer Research Question 1, we used a graphical category system to present the study programs in a comparable format. That is, we developed charts that visualize the timeline of study components in relevant parts of teacher education (i.e., studies in subjects, subject didactics, education, and practical studies). Figure 1 illustrates these charts. As for Research Question 2, we used the amount of obligatory educational courses and their location in time during the Bachelor-phase as indicators of polyvalence. Polyvalent programs should require few or no educational studies in the Bachelor-phase and, therefore, a late decision for becoming a teacher (Terhart et al., 2010). Hence, study programs are considered less polyvalent when students have to earn many credit points (CP) in educational courses during the early phases of their studies.

We validated our analyses both internally within the research group and externally through our partners at the universities.

Findings

As expected, our findings revealed a great degree of heterogeneity in the study programs, even between universities within the same federal states. This diversity can be illustrated by looking at two examples. (a) The quantity of obligatory educational studies over the whole course of study ranges from 18 to 56 CP ($M = 39$; $SD = 9$ CP). That is, the minimum and maximum demand of educational studies necessary for becoming a teacher for the academic school track differs approximately by factor 3. (b) The total days of school internships varies between 50 and 110 days ($M = 73.08$; $SD = 18.9$ days). For these practical studies, students receive between 8 and 38 CP ($M = 19.5$; $SD = 7.7$ CP; not all internships are credited).

As for Research Question 2, we found that the denomination of study programs as profession-oriented versus polyvalent is often invalid. Of the seven investigated programs that are espoused to be polyvalent, five require educational and practical studies between 10 and 25 CP ($M = 18.2$, $SD = 6.1$ CP) during the Bachelor-phase.

Theoretical and educational significance

While arriving with a great potential to introduce competence-oriented study programs (Darling-Hammond & Bransford, 2005), the Bologna reforms in teacher education have brought a confusing heterogeneity of reform-approaches, at least in Germany. While there is a fierce debate between sceptics and advocates of the reforms—particularly concerning a polyvalent versus profession-specific orientation—this debate is neither informed by theories on professional learning (Boshuizen, Bromme, & Gruber, 2004) nor by empirical evidence on the actual implementation and impact of the reforms. Our study provides descriptive knowledge that, firstly, may lend this debate a more objective basis. Secondly, our findings add to comparative research on teacher education programs (Zeichner & Conklin, 2005) and the implementation of the Bologna-Process (Maassen & Olsen, 2007). Finally, our study is of practical relevance for teacher educators and students. The indicated diversity is likely to impair the transparency of study demands, as well as student flexibility and mobility, which are major goals of the Bologna reforms. The findings on polyvalence indicate that neither students—who want to choose a course of study—nor comparative studies on teacher education programs should rely on this label.

National Reforms and Local Challenges in Teacher Education

Elaine Munthe, Stavanger University College, Norway; Kari-Anne Svensen Malmo, University of Stavanger, Norway

The implementation of a teacher education reform in Norway started in August 2010. It involves the creation of two distinct programs, as opposed to one program (grades 1-7 and grades 5-10), an increased emphasis on pedagogy, and no other compulsory subjects for grades 5-10, whereas students who choose grades 1-7 study math (30 ECTS) and Norwegian (30 ECTS). It also entails an emphasis on coherence and research.

A national panel was appointed to follow the implementation and development of the reform over the next five years. This paper addresses the initial phase of the reform and will present analyses based on site visits to all 20 teacher education institutes for grades 1-7 and 5-10 in Norway, as well as analyses of student responses to a questionnaire survey conducted in December 2010. Recruitment to the two programs will be compared and discussed, as well as their integrity with reform intentions and local challenges that have surfaced.

SYMPOSIUM

Learning with metacognitive prompts in technological environments: When and how do students benefit?

Chairperson: Bracha Kramarski, Bar-Ilan University, Israel

Organiser: Bracha Kramarski, Bar-Ilan University, Israel
Discussant: Alexander Renkl, University of Freiburg, Germany

Although technology learning environments (TLE) are powerful cognitive tools for enhancing domain knowledge, using such environments is a complex process that demands self-regulated learning (SRL) support. One promising form of SRL instructional support is the use of metacognitive prompts that is an important factor in developing SRL (Zimmerman, 2000).

Our symposium addresses two questions: (a) What characteristics should metacognitive prompts have in order to promote SRL and sustain complex domains knowledge (i.e., mathematics and science) in TLE, and under what instructional conditions? (b) How can their effectiveness be evaluated properly?

The symposium starts with Kramarski and Friedeman's (Israel) study in secondary school that presents the role of solicited vs. unsolicited metacognitive prompts in constructing mathematical knowledge and metacognitive discourse with a multimedia environment. After that Jacobse and de Kock (Netherlands) present a study in Primary school. In their study they try to understand the effects of written and auditive metacognitive hints on mathematics problem solving and metacognitive accuracy in CBL. We close the symposium with a study conducted by Azevedo and his colleagues (Canada) who tested the effectiveness of an intelligent multi-agent hypermedia system (MetaTutor) designed to prompt and scaffold the use of SRL processes during college students' learning about the human circulatory system under one of three conditions: Prompt and feedback, prompt-only, and control. The studies use various measures such as log-file, eye-tracking, think-aloud protocols, facial recognition as well as pretest-posttest data. The presented studies will be discussed regarding their theoretical and educational significance (Renkl, Germany).

Solicited vs. unsolicited metacognitive prompts in mathematical multimedia environment

Bracha Kramarski, Bar-Ilan University, Israel; Sheli Brenner, Bar Ilan University, Israel

Our study examines how the learner's control over choosing metacognitive prompts in a mathematical multimedia environment affected their learning outcomes. We compared the effects of solicited vs. unsolicited metacognitive prompts (based on the IMPROVE-method self-questioning) in a multimedia environment on learners' mathematical problem solving, discourse, use of computer help resources and cognitive load. The participants in the study consisted of sixty eighth-grade students (boys and girls) who were divided into three groups:

1. Group A – The participants received unsolicited metacognitive prompts and explanations in a multimedia environment, which consistently and regularly appeared on the screen.
2. Group B - The participants received solicited metacognitive prompts and explanations in a multimedia environment, which were accessible by clicking on a button at the learner's discretion.
3. Group C - The participants received no metacognitive prompts and explanations in a multimedia environment.

Results: The unsolicited-prompts group had the highest scores in the word problems and transfer tasks of the three intervention groups. They also maintained metacognitive discourse (assessed by thinking aloud protocols) on a higher level, and used the help resources more than the other two groups. Additionally, in the complex topics, which demand high levels of abstract thought, the solicited-prompts group felt they were under heavier cognitive load than the other two groups. Both theoretical and practical applications will be discussed at the conference.

Introduction

Many studies have examined different types of metacognitive prompts in a multimedia learning environment. Prompts provided automatically in a computerized environment, prompts provided upon request and prompts adapted to the learner's needs were examined. Results show that the prompts improved the learner's achievements, encouraged self-regulation of constructive learning and enhanced comprehension of learned material (e.g., Azevedo, Cromley, & Seibert, 2004; Davis, 2003; Ge & Land, 2003; King, 1991; Kramarski & Dudai, 2009; Kramarski & Michalsky, 2009; 2010).

Our study compared the effects of solicited vs. unsolicited metacognitive prompts based on the IMPROVE-method questioning (comprehension, connection, strategy and reflection self-questions; Kramarski & Mevarech, 2003) in a multimedia environment on the learner's outcomes. We examined whether it is more beneficial to give the learner prompts throughout the task and demand they acknowledge every cue, or whether it is preferable to allow the learner to choose when to use the cue and receive support.

In order to examine this issue, the participants were divided into three groups:

1. Group A – The participants received unsolicited metacognitive prompts and explanations in a multimedia environment, which consistently and regularly appeared on the screen.

2. Group B - The participants received solicited metacognitive prompts and explanations in a multimedia environment, which were accessible by clicking on a button at the learner's discretion.
3. Group C - The participants received no metacognitive prompts or explanations in a multimedia environment.

We examined how metacognitive support via solicited and unsolicited prompts in a multimedia environment affects (1) solving word problems; (2) mathematical discourse while problem solving; (3) utilization of help resources (cue – e.g. "imagine the situation in your mind or illustrate it another way," explanation – detailed presentation of the stages or principles of the full solution); and (4) students' cognitive load. A one-tailed hypothesis was formulated only with regards to the two supported groups' achievements vs. the no-support group.

Methodology

The participants consisted of sixty students (boys and girls) randomly chosen from five eighth-grade classes in a junior-high school in the center of Israel. The intervention was executed on heterogeneous pairs in the multimedia environment. Three meetings were held with each pair separately, each meeting approximately 3-4 hours in length. At first the students were told about the multimedia and the metacognitive approach to problem solving through IMPROVE-method questioning and its goals. The students were told to work according to the following stages: 1. Both partners read the problem. 2. One of the partners raises an idea for a solution. 3. Either the other partner agrees with their partner and explains why, or they disagree and suggest an alternative solution. If the partners disagree, each must explain their opinion to the other. Only once they have reached an agreement, they click on the solution and check whether their answer is correct. This method ensured mathematical discourse between the students even when they both agreed on the solution.

The three groups learned about graphs in a multimedia environment which was designed for the study by the second researcher. Each group received identical problems divided into different levels of complexity (e.g., basic graphs, general phenomenon and complex usage of graphs).

Six measures were used: (1) Pre/post-test of problem solving based on the graph unit (PISA, 2003); (2) Novel tasks for transfer ability of problem-solving skills (PISA, 2003); (3) Log-files for using computer help resources; (4) Thinking-aloud protocol during mathematical discourse from cognitive, metacognitive and motivational aspects (Kramerski, in press); (5) Cognitive load (Paas et al., 2003); (6) Personal interview about their feelings regarding the intervention.

Findings

In order to examine the hypotheses regarding the interventions' effects, analysis of variance was computed to compare the groups' problem-solving skills before and after the interventions. In these cases, a two-way ANOVA (groups(3) X time (2)) with time as a repeated measure was computed. When variables were measured only after the intervention, one-way ANOVAs were computed between groups on the mathematical discourse variable. Qualitative analysis of the mathematical discourse was also performed using an analysis schema designed for the study, which examined the cognitive, metacognitive and motivation aspects of the learner when they have difficulty understanding how to solve the word problems.

The results show that:

- (1) The unsolicited-prompts group had the highest scores in the word problems and transfer tasks of the three intervention groups ($F = 4.67$; $\eta^2 = 0.26$).
- (2) The unsolicited-prompts group maintained metacognitive discourse on a higher level than the other two groups ($F = 12.6$; $\eta^2 = 0.63$).
- (3) The unsolicited-prompts group used the help resources more than the other two groups ($F = 11.7$; $\eta^2 = 0.95$). Additionally, a positive correlation was found between the use of help resources and the level of the mathematical discourse, as well as between use of help resources and understanding of the problem ($r = 0.81$).
- (4) In the complex topics in the graph unit, which demand high levels of abstract thought, the solicited-prompts group felt they were under heavier cognitive load than the other two groups ($F = 4.16$; $\eta^2 = 0.62$).
- (5) Qualitative analysis of the discourse and interviews showed that mathematical discourse was directly affected by the number of prompts used. Students who used more clues understood the problems better, dealt better with situations where they did understand the problem, and had higher motivation by the end of the learning session.

Conclusions and Implications

This study has both theoretical and practical applications. It shows the importance of providing the learner with unsolicited prompts as a means for constructing mathematical knowledge. In practice, the study recommends using a multimedia environment for the teaching of mathematics in a challenging manner. It is recommended to continue examining the effects of the various prompts over time, their effects on problem-solving skills and especially on the

learner's cognitive load. It is also important to examine the effects of solicited and unsolicited prompts on the different types of learners, such as higher achievers vs. lower achievers.

Effects of written and auditive metacognitive hints on mathematics performance and accuracy in CBLe

Annemieke Jacobse, University of Groningen, Netherlands; Willem de Kock, University of Groningen, Netherlands

Currently, it is widely recognized that metacognitive skillfulness can greatly contribute to student learning. The call for interventions stimulating metacognitive skills is strong. In this respect, the use of computer programs is an attractive option since computer programs are easy to use in practice and generally appeal to students. Stimulation of metacognitive skills in upper elementary school especially seems to be important in contextually rich domains as comprehensive reading and mathematics. In mathematics, word problems are often used which require students to use various strategies to acquire the correct answer. Students frequently experience difficulties solving such problems. One way to support effective problem solving is providing students with metacognitive hints alongside word tasks in a computer environment. It is hypothesized that practice in a computer environment where cognitive as well as procedural content is practiced will enhance mathematics performance. This is tested in a quasi-experimental design in grade 5 ($N = 106$). A control condition working with a computer program with word tasks is compared with two experimental groups with metacognitive hints added to the word tasks (either auditive or written hints). Preliminary results show positive effects of both metacognitive hint-conditions over the control group. Additionally, effects on metacognitive variables measured by accuracy indexes are discussed.

1. Introduction

Metacognitive skillfulness can greatly contribute to learning. In mathematics, word problems are often used. Primary school students frequently experience difficulties solving such problems. Researchers conclude that difficulties in solving word problems often originate from a lack of metacognitive skills (Hegarty, Mayer, & Monk, 1995; Schoenfeld, 1992; Verschaffel et al., 1999).

One way to support problem solving is providing students with metacognitive hints alongside cognitive content in a computer environment. An important aspect of enhancing transfer is giving students a certain level of control over their instructional decisions (compare Harskamp and Suhre, 2007; Mathan & Koedinger, 2005; Pol, Harskamp, Suhre, & Goedhart, 2008). It is also important that the metacognitive content is explicitly linked to the cognitive content (Azevedo, 2007).

2. Materials

A computer program applied in previous research is used (Jacobse & Harskamp, 2009). In this program, students are free to choose hints themselves. The hints contain metacognitive questions combined with cognitive prompts over the steps: orientation (I read carefully), planning (I make a plan), evaluation (I check my answer) and reflection (What did I learn?).

The hints are presented through text or through audio. Based on previous studies, it is expected that support by a human voice will be more effective (Litman, Rose et al., 2006; Moreno, Mayer, Spires & Lester, 2001).

3. Research questions

What is the effect of practice with a computer program with metacognitive hints on mathematical problem solving of upper primary school students? What is the effect of practice with a computer program with metacognitive hints on accuracy of performance estimation of upper primary school students? Do the effects of the auditive hints differ from the effects of written hints?

4. Method

4.1 Design: The study has been set up as a quasi-experimental design with a division over 3 conditions. The students practiced with the computer program for 2 times 20 minutes per week over 6 weeks.

4.2 Sample: The research is performed in grade 5 with a total number of 106 participants (47 boys / 59 girls). The students had a mean age of 10.91 years ($sd .44$).

4.3 Mathematics: Mathematical problem solving performance is measured with a pre- and posttest of 20 word tasks. Both tests have a good reliability of a .88 and a .86 respectively.

4.4 Accuracy: Accuracy of the estimation of one's performance is indicative for one's metacognitive processes. In this study the students were asked to rate their accuracy by filling in a traffic light with 3 options: red (I am sure I will execute this task wrong), orange (I am not sure whether I will execute this task correct) and green (I am sure I will execute this task correct). The traffic lights were given in reference to 4 different word tasks in the pre- and post-test.

As an absolute accuracy measure bias indexes are calculated. With a correct estimation a score of 0 is given while overconfidence is represented by a positive score and under confidence with a negative score (table 1).

5. Results

Results of an ANCOVA show that the conditions differ significantly on the post-test mathematics ($F=3.15$; $p=.05$). Contrasts show no difference between the two experimental groups with written or auditive hints (mean difference 1.1%; $p=.39$). However, both the text (mean difference 7.9%; $p=.03$) as the auditive condition (mean difference 8.99%; $p=.01$) perform significantly better than the students in the control condition

However, the conditions vary significantly on the bias indexes in the post-test ($F=3.15$; $p=.00$). Contrasts show that there is no difference between the two experimental groups with written or auditive hints (mean difference 3.1; $p=.61$). But both the text (mean difference 14.8; $p=.01$) and the auditive condition (mean difference 17.87; $p=.00$) overestimate their performance to a significantly smaller degree than students in the control group.

Moreover, it was found that overestimation negatively correlates with performance ($r=-.34$; $p=.00$). Thus the more students overestimate their performance, the less well they perform on the test.

6. Conclusion

The effect of practice with a computer program with metacognitive hints on performance and accuracy was tested. Preliminary results make clear that there are no differential effects between the auditive and written metacognitive hints. However, both experimental conditions do have a positive effect on problem solving on the posttest mathematics as well as on the estimation of one's own performance. This is probably due to the fact that the metacognitive questions give students a more realistic insight in their own working method. The relationship between overestimation and performance confirms that the metacognitive skill of accurately estimating one's proficiency indeed is indicative of performance.

Metacognitive prompts in fostering science understanding with MetaTutor

Roger Azevedo, McGill University, Canada; Amy Johnson, University of Memphis, United States; Candice Burkett, University of Memphis, United States; Reza Behnagh, mcgill university, Canada; Zohreh Khezri, Mcgill university, Canada; Marooful Moral, mcgill university, Canada; Engida Gebre, Mcgill university, Canada; Melissa Stern, mcgill university, Canada

This presentation focuses on a laboratory experiment that was conducted to test the effectiveness of MetaTutor, an intelligent and adaptive multi-agent hypermedia system designed to prompt and scaffold the use of self-regulated learning (SRL) processes during learning about the human circulatory system. Sixty-nine ($N=69$) undergraduate students learned about the human circulatory system under one of three conditions: prompt and feedback (PF), prompt-only (PO), and control (C) condition. The PF condition received timely prompts from animated pedagogical agents to engage in planning processes, monitoring processes, and learning strategies and also received immediate directive feedback from the agents concerning the deployment of the processes. The PO condition received the same timely prompts, but did not receive any feedback following the deployment of the processes. Finally, the control condition learned without any assistance from the agents during the learning session. All participants had two hours to learn using a 41-page hypermedia environment which included texts describing and static diagrams depicting various topics concerning the human circulatory system. Log-file, eye-tracking, concurrent think-aloud protocols, and facial recognition data were collected during learning as well as pretest-posttest data. Overall, the results showed significant difference those in the PF condition significantly outperformed those in the other two conditions. Those in the PF condition also spent significantly more time creating relevant sub-goals, spent more time on relevant text and diagrams, and deployed significantly more SRL processes associated with learning gains. These results are discussed in the context of development of a fully-adaptive hypermedia learning system intended to scaffold self-regulated learning.

Aims

This experiment used a mixed-methodology design that combined product and process data to examine the effect of various types of SRL prompting and scaffolding delivered by pedagogical agents (PAs) in an adaptive intelligent hypermedia learning environment. Three learning conditions were used to determine the efficacy of scaffolding SRL through pedagogical agents: 1) prompting with feedback condition (PF), 2) prompting only condition (PO), and 3) no prompting condition (NP). Participants were randomly assigned to one of the three conditions and asked to learn about the human circulatory system using a hypermedia learning environment, MetaTutor, during a two-day experiment. This experiment included the collection of concurrent think-aloud protocols, eye-tracking data, human-agent dialogue, learning outcome measures, log-file data, metacognitive judgments during learning, embedded quizzes, and facial recognition data for affect classification. Due to the complexity of the data analyses, we only report on a few of the log-file variables and the learning outcomes data (presented here as learning efficiency).

Methodology:

Participants: 69 undergraduate students from a large public university in Southeastern US. The mean age of the participants was 23. All participants were paid up to \$40 for completion of the 2-day, 4-hour experiment.

Conditions. We designed and tested three versions of the MetaTutor environment that covered the human circulatory system. In the Prompt and Feedback (PF) version, participants were prompted (by PAs) to use specific self-regulatory processes, and given immediate feedback about their use of those processes. In the Prompt only (PO) version, participants received the same prompts as the ones provided to those in the PF version. However, the agents in the PO version did not provide feedback. The timing of the prompts used in both the PF version and the PO version was adaptive to the individual learner and was determined using various factors of learner interaction, including time on page, time on current sub-goal, number of pages visited, relevancy of the current page for the current sub-goal, etc. In the No Prompt (NP) version of MetaTutor, participants did not receive prompts or feedback. All three versions (PF, PO, NP) provided an SRL palette which allowed participants to self-select any SRL processes they would like to use during the learning session.

Procedure: On day one of the experiment, participants completed a demographics questionnaire and the pretest on the human circulatory system. Learners were given up to 20 minutes to complete the pretest. On day two, the learners engaged in the learning session and completed the posttest on the human circulatory system. Before beginning the learning session, the Tobii T60 eye-tracker was calibrated to each participant individually. All participants were then instructed in the think-aloud procedure and shown a short video demonstrating thinking aloud. Next, each participant was shown another short video explaining and demonstrating the various functionalities of MetaTutor and providing the learners with their overall learning goal. This introductory video also demonstrated the use of an electronic note-taking feature within the environment and instructed the participants to use the peripheral drawing pad if and when they chose to draw. Following the introductory videos, the learners were given two hours to learn about the human circulatory system using MetaTutor. All participants were provided the opportunity to take a break during the two hours, although not all chose to do so. During the learning session, participant verbalizations and gross looking behaviors were recorded using an embedded webcam within the eye-tracker monitor. Immediately after the learning session, participants were given up to 20 minutes to complete the posttest. Finally, all participants were paid and debriefed before leaving the lab.

Findings

Learning Time with the Science Content. Learning time was calculated by summing the amount of time spent viewing the instructional content. Interactions with the agents, in which the instructional content was not visible, were not included in learning time. An ANOVA indicated a significant difference among the groups in learning time, $F(2,66) = 40.71$, $p < .001$, $M = 87.94$, $SD = 12.42$) when compared to both the PO condition ($M = 68.31$, $SD = 11.18$) and the PF condition ($M = 56.84$, $SD = 11.82$), $p < .001$. The PO condition had a significantly longer learning time compared to the PF condition, $p < .001$. **Number of Pages Visited.** An ANOVA indicated a significant difference among the groups in the mean number of pages visited (out of 41 possible) during the learning session, $F(2,66) = 22.17$, $p < .001$, $M = 38.87$, $SD = 3.84$) than both the PO condition ($M = 33.26$, $SD = 8.39$; $p < .001$) and the PF condition ($M = 23.56$, $SD = 10.07$; $p < .001$). The PO condition visited significantly more pages than the PF condition, $p < .001$. **Amount of Time on Pages and Diagrams.** The results indicate that students did not differ significantly in the amount of time spent on each page. On average, students spent anywhere from 60 seconds to 90 seconds on each page ($p > .05$). By contrast, an ANOVA revealed a significant difference among groups in the mean time spent viewing individual diagrams within the environment, $F(2,66) = 3.02$, $p = .052$. LSD Post-hoc analyses revealed that mean diagram view time was greater for the PF condition ($M = 1.05$ min, $SD = 0.99$) compared to the Control condition ($M = 0.54$ min, $SD = 0.46$), $p = .016$. The PO condition did not differ significantly from the remaining two conditions ($M = 0.75$ min, $SD = 0.51$).

Theoretical and Educational Significance

Our study contributes to an emerging body of evidence which illustrates the critical role of SRL in students' learning with hypermedia, and extends recent research regarding the role of intelligent, adaptive scaffolding in facilitating students' learning with hypermedia. Converging temporally-aligned, multi-level data will allow us to examine the critical role of PAs as external regulatory agents whose scaffolding methods facilitate students' self-regulated learning. Lastly, both our product and process data can be applied to inform the design of intelligent multi-agent hypermedia environments as Metacognitive tools to foster learners' self-regulated learning of challenging science topics by providing adaptive scaffolding.

SYMPOSIUM

The role of working memory in the development of mathematical skills

Chairperson: Pirjo Aunio, University of Helsinki, Finland

Organiser: Evelyn Kroesbergen, University of Utrecht, Netherlands

Johannes E.H. Van Luit, Langeveld Institute, Netherlands

Discussant: Liane Kaufmann, UMIT-Private University for Health Sciences, Medical Informatics and Technology, Austria

Recent research has shown that working memory can explain a large part of the variance in mathematical performance. Furthermore, it appears to be one of the causal factors underlying mathematical learning disabilities. In this symposium the role of working memory and executive functions in math is further explored. Three studies will be presented, in which the role of different working memory components or executive functions in math are investigated, in primary schools in Belgium and Germany. The first study focuses on the role of phonological and visuo-spatial working memory in children with dyscalculia (and ADHD). The results show specific deficits in visuo-spatial working memory. The second paper relates working memory and other cognitive factors as magnitude comparison to the children's math performance. Given the found relations between the cognitive factors and math, in the third study it was investigated if these factors could also be related to behavioral manifestations of executive functions. Together these three papers give an important contribution to the question which factors are important in the development of mathematical skills. The results provide suggestions for early identification and possibilities for remediation of mathematical learning disabilities.

Working memory functioning in children with dyscalculia and/or attention deficits

Claudia Maehler, Institute of Psychology, Germany; Kirsten Schuchardt, Institute for Psychology, Germany

Working memory deficits have recently been identified as possible causal factors underlying learning disabilities. Specific patterns of impairment have been found for different learning disorders (dyslexia, dyscalculia). Often these learning disorders come along with attention deficits that also are being associated with working memory problems. Could this comorbidity be caused or at least influenced by common working memory deficits?

This question was examined in a study in which several functions of working memory according to Baddeley (1986) were explored. A working memory battery with tasks for the phonological loop, the visual-spatial sketchpad and central executive skills was presented in individual sessions to children with dyscalculia or attention deficits or both (comorbid group), and to a typically developing control group. Results reveal specific working memory problems in the different groups, i.e. visual-spatial deficits in children with dyscalculia and deficits in executive functioning in children with attention deficits, while comorbidity is influenced by both single disorders. Our results enhance our causal understanding of learning problems and might lead to a more careful interpretation of different learning problems at school followed by more specific interventions.

Aims

Working memory deficits are widely being discussed and identified as possible causal factors underlying learning disabilities. In his influential model of working memory, Baddeley (1986) distinguished three components of the working memory system: the modality-free central executive, which is responsible for the control, regulation, and monitoring of complex cognitive processes, and two modality-specific and limited-capacity components, the visual-spatial sketchpad and the phonological loop. Children with dyslexia or dyscalculia have been examined concerning their functioning of working memory. For children with dyscalculia results were mixed, revealing problems in one, two or all three components of working memory (phonological loop, visual-spatial sketchpad and central executive). However recent studies have reported especially visual-spatial deficits in children with specific arithmetic disabilities. On the other hand working memory problems have also been detected in children with attention deficit (hyperactivity) disorders. Especially impaired selective attention or inhibition - both functions being located within the central executive of working memory - can be observed in children with attention deficit disorders. Yet there is not much research with children who show both learning and attention deficit problems, although there is a significant rate of comorbidity.

Given this theoretical background the central question of the reported study was: What patterns of working memory deficits underlie dyscalculia vs. attention deficits? Or put more precisely: Can specific and distinct patterns be identified in children with dyscalculia or attention deficits or both? The answer to these questions could lead to specific recommendations for schooling and treatment.

Methodology

The reported study compared working memory functioning of children with different characteristics. Four different groups took part in the study: A group of children with maths problems, that fulfilled the criterion of discrepancy between (below-average) school achievement and (normal) IQ and therefore met the ICD-10 criteria of dyscalculia (N = 18); a second group characterized by attention deficits, reported by parents and teachers in a clinical questionnaire

(N = 34); a comorbid group (N = 21) with dyscalculia and attention deficits and a typically developing control group (N = 31). The groups of children with learning and attention disabilities were recruited from our counseling center. All of them attended regular primary schools (2nd, 3rd or 4th graders) but did not reach sufficient achievement. Data were available for intelligence (K-ABC) and scholastic skills (DEMAT, WRT, SLRT) in order to match the groups. The control group and the group with attention deficits performed on average in all these measures, the children with math problems were below average in the DEMAT but did not have problems in reading or writing. A rather long battery of working memory tasks was presented to the children in individual sessions. The phonological loop was examined by different memory span tasks (memory span for images, mono-syllabic and three-syllable words, numbers, mono-syllabic and three-syllable non-words, non-word repetition). To test the visual-spatial sketchpad children were presented with three memory span tasks for locations (corsi-block) and patterns (matrix), and the central executive functioning was tested by a double span, backward spans for words and numbers and a counting span.

Findings

Scores on the working memory tasks were entered in a multivariate analysis of variance with dyscalculia and ADHD as fixed factors. IQ was included as covariate in all subsequent analyses. The significance level for all analyses was set at $\alpha = .05$. For the phonological loop the multivariate main effect for dyscalculia, $F(14, 170) h^3 = .34$, attention deficit, $F(14, 170) = 1.15$, $h^3 = .087$, $p > .05$ and the dyscalculia by attention deficit interaction were not significant, $F(14, 170) = 2.11$, $h^3 = .103$, p proved significant; in contrast, the multivariate main effect for attention deficit, $F(10, 180) h^3 = .048$ and the dyscalculia x dyslexia interaction, $F(10, 180) h^3 = .033$, were not significant. Finally, for the central executive the multivariate main effect for dyscalculia, $F(8, 186) = 1.41$, $h^3 = .057$, $p > .05$. was not significant. In contrast, the multivariate main effect for attention deficit, $F(8, 186) = 2.31$, $h^3 = .090$, $p F(4, 92)$

Theoretical and practical relevance

Taken together, the results reveal special deficits in working memory in the different groups (dyscalculia vs. attention deficit compared to the control group). While children with dyscalculia have problems within the visual-spatial sketchpad, children with attention deficits show problems in the central executive tasks. Comorbidity comes along with the addition of problems in both subsystems of working memory. Our results enhance our causal understanding of learning problems and might lead to a more careful interpretation of different learning problems at school followed by more specific interventions.

Domain-general and domain-specific cognitive correlates of individual differences in arithmetic

Kiran Vanbinst, Katholieke Universiteit Leuven, Belgium; Pol Ghesquiere, Katholieke Universiteit Leuven, Belgium; Bert De Smedt, University of Leuven, Belgium

It is an important goal in educational science to unravel the unique contribution of cognitive factors to individual differences in specific math skills, such as single-digit arithmetic and strategy use. The present study addresses this issue by examining the influence of domain-general cognitive abilities, such as working memory, verbal short-term memory, retrieval from long-term memory and phonological awareness, and domain-specific cognitive skills, such as the representation of numerical magnitudes, on individual differences in single-digit arithmetic and strategy use. Participants were 61 typically developing children of third grade who completed various cognitive measures and an arithmetic task. Findings indicated that particularly the ability to represent numerical magnitudes was strongly and uniquely associated with individual differences in arithmetic and strategy use. Domain-general cognitive correlates only had limited influence on arithmetical performance. These data indicate that the ability to represent numerical magnitudes is an important determinant of individual differences in arithmetic. These findings further suggest that instructional methods or targeted interventions, that aim to reduce or eliminate achievement gaps in school mathematics, should focus on the representation of numerical magnitudes.

Aims

Understanding the origins of individual differences in mathematical achievement represents an important goal in educational science. Previous studies have highlighted that working memory, verbal short-term memory, retrieval from long-term memory and phonological awareness correlate with individual differences in mathematical achievement. In addition to these domain-general cognitive factors, it has been suggested that more domain-specific numerical processing skills, such as the representation of numerical magnitudes, are an important predictor of mathematical achievement. One major limitation to these studies is that most of them have assessed mathematical achievement with general standardized mathematical achievement tests. These tests, however, typically yield a total score which reflects performance averaged over a wide range of mathematical skills. From these general tests it is not possible to determine the cognitive correlates of more specific mathematical skills. The present study therefore aimed

to investigate the cognitive correlates of individual differences in single-digit arithmetic and strategy use during arithmetic.

We focused on single-digit addition, subtraction and multiplication. These problems can usually be solved either by directly retrieving the (correct) answer from long-term memory (retrieval strategy) or by using a procedural strategy, such as counting or decomposing the problem into small facts. There is large inter-subject variability in the use of these strategies (Dowker, 2005), yet the cognitive correlates of these individual differences remain to be determined. This was precisely the aim of the current study.

Methodology

Participants were 61 typically developing children (30 girls, 31 boys), who attended third grade (mean age = 8 years, 8 months; SD = 4 months). All children completed a computerized experimental arithmetic task during which they had to solve single-digit addition, subtraction and multiplication problems. Both speed and accuracy were registered. After each problem, children had to verbally report which strategy they used to solve that problem. Strategies were classified into retrieval (i.e., if the child immediately knew the answer and there was no evidence of overt calculations), procedural (i.e., if the child indicated that he or she used counting or decomposed the problem into smaller sub-problems to arrive at the solution) or other (if the child did not know how he or she solved the problem). We investigated the frequency and efficiency (i.e., the average accuracy and speed) with which these strategies were used.

Domain-general cognitive correlates were evaluated by means of several paper-and-pencil tests. Working memory was measured by means of a listening span task (De Smedt et al., 2009) and verbal short-term memory was assessed using a nonword repetition test (De Smedt et al., 2009). The speed of retrieving information was evaluated by means of a color naming task (Van den Bos et al., 2003) and phonological awareness was assessed with a phoneme deletion task (Boets et al., 2010). Turning to the domain-specific cognitive correlates, we administered a classic computerized number comparison task that measured children's representation of numerical magnitudes, in which children had to indicate the larger of two presented numbers.

Pearson correlation coefficients were calculated to examine associations between arithmetic strategy use and the administered cognitive variables. Additionally, regression analyses were executed to unravel the unique contribution of cognitive factors to individual differences in arithmetical performance and strategy use. To simplify interpretation, the signs of the speeded measures were reversed (thus, a positive relationship indicates that better performance on one task was associated with better performance on the other task).

Findings

Children solved the arithmetic task with a mean accuracy of 95% (SD = 4%) and a mean speed of 3599.45ms (SD = 1128.08 ms).

Only phonological awareness ($r(61) = .35$, $p = .002$, $b = .35$, $t = 2.84$, $p = .002$). Turning to reaction time, children's representation of numerical magnitudes was the sole variable that correlated with speed in single-digit arithmetic ($r(61) = .52$, $p = .000$, $b = .52$, $t = 4.12$, $p = .000$). The average frequencies of retrieval and procedural strategy use were 70% (SD = 14%) and 30% (SD = 18%), respectively. Retrieval strategies were executed significantly more accurately ($F(1,40) = 25.54$, $p = .000$, $\eta^2 = .40$) and faster ($F(1,40) = 133.79$, $p = .000$, $\eta^2 = .77$) than procedural strategies. Because the accuracy of retrieval (M = 97%, SD = 2%) was very high and at ceiling level, only associations with strategy frequency and strategy speed were considered. Surprisingly, no significant associations between strategy frequency and the cognitive variables were found. Working memory ($r(56) = .26$, $p = .010$).

Theoretical & educational significance

The current findings indicate that particularly the ability to represent numerical magnitudes was strongly and uniquely associated with individual differences in arithmetic and strategy use. In contrast to earlier studies, domain-general cognitive correlates, such as working memory, verbal short-term memory, retrieval from long-term memory and phonological awareness, exerted only limited influence on individual differences in arithmetic. These data indicate that domain-specific factors, such as the ability to represent numerical magnitudes, are a crucial determinant of individual differences in mathematical achievement. These findings further suggest that instructional methods or targeted interventions that aim at reducing or eliminating achievement gaps in school mathematics should focus on the representation of numerical magnitudes.

Behavioural manifestations of working memory and inhibition in children with MLD

Annemie Desoete, Ghent University, Belgium; Frauke De Weerd, Ghent University, Belgium

This study investigated working memory, inhibition and fluency skills in 14 average intelligent children with a severe and persistent mathematical learning disability (MD) compared to 17 age-matched typical achieving (TA) children without learning disabilities. All children were followed from kindergarten till grade 4. Behavioral manifestations as well as results on experimental tasks are analyzed in grade 4.

Children with MD had higher behavioral manifestations of inhibition (IN) problems according to parents and teachers. Moreover there was a trend towards behavioral manifestations of working memory (WM) problems according to the teacher. In addition children with MD experienced more problems with categorical but not with verbal fluency (FL) tasks. From theoretical perspective our data underline the importance of IN, categorical FL and WM in the comprehension of problems of children with MD. From educational perspective, it might be a good idea to concentrate on IN, WM, and categorical FL strategies, besides focusing on mathematics. In that way, children might learn to cope their problems in a more profound manner. In the classroom, it could be helpful if children were supported in tasks with a high inhibition and working memory load.

Theoretical Background

Children with a mathematical learning disability (MD) have a significant degree of impairment in the arithmetical skills (with substantially low performances). In addition, children do not profit from (good) help. Recently the problems of children with MD are often explained as results of a 'core' deficit in 'number sense' a term denoting the ability to picture and manipulate numerical magnitude on an internal number line. In addition, several authors also propose that deficits in working memory (WM), inhibition (IN) and speed of processing or fluency (FL) underlie MD. However, most of the studies on WM, IN and FL have been based on experimental and/or performance-based tests only. Consequently, little is known about the behavioral manifestations of WM, IN and FL in daily live.

Aim

We aim to investigate if children with with severe and persistent MD have more problems with FL, WM and IN compared to typical achieving children without learning disabilities. In addition we aim to look for those problems in behavioral manifestations in daily life as well as in experimental tasks.

Method

Therefore, a study was conducted on 31 school aged children that were followed from kindergarten during five consecutive years. Only at least average intelligent children were included in the analyses.

Children were retrospectively classified as having mathematical disabilities (MD) if they had disabilities non-responsive to remediation and if they scored \leq the 25th percentile in at least two grades on tests used to assess procedural or semantic disabilities ($n = 14$). The TIQ on the WISC-III (Wechsler et al., 2002) of the MD children was 104.00 ($SD = 10.41$).

The control group consisted of children who scored $>$ the 25th percentile on all arithmetic achievement tests in all grades, these children were classified as typical achievers (TA, $n = 17$). The TIQ on the WISC-III of the TA children was 106.18 ($SD = 9.86$).

A socio-economic status was derived from the total number of years of education of the parents (starting from the beginning of elementary school). No significant differences in SES were found between the MD and TA groups ($F(2, 25) = 0.55$; $p = NS$), with $M = 15.38$ ($SD = 2.87$) for MD, $M = 15.73$ ($SD = 1.16$) for TA for number of years of scholarship of mothers and $M = 14.92$ ($SD = 3.49$) for MD, $M = 16.00$ ($SD = 2.33$) for TA for number of years of scholarship of fathers.

All children were assessed on WM, IN and FL. Several experimental WM tasks were completed, i.e. Digit Recall and Word Recall (phonological loop), Block Recall (visuospatial sketchpad), Listening Recall, Spatial Span, Backward Digit Recall and Backward Word Recall (central executive). These tasks were computerized versions of subtests of the Working Memory Test Battery for Children (WMTB-C; Pickering & Gathercole, 2001) and the Automated Working Memory Assessment (AWMA, Alloway, 2007). Both WMTB-C and AWMA are based on Baddeley's WM model. Also IN was measured by experimental computerized go-no go, stop signal and stroop-tests. FL was experimentally measured by looking at the verbal and categorical fluency of the children. In addition all parents and teachers completed a questionnaire on behavioral manifestations in daily life of problems with executive functions, namely the BRIEF (Gioia, Isquith, Guy, & Kenworthy, 2000).

Findings

Behavioral results: Children with MD scored according to the parents (on the BRIEF) significant higher on IN ($F(1,28) = 4.76$; p partial $\eta^2 = .14$) and emotion regulation problems ($F(1,28) = 71.08$; p partial $\eta^2 = .26$). Moreover a trend was found for WM problems ($F(1,29) = 2.79$; $p = 0.10$; partial $\eta^2 = .09$) and for planning problems ($F(1,29) = 3.17$; $p = .08$; partial $\eta^2 = .09$).

No significant differences between children with MD and TA peers was found on FL according to the parents and teacher ($F(2,28) = 1.44$; $p = NS$).

Moreover, on the teacher questionnaire children with MD scored significant higher on emotion regulation problems ($F(1,29) = 43.88$; $p_{\text{partial } \eta^2} = .14$) than TA peers. A trend was found for IN problems ($F(1,29) = 37.31$, $p = .10$; $\text{partial } \eta^2 = .07$) and WM problems ($F(1,29) = 13.07$; $p = .10$; $\text{partial } \eta^2 = .06$) in MD children compared to TA peers. Significant correlations were found between the behavioral ratings of teachers and parents on IN ($r = .74$; p

Experimental measures

For the experimental measure of FL, the MANOVA with as dependent variables the number of correct answers on the two verbal fluency tasks and on the two categorical fluency tasks and group (MD, TA) was significant on the multivariate level ($F(4, 26) = 2.97$; $p_{\text{partial } \eta^2} = .31$). Both categorical fluency tasks and non of the verbal fluency tasks were significant on the univariate level.

The data on the experimental measures of WM and IN and the relationships with the behavioural data are currently being analysed but will be presented at the conference.

Theoretical & educational significance

The replication of the deficits in WM, IN and FL in children with DC as found in experimental and clinical studies (e.g., Bull & Scerif, 2001) and the finding that parents gave significantly higher scores on the IN scale and teachers gave higher scores on WM and IN scale of the BRIEF to children with MD than to TA children, might have both theoretical and educational implications for children with MD.

From theoretical perspective our data underline the importance of IN, categorical FL and WM in the comprehension of problems of children with MD. From educational perspective, it might be a good idea to concentrate on IN, WM, and categorical FL strategies, besides focusing on mathematics. In that way, children might learn to cope their problems in a more profound manner. In the classroom, it could be helpful if children were supported in tasks with a high inhibition and working memory load.

SYMPOSIUM

Self-processes under the measurement spotlight

Chairperson: Dennis McNerney, Hong Kong Institute of Education, Hong Kong

Organiser: Dennis McNerney, Hong Kong Institute of Education, Hong Kong

Discussant: Benjamin Nagengast, University of Oxford, United Kingdom

Self-processes such as motivation, self-concept, self-regulation, and self-efficacy have been the focus of considerable research for many years and the results of this research have impacted educational practice in many ways. What is to be noted about much self-processes related research today is the increasing sophistication in the methodological and measurement tools used. Building on the existing substantive-methodological research corpus on self-processes this symposium will focus on a range of methodological and measurement advances by presenting a set of papers utilizing cutting-edge approaches to examine issues of theoretical and applied significance. These include multilevel and multidimensional RASCH, and ESEM -- exploratory structural equation modeling -- an evolving statistical tool that integrates many of the best features of exploratory factor analysis, and confirmatory factor analysis. The paper will make a significant contribution to advances in quality research in the educational and psychological domains.

Exploratory Structural Equation Modeling in motivation and engagement research

Herb Marsh, University of Oxford, United Kingdom; Gregory Arief D. Liem, University of Sydney, Australia; Andrew J. Martin, University of Sydney, Australia; Alexandre J. S. Morin, University of Sherbrooke, Canada; Benjamin Nagengast, University of Oxford, United Kingdom

The most popular measures of multidimensional constructs typically fail to meet standards of good measurement: goodness of fit, measurement invariance, lack of differential item functioning, and well differentiated factors that are not so highly correlated as to detract from their discriminant validity. Part of the problem, we argue, is undue reliance on overly restrictive independent cluster models of confirmatory factor analysis (ICM-CFA) in which each item loads on one, and only one, factor. Here we demonstrate exploratory structural equation modeling (ESEM), an integration of the best aspects of CFA and traditional exploratory factor analyses (EFA). Based on responses to the 11-factor Motivation and Engagement Scale ($n = 7,420$, $M \text{ age} = 14.22$), we demonstrate that ESEM fits the data much better and results in substantially more differentiated (less correlated) factors than corresponding CFA models. Guided by a 13-model taxonomy of ESEM full (mean structure) measurement invariance, we then demonstrate invariance of factor loadings, item intercepts, item uniquenesses, and factor variances-covariances over time. ESEM has broad applicability to other areas of research that cannot be appropriately addressed with either traditional EFA or CFA, and should become a standard tool for use in psychometric tests of psychological assessment instruments.

Participants

Sample comprised 7,420 students (mean age=14.22, SD=1.56; 45% girls) and 1,866 (38.8% girls) students were part of studies in which test-retest data were collected approximately one year later. The average age of the participants was 13.86 years (SD=1.28) at Time 1. Motivation and Engagement Scale (MES) version designed for high school students (MES-HS) comprises 11 motivation and engagement scales, each assessed by four items on with a 7-point response scale: 1 (Strongly Disagree) to 7 (Strongly Agree).

Results

MES Factor Structures and Correlations: ESEM vs. CFA: the critical starting point for the present investigation is the hypothesis that the ESEM model provides a better fit to responses to the MES items than a traditional ICM-CFA model and that it reduces the size of the typically large factor correlations. The ICM-CFA solution provides an acceptable fit to the data (CFI=.935, TLI=.928, RMSEA=.033). However, the corresponding ESEM solution fits the data even better (CFI=.977, TLI=.958, RMSEA=.025). We then proceeded with an evaluation of parameter estimates in the ESEM and ICM-CFA solutions. In terms of the 44 target factor loadings, the sizes of most loadings are substantial. When both target and non-target factor loadings are considered together, the ICM-CFA and ESEM solutions resulted in a very similar pattern with a profile similarity index=.925 suggesting that the ESEM and ICM-CFA factor loadings were highly related.

An evaluation of the factor correlations among the MES factors demonstrates a critical advantage of the ESEM approach over the ICM-CFA approach. Although patterns of correlations between the ESEM and CFA solutions are similar (PSI=.803), the ICM-CFA factor correlations (-.70 to +.77; $|M|$ =.40, SD=.22) tend to be systematically larger than the ESEM factor correlations (-.33 to +.38; $|M|$ =.17, SD=.11). Thus, for example, the negative correlation between Valuing of School and Disengagement is $r=-.70$ based on the ICM-CFA solution but $r=-.33$ for the ESEM solution. Similarly, the correlation between Planning and Study Management is $r=+.77$ for the ICM-CFA solution, but $r=+.38$ for the ESEM solution. These show that the 11 motivation and engagement factors are substantially more distinct in the ESEM solution than in the CFA solution.

Invariance over Time: Latent Mean Structure Approach Marsh et al. (2009, Marsh, Lýdtke et al., in press) suggested that, with some adaptations, it is possible to apply the same set of 13-model taxonomy to test the invariance of ESEM factor structures over with test-retest data. In this longitudinal ESEM application, we constrain an a priori set of 44 cross-wave correlated uniquenesses (CUs) to account for the residual associations between matching items at 44 MES items at T1 and T2. Indeed, when the same item is used on multiple occasions, a correlation between the unique components of each item on the two occasions that cannot be explained by the correlations between the factors is likely to exist. The failure to include these CU is likely to systematically bias parameter estimates such that test-retest correlations among matching latent factors are systematically inflated (Marsh et al., 2004). Thus, we first tested the configural invariance of the responses to the MES with and without these 44 a priori CUs (Models LGI0 and LGI1). Fit indices for Model LGI0 and LGI1 clearly support the inclusion of 44 CUs (.934 vs. .960 for TLI; .951 vs. .970 for CFI; .024 vs. .019 for RMSEA). Consistent with a priori expectations, the test-retest correlations for the 11 MES factors in LGI0 were inflated (.49 to .73, $M = .58$) compared to those in LGI1 (.47 to .68, $M = .55$).

Based on these initial analyses, these a priori CU are included in all subsequent models. Tests of weak factorial/measurement invariance (LGI2 vs. LGI1) demonstrate the invariance of factor loadings over time. Fit indices controlling for model parsimony are slightly better for the more parsimonious LGI2 than for the less parsimonious LGI1 (TLI=.963 vs. .960; RMSEA=.018 vs. .019), whilst the CFIs are the same (.970). Tests of strong measurement invariance (LGI2 vs. LGI5) requires that item intercepts – as well as factor loadings – be invariant over time. Differences in fit indices for LGI5 and LGI2 (.962 vs. .963 for TLI; .018 vs. 0.18 for RMSEA; .969 vs. .970 for CFI) are small in relation to traditional guidelines. Results based on LGI5 support strong measurement invariance of MES responses (and a lack of differential item functioning) and justify the comparison of latent means over time. Tests of strict measurement invariance (LGI5 vs. LGI7) require the invariance of item uniquenesses – as well as item intercepts and factors loadings. Fit indices for LGI7 are comparable to those of LGI5 (.961 vs. .962 for TLI; .967 vs. .969 for CFI; .019 vs. .018 for RMSEA), supporting the more parsimonious model in relation to traditional cut-off values. Results based on LGI7 support the strict longitudinal invariance of the MES responses. The invariance of the latent factor variance-covariance matrix (LGI4 vs. LGI2) provides good support for the invariance of these parameters (Δ CFI=.001, Δ TLI=.000, Δ RMSEA=.000). Models LGI10 - LGI13 each test the invariance of latent means in combination with the invariance of other sets of parameters. In each case, the fits of these models positing no latent mean differences is equally good and acceptable to the corresponding models in which latent mean differences are freely estimated: Δ CFIs (.002), Δ TLIs (.002), and Δ RMSEAs (.000 to .001) based on comparisons of Models LGI10 and LGI5, LGI11 and LGI7, LGI12 and LGI8, and LGI13 and LGI9. These findings suggest that the 11 MES factor means do not differ systematically over time.

In summary, the ESEM approach applied to the motivation and engagement factors based on response to the MES provides reasonable support for the invariance of factor loadings, item intercepts, item uniquenesses, factor variances-covariances, and latent means over time.

Theoretical and educational significance of the research

The present investigation is a substantive-methodological synergy that explores the utility of ESEM in testing (a) the invariance of the factor structure (factor loadings, variances-covariances), (b) the invariance of measurement parameters (item uniquenesses, item intercepts, and latent factor means), and (c) its potential for reducing otherwise high correlations that can pose problems of multicollinearity and threats to support for discriminant validity. These issues cannot be appropriately addressed with either traditional EFA or CFA approaches and so this study offers methodological insights to those interested in measurement and substantive insights in relation to diverse psychological assessment instruments.

Using Exploratory Structural Equation Modeling (ESEM) to Provide Further Evidences on its Construct

Frederic Guay, Laval University, Canada; Feng Bei, Université Laval Québec, Canada; Pierre Valois, University of Luxembourg, Luxembourg; David Litalien, Université Laval Québec, Canada

The Academic Motivation Scale (AMS) is a widely used instrument that measures students' motivation. This instrument is made of 7 factors derived from Self-Determination Theory (SDT). The AMS has been criticized in the past because fit indices from a CFA solution are not very high and that correlations among motivation subscales are not in line with the theory. The goal of this research is thus to verify if some of the problems highlighted in past studies with the AMS are reproduced when using an Exploratory Structural Equation Modeling (ESEM) approach. In two studies, a total of 1417 college students completed the AMS. Fit indices based on the ESEM approach were higher than those from the traditional CFA approach. Correlations from the CFA solution were higher than those from the ESMS one. Interestingly, the correlations were in line with theoretical expectations when based on the ESMS solution, which was not the case for correlations based on the CFA. Results thus provide reasonable evidence that an ESEM approach is more appropriate than a traditional CFA approach when analyzing responses from the AMS. Instead of rewriting old items and/or writing new items to have a more optimal version of the AMS, we rather encourage researchers to use the ESEM method to analyse their data based on the AMS.

Aims

Educational researchers and practitioners recognize that motivation is vital for academic achievement and persistence (Pintrich, 2003). According to Self-Determination Theory (SDT; Deci & Ryan, 2002), motivation is not a global and undifferentiated concept. Rather, motivation is a multidimensional concept that varies in terms of quality. SDT has proposed various types of motivation that vary in quality or in levels of self-determination. From high to low levels of self-determination these are intrinsic motivation (behaviour is regulated by satisfaction and pleasure), integrated regulation (behaviour is congruent with the individual's values and needs), identified regulation (behaviour is regulated by choice and because the activity is important), introjected regulation (behaviour is regulated by internal pressures), external regulation (behaviour is regulated by rewards and punishment), and amotivation (neither intrinsic nor extrinsic). Student motivation is high quality or highly self-determined (i.e., associated with optimal indices of functioning) when primarily based on intrinsic, integrated and identified regulations, and is poor quality or low self-determined (i.e., associated with negative indices of functioning) when based on external and introjected regulations as well as on amotivation. Many efforts have been made to measure these types of regulations at school. In fact, carefully designed instruments are required to make genuine advances in motivational research and theory as well as to derive practical applications. Vallerand and his colleagues (1989) have thus developed the Academic Motivation Scale (AMS), which assesses three types of intrinsic motivation (knowledge, accomplishment and stimulation), three types of extrinsic motivation (identified, introjected and external), and amotivation. Results of Vallerand et al. (1989) provide some support for the factor structure, the construct validity, and reliability of the AMS (see also Vallerand et al., 1992, 1993). In addition, the construct validity of the AMS has been supported in studies focusing on the determinants and outcomes of types of motivation (Otis, Grouzet, & Pelletier, 2005; Ratelle, Larose, Guay, & Senécal, 2005). Recently, Grouzet, Otis and Pelletier (2006) went a step further by showing that the AMS is time and gender invariant. Finally, some studies (Grouzet et al., 2006; Otis et al., 2005; Vallerand et al., 1989) using the AMS have shown proximal motivations on the self-determination continuum (e.g., intrinsic motivation and identified regulation) were more highly and positively correlated with each other than with distal ones (e.g., intrinsic motivation and external regulation). This correlation pattern supports one of SDT's central postulates, which is that the energy underlying a given behaviour varies in terms of quality. Despite these encouraging results, the AMS has been criticized in the past because fit indices from CFA are not very high (Cokley et al., 2001; Fairchild et al., 2005). For example, in Vallerand et al. (1992) the NFI, GFI, and AGFI values are all below .90 when no post-hoc modifications are performed. Furthermore, in some studies the expected pattern of correlation among the AMS subscales was not perfectly

supported. For example, in contrast to what the theory predicts some studies have found strong and positive correlations between the introjection subscale and the three intrinsic motivation dimensions (Fairchild et al., 2005).

The aim of this research is to verify if some of the problems highlighted in past studies with the AMS are reproduced when using a more sophisticated method, namely the Exploratory Structural Equation Modeling approach (ESEM see Marsh et al., 2009). ESEM is more powerful than a traditional Independent Cluster Model (ICM; all indicators load on the respective construct without any cross-loadings) based on a CFA because ESEM takes into account all cross-loadings thereby attenuating correlations among factors. This aim will be accomplished within the confines of two studies.

Method

Study 1 includes 583 college students with a mean age of 19 years (217 girls and 365 boys). Study 2 comprises 834 college students (236 men, 581 women, and 17 without gender identification) with a mean age of 18 years. In these two studies, the French version of the AMS (Vallerand, Blais, Bri  re, & Pelletier, 1989) was used. Participants indicated, on a 7-point scale, the extent to which they pursued their studies out of IM to know, IM to accomplishment, IM to stimulation, identified regulation, introjected regulation, external regulation, and amotivation. There are four items per types of motivation for a total of 28 items.

Results

Fit indices of the traditional CFA-ICM method (study 1: $\chi^2 = 570.651$, $df = 78$, CFI = .932 , TLI = .971, RMSEA = .104; study 2: $\chi^2 = 1129.747$, $df = 85$, CFI = .879 , TLI = .963 , RMSEA = .121) were lower than those obtained from the ESMS solution (study 1: $\chi^2 = 527.813$, $df = 203$, CFI=.996, TLI .993, RMSEA = .052; study 2: ($\chi^2 = 744.365$, $df = 203$, CFI=.996, TLI=.992, RMSEA = .057). For both studies, correlations from the CFA-ICM solution were higher than those from the ESMS one. Interestingly, the expected pattern of correlations among AMS subscales was more supported when correlations are based on the ESMS solution, comparatively to correlations based on the CFA-ICM method. For example, in study 1 and 2 the correlation between introjected and intrinsic motivation is positive with the CFA-ICM solution, whereas this correlation is negative with the ESMS solution as expected by the theory.

Theoretical and educational significance of the research

Based on responses of 1417 college students, results provide very good support for the AMS factor structure and its construct validity as evidenced by the pattern of correlations obtained. Results also provide reasonable evidences that an ESEM approach is more appropriate than a traditional ICM-CFA approach when analyzing responses from the AMS. Thus, instead of rewriting old items and/or writing new items to have a more optimal version of the AMS (Fairchild et al., 2005), we rather encourage researchers to use the ESEM method to analyse their data based on the AMS.

Using Multidimensional Rasch to enhance measurement precision: The case of self-processes scales

Mo Ching Mok, The Hong Kong Institute of Education, Hong Kong; Rebecca Wing-yi Cheng, The Hong Kong Institute of Education, Hong Kong; Dennis McInerney, Hong Kong Institute of Education, Hong Kong

The Rasch model (Bond & Fox, 2007) is a stochastic model that applies the logarithmic transformation to estimate log-odds (logit) of each item and each person. Benefits of the Rasch model over Classical Test Theory approaches in scale construction are well documented, and substantial increase in using the Rasch approach are observed in recent years. Nevertheless, the application of multidimensional Rasch models is still limited, particularly among self-processes studies. Scales designed to measure self-processes are usually multidimensional. The conventional approach is to ignore the correlations among the latent traits in these scales and estimate the scales individually. Such unidimensional approach yields imprecise estimates. This study therefore, sets out to demonstrate how the multidimensional Rasch method can be used to enhance measurement precision. Participants were 8,354 junior secondary students (4,358 males, 3,702 females) who joined a 3-year longitudinal study entitled, "Optimizing the Potential of Hong Kong Students: Harnessing the Interaction between Psychological Variables and Student Achievement". Seven scales, each comprised a number of subscales and designed to measure key psychological variables, were used in the study, namely: Inventory of School Motivation, Academic Self-Concept, Self-Directed Learning, Basic Values, Future Goals, Learning Strategies and Utility Values of Education. Each scale was analysed using both the multidimensional and the unidimensional Rasch approach, and precision of estimates compared using the Averaged Relative Efficiency statistic. Results indicated that the multidimensional approach yielded better measurement precision for the majority of scales, particularly for short scales with a small number of items.

Sample.

Participants comprised the first wave of data collected in 2009-2010 for a 3-year longitudinal study entitled, "Optimizing the Potential of Hong Kong Students: Harnessing the Interaction between Psychological Variables and

Student Achievement". Total sample size comprised 8,354 students between Secondary 1 and Secondary 3. 4,358 of them were males, and 3,702 females.

Instrument.

Seven multidimensional Likert-type scales, each comprised a number of subscales, designed to measure key psychological variables were used in the study. The scales are:

1. Inventory of School Motivation (ISM) – a scale designed to measure eight dimensions of school motivation, namely, task, effort, competition, social power, affiliation, social concern, praise and token (McInerney & Ali, 2006). The ISM has been translated and validated in Chinese populations (Watkins et al, 2003). Factor analytic studies have demonstrated the validity and reliability of the eight measures drawn from the ISM, as well as four second order factors, across a wide range of cultural groups (e.g., McInerney & Ali, 2006; McInerney & Sinclair, 1992; McInerney, Marsh, & Yeung, 2003; Watkins et al., 2003).
2. Academic Self-Concept (SC) – a scale drawn from the Academic Self Description Questionnaire (ASDQ) (Marsh, 1992). The scales measures two dimensions, namely, self-concept in Mathematics, and self-concept in English. The scale has been shown to demonstrated good Rasch reliability and validity with Hong Kong students (Mok, Wong, Lau, 2010).
3. Self-Directed Learning (SDL) – a scale designed to measure three dimensions of secondary students' capacity for self-regulated learning (Mok, Cheng, Moore, & Kennedy, 2006). It includes processes such as planning and managing time, attending to and concentrating on instruction, organizing information, establishing a productive work environment, and seeking help effectively
4. Basic Values (BV) – a scale designed to measure five dimensions of basic values held by secondary students, namely perseverance, self-control, commitment, code of conduct and civic oriented behavior. (REFS)
5. Future Goals (FG) – a scale designed to measure five self-relevant, self-defining goals that provide incentive for action and help give meaning to school tasks. The five dimensions reflect students' pursuit in learning in order to become famous, to establish work or career, wealth, establishing a family and making a contribution to society. (Lee, Liem, & Ortiga, 2009; McInerney & Liem, 2008; McInerney, McInerney, Liem, Ortiga, Lee, & Manzano, 2008)
6. Learning Strategies (LS) - the scale is drawn from the Learning Process Questionnaire (LPQ) (Biggs, 1987). It has two dimensions, namely Deep and Surface scales which measures students' approaches used in their learning.
7. Utility Values of Education (UOE) – perceive values of schooling instrumental to obtaining particular desired outcomes, such as advancing one's fame, career prospects, wealth, establishing a family, and making a contribution to society. The scale has five dimensions. The scale has five dimensions. Fifteen items were written by Dennis McInerney parallel to the fifteen items in the FGO scale to measure students' perception of the importance of schooling to achieve the goals.

Method.

Each scale was estimated using two methods: (a) the multidimensional random coefficients multinomial logit model (MRCMLM; Adams, Wilson, & Wang, 1997); and (b) unidimensional Rasch model. The Average Relative Efficiency (ARE) (Wang, Chen, Cheng, 2004) was used to estimate the ratio of precision of the multidimensional approach over the unidimensional approach averaged over the range of person abilities. Building upon derivation from Wang, Chen, Cheng (2004, pp. 121-122), ARE can be estimated from the equation that shown in Figure 1, where VARIANCEU and VARIANCEM are variances of the scale estimated using unidimensional and multidimensional approaches respectively, and RELIABILITYU and RELIABILITYM are reliabilities of the scale estimated using unidimensional and multidimensional approaches respectively. The ARE ratio indicates the number of times the multidimensional approach is more precise than the unidimensional approach on average.

Results

Results indicated that the multidimensional approach improves measurement precision for the majority of scales, particularly for short scales with small number of items. Results show that that the multidimensional approach yielded better measurement precision for the majority of subscales.

Theoretical and educational significance of the research.

This paper addressed the important issue of precision in the estimation of scale values. Based on responses of 8,354 secondary students and 7 scales, which involved 30 measurement subscales commonly used by self-researchers, results provided strong evidence in support of substantial gain in precision if analysis capitalized on multidimensionality of the scales. The Average Relative Efficiency (ARE) ratio averaged 1.33, which means that the multidimensional approach was on average 33% more precise than the unidimensional approach. The maximum ARE ratio was 1.91. Putting in efficiency terms, this means researchers might be able to administer much shorter surveys (on average using only 2/3 of the original items) to achieve the same level of precision if multidimensional approach was used. This study further found that the gain was most significant for scales with small number of items. Given that

concepts involved in self-research are often complex and hierarchical in nature, we encourage researchers to consider exploiting correlations among subscales by using multidimensional approach for better measurement precisions.

SYMPOSIUM

Understanding the relationship between the approximate number system and mathematics education

Chairperson: Camilla Gilmore, University of Nottingham, United Kingdom

Organiser: Matthew Inglis, Loughborough University, United Kingdom

Discussant: Bert De Smedt, University of Leuven, Belgium

Recently psychologists have proposed that there is an innate cognitive system that is involved in the development of early number skills. Using the so-called Approximate Number System (ANS) humans and some non-human animals are able to form rapid, but approximate, representations of numerical stimuli. The system can be used to support various numerical operations including the comparison, addition and subtraction of two numerosities. It has recently been found that the accuracy of children's ANS representations are related to their achievement on whole-number problems of the sort taught in school mathematics. This result raises the possibility that the ANS may be implicated in the development of formal mathematical competence.

This symposium brings together three presentations which shed further light on the link between the ANS and school mathematics. Siegler, Thompson and Schneider present evidence which demonstrates that the previously established link between the ANS and school mathematics that has been demonstrated in the context of whole numbers also extends to the domain of fractions. Inglis, Attridge, Batchelor and Gilmore find that, although there is a correlation between ANS accuracy and mathematics achievement in children, the same relationship does not hold in adults. They discuss possible developmental trends that might account for such a discrepancy. Finally, Piazza reports new data from an Amazonian indigene population which she argues demonstrates a causal relationship between ANS accuracy and mathematics achievement. The discussion following the presentations will focus on prospects for how early mathematics education can be developed using our expanding knowledge of the ANS.

Magnitude Representations Are Central to Fractions Understanding

Robert Siegler, Carnegie Mellon University, United States; Clarissa Thompson, The University of Oklahoma, United States; Michael Schneider, ETH Zurich, Switzerland

Numerical magnitude representations are related both causally and correlationally to a wide range of mathematical capabilities. However, past research has left unclear whether these relations are unique to whole numbers or whether magnitude representations play a similarly central role in understanding fractions. The present findings indicate that accuracy of fraction magnitude representations are closely related to both fractions arithmetic proficiency and overall mathematics achievement test scores. The fraction magnitude representations also account for substantial variance in mathematics achievement test scores beyond that explained by fraction arithmetic proficiency. Considerable learning was found to occur between 6th and 8th grade, though even 8th graders were far from proficient in understanding fraction magnitudes and fraction arithmetic. Instructional implications of the findings are discussed.

Introduction

Numerical magnitude representations are central to mathematical knowledge. Strong correlations are present between accuracy of magnitude representations and many other important aspects of numerical knowledge: arithmetic, counting, estimation, categorization, memory for numbers, mathematics grades, and mathematics achievement test scores (Booth & Siegler, 2006; Geary et al., 2007; Halberda, Mazzocco, & Feigenson, 2008; Opfer & Thompson, 2008; Opfer, Thompson, & Furlong, 2010; Schneider et al., 2008; Thompson & Siegler, 2010). Experiences designed to improve accuracy of magnitude representations also improve other numerical competencies, including counting, categorization, and ability to learn answers to novel arithmetic problems.

The vast majority of studies examining numerical magnitude representations have focused on whole numbers. This is understandable, given the importance of whole numbers, but restricts generality of understanding of numerical cognition and its development.

In the present research, we examine whether theories and methods that have proved useful for studying the development of knowledge of whole numbers (e.g., privileged domains, neo-Piagetian, and information-processing theories) can also increase understanding of the development of fractions knowledge. The main goal of the research is to increase understanding of developmental and individual differences in acquisition of fractions knowledge and thus to provide an empirical base for theories of numerical representation that are more general and more differentiated than existing theories.

Method

To pursue this goal, we examined 6th ($N = 24$, Mean age = 11.69 years) and 8th graders' ($N = 24$, Mean age = 13.69 years) performance on three tasks that assessed knowledge of fractions magnitudes—estimation of the position of fractions on number lines ranging from 0-1 and 0-5 and magnitude comparisons of fractions in the range of 0-1—and also the students' performance on fractions arithmetic (e.g., addition, subtraction, multiplication, and division) and standardized mathematics achievement tests. Immediately after children answered number line estimation and fractions arithmetic problems, they described the strategies used to solve each problem.

Results and Discussion

Most 6th and 8th graders showed little understanding of fractions magnitudes on number line estimation and magnitude comparison problems. Performance was better for fractions in the 0-1 range than in the 0-5 range; for example, percent absolute error ($PAE = [?Child's Answer - Correct Answer?] / Numerical Range$) on number line estimation was 13% on 0-1 number lines and 24% on 0-5 number lines. For purposes of comparison, kindergartners' PAE on whole number estimation for the 0-100 range tends to be around 20%. Eighth graders' number line estimation ($PAE = 15\%$) was more accurate than that of 6th graders ($PAE = 22\%$), showing that fractions knowledge is still developing years after fractions are first taught. The mean of the median solution times across number lines and age groups was 9.5 s suggesting that fractions number line estimation is a controlled, strategic process, unlike whole number estimation. The magnitude comparison task in the 0-1 range yielded similar findings: 6th graders were correct on 68% and 8th graders on 79% of comparisons.

Considerable strategy use was apparent on fractions number line estimation, particularly on 0-5 number lines. Moreover, frequency of strategy use was related to accuracy of estimates. Two main types of number line estimation strategies were numerical transformation strategies (e.g., participants transformed presented fractions to more convenient numbers), and number line segmentation strategies (e.g., participants generated subjective landmarks on number lines to locate fractions). The most common numerical transformations were rounding the fractions, simplifying them, or translating them into different forms. The main number line segmentation strategies were division into halves; division into fifths or whole number units; division into units corresponding to denominators; flawed approaches; and none/unknown. Transformation and segmentation strategies were used on some trials by the majority of 6th and 8th graders. Among 8th graders, 75% of children used a numerical transformation strategy at least once on 0-1 number lines, as did 79% on 0-5 number lines. The corresponding percentages for the segmentation strategy were 83% and 92%. Among 6th graders, 50% used a numerical transformation strategy at least once on 0-1 number lines, as did 58% on 0-5 number lines. The corresponding percentages for segmentation strategies were 83% and 79%.

The most striking findings concerned consistency of individual differences. Tables 1 and 2 show the quality of fractions magnitude representations correlated highly with both fractions arithmetic accuracy and with overall Pennsylvania System of School Assessment (PSSA) Math achievement test scores. Correlations were even higher than ones previously observed with whole numbers (e.g., Booth & Siegler, 2006). Accuracy of number line estimation was related to math achievement test scores above and beyond variance in achievement test scores that could be accounted for by arithmetic performance, but arithmetic proficiency did not add to variance that could be accounted for by number line estimation.

Children used four main fractions arithmetic strategies across trials: 1) correct strategies yielded the correct answer if executed correctly ($M = 49\%$), 2) independent whole numbers strategies involved performing the arithmetic operation on the numerators and denominators separately ($M = 27\%$), 3) wrong fractions operation strategies involved treating the numerator or denominator incorrectly in a way that would be correct for that component in a different fractions arithmetic operation (e.g., maintaining the common denominator on a multiplication problem) ($M = 15\%$), and 4) none/unknown strategy ($M = 6\%$). Idiosyncratic incorrect strategies accounted for 3% of trials.

In summary, the mental number line is a useful construct for thinking about whole number magnitude representations, and the present findings indicate the mental number line is also a useful way of thinking about fractions magnitudes. In the United States, fractions instruction emphasizes part-whole interpretations (e.g., $1/5$ is one of five slices of pizza) far more than other interpretations (Ni & Zhou, 2005). Our results imply emphasizing fractions are measurements of quantity (e.g., $1/5$ is 20% of distance from 0 to 1 on a number line) might improve learning about fractions and dispel common misconceptions like thinking about numerators and denominators as independent whole numbers. Magnitude representations are a key component of fractions understanding, just as they are with whole numbers.

Non-symbolic number acuity correlates with formal mathematics achievement: But only in children

Matthew Inglis, Loughborough University, United Kingdom; Nina Attridge, Loughborough University, United Kingdom; Sophie Batchelor, University of Nottingham, United Kingdom; Camilla Gilmore, University of Nottingham, United Kingdom

The process by which adults develop competence in symbolic mathematics tasks is poorly understood. Non-human animals, human infants, and human adults all form non-verbal representations of the approximate numerosity of arrays of dots, and are capable of using these representations to perform basic mathematical operations. Several researchers have speculated that individual differences in the acuity of such non-verbal number representations provide the basis for individual differences in symbolic mathematical competence. Specifically, prior research has found that 14-year-old children's ability to rapidly compare the numerosities of two sets of colored dots is correlated with their mathematics achievements at ages 5-11. Here we demonstrate that although when measured concurrently the same relationship holds in children, it does not hold in adults. We propose that, if indeed non-verbal number representations are the cognitive basis of mathematical skill, they fulfill a bootstrapping role and do not hold the key to explaining the wide variety of mathematical performance levels in adults.

The ability to deal accurately with numerical quantities is a fundamental goal of education. On a daily basis we are asked to make judgments about concepts that are expressed numerically, but what is the cognitive basis for such abilities? Recently it has been proposed that the answer to this question is an innate and inexact analog system known as the Approximate Number System (ANS). This evolutionarily ancient system enables us, for example, to rapidly decide, without explicitly counting, which of two orange trees has the greatest number of fruit, or which of two herds has the greatest number of gazelle. The ANS supports approximate numerical operations, such as comparison and addition, on both visual and auditory arrays, in adults, children and perhaps even in non-human animals (e.g. Dehaene 1992, 1997).

Halberda et al. (2008) gave 14-year-old children a non-symbolic comparison task, calculated each individual's ANS acuity (a measure of the accuracy of their ANS), and related these to standardized mathematics achievement tests which had been taken at ages 5-11. They found strong relationships between these two measures at each testing-point, and raised the possibility that the ANS is implicated in the development of symbolic mathematical skills.

Both ANS acuity (Halberda & Feigenson, 2008) and symbolic mathematics achievement are developmental and consequently, since Halberda et al. did not test their participants concurrently on the two tasks they were investigating, it is possible that their ANS measure (taken at age 14) had been influenced by developmental patterns not reflected in the standardized mathematics achievement tests taken by participants at ages 5-11. Some support for this possibility comes from Luculano, Tang, Hall & Butterworth's (2008) finding that the non-symbolic addition performance of 8-9 year old children did not correlate with their exact symbolic addition performance.

To investigate this issue, in Experiment 1 we measured the ANS acuity of 39 schoolchildren aged 7.6-9.4 years ($M=8.4$) using a nonsymbolic comparison task. In 128 trials children were asked to select the more numerous of two arrays of coloured dots (stimuli were prepared following the method of Pica et al., 2004). We also measured participants' scores on the calculation subtest of the Woodcock Johnson III Tests of Achievement and the matrix reasoning subtest of the Weschler Abbreviated Scale of Intelligence.

Participants who appeared to be using strategies based on continuous quantities correlated with number (i.e. those who were not using their ANS) on a majority of trials were eliminated from the sample. In addition we removed participants whose performance was not above chance. This left 24 participants for the main analysis. Accuracy rates were subjected to an ANOVA with ratio as a within-subjects factor. There was a significant effect of ratio, $F(3,69)=11.76$, $p<.001$, and a significant linear trend, $F(1,23)=50.32$, $p<.001$. As is characteristic of the ANS, accuracy rates were lowest when the two numerosities had ratios close to 1. ANS acuity (as measured by w parameters, Barth et al., 2006) was found to negatively correlate with WJ-Calc scores, after controlling for age-standardized WASI scores, $r=-.57$, $p=.005$. In other words, high ANS acuities (w parameters close to zero) were related to high scores on the Woodcock-Johnson calculation subtest.

These results, found using concurrent testing, replicated Halberda et al.'s (2008) findings. They suggest that a child's ANS acuity is related to their achievement in symbolic mathematics. To explore this relationship further, and in particular its developmental trajectory, in Experiment 2 we investigated whether a similar relationship holds in adults.

Participants were 101 adults aged 18-48 ($M=23$). Participants were undergraduates or postgraduates studying a variety of disciplines and had varying levels of experience of mathematics (from school to PhD level). Again

participants were asked to select the larger of two arrays of coloured dots in 120 trials. Scores on the WJ-Calc and WASI matrix reasoning subtests were again recorded.

Accuracy rates were subjected to an ANOVA with ratio as a within-subjects factor. Again, responses showed the ratio effect characteristic of the ANS, $F(2,136)=103.9$, $p<.001$, and a significant linear trend, $F(1,68)=220.3$, $p<.001$. Unlike in Experiment 1, ANS acuity, as measured by w parameters, was not found to correlate with WJ-Calc scores, after controlling for age-standardized WASI scores, $r=+.17$, $p=.184$. This non-significant positive correlation was found to be significantly different to the negative correlation found in Experiment 1, $z=3.26$, $p<.001$.

These results are consistent with the suggestion that the ANS could act as a bootstrapping mechanism for mathematical competence. It is possible that the ANS starts the development of symbolic number skills, but then co-develops with symbolic mathematics until some point during adolescence where the two systems decouple (presumably because the ANS reaches ceiling level). Studying the developmental pattern of the relationship between ANS acuity and mathematics achievement as participants gain in maturity and mathematical experience may ultimately shed further light on the cognitive basis of the wide range of numerical operations that we each perform during day-to-day life; and, consequently, how effective instruction can be designed to help support children's mathematical development.

Neurocognitive start-up tools for symbolic number representations

Manuela Piazza, Neuroimaging Unit, Neurospin Center, France

Attaching meaning to arbitrary symbols (i.e., words) is a highly complex and lengthy process. In the case of numbers it was previously suggested that this process is grounded onto two early pre-verbal systems for numerical quantification, the approximate number system (ANS or "analogue magnitude"), and the object tracking system (OTS or "parallel individuation"), which children are equipped with prior to symbolic learning. Each of these systems is based on dedicated neural circuits, characterized by specific computational limits, and undergoes a separate developmental trajectory. Reviewing the available cognitive and neuroscientific data, I argue that evidence is more consistent with a crucial role for the ANS, but not the OTS, in the acquisition of abstract numerical concepts that are uniquely human.

Attaching meaning to arbitrary symbols (i.e., words) is a highly complex process that takes years during infancy. In the case of numbers it was previously suggested that this process is grounded onto two early pre-verbal systems for numerical quantification, the approximate number system (ANS or "analogue magnitude"), and the object tracking system (OTS or "parallel individuation"), which children are equipped with prior to symbolic learning. Each of these systems is based on dedicated neural circuits, characterized by specific computational limits, and undergoes a separate developmental trajectory. Here I review the main features of these two systems, and critically review the available cognitive and neuroimaging evidence supporting the idea that they play a foundational role in symbolic numerical acquisitions.

I define two criteria which I claim being definitional for a foundational system:

1. Its integrity should be a necessary (albeit not sufficient) condition for efficient learning. Thus, early impairments in a foundational system should systematically lead to specific learning difficulties (in this case, dyscalculia).
2. Its computational constraints should predict speed and ease of cultural knowledge acquisition in children.

I also assess a third criterion, which is a less stringent one, stating that traces of the computational constraints of foundational systems may be found even in adults after successful learning. Even if this criterion is not a necessary

one, because a foundational system might be qualitatively transformed or totally replaced during development, its fulfillment supports a key role of the system for the cultural acquisition of more elaborate concepts.

Following these criteria, the provided literature review indicates that:

1. there is ample evidence that ANS, but not the OTS is impaired in dyscalculia,
2. detailed analysis of the developmental trajectory of the ANS, but not of the OTS, suggests a direct explanation of the seriality and timing of lexical acquisition of the first number words in children before they learn the counting procedures.

Finally, behavioral and neuroimaging data indicate the presence of computational signatures of the ANS, but not of the OTS in symbolic numerical representations.

I thus conclude that evidence supports a crucial role for the ANS, but not the OTS, in the acquisition of abstract numerical concepts that are uniquely human, and offer possible speculations on the neural mechanisms by which symbolic number acquisitions may stem upon pre-existing pre-verbal representation of numerical quantity. I finally provide novel behavioral data gathered from the Mundurucu, an Amazonian indigene population with a reduced numerical lexicon and highly variable access to education. We test a group of Mundurucu subjects spanning a large age range (from 4 to 60 years of age) with a test devoid of verbal content, developed to assess the ability to compare sets on the basis of their approximate number of elements. On an individual subject basis, using the accuracy distribution on this test, we derive, using a very simple psychophysical model, the acuity of the internal representation of number (ANS acuity). Results show that, in the absence of mathematical education, even adult subjects remain at a very coarse ANS acuity, equivalent to that observed in 6-year-old Western children. Conversely, in Mundurucu subjects who received some schooling, the acuity of the approximate non-symbolic number sense is drastically refined. Indeed, years of schooling remain a significant predictor of the ANS acuity even after controlling for the effect of age. Our results establish that training with numerical symbols and exact numerical concepts in turns deeply modify the pre-existing evolutionary ancient pre-verbal quantity representations. Direct demonstration of a causal link between pre-symbolic and symbolic numerical thinking might be of capital importance for developing efficient educational and re-educational programs, which could capitalize on the use of intuitive pre-verbal numerical abilities to strengthen the efficacy of the more classical training methods.

SYMPOSIUM

Language and Thought Provoking Interaction: Powerful Features for Teacher Professionalization

Chairperson: Resi Damhuis, Marnix Academie, University of Professional Education, Netherlands

Organiser: Resi Damhuis, Marnix Academie, University of Professional Education, Netherlands

Discussant: David Clarke, University of Melbourne, Australia

Teacher-pupil interaction is a key factor in pupils' successful learning according to sociocultural and constructivist approaches to learning (Alexander, 2008; Barnes, 2008; Mercer & Littleton, 2007; Renshaw, 2004; Wertsch & Toma, 1995). The thought-provoking requirement of such interaction has been accentuated (Marzano & Kendall, 2007). Moreover, from a language acquisition perspective (Gass & Mackey, 2006; Snow, 1999; Swain, 2005), interaction must be language provoking: it must allow for ample, varied language production by the children. The provocative aspect is crucial: optimal learning occurs when high support is combined with high challenge (Mariani, 1997). Such teacher behaviour requires new ways of thinking, doing and using language (Gibbons, 2010). School needs to prepare pupils for interaction: the heart of collaborative learning and living in a global society. Aiming at teacher professionalization, we investigate ways in which teachers can be supported to change the nature of interaction towards being more language and thought provoking.

The symposium brings together three research approaches that aim at identifying the ways teachers and pupils realize such interaction: teacher-pupil and peer dialogic interactions when implementing an innovative educational programme in primary school; teacher-pupil group interactions in primary school before and after teachers followed an intensive interaction training; and teacher-second language learner dyadic interaction in secondary school before and after student teachers experienced Socratic Dialogues. Though performed in different settings, all studies address the thought provoking as well as the language provoking aspects of interaction. They share a common goal: to reveal important features of interaction that are concrete enough to incorporate in teachers' professional development.

Scaffolding Dialogue for Reasoning in Primary Students

Sylvia Rojas-Drummond, National Autonomous University of Mexico, Mexico; Kissy Guzman, Universidad Nacional Autonoma de Mexico, Mexico; Guadalupe Vega, El Colegio de Mexico, Mexico; Haydee Pedraza, Universidad Pedagogica Nacional, Mexico; Maricela Velez, Universidad Pedagogica Nacional, Mexico

In this paper we analyzed the nature and quality of primary students' and teachers' dialogic interactions while working on collaborative writing projects. In particular, we investigated how teacher-student and peer interactions could create 'Intermental Development Zones' and 'dialogic spaces', as scaffolds for enhancing children's understanding, reasoning and learning. Our work is underpinned by a socio-cultural perspective to conceptualizing development, and contributes to recent efforts to understand and promote 'dialogic approaches' to learning and teaching in classroom settings (Alexander, 2008; Mercer, 2000; 2009; Wegerif, 2007).

Children created their projects in the context of an educational programme called Learning Together, designed to: 1) foster the development of 'learning communities' within which children and adults co-construct knowledge, and 2) promote social, cognitive, psycholinguistic and technological abilities in the children. Participants were 120 Mexican sixth graders (11 to 12 y.o.), and their corresponding teachers. Four focal triads were randomly selected and their work was videotaped during selected sessions. This enabled micro-genetic analyses of adult-child and peer dialogic interactions during different phases of the creation of the projects.

To illustrate our approach to the in-depth microanalyses of such interactions, we present some representative examples of dialogues by specific focal triads and their teacher. Results exemplify ways in which these dialogical interactions can lead to elaborate ways of understanding and reasoning by the children. The theoretical and practical contributions of the findings are discussed in relation to understanding and enhancing oracy and literacy, as well as reasoning and learning in school settings.

In this paper we analyze the nature and quality of primary students' and teachers' dialogic interactions while working on collaborative writing projects using ICT. As part of these projects, triads of children carried out investigations, produced and published articles in magazines and delivered conferences. Throughout this process, we investigated how teacher-student and peer interactions could create Intermental Development Zones (Mercer, 2000) and 'dialogic spaces' (Wegerif, 2007), as scaffolds for enhancing children's understanding, reasoning and learning.

Our work is underpinned by a socio-cultural approach to conceptualizing processes of development, teaching-and-learning. Inherent in this approach is the notion that if we are to understand the nature of thinking, learning and development we need to take account of the intrinsically social and communicative nature of human life. Socio-cultural theory posits that intellectual development is achieved through dialogue and that education is enacted through the interactions between students and teachers. These reflect the cultural and social practices of the communities in which educational institutions exist.

Research in the field of educational practices has explored two functional aspects of interaction and communication in classrooms. The first is teachers' use of dialogue as a means for promoting guided participation and 'scaffolding' children's learning and development (Rogoff, 1990, 2003; Rogoff, Goodman-Turkianis & Bartlett, 2001; Wells, 2001). The second is the potential value of peer group interaction and talk as another means of promoting these processes, but in a more symmetrical environment (Mercer & Littleton, 2007).

In the work reported we attempt to integrate these two lines of research by analysing the quality of both teacher-student and peer dialogic interactions in child-led discussions. Our work contributes to recent efforts to understand and promote 'dialogic approaches' to learning and teaching in classroom settings. Dialogic interactions are conceived as those that harness the power of talk to stimulate and extend children's thinking. These interactions are collective, reciprocal, supportive, cumulative and purposeful (e.g. Alexander, 2008; Lyle, 2008; Mercer, 2009; Mercer & Littleton, 2007; Skidmore, 2006; Wegerif, 2007).

The context of the study: The Learning Together Programme

Children created their writing projects in the context of an innovative Mexican educational programme called Learning Together (Rojas-Drummond et al., 2010). The programme has been designed to: 1) foster the development of 'learning communities' within which children and adults co-construct knowledge, and 2) promote social, cognitive, psycholinguistic and technological abilities in the children, and particularly oral and written communication.

Throughout the implementation of the programme, teachers use diverse instructional strategies. These include: (a) the creation of situated learning environments rich in social interactions where the diverse activities carried out are meaningful and mediated by cultural artefacts, including ICT (Cole, 1996; Lave & Wenger, 2001; Wegerif & Daws, 2004); (b) guided participation between experts and novices where adults scaffold children's learning activities (Bruner, 1978; Koole & Elbers, 2010; Rogoff, 1990); (c) dialogic styles of interaction between adults and children and among peers which encourage elaborate ways of thinking and understanding (Alexander, 2008; Mercer, 2009; Rojas-Drummond, 2000; Wegerif, 2007); and (d) collaborative learning where peers engage in diverse creative projects and

joint problem solving (Littleton, Miell & Faulkner, 2004; Rojas-Drummond et al., 1998; Rojas-Drummond et al., 2008; Rojas-Drummond et al., 2010).

Method

Participants were 120 Mexican sixth graders (11 to 12 y.o.) from four groups, and their corresponding teachers. These groups participated in the Learning Together Programme over the academic year. Children worked in triads to carry out investigations on a topic of their choice, and eventually produced an article, which was published in a popular magazine. They also created a conference supported by a Power Point presentation and delivered it to an audience conformed by members of the whole learning community, as part of a cultural fair. Throughout the implementation of the programme, adults supported children's activities so that they learned: a) to use exploratory talk for discussing and solving problems effectively; b) to comprehend and produce texts of different genres, and c) to use ICT for specific purposes. Four focal triads were randomly selected and their collaborative work was videotaped during selected sessions of the creation of their project. This enabled micro-genetic analyses of adult-child as well as peer dialogic interactions during different phases of the overall process. (In total, 32 hours of videotape furnished the corpus of data). In addition, the consecutive and final drafts of the digital texts produced by the four focal triads were collected and integrated into this corpus.

Analysis of data

For data analysis, all videos were transcribed verbatim together with a description of the context, following procedures developed by Edwards and Mercer (1987). Videos and transcripts were consecutively analyzed qualitatively using methods created by Mercer and colleagues (e.g. Mercer, 1995, 2000; Mercer & Littleton, 2007). These were complemented by qualitative and quantitative analyses by adapting methods derived from the Ethnography of Communication (Hymes, 1972; Saville-Troike, 2003). In particular, we employed the system of hierarchical and nested units of analysis they proposed to investigate conversations among participants, consisting of communicative acts embedded in communicative events, which are in turn part of broader communicative situations. In addition, the texts produced by the focal triads were analysed qualitatively and quantitatively, using rubrics designed ex-professo.

Results

To illustrate our approach to the in-depth microanalyses of adult-child and peer interactions, we present some representative examples of dialogues by specific focal triads while working on various phases of their projects. These include events with and without the presence of an adult. Results exemplify ways in which these dialogical interactions can lead to elaborate ways of understanding and reasoning by the children. They also depict the dynamic and iterative nature of some inter-textual processes holding between oral and written modes of communication.

The theoretical and practical contributions of the findings are discussed in relation to understanding and promoting oracy and literacy, as well as reasoning and learning in school settings. In particular, results can inform the development of teacher professionalization and training programmes, so that teachers can be encouraged to engage in effective dialogic interactions which enhance their students' intellectual development.

How to Measure Quality of Content in Language and Thought Provoking Interaction in Primary School

Resi Damhuis, Marnix Academie, University of Professional Education, Netherlands; Akke De Blauw, Amsterdam Center for Language and Communication, Universiteit van Amsterdam, Netherlands

Interaction conducive to learning should be thought provoking (Mercer & Littleton 2007) and language provoking (Swain 2005). Primary school teachers often find it difficult to effectively change their classroom interaction with pupils. Therefore, we developed a training built around teacher-pupil interaction strategies that promote language and thinking. The training combines team meetings and individual coaching sessions on the basis of video recordings. Key strategies concern promoting pupils' extensive output and high quality content of the output. Teachers choose learning objectives individually.

Our research focuses on measuring quality of the content of teacher-pupil interaction. First qualitative explorations indicated that the combination of thought provoking prompts and the quality of children's thinking on the one hand and the extent of children's output on the other hand might well represent differences in interaction quality.

The present paper investigates whether these features can be operationalized for quantitative analyses, in order to assess efficacy of the training and to improve teacher professionalization. We selected four participants with the learning objective 'encouraging a higher level of thinking'. Video recordings before and after the interaction training are compared. 'Encouraging a higher level of thinking' was operationalized in three variables. 'Extent of pupils' output' was measured by an ordinal scale.

The results reveal that features of extent and quality of interaction content can indeed be operationalized for quantitative analysis. The participant teachers did acquire strategies to enhance language and thought. We propose to incorporate the combination of these features explicitly in teacher training.

Aims

The current perspective on learning requires children to participate actively in the learning process. Teacher-pupil interaction constitutes a crucial part of that learning process, providing that this interaction is thought provoking (Barnes, 2008; Mercer & Littleton, 2007; Renshaw, 2004; Wertsch & Toma, 1995). Moreover, from a language acquisition point of view the interaction must be language provoking (Gass & Mackey, 2006; Snow, 1999; Swain, 2005). Thus, interaction that is conducive to learning should be language provoking and thought provoking. Pupils who get accustomed in school to learning and thinking together through interaction, will be better equipped for the increasingly global society in which they will live their adult lives.

Although most teachers are aware of the need for children's active participation in interaction, they often lack the competencies and strategies to effectively change their classroom interaction towards being more language and thought provoking. Demonstrations of good practice are available on video on sites such as 'Thinking Together' (Mercer c.s.) and for the Netherlands LEONED. However, studying models and examples is insufficient to fully acquire the desired strategies. Intensive practice and coaching is required (Damhuis & De Blauw, 2008a). The general goal of our research is to design a training that enables teachers to bring about language and thought provoking teacher-pupil interaction, in order to increase pupils' learning.

Context of the study

We developed a training that includes team meetings, intensive practice of interaction strategies promoting language and thinking in real classroom discourse combined with coaching based on video recordings of classroom discourse (De Blauw & Damhuis, 2006; Damhuis & De Blauw, 2008b). The training covers approximately half a year. In the training a checklist of child behaviour favourable for language and cognitive development and corresponding teacher strategies is presented (Damhuis, De Blauw & Brandenbarg, 2004). The two most important categories of this checklist contain strategies that promote pupil's extensive output and high quality content of pupil's output. Extensive output refers to language production that exceeds a minimal response, and may stretch for several utterances. High quality content goes beyond labelling or describing, and involves reasoning, concluding and other complex cognitive language functions. In the training participants select their own learning objectives from these checklist categories and practice them in their own classrooms. Coaching addresses these points specifically.

Method

The central research question is: to what extent do teachers who follow an interaction strategies training, change their interaction behaviour? An earlier investigation focused on strategies that promote extensive production by the pupils (Damhuis et al., 2009). The study we report on here, focuses on the quality of the content.

First qualitative explorations indicated that the combination of thought provoking prompts and the quality of children's thinking on the one hand and the extent of children's output on the other hand may represent differences in quality of interaction (De Blauw et al., 2010). These two features and their combination are potentially concrete enough to be useful in teacher professionalization.

The specific research question in this paper is: how can we measure the quality of the content of teacher-pupil interaction in the light of language and thought provoking interaction? We distinguish three sub questions:

- Can features of extent and quality of the interaction content be operationalized in a way that allows for quantitative analysis?
- Do these features reveal differences between interactions before and after the training, qualitatively as well as quantitatively?
- Could these features be implemented in teacher professionalization?

This paper presents a pilot analysis. Data are used from an in-service course in Dutch primary schools and from a pre-service course in a Dutch teacher training college for primary education. The data consist of video recordings of classroom interaction between (student) teacher and pupils. We selected two student teachers and two teachers who had chosen as their specific learning objective 'encouraging a higher level of thinking'.

Analysis

Video registrations before and after the interaction training are compared. A ten minute 'window of opportunity' of each video was transcribed and analyzed. Strategies from the checklist with respect to thought provoking prompts and children's thinking were operationalized in three variables: line of enquiry (see also Alexander, 2004), negotiation of meaning, and complex cognitive language functions (see also Anderson & Krathwohl, 2001; Bloom et al., 1956).

Extent of pupils' output was measured by an ordinal scale from minimal answer to extensive answer, analogous to the extent aspect of our question analysis in earlier research.

Results

Student teachers and teachers do acquire strategies to enhance language and thought. Most participants engage their pupils regularly in long lines of enquiry, and do so more after the course than before. A discriminating factor between the two student teachers after the course is the combination of 'complex cognitive language functions' and 'extensive output'. Only one student teacher succeeded after the course in realizing interaction in which pupils were challenged to think and to talk extensively. For the two teachers this combination characterises the difference between their interactions before and after the course. It was not found before the course, but both teachers were successful with it after the course.

Theoretical and educational implications

So we conclude that extent and quality of interaction content can indeed be operationalized for quantitative analysis. This opens up the way to collect evidence for the efficacy of the training. However, the quantitative generalization does not completely cover perceived differences in the quality of the interactions. This has implications for teacher professionalization. It seems to be worthwhile to incorporate the combination of features explicitly in teacher training. The general idea can be emphasized and illustrated in the team meetings. In individual coaching sessions the trainer has to focus specifically on the qualitative features of the actual interaction.

Making Teacher Interaction with Second Language Learners More Thought and Language Provoking

Dubravka Knezic, University of Applied Sciences Utrecht, Netherlands; Maaïke Hajer, University of Applied Sciences, Netherlands; Ed Elbers, Utrecht University, Netherlands; Theo Wubbels, Utrecht University, Netherlands

Research on individual teachers' interaction with individual second language learners in content area classes reveals the need for a specific teacher sensitivity to these learners' language needs (Elbers, Hajer, Jonker, Koole & Prenger, 2008; Gibbons, 2006, 2009). This paper presents research aiming at increasing this sensitivity through fostering teachers' language awareness and improving their interactional skills by means of an intensive experience of Socratic Dialogue. Contrary to Socratic method, the Socratic Dialogue is a group dialogue developed by Nelson (1920's) and Heckmann (1981) in which the participants guided by a facilitator and a number of ground rules strive to reach a consensus in answering a fundamental question. Results show a significant improvement at a macro and micro level of interaction in the learning talks between content teachers and secondary education second language learners before and after the teachers followed a course in the Socratic Dialogues. The MANOVA analysis established significant effects: teachers' micro-scaffolding behaviour has improved. The micro level Conversation Analysis looked at the teacher and pupil behaviour together and revealed some aspects of successful learning talks.

Aims

The paper presents research aiming at increasing learning chances of secondary school second-language learners in dyadic interaction with content teachers. Drawing on sociocultural views of learning as a situated dialogic inquiry (Wells, 1999; Mercer & Littleton, 2007; Wegerif, 2007) we focused on the dialogic skills and strategies student teachers would need in order to respond sensitively to the special linguistic learning needs of their second language learners such as slowing down the pace of the talk (Cazden, 2001) and paying attention to language. We also regarded the language and thought provoking teacher moves such as eliciting the learner's contribution, probing his/her statements and asking follow up questions. These strategies, also recognized in micro-scaffolding (Gibbons, 2009), happen to be extensively employed in the Socratic Dialogue. Contrary to Socratic method, the Socratic Dialogue applied here is a group dialogue developed in the tradition of Plato's Dialogues by Nelson in the 1920's (translated by J. Kessels, 1984) and Heckmann (1981). In the Socratic Dialogue, the participants strive to reach a consensus in answering a fundamental question under the guidance of a facilitator and a number of ground rules. So, the central question was: "Will the quality of student teachers' interaction with their second language learners improve after they had taken part in a series of Socratic Dialogues?" In order to measure the improvement of the dialogic strategies we developed a concept of Teacher Pupil Learning Dialogue and the accompanying scoring scheme. We defined the Teacher Pupil Learning Dialogue (henceforth TPLD) as a dialogue between the teacher and the pupil in which the teacher evidently tries to scaffold the pupils' learning by means of a number of strategies: asking open-ended and follow up questions, slowing down the pace of the dialogue, inviting the pupil to contribute, allowing the pupil time to express him/herself, checking for understanding and paying attention to language. Empirical research on the Socratic Dialogue (Griessler, Littig, Husing, Zimmer, Santos, Munoz, et al., 2004; Pihlgren, 2008) pointed out the positive effects of the Socratic Dialogue on communicative skills. Also Knezic, Wubbels, Elbers and Hajer (2010) recommend integration of the Socratic Dialogue in teacher education. Thus encouraged, we employed this substantive method for

an integrative development of teacher dialogic skills and their thinking and beliefs about some essential aspects of communication in learning and instruction.

Method

Quasi-experimental research was conducted among pre-service Bachelor and in-service Master of Education students in various content subjects in secondary education. The participants were matched into two groups of 16. The experimental group participated in a series of seven weekly two-hour Socratic Dialogues. Three measurements, before, after and a 3-month follow up, consisted of audio files of ten minute TPLDs. The participants were asked to carry out TPLDs individually with three second language learners for each measurement, outside the classroom with the task to check the learner's knowledge of subject matter discussed in class and increase that knowledge.

Analysis

The data was analysed in two steps and at two levels: a macro level analysis of 202 TPLDs followed by a micro level analysis of a selection of 20 TPLDs. Trained observers, their inter-rater reliability established, scored the TPLDs by listening and using the TPLD scoring scheme. They used the TPLD scoring scheme in two steps: they first scored each of the eight separate features and then answered the main question regarding the overall quality of the TPLD. The scores were analysed by means of a two-way between groups MANOVA. The micro level analysis was carried out on a selection of 20 TPLDs by 10 teachers that had been scored as most different in quality on comparison for each teacher before and after the intervention. The micro level analysis employed conversation analysis and focused on the organisation of the talk, the teacher's responsiveness to the learner's level of knowledge and understanding and his or her addressing different levels of thinking skills (Marzano & Kendall, 2007; Wells & Arauz, 2006).

Results

The MANOVA of the macro level quantitative data established a statistically significant effect regarding the overall quality of the talks, $F(1,58) = 7,18$, $p = .01$; partial eta squared = .11. Also the separate features of the TPLD scoring scheme representing the micro-scaffolding strategies appeared to have developed after the intervention. So, not only the overall quality of the TPLDs improved after the intervention, but also the separate features representing micro-scaffolding strategies developed. These results give us reason to believe that the improvement of the overall quality of the TPLDs and the student teachers' micro-scaffolding behaviour was due to the Socratic Dialogue course. Preliminary results of the qualitative analyses have revealed the emergence of the following patterns in the successful TPLDs: the pupil 'leads' the TPLD, teacher addresses higher level thinking skills (Marzano & Kendall, 2007) and the pupil employs them, the continuity of the TPLDs is sustained by placing connections between the concepts discussed, and the teacher's feedback is contingent (Van Lier, 1996).

Theoretical and educational implications

The research contributes to the theory of scaffolding learning and language development. Its educational significance lies in the empirical evidence of improving the teachers' interactional skills in the context of scaffolding the pupil's learning. As such, it informs teacher education programmes aiming at developing teacher dialogic skills indispensable for successful micro-scaffolding.

SYMPOSIUM

Orchestrating learning in TEL – more than just a metaphor?

Chairperson: Bram De Wever, Ghent University, Belgium

Organiser: Bram De Wever, Ghent University, Belgium

Raija Hamalainen, University of Jyväskylä, Finland

Discussant: Rosamund Sutherland, University of Bristol, United Kingdom

Orchestrating learning (e.g. Dillenbourg, Jarvela, & Fischer, 2009) is a term that has lately been introduced within the research area of Technology-Enhanced Learning. The aim of orchestrating TEL is to engage groups in shared knowledge construction processes and high-level collaborative learning (based on research findings) in naturalistic learning settings with the aid of teacher's pedagogic design and timely support. However, since this term is used by a variety of researchers with different research backgrounds, this symposium aims to bring contributions from different strands of TEL research together, in particular research from a cognitive and from a socio-cultural perspective.

The symposium comprises one theoretical paper and two empirical ones.

The theoretical paper focuses on the metaphor of "orchestrating" learning activities. The opportunities and challenges of drawing on "orchestration" as a concept to advance research are discussed and two theoretical and methodological routes are identified and presented.

The first empirical study focuses on orchestrating learning in a formal, inquiry-oriented curriculum unit employed in high school biology classrooms, which used a cognitively oriented, rather quantitative methodology to analyze collaboration processes and their effects on individual knowledge construction.

In the second empirical paper, quantitative and qualitative content analyses are used to study the group knowledge-construction processes. The former analyses study whether shared knowledge construction in two different research settings differ, whereas the latter aim to develop understanding of how teachers' activities enhance high-level knowledge construction.

Both empirical papers present different ways to orchestrate learning activities.
Ros Sutherland will discuss the links drawn between the papers.

Orchestrating learning in TEL: Theoretical and methodological considerations to advance research

Carlo Perrotta, Institute of Education, United Kingdom; Michael Evans, Virginia Tech, United States; Raija Hamalainen, University of Jyväskylä, Finland; Ingo Kollar, University of Munich, Germany; Bram De Wever, Ghent University, Belgium

"Orchestration" is an emerging metaphor in the field of Technology-Enhanced Learning (TEL), reflecting a possible moment of evolution in the design of future learning environments moving from explicit, rote scripting to emergent, interpretive scoring. Scoring, the act of composing an original work in musical terminology, aligns well with the orchestration metaphor while connoting a degree of artistic license granted, in this case, to the teacher or designer. Scoring is submitted to provide contrast to scripting while intending to spur dialogue around the general metaphor. However, with this change arise warranted questions as to whether this advancing metaphor can do sufficient justice to the complexity of teaching and learning in technology-enhanced settings than those already available. Therefore, the main aim of this paper is to summarise the opportunities and challenges noted while exploring the potential of orchestration as a framework or lens to advance research in TEL. In this paper we describe at least two routes that lead to distinct scenarios, each characterised by more or less specific research questions and methodological considerations. Our primary suggestion is that orchestration as a metaphor has the potential to advance research and illuminate important issues in TEL; this is deemed possible on the condition that the metaphor is not used to advocate a new paradigm, but used selectively in two complementary ways:

- (a) a reflection on, and an expansion of, the scripting approach;
- (b) a framework to develop a more critical type of inquiry around the function of teachers in the educational process.

Metaphors can serve empirical investigation when they help generate research questions (Sfard, 1998). Scripting is one such example. The notion of a script originated as a metaphor to equate sequences of tasks and interactions in a computer-supported environment to the behaviours prompted and coordinated during a staged performance.

More recently, however, an existing metaphor (e.g., Brown, 1992) has received renewed attention in TEL, namely the "orchestration" of learning activities (e.g. Dillenbourg, Jarvela, & Fischer, 2009). However, questions arise as to whether this metaphor can do sufficient justice to the complexity of learning in technology-enhanced settings contributing insights beyond those already available. Therefore, the main aim of this paper is to summarise the opportunities and the challenges noted while exploring the potential of orchestration as a concept to advance research, opening previously unconsidered or unexplored avenues.

This proposed agenda is possible by tracing at least two routes that lead to different scenarios, each characterised by specific research questions and methodological considerations. Through this exercise we will attempt to provide a tentative evaluation of orchestration as a means to bring different approaches in TEL under a common paradigmatic umbrella.

The first route is that of isomorphism, that is, the degree to which interactions, tasks, tools and roles in a learning context can be mapped over the kinds of interactions, tasks, tools and roles in an actual orchestra. For instance, the teacher in a classroom may be seen as the conductor, the students may be regarded as members of the orchestra, their learning activities may be understood as an analogue to the music produced by the orchestra, and digital technologies may be viewed as instruments. Further, all must be set to a particular tempo that best benefits teaching and learning.

In line with the original theorisations from Dillenbourg et al. (2009), it is possible to investigate such isomorphic relation by asking whether and how the coordination of the cognitive, pedagogic and technological dimensions across multiple social planes (individual work, group work and whole-class activities) can be equated with the coordination

that is carried out in an orchestra. Isomorphic equation is also useful in exposing the limits of the metaphor when applied to a classroom context; although both classrooms and orchestras are social entities organised around common roles, activities and resources, classrooms typically are much more dynamic and variable, as learners do not all learn at the same rate and in the same way (Watts, 2003).

The second theoretical and methodological route is that of socio-cultural and socio-historical critique, in which orchestration can be regarded as a response to an emerging trend within academia, but also in the wider educational discourse in Europe, North America, and perhaps globally, that seeks to reinstate the centrality of the teacher in contexts characterised by ubiquitous technology, open-access resources, and by many cognitive and socio-cultural factors in need of, indeed, orchestration. Dillenbourg (2010) explicitly refers to orchestration as a “teacher-centric approach” in order to stress the elements of proactive guidance and scaffolding, which may be interpreted as an implicit remark on the frustration with unguided discovery- or experientially-based instruction (see e.g. Kirschner, Sweller, & Clark, 2006).

From such a perspective, the overarching research question would focus on methods of critical social analysis to identify and overcome the barriers to teaching as orchestration in real classrooms. In most educational systems, teachers do not have control over important dimensions of their profession; therefore their role as orchestrators appears seriously compromised. Nowhere is this more evident than with respect to educational assessment, as key aspects of student performance are usually evaluated in the context of summative external exams, which have a negative “backwash effect” (Boud, 1995) on how interactions and tasks are planned and coordinated in many real classrooms (the infamous “teaching to the test”).

In conclusion, we suggest that orchestration has the potential to advance research and illuminate previously under-investigated issues in TEL research. This is possible when the metaphor is used with moderation, not as a completely new paradigm, but in two complementary ways:

(a) A reflection on, and an expansion of, the scripting approach. Whereas scripts aim to foster collaborative learning by shaping the way in which learners interact with one another, orchestrating learning may include collaboration scripts but also consider more complex learning settings (e.g. different social planes, internal and external resources of learning, etc.). From this perspective orchestration may advance research by exploring the different facets and iterations of an overarching research question: how can we develop tools and principles that allow teachers to adaptively choose and implement collaboration scripts on the basis of what different naturalistic settings and different social planes demand?

(b) A framework to develop a more critical type of inquiry around the function of teachers in the educational process. Orchestra conductors are usually highly prestigious figures; hence, orchestration can be a means for reconfiguring teacher professionalism and stimulate an overdue public debate around the necessity to raise the social status of the profession, by acknowledging and empowering the crucial role of teachers as facilitators and, indeed, orchestrators of very complex dynamics. The main aim of such an approach would therefore be to shift the balance from “teacherless” instructional design to the actual educational practice of coordinating and scaffolding learning in highly diverse and dynamic classrooms.

Orchestrating web-based inquiry learning with small-group and classroom scripts

Ingo Kollar, University of Munich, Germany

Christof Wecker, University of Munich, Germany

Sybille Langer, Ludwig-Maximilians-University of Munich, Germany

Frank Fischer, Universität München, Germany

Online search skills may be regarded as an important component of scientific literacy. A promising approach to support learners in acquiring online search skills is web-based inquiry learning. However, to be successful, inquiry learning typically needs to be scaffolded. In a quasi-experimental 2x2 factorial study, we examined to what extent a small-group collaboration script (present vs. not present), two versions of a classroom script (version A: all online search activities located on the small group level vs. version B: online search activities alternately on the small group and the plenary level) and their different combinations may foster high school students' acquisition of online search skills in a web-based inquiry curriculum unit on Genetic Engineering. Results indicate that employing a classroom script that alternates search activities between the small group and the plenary level can make further structuring on the small-group level (through a small-group collaboration script) obsolete. Adding a small group collaboration script to the alternating classroom script did not lead to further improvement, possibly because the modelling phases that were part of the classroom script reduced time for actually performing the proposed search strategy. Currently, process analyses are performed to find evidence to confirm or disconfirm this interpretation. Nevertheless, this study demonstrates that the effectiveness of inquiry learning can be improved by scaffolding, especially when the used scaffold includes activities on the plenary level.

Online search skills are an important component of both information literacy (Kafai & Bates, 1997) and scientific literacy (Laugksch, 2000). However, searching and finding credible and scientifically acceptable information on the Web to form a well-grounded position in a science debate (e.g., whether pre-implantation diagnostics should be allowed or not) is a challenging task, especially for high school students (Lazonder, 2005).

One promising approach to foster high school students' online search skills is (web-based) inquiry learning. Yet, as research has repeatedly shown, inquiry learning needs to be properly scaffolded (de Jong, 2006). When implemented in the classroom, two types of scaffolds can be distinguished: (a) scaffolds on the classroom level (e.g., classroom scripts that distribute learning activities over the different social planes of the classroom such as plenary level, small group level, individual level; see Dillenbourg & Jermann, 2007) and (b) scaffolds on the small-group level (e.g., collaboration scripts that specify, sequence and distribute learning activities and roles among the members of a small group; see Kollar, Fischer & Hesse, 2006).

In this study, we examined the effects of a small-group collaboration script (present vs. not present) and two different versions of a classroom script (online search activities to be conducted in small-groups only vs. alternately in small-groups and in the plenary) and their different combinations in a web-based inquiry learning curriculum unit on the acquisition of online search skills. We expected the combination of a small-group collaboration script and a classroom script that alternated between plenary and small group search activities to produce the highest skill levels.

174 9th graders participated in the study, which was conducted within regular Biology lessons. Students were equipped with laptops and worked on a web-based inquiry learning curriculum unit asking them to develop a well-grounded position towards whether Genetic Engineering should be allowed or not. The learning phase spanned seven regular Biology lessons and included three online search activities. We implemented a quasi-experimental 2x2-factorial design with the independent factors "small-group collaboration script" (present vs. not present) and "type of classroom script" (small-group level only vs. alternations between small-group and plenary level). Classes were randomly assigned to experimental conditions. Both independent variables were manipulated during each of the three collaborative search phases. In all groups, a software tool called S-COL (Wecker et al., in press) was used to allow for collaborative browsing. The small-group collaboration script was implemented as a plug-in in the S-COL software which distributed prompts related to the current step in the search process (selecting search terms, selecting links from a hit list, finding information on a chosen website) among the two learning partners, for example pointing to the scientific quality of a web site. The type of classroom script was also manipulated during collaborative online search. In the classroom script that alternated plenary and small-group search activities, single steps (such as "selecting search terms", or "finding information on a website") were modeled in front of the class before this activity was to be conducted by the dyads. In the classroom script that located online search activities solely on the small-group level, no such modeling on the plenary level took place and the dyads performed all online searches on the small group level.

Online search skills were measured by the students' performance in an individual test that asked them to describe how they would use the Internet to form a position in a different science debate. The responses were analyzed using a

coding scheme capturing adequate steps and important quality characteristics during successful online search. The agreement of two independent coders determined on a subset of the material was sufficient (ICC = .83).

An ANCOVA with the scores in the online search skills post test as the dependent variable, the small-group collaboration script and the classroom script and classes nested within the two kinds of instructional support as independent variables, and prior online search skills as covariate showed a significant interaction effect ($F(1,165) = 12.41$; $p < .01$; partial $\eta^2 = .07$): Students with the classroom script that alternated between plenary and small-group activities, but without the small-group collaboration script reached the highest skill levels; students with the classroom script that located search activities solely on the small-group level and without a small-group collaboration script reached the lowest scores. Students equipped with the small-group script were in between, no matter with which of the two classroom scripts they had learned. Thus, combining modeling phases (as part of a classroom script) and small-group collaboration scripts may produce have called “over-scripting” effects (Dillenbourg & Jermann, 2007). Process analyses are underway to test this assumption. Overall, the results demonstrate that online search skills as an important component of both scientific and information literacy can be fostered by inquiry learning, but that careful orchestration by the teacher is needed. To provide structure, learning activities should obviously be alternated between the different social planes of the classroom. If this is done, further structuring on a small-group level may become obsolete.

Orchestrating collaboration in 3D learning space for vocational education

Collaborative Learning, Computer supported Learning Environments, Vocational education

Raija Hamalainen, University of Jyväskylä, Finland

Kimmo Oksanen, Finnish Institute for Educational Research, University of Jyväskylä, Finland

The changing needs of people's work lives are creating new challenges for educational settings. Nowadays, work is typically dependent upon interprofessional expertise and the shared construction of new knowledge. Technology can be used to enhance collaboration in learning and working practices—for example, by offering spaces that are more illustrative for practicing interprofessional work. Our previous research has focused on the collaboration scripts as a particular kind of instructional approach to support CSCL, without real-time teacher orchestration. Therefore this study supplements collaboration scripts with teachers' timely support and focus on ways of orchestrating learning in 3D space. The aim of the study is to find out how real-time teachers' orchestration affects knowledge-construction processes. The study used content analysis to compare shared knowledge construction within different scripted 3D-learning conditions (with and without real-time teacher orchestration). Between the groups studying with and those studying without a real-time teacher's orchestration, the findings indicated two main differences in knowledge-construction activities in the categories “providing information” and “other inputs”. More specifically, groups with teacher orchestration used 18 percent of their utterances for explaining their own situation, while groups without teacher orchestration only used 5.9 percent of their utterances for this. The other difference concerned the amount of other inputs; especially off-task talks which was higher with groups without teacher orchestration. Thus, scripted 3D space gave guidance in task solving. However, a teacher's professional competencies were helpful, especially for reducing off task discussions in 3D space and for understanding the interprofessional nature of the task.

The changing needs of people's work lives are creating new challenges for both learning and teaching in an educational setting. Work tasks have become increasingly complicated, and work is typically dependent upon interprofessional expertise and the shared construction of new knowledge (Billett, 2008). As vocational jobs are likely to call for more collaboration, it is necessary to find new ways of supporting collaboration in vocational learning. One way to respond to this need is to create new, technology-enhanced learning spaces that offer learners added incentives to practice interprofessional collaboration. Many researchers have reported on the beneficial effects of

computer-supported collaborative learning (CSCL). As well, the rapid development and improvement perception of 3D spaces offer new potential for learning. Thus, technology can be used to enhance collaboration in learning and working practices—for example, by offering spaces that are more illustrative for practicing interprofessional work. Our previous research has focused on the collaboration scripts as a particular kind of instructional approach to supporting CSCL (typically without real-time teacher orchestration) (e.g. Hamalainen, 2010). Therefore this study supplements collaboration scripts with teachers' timely support and focus on ways of orchestrating learning in 3D space. The concept of orchestrated learning is not new (see e.g. Brown, 1992); along with the development of new 3D spaces, orchestrating has again become a topical issue because new learning spaces challenge teachers to support collaborative learning in new ways. The aim of the study is to find out how real-time teachers' orchestration affects knowledge-construction processes in 3D-learning space.

CONTEXT

The empirical study was conducted in an authentic classroom setting (cameras and recording systems were used). In 2010 (spring), 18 vocational students and two teachers (four groups of five persons) participated in the study. The experiment included a two-to-three hour working period in a scripted 3D learning space at the College of Jyväskylä, Finland. Data were gathered using observational notes on the sessions as well as by videotaping and recording the groups' discussions (6016 transcribed utterances).

METHOD

The aim of the study is to deepen the understanding of the relationship between two different instructional approaches and productive knowledge-construction. More specifically, the study compared shared knowledge construction within different scripted 3D-learning conditions (with and without real-time teacher orchestration). This approach is derived from the methodological development of our earlier studies (e.g. Hamalainen, 2010). After the experiment, all video data were transcribed (four groups with a total of 6016 utterances), and discussion entries were read through several times. Then, all the data were verified: videos were watched, observations were rechecked and transcribed utterances were re-examined (at this stage, 5386 of 6016 utterances were categorised to include activities of shared knowledge-construction). To evaluate whether groups engaged in high-level knowledge construction and how different collaboration settings differed, two types of content analysis were conducted (unit of analysis=utterance). The analysis used quantitative and qualitative content analyses to focus on the group knowledge-construction processes (Berelson, 1952). 5386 utterances were categorized into six main categories ("providing information", "contextual questions", "shared problem solving", "management of interaction", "summing up/discovering solution" and "other inputs"). Then, to find qualitative differences within the knowledge-construction processes, the utterances were sorted further into 26 different data-driven subcategories (for more details, see Hamalainen, 2010). Regarding the quantitative content analysis, the aim was to describe whether shared knowledge construction in two different research settings would be dissimilar, while the aim of the qualitative content analysis was to develop understanding how real-time teachers' activities enhance high-level knowledge construction.

RESULTS

Between the groups studying with (2405 utterances) and those studying without (2981 utterances) a real-time teacher's orchestration, the findings indicated two main differences in knowledge-construction activities in the categories "providing information" and "other inputs". More specifically, in providing information, both groups brought in new knowledge, gave technical and contextual advices to group members and stated their opinions. However, groups with teacher orchestration used 18 percent of their utterances for explaining their own situation, while groups without teacher orchestration only used 5.9 percent of their utterances for this. The other difference concerned the amount of other inputs; especially off-task talks. Groups without teacher orchestration used 36.1 percent (1077 utterances, of which 452 off task) of their utterances for other inputs, while groups with teacher orchestration used 13 percent (315 utterances, of which 35 off task) of their utterances for this. Thus, scripted 3D space itself gave guidance and help in task solving. However, a teacher's professional competencies were helpful, especially for reducing off task discussions in 3D space and for understanding the interprofessional nature of the task.

CONCLUSIONS

The precondition for orchestrating collaboration is the understanding of collaboration processes and the reasons for the differences in the knowledge-construction processes. This study indicated that groups studying with real-time teacher orchestration used more effort for providing information (especially explaining one's own situation) and less effort for other inputs (especially off-task talk). This suggests the potential of real-time teacher orchestration as explaining one's own situation is highly related to interprofessional work and practicing that is one way to respond to the changing needs of the future of people's work lives. Thus, the findings are in line with the notion that real-time teacher orchestration is suited to collaborative learning (Dillenbourg et al., 2009). However, future research needs to

focus further on how to support collaborative learning with both technology and human guidance, as no technology alone can replace the teacher in supporting creative collaboration processes.

SYMPOSIUM

Beliefs About Being a Teacher: Motives for Teaching and What It Means To Be a Teacher

Chairperson: Stuart Karabenick, University of Michigan, United States

Organiser: Stuart Karabenick, University of Michigan, United States

Fani Lauermann, University of Michigan, United States

Discussant: Julianne Turner, U. of Notre Dame, United States

This symposium explores several aspects and implications of beliefs about being a teacher. First, Author1 and Author2 (Paper 1) examine teachers' motives to choose teaching as a career across two educational contexts—Australia and the USA—and demonstrate that these motives have important implications for teachers' perceptions about the profession, including job satisfaction, leadership aspirations and planned persistence. Second, Author3 and Author4 (Paper 2) utilize Author1 and Author2's theoretical framework to examine the relations between teachers' motives to enter the profession and a different set of beliefs about the profession, namely teachers' sense of professional responsibility and implications for their approaches to instruction. This study also compares two educational contexts: Germany and the USA. Finally, Author5 and Author6 (Paper 3) present a mixed-methods study that complements the previous two studies by exploring students' perspectives on what teachers should be like, as well as what teachers should be responsible for. The researchers adapt Author3 and Author4's theoretical framework to examine potential discrepancies between students' and teachers' beliefs about teacher responsibility. In sum, the presenters employ a diverse set of samples (Australia, USA, and Germany), conceptual frameworks and analytical approaches to examine convergent facets of teachers' and students' perceptions of what it means to be a teacher. These include motives to become a teacher (Papers 1 & 2) and perceptions about the profession (Papers 1, 2 & 3) from the perspective of teachers (Papers 1 & 2) and students (Paper 3).

Teachers' Profiles of Professional Engagement and Career Development in Australia and the U.S.

Helen Watt, Monash University, Australia; Paul W. Richardson, Monash University, Australia

Previous studies of graduate-entry primary/elementary and secondary teacher education candidates in Australia (N = 510) identified three beginning teacher types, based on their profiles of planned persistence, effort, professional development, and leadership aspirations (measured by the PECDA scale, Author1 & Author2, 2008): highly engaged persisters, highly engaged switchers, and lower engaged desisters. These types differed in their initial motivations for having chosen teaching as a career, perceptions about the profession, career intentions, and demographic characteristics. The present study tested whether these teacher types would be detected in other cultures by conducting a parallel investigation with a new sample of preservice elementary and secondary teacher candidates from two midwestern universities in the U.S. (N = 246). Three distinct clusters were identified: highly engaged persisters and lower engaged desisters resembled two of the clusters identified in Australia. However, in contrast to the highly engaged switchers in Australia, a new third cluster emerged in the U.S.: classroom engaged careerists. We will describe the motivational profiles, perceptions about the profession, career intentions, and demographic characteristics of the three teacher types and advance an explanation for the presence of classroom engaged careerists in the U.S.

AIMS

We aimed to explore a typology of beginning U.S. teachers, in light of the 3 beginning teacher types previously identified in the Australian context, based on profiles of professional engagement and career development aspirations, measured by the PECDA scale (Author1 & Author2, 2008). Next, we compared motivations, perceptions, career intentions and demographic characteristics for the derived teacher types, to contrast with our earlier

Australian findings. Our previous study with Australian preservice teachers (N = 510) adopted a multidimensional and person-centered approach to identify different types of beginning teachers at the outset of their careers (Author1 & Author2, 2008). The 3 types had high, lower, and mixed engagement profiles, which also differed on initial motivations for choosing teaching, perceptions of the career, career intentions, and demographic characteristics.

METHODOLOGY

U.S. data were collected from elementary and secondary preservice teachers (N = 246), at two universities in midwestern United States, using the previously validated PECDA scale (Author1 & Author2, 2008) to develop teacher type profiles; as well, the FIT-Choice scale (Author2 & Author1, 2006; Author1 & Author2, 2007) measured teaching motivations and perceptions. As previously, hierarchical cluster analysis (Ward's method) investigated the different types of preservice teachers. The decision regarding the final number of clusters was based on the cluster dendrogram, "steps" in the scree-type plot of fusion coefficients relative to number of clusters, and on substantive interpretability.

MANOVA tested for significant effects of cluster membership on PECDA and FIT-Choice variables. ANOVA compared career intentions to not teach at all, in the short term, or whole career. Repeated-measures ANOVA tested changes in satisfaction with teaching as a career choice through teacher education studies. Chi-square compared beginning teacher types on background demographic characteristics measured as categorical variables (i.e., gender, ethnicity, elementary vs. secondary enrolment, having children or not and whether teaching was their first career choice), and one-way ANOVAs tested for cluster differences on the other background factors of age, socioeconomic background, level of prior qualifications, how many years ago they had decided to teach, having previously pursued or seriously considered another career to teaching (0 = not, 1 = seriously considered, 2 = pursued), and, levels of satisfaction with previously pursued and seriously considered careers.

FINDINGS

Teacher types. Three clusters of beginning teachers were empirically and theoretically supported: "highly engaged persisters" (n = 119) had high responses for all 4 clustering variables (planned effort, professional development, persistence, and leadership aspirations), and statistically significantly highest scores on leadership. This resembled that identified in the earlier Australian sample; 78.2% wanted to teach for their whole career, and 21.8% to teach in the short term.

"Lower engaged desisters" (n = 78) also resembled one of the Australian clusters. They reported significantly lower scores on all 4 subscales than the "highly engaged persisters"; and, significantly lower scores than the following third cluster, on planned effort, persistence and professional development. Although their mean scores on planned effort and professional development were quite high relative to the 7-point scale, they were lower than the other clusters. Planned persistence and leadership aspirations were low relative to both the scale and other clusters. 59% planned to teach their whole career, 37% only in the short term. Only 1.2% (3 participants) planned not to teach at all, and these belonged to the "lower engaged desisters".

The final cluster (n = 49) did not resemble any type we had identified previously. They gave similarly high ratings to the "highly engaged persisters" for planned effort, persistence and professional development, but, significantly lowest scores for leadership aspirations. We named this group the "classroom engaged careerists". The overwhelming majority (95.9%) planned to teach for their whole career, 4.1% only in the short term.

Cluster differences. As predicted from our previous study, "highly engaged persisters" retained high stable satisfaction with teaching as a career choice stable through their preservice teacher education programs; "highly engaged desisters" started out and remained lowest; the newly identified "classroom engaged careerists" increased in their satisfaction. "Classroom engaged careerists" and the "highly engaged persisters" scored significantly higher than their "lower engaged" counterparts on a range of measured FIT-Choice motivations: they were more motivated to teach on the basis of their perceived teaching abilities, intrinsic values, to work with youth, shape the future of youth, and enhance social equity. There were no significant cluster differences on any of the personal utility value motivations (job security, time for family, job transferability), or the negative "fallback career" motivation. For perceptions of teaching, "highly engaged persisters" perceived the expert status of a teaching career higher than "lower engaged desisters"; "classroom engaged careerists" reported significantly least social dissuasion. The 3 clusters held similar perceptions about teaching difficulty, salary, and social status.

The only demographic characteristic on which clusters differed, was higher levels of prior qualification among "highly engaged persisters". There were no significant differences according to age, gender, language spoken at home, parental income background, whether participants had children or not, whether teaching was their first career choice, the number of years prior they had decided to teach, or, whether they had considered or pursued a different career

prior to enrolling in teacher education. Of the 45 individuals who had pursued a career other than teaching (“highly engaged persisters” $n=21$, “highly engaged desisters” $n=14$, “classroom engaged careerists” $n=10$), there were no significant cluster differences in satisfaction with these previously held careers.

CONCLUSIONS

Teacher education and employing authorities need to take seriously these different types of beginning teachers having different profiles of professional engagement and different kinds of motivations for teaching, which likely will lead to different pathways of professional development. Highly engaged persisters and desisters appear robust clusters across the culturally similar two contexts. Australian “highly engaged switchers” and U.S. “classroom engaged careerists” were in some ways a reversal of each other; the former had high leadership aspirations and low planned persistence, the latter had low leadership aspirations and high planned persistence. Explanations are advanced for this difference in terms of cultural differences in teaching career structures in the two settings.

Beliefs about Teaching: Motives for Teaching, Sense of Responsibility and Approaches to Instruction

Fani Lauermann, University of Michigan, United States; Stuart Karabenick, University of Michigan, United States

In the context of strong political emphasis on teachers’ formal obligations and accountability for educational outcomes such as student performance on standardized tests, there has been increasing interest among educational researchers in teachers’ beliefs about their professional roles and sense of professional responsibility. The majority of research, however, has focused on teachers’ formal accountability and its consequences for student performance, but not on teachers’ willingness to accept personal responsibility. The present study explored relations between teachers’ motives to enter the profession, their beliefs about their professional responsibilities, and beliefs about mastery- and performance-oriented instruction. The results indicate that only social motives but not intrinsic or extrinsic motives for becoming a teacher predict teachers’ sense of responsibility for important educational outcomes such as student motivation, student achievement, and relationships with students. Furthermore, structural modeling provided evidence for consistency between responsibility and teachers’ approaches to instruction. Discussion focuses on the potential of responsibility as a critical mediating factor in instructional practices and student outcomes.

AIMS

Teachers’ beliefs about their professional roles have been a major focus in educational research due to the critical importance of such beliefs for teachers’ classroom behaviors, decision making and instructional practices (Berg, 2002; Pajares, 1992; Porter & Freeman, 1986). Furthermore, in the context of strong political emphasis on teachers’ formal obligations and accountability for educational outcomes such as student performance on standardized tests, there has been increasing interest among educational researchers in teachers’ beliefs about their professional roles and sense of professional responsibility (Author3 & Author4, 2009; Linn, 2006; Schalock, 1998). The majority of research, however, has focused on teachers’ formal accountability and its consequences for student performance, whereas teachers’ internal sense of responsibility, the conditions under which teachers are willing to accept personal responsibility, and the things for which teachers feel responsible remain an understudied area of research (Author3 & Author4, 2009, 2010).

We define personal responsibility as a sense of internal obligation and commitment to produce or prevent designated outcomes or that these outcomes should have been produced or prevented (Author3 & Author4, 2009; Author3 & Author4 & Author5, 2010). In previous research, we examined four domains of teacher responsibility—for student motivation, student achievement, relationships with students, and teaching—and demonstrated that our measure is empirically distinguishable from teachers’ sense of efficacy for the same educational outcomes (Author3, Author4, & Author5, 2010). That is, “I can” does not necessarily imply “I feel responsible.” Here, we explore factors that are likely to shape teachers’ sense of responsibility, as well as implications for approaches to instruction. Specifically, the present study examined the relations between: motives to become a teacher (Author1 & Author2, 2007, 2008), teachers’ sense of professional responsibility (Author3 & Author4, 2009), and teachers’ beliefs about mastery and performance approaches to instruction (Midgley, 2002; Roeser, Marachi, & Gehlbach, 2002). We propose that the reasons why individuals decide to enter the teaching profession may shape their sense of professional responsibility, which in turn is likely to predict different approaches to instruction; i.e. teachers would endorse instructional approaches that they believe would help them to fulfill their professional responsibilities.

METHODOLOGY

The research questions are examined in two samples: (a) an online study with 316 German pre-service teachers and (b) in an ongoing replication study with approximately 1000 American pre-service and in-service teachers. The data collection for the American sample will be completed at the end of November, 2010. The following scales are included: intrinsic ($\alpha = .81$), social ($\alpha = .71$), and extrinsic ($\alpha = .86$) motives for teaching (FIT-Choice, Author1 & Author2,

2007); mastery ($\beta = .70$) and performance ($\beta = .71$) approaches to instruction (Midgley, et al., 2000); and a four-factor scale of teacher responsibility for negative educational outcomes, including responsibility for student motivation ($\beta = .84$), student achievement ($\beta = .86$), relationships with students ($\beta = .77$), and teaching ($\beta = .79$). Scales that were not available in both languages, German and English, were translated and back-translated to assure comparability. Sample items are shown in Table 1.

FINDINGS

All analyses were performed with Mplus. Analysis of the German sample indicated that participants preparing to teach in the lowest academic track schools were significantly more likely to report extrinsic motives for teaching and higher personal responsibility for teaching (but not for student outcomes); therefore, academic track was included as a control variable. The model fit was very good (see Figure 1; S-B-Chi-square(396)= 516.467, CFI = .96, TLI = .95, RMSEA = .03 (90% CI .02, .04), SRMR = .05). The four responsibility factors accounted for 21% of the variance in mastery and 6% in performance approach to instruction. Responsibility for student motivation predicted performance approach and responsibility for student achievement and relationships with students predicted mastery approach. Social motives, but not intrinsic or extrinsic motives, predicted teacher responsibility for student outcomes. Alternative models were also tested. The replication study with American teachers will allow us to test the generalizability of these findings across educational contexts.

CONCLUSIONS

The analyses indicate that teachers' motivations for teaching are related to their sense of professional responsibility. Furthermore, after accounting for social motives and academic track, neither intrinsic, nor extrinsic motives predicted responsibility for student outcomes. These findings suggest that extrinsic incentives may have little impact on teachers' willingness to accept personal responsibility, particularly if students' outcomes are negative. In addition, the present findings indicate that teachers' sense of professional responsibility predicts their mastery and performance approaches to instruction. Although prior research suggests that performance-oriented instruction can be detrimental to student motivation and achievement, particularly for low-achieving students (Midgley, 2002; Roeser, et al., 2002), sense of responsibility for student motivation may be one of the reasons why teachers endorse such practices. Thus, good intentions may lead to negative outcomes. Understanding the motivational underpinnings of mastery and performance approaches to instruction is therefore critical.

Teacher Responsibility – What Do Students Think?

Kerstin Helker, RWTH Aachen University, Germany; Marold Wosnitza, RWTHUniversity Aachen, Germany

The present study expands upon prior research on teachers' beliefs about their professional roles and sense of professional responsibility by exploring students' beliefs about different dimensions of teacher responsibility. In a first quantitative study, 205 German high-school students rated four dimensions of teacher responsibility identified in prior research – responsibility for student achievement, student motivation, teaching and relationships with students. In contrast to prior findings with teachers, students did not distinguish between teacher responsibility for teaching and teacher responsibility for having close and trusting relationships with students. A second qualitative study with 196 high-school students was conducted to learn more about students' perceptions of teacher responsibility. Although many of the dimensions identified in earlier research were confirmed in the student sample, new categories of teacher responsibility were also identified, which explained the findings of the first study. These findings indicate that teachers' and students' beliefs about teacher responsibility may not always overlap.

AIMS

Previous research with teachers has focused on four dimensions of teacher responsibility: teachers' sense of personal responsibility for student motivation, student achievement, relationships with students and teaching (Author3 & Author4, 2009; Author3 & Author4 & Author5, 2010). A qualitative study revealed that teachers view teacher responsibility as an overarching concept with ties to intrinsic motivation, locus of control, organizational citizenship, and other constructs closely related to student learning and achievement (Author3 & Author4, 2009). It is unknown, however, whether students share such beliefs about teacher responsibility and whether the responsibility students ascribe to their teachers reflects the same four dimensions identified with teachers.

This paper examines secondary school students' perceptions of teacher responsibility. The main focus is on the domains of teacher responsibility students identify and whether these diverge from previous research studying teacher responsibility from the teachers' perspective. Two consecutive studies were conducted: results of the first (quantitative) study yielded a different pattern of responsibility from that of teachers, whereas the second (qualitative) study provided information that explained results from the first study.

METHODOLOGY

Participants in the first study were 205 secondary school students from different schools in Germany. Participants completed an online questionnaire that included a modified version of a responsibility scale used in prior research on teacher responsibility; the scale was modified with regard to the students' perspective and language. Twelve items represented the previously identified dimensions of teacher responsibility: student achievement, student motivation and teaching and teachers' relationships with students. Students rated these teacher responsibility items on an eleven-point Likert scale (0 = "not at all responsible" to 100 = "completely responsible", in 10-point increments). A sample item is "The teacher would be responsible if I did not like his/her subject.). Data were analysed using factor and reliability analysis, ANOVAs and t-tests.

In the second, qualitative study, 196 students from secondary schools in different locations in Germany completed an online questionnaire that included three open-ended questions asking about domains of teacher responsibility. Students were asked to state their understanding of teacher responsibility and to describe the characteristics of responsible and irresponsible teacher behaviors. Furthermore, students were asked to name the five most important domains of teacher responsibility and to explain why they consider these domains important.

A combination of deductive and inductive approaches was used to analyze the qualitative data with the aim to identify central dimensions of teacher responsibility. In order to maintain high consistency with previous research (Author3 & Author4, 2009), categories identified in those data were used for the students' data as well. Whenever categories could not be identified in the students' data, they were dismissed. Whenever data could not be clearly assigned to a specific category, a new category was created.

FINDINGS

Results of study one show that secondary school students endorse diverging perspectives on teacher responsibility. The postulated four-dimensional structure identified in prior research with teachers could be only partially replicated with the student data. Factor analysis indicated a three-dimensional structure: achievement, motivation and a combined dimension of responsibility for teaching and for relationships with students. Using these three dimensions the study furthermore showed that students hold teachers responsible primarily for teaching and relationships ($M = 69.0$, $SD = 17.8$) followed by achievement ($M = 34.8$, $SD = 17.8$) and motivation ($M = 21.8$, $SD = 20.2$). There were no significant effects of gender, age and grade level.

Results of the qualitative study indicate that in agreement with the quantitative data, students highlight domains of teacher responsibility that are closely connected with their own perspective on the teachers' professional roles. A range of dimensions of teacher responsibility identified in prior research with teachers were confirmed: responsibility for teaching-related activities, student outcomes (e.g., student achievement and motivation), interactions with students, creating a positive classroom atmosphere, communication/interactions with others, school policies and external regulations, school activities (duties and voluntary work) (Author3 & Author4, 2009). In addition, teacher responsibility for interactions between students emerged as a salient theme. Students considered this aspect to be most important, as cooperation and a sense of community in the class are perceived to be crucial factors for a supportive learning environment. According to students, in other words, teachers are responsible to care for friendly interactions between students as part of their responsibility for teaching.

These findings explain the results of the quantitative study as students assigned certain responsibilities to a teacher they perceive to be crucial for fulfilling other responsibilities such as the responsibility for teaching. Good teaching is perceived to be impossible when the relationships with students are not well-established and cared for, which is again seen as attributed to certain characteristics of a teacher's personality.

CONCLUSIONS

Secondary school students' views of teacher responsibility differ from teachers' perceptions of what they are responsible for. The results of the first study support the need for further research, as teacher responsibility appears to be highly dependent on the adopted perspective and cannot be left to personal interpretations of teachers' tasks and liabilities. For students to receive the best education possible, teachers have to be aware of their responsibilities; especially those assigned to them by their students. The chain of causation the students stated in the qualitative study seems particularly important as it has major implications for questions such as who should choose a teaching profession or how teachers' tasks can be defined in a comprehensive and coherent way.

SYMPOSIUM

Scaffolding in dyadic teacher-student interactions: Analyses of learning support in math education

Chairperson: Christine Pauli, University of Zurich, Switzerland
Organiser: Christine Pauli, University of Zurich, Switzerland
Discussant: Pekka Salonen, University of Turku, Finland

Current concepts of learning and teaching on a constructivist and sociocultural basis emphasise both the importance of learners dealing with the learning contents independently and actively, and the social embedding of learning processes. Due to the growing heterogeneity of school classes as a consequence of migration and integrative school models, the important role of individual learning support in instruction in particular is increasingly recognised. Thus, the concept of scaffolding, originally introduced by Wood, Bruner and Ross (1976) as a support that is optimally attuned to a student's current ability and needs, has attracted much attention in educational research in the last years. However, the literature contains numerous and varying conceptualisations of scaffolding, and besides the consensus that it is an effective form of learning support, many questions remain open regarding definition, delimitation and mode of action, and particularly measurement of scaffolding, even though several important core elements like contingency, fading and transfer of responsibility (van de Pol et al., 2010) have been worked out. The symposium incorporates three presentations, all addressing processes of scaffolding in the context of mathematics instruction. Besides the joint focus on scaffolding in one-to-one teacher-student interactions, the research projects differ regarding the aspects focused upon and the methodological procedure of video-based analysis of scaffolding. The symposium should enable a discussion regarding (1) what distinguishes successful processes of scaffolding in teacher-student interactions in mathematics instruction and (2) how different analytical and theoretical approaches can contribute to the measurement and conceptualisation of core processes of scaffolding.

Scaffolding and teachers' use of questions. A conversation analysis of questions in explanations

Ed Elbers, Utrecht University, Netherlands; Tom Koole, Utrecht University, Netherlands

We use conversation analysis to study the process of scaffolding in dyadic teacher-pupil interactions in the classroom. The concept of scaffolding has been diluted by researchers who use the term 'scaffolding' for any assistance teachers offer, without taking into account that scaffolding requires responsive instruction, adapted to the level the student is demonstrating. Conversation analysis allows us to show in detail how teacher and pupil regulate their interaction and how the utterances of the interlocutors are responsive or fail to be responsive to each other's previous contributions. Building upon recent conversation-analytic studies of question-answer sequences, we look, in particular, at the way the teacher uses questions as scaffolding tools. The analysis is based on a corpus of 52 dyadic teacher-pupil interactions (with 12-to-13-year-old pupils) in two classes during mathematics lessons. We analysed how the teacher made use of the preference organization of question-answer sequences. We found three contexts in which the teacher used questions as scaffolding tools. (1) The teacher asked a known answer question as part of the IRF cycle (but this occurred little). (2) The teacher asked a series of easy questions to lead a pupil to the solution of the assignment. (3) The teacher checked the student's understanding with questions that interactionally prefer confirmations. We looked at the extent to which the teacher's questions were responsive to the pupil's expressed difficulties with the assignments.

Aims

We use conversation analysis to study the process of scaffolding in the interaction between teacher and pupils in the classroom. We consider scaffolding as an interactional process between a teacher and one or more pupils. Teachers' scaffolding consists of responsive actions that take account of the competences and knowledge the pupil is demonstrating. Hitherto, most studies of scaffolding in the classroom are concerned with whole class teaching. These studies often concentrate exclusively on teacher actions and do not take account of the interactional context of the teacher's support. In this presentation we will neither look at teacher behavior as a separate process, nor will we focus on whether the pupil succeeds in profiting from the teacher's assistance. Conversation analysis gives us tools to concentrate on the interaction and see what information the interlocutors make available to each other and how they use this information in shaping the interaction. We (1) study dyadic interactions, that is teacher's dialogues with one pupil at a time, in the context of classroom processes. We (2) analyse teacher actions in the context of the conversation and establish whether the teacher actions are responsive to previous contributions by the pupil. We (3) look at the way the teacher uses questions as scaffolding tools, building upon recent conversation analytic studies of question-answer relations, both in educational contexts (Koshik, 2002; Author, 2010) and elsewhere (Raymond, 2002; Schegloff, 2007).

Methodology

The analysis is based on a corpus of video and audio recordings and transcripts of interactions. The recordings were made during mathematics lessons in two first year classes in two secondary schools in the Netherlands with pupils of 12 and 13 years of age. In the two classes a regular mathematics lesson consisted of two broad teaching/learning

arrangements: a part with whole class instruction and a part in which pupils worked more or less individually on their tasks and assignments. During these phases of individual work there was no whole class teaching, but the teacher gave individual pupils the opportunity to ask questions, or asked them to show him their work. This is a pattern which involves private interactions between one pupil and the teacher: the teacher offers help and support, the pupil asks for feedback and clarification.

We selected all dialogic situations between teacher and one pupil at a time which were concerned with mathematical content and which encompassed more than three turns. This resulted in a corpus of 52 dyadic interactions in the two classes. We analysed the conversations and studied in detail how teachers used questions in their reaction to pupil's difficulties and requests for support. We related the questions to the pupil's previous utterances and looked at how the pupil answered the questions. We analysed in detail how the teacher made use of the preference organization of question-answer sequences. Moreover, we looked at the extent to which the teacher questions were responsive to the pupil's expressed difficulties with the assignments.

Findings

We found three contexts in which the teacher used questions as scaffolding tools. In the first context a question was part of the IRF cycle, in which the teacher asked a known answer question in order to check the pupil's knowledge or understanding. Despite the attention given to known answer questions in educational research (e.g., Cazden, 2001), we found only a few instances of this type of question use. This has to do with the fact that the teachers, in interactions with their pupils, made little, if any, attempt to find out what the pupil's problem was and mostly started explaining without giving the pupil the possibility to specify her problem and to clarify why she needed help (Authors, 2010). The second type involved situations in which the teacher exploited the interactional mechanisms of 'preference organization' by asking questions with 'easy' answers. Here, the teacher used questions to lead pupils to the correct answer, such as the solution of the assignment. These questions should be seen interactionally as producing the pupil's knowledge (often in a series of questions that the pupil can answer easily and lead her to the correct answer) rather than as checking their knowledge. Interestingly, despite the correct answer by the pupil, the teacher did not consider this sufficient proof of the pupil's knowledge, because the teacher followed by further explanation. Therefore, we consider this type of questions as interactionally responsive to the pupil's responses. The third context occurred when the teacher checked the student's understanding with questions that interactionally prefer confirmations. These checks were made at the closure of a monological explanation when the teacher asked whether the pupil had understood the explanation. In almost all instances, the pupils provided the preferred answer and answered that they understood the teacher's explanation. Often, the teachers treated this claim of understanding as sufficient evidence and closed the conversation without asking the pupil to further demonstrate her understanding. This can be seen as interactionally non-responsive since these teachers treated the answer as evidence of the pupil's understanding rather than as a response that was projected by the teacher's question.

Scientific and educational significance

Since the introduction of 'scaffolding' by Wood, Bruner and Ross (1976), the concept has gained popularity in studies of learning and teaching. The concept allows showing how teachers can promote learning by adapting their instruction to the comprehension the pupil is exhibiting. However, the concept has been diluted by researchers who use the term 'scaffolding' for any assistance teachers offer, without taking into account that scaffolding requires responsive instruction, adapted to the level the student is demonstrating. By using conversation analysis we can show how teacher and pupil regulate the interaction and how the utterances of the interlocutors are responsive or fail to be responsive to each other's previous contributions. Since scaffolding has become a standard subject in teacher training and in textbooks for teacher education, we think that the conceptual and empirical clarification that our analysis makes possible will contribute to the understanding of scaffolding and teacher support.

Scaffolding dynamics during instruction and its role in problematic learning trajectories

Henderien Steenbeek, Rijksuniversiteit Groningen, Netherlands; Louise Jansen, Rijksuniversiteit Groningen, Netherlands; Paul van Geert, University of Groningen, Netherlands

Currently, most researchers agree that learning is a socially situated, transactional process, in which both the teacher and the learner make their own unique contribution. But how does one get insight into such a complex process, and what are its central properties? The aim of this study is to examine problematic learning trajectories of children with psychiatric and behavioral problems, by focusing on individual scaffolding sessions during math education. Longitudinal data of four primary school students from a group in a special school for children with emotional behavioral disorders were collected, by making videotapes of math lessons in two-weekly intervals over a two-year period. Interaction variables were the teacher-student 'response matches', and the teacher's 'feedback responses'. First empirical results point to few verbal actions initiated by the students in interaction with the teacher.

With regard to the scaffolding dynamics, intra-individual and inter-individual variability occurs over all lessons in all students. Furthermore, students receive far more positive than negative feedback and, most of the times, feedback isn't followed by any form of instruction. In the presentation, we will go into the surplus value of using a case study approach, i.e., in examining 'response matches' per individual student-teacher dyad, and how they are linked to long term developmental trajectories of students' learning processes.

The literature indicates that students with psychiatric and behavioral problems show extremely poor outcomes with regard to both academic and behavioral performance, and that the educational needs of these students continue to be unmet (see Hayling, Cook, Gresham, State, & Kern, 2008). The aim of this study is to examine problematic learning trajectories of children with psychiatric and behavioral problems, by focusing on individual instruction sessions in math education in which scaffolding occurs. What happens in these scaffolding sessions and, by focusing on short-term processes, can we get insight into long-term development of problematic learning trajectories? When studying learning-in-interaction as a dynamic, complex process, it is fundamental to capture it by means of a variable that reflects the important characteristics of the dynamics of that process (Broer & Takens, 2009). Instead of examining the roles of the interaction partners separately, it is important to take the 'iterative action-reaction responses' of both partners together as defining variable. A means to do so is by focusing on scaffolding, which is an important tool for the teacher to promote learning in the student. In our view, scaffolding is an intrinsically dynamic notion (Authors, 2005), in that it describes how a particular level of knowledge or skill in a student changes as a result of the scaffolding process. In addition, we hypothesize that the level of the pupil will determine the level of the scaffold (which should be ahead of the first), while the level of the scaffold will determine the level of the student (Authors, 2006). Given this definition of scaffolding as a mechanism of coupled teaching-learning processes, optimal scaffolding implies optimal learning and optimal teaching at the same time.

A significant part of the scaffolding process is giving the right type of feedback at the right moment. Teacher-student feedback can be either (positive or negative) task related or (positive or negative) personal. The literature indicates that negative task related feedback accompanied by additional information about the task and how to do it more effectively, is most effective for learning (Solomon & Rosenberg, 1964; Hattie & Timperley 2007; Gable, Hester, Rock, & Hughes, 2009). An important question now is: What are the empirical indicators of optimal versus suboptimal scaffolding sessions? We assume that those empirical indicators are reflected in the scaffolding dynamics as present in the unfolding interaction between student and teacher in real time, during e.g. arithmetic scaffolding sessions. But how do those (sub)optimal levels of scaffolding show themselves? First, we hypothesize that those levels are expressed and can be observed in the level of 'response-match-in-interaction', i.e., in a variable that represents the match between an initiation of the student (or teacher), followed by a response of the teacher (or student). Second, we hypothesize that problematic learning trajectories are accompanied by inadequate teacher feedback.

In the present study we will show how we worked on exploring the scaffolding dynamics in interaction between student and teacher, by studying the variables 'response match' and 'feedback of the teacher', in using short-term variability patterns of distinct dyads as important sources of information. Longitudinal data of four primary school students (all boys, mean age 9.7 years, lower limit 9.2 years, upper limit 10.3 years) from a group in a special school for children with emotional behavioral disorders were collected, by making videotapes of math lessons in two-weekly intervals over a two-year period. The participants were selected by the teacher as being representative of the diversity of the group population. All students were still in the starting phase of learning mathematics.

In order to be able to code the variable 'response match', we coded the verbal utterances first. Main categories that were distinguished were: teacher's 'order remarks', 'procedural remarks', 'instructions', 'feedback', and student's 'questions', 'answers', and 'remarks' (see coding system, [Authors, 2008]). The variable 'response matches' is a second-order variable, which is based on all the initial categories as described above. A response match can be defined as an antecedent initiative utterance of a participant (the student or teacher), followed by a consequent utterance of the other participant (the teacher or student) that provides a match to the antecedent and that is – in principle – beneficial for learning to occur. To get insight into the types of feedback that were given during the individual scaffolding sessions, we filtered all the feedback codes out of the transcripts. We made a distinction between task related feedback and personal feedback, and feedback that is positive neutral, or negative. Empirical results point to few verbal actions from the students in interaction with the teacher. With regard to the scaffolding dynamics, intra-individual and inter-individual variability occurs over all lessons in all students. By examining 'response matches' per individual student-teacher dyad, other things come to the fore than would be the case if we would average our findings, which lead us to perform case-study analyses of all four students individually. A striking observation in one of the students' data, is that his 'response matches' occur more frequently in the first phase of the learning trajectory than in the second (p In the presentation, we will go into the surplus value of using a case study approach, i.e., in examining 'response matches' per individual student-teacher dyad, and the link with long term

developmental trajectories of students' learning processes. In addition, we will discuss the applied value of our results, i.e., of working with empirical variables that capture the iterative character of the ongoing dynamics in scaffolding sessions, at the level at which teachers actually act.

Scaffolding in teacher-student dialogues during joint problem-solving activities

Anke Wischgoll, IFE UZH, Germany; Christine Pauli, University of Zurich, Switzerland; Kurt Reusser, University of Zurich, Switzerland

In current approaches of mathematics instruction, individual learning support plays an increasingly important role, owing to the growing importance of independent, demanding problem-solving activities and increasing heterogeneity of students' learning prerequisites. Scaffolding represents an attractive model of productive support. Despite comprehensive research, however, clarification is still required regarding the question of what, precisely, constitutes effective scaffolding in the context of school teaching and learning processes. The current investigation pursues this question using video analyses of 26 tutoring sessions, in which teachers each supported one student in solving an algebraic word problem. Based on students' success in independently solving a transfer task upon completion of the tutoring session, a distinction was made between successful and unsuccessful tutoring sessions. The analyses are based on a qualitatively oriented multi-methods approach. Starting from a task analysis, the analyses of teacher-student interaction and of the problem-solving process focused on the match between teacher support and student behaviour and on the occurrence and tackling of impasses, taking into account the progression of the problem-solving process.

The results indicate the importance of picking up on and tackling all impasses. Compared to unsuccessful tutoring sessions, the successful sessions were distinguished, moreover, by an optimal match between the type of teacher's support and the student's needs, and by fading attuned to the student behaviour and the situation once the impasse was resolved.

Theoretical background and aims

In current approaches, the individual support of students is playing an increasingly important role (not only) in mathematics instruction. On the one hand, on the basis of a social-constructivist and learning theory, increased opportunities for demanding learning activities, such as independent problem-solving, should be created, requiring adaptive support of the students (e.g. Hmelo-Silver, Duncan, & Chinn, 2007). On the other hand, the increasingly heterogeneous composition of school classes necessitates support from the teacher that is optimally attuned to the individual learning prerequisites and learning progress of each student.

Scaffolding (Wood, Bruner, & Ross, 1976), as support which is temporary, adaptive and oriented towards building competence, represents an attractive concept in this regard. Although no uniform definition of scaffolding is available to date, the more recent literature points to three core features of scaffolding: contingency, fading and transfer of responsibility (van de Pol, Volman, & Beishuizen, 2010). Examinations into the relationship between tutoring and learning have, moreover, emphasised the importance of dealing with impasses for learning success (VanLehn et al., 2003). Despite the broad consensus that scaffolding represents an effective form of learning support, there continues to be a need for empirical investigations showing what, precisely, distinguishes productive scaffolding processes in the context of school learning. The current study makes a contribution in this regard.

The goal of the study was to examine scaffolding processes when solving a task that would typically arise in mathematics instruction. To this aim, for each of 26 teachers, a tutoring session outside of the classroom was recorded and analysed, in order (among other things) to answer the following questions: Do successful tutorial dialogues differ from unsuccessful tutorial dialogues (1) with regard to the occurrence and treatment of impasses, and (2) with regard to the responsiveness of the support?

Method

The data base consists of 26 video-taped tutoring dialogues of 26 different teachers from Germany and Switzerland, each with one student (8th/9th school year), which had been obtained in the framework of an earlier video study (Authors, 2009). The task worked on (algebraic word problem) was set by the research team so that all students solved the same task. Following the tutorial session, the students independently solved a similar task. Based on the success of the solution in this transfer task, the tutorial dialogues were divided into "successful" (n=11) and "unsuccessful" (n=15). The analysis was based on a qualitatively oriented multiple methods approach and comprised 4 steps: (1) Based on a task analysis, the problem solving process was segmented with regard to the key steps. (2) Teacher-student interaction: A rating instrument was developed, which assessed, for each segment, (a) the degree of supportive behaviour of the tutor (e.g. "no support" to "complete explanation") and (b) the extent of the student's

contribution. Moreover, the match between (a) and (b) was taken into consideration. (3) Impasses (including errors): Four types of impasses (e.g. misinterpretation of the text, false numerical linking) were identified. Moreover, based on the work of VanLehn et al. (2003), the extent of the impasse with regard to the problem-solving process was determined. The importance of impasses for the problem-solving process was evaluated as a whole. (4) Analyses (1) to (3) formed the starting point for creating progression graphs and narrative descriptions of different types of joint problem-solving based on a type-building procedure.

Results

Results show that impasses related to a misinterpretation of the problem text were the most frequent type of impasse in this analysis. Further results show that in successful tutoring sessions (e.g. for students who subsequently solved the transfer task successfully), all impasses had been resolved. This was not the case for the unsuccessful sessions. With respect to the teacher-student interaction, our analyses show that in successful tutoring sessions, the tutor's support and the student's needs were matching in nearly all segments. In contrast, non-successful tutoring sessions included more segments in which the tutor's support and the student's needs were not matching. When the whole course of the problem-solving process is taken into account, with regard to the scaffolding activities of the tutor, it is apparent that a controlled fading (e.g. fading that is finely tuned to the student's current level of understanding) after impasses was more frequently observed during the successful tutorial sessions than in unsuccessful sessions. In unsuccessful tutorial situations, support and positive reinforcement of the student once the impasse had been resolved was rarely observed.

Conclusion and significance

Our results underline the role of responsiveness of teacher's support and of the productive handling of impasses when supporting problem-solving activities. Support that is optimally attuned to the progression of students' understanding in the course of problem-solving proved to be particularly important for learning success with regard to resolving impasses. This appears to be consistent with three key characteristics of scaffolding (contingency, fading and transfer of responsibility), which were suggested by van de Pol et al. (2010).

The current investigation contributes to clarifying the question of how scaffolding (particularly contingency and fading) can be effectively afforded. This is also important for teacher education and training, as empirical investigations into individual learning support in instruction show that it is predominantly of only modest quality (Krammer, 2009).

From a methodological perspective, the study contributes to the development of instruments aimed at measuring scaffolding. As mentioned, for instance, by van de Pol et al. (2010), the main challenge is to measure scaffolding. With our analyses, which take into consideration the task, the problem-solving process, the handling of impasses, and teachers' and students' behaviour as well as the match between them, we hope to make a contribution in this regard.

SYMPOSIUM

The relational dimension of collaborative learning

Chairperson: Charles Crook, LSRI, United Kingdom

Organiser: Sanna Jarvela, University of Oulu, Finland

Discussant: Michael Baker, CNRS - Telecom ParisTech, France

The way that students try to solve problems together, and what they learn, depends on the relations between three dimensions of their collective activity: what task they are trying to achieve (the cognitive dimension), how they relate to each other (the socio-relational dimension) and what they feel about that (the affective dimensions). In this symposium we address the role of socio-relational aspects in collaborative learning. Although our primary concern here is with the *hic et nunc* of learning that can occur in interactions between students engaged in cooperative problem-solving, the three studies we present also address a broader vision that relates the study of such microgenesis with the levels of ontogenesis (the social elaboration of knowledge) and of sociogenesis, when the social, institutionalised and artefactually mediated organisation of knowledge elaboration is in focus.

(1) The contribution by Crook addresses the social elaboration of knowledge, seen as the striving for shared experiences, leading to "togetherness". This paper discusses factors that are likely to mediate or disturb togetherness.

(2) Sins and Karlgren combine two studies about the role of tensions and their resolution in professional practices: tensions within medical teams, and tensions between teachers and researchers during reflective meetings.

(3) Damsa and Ludvigsen take collaborative learning as a phenomenon which has to be analytically accounted for. The case study focuses on how students deal with disagreements when co-constructing knowledge, in the context of a collaborative research project.

The mediation of 'togetherness' in learning

Collaborative Learning, Social Aspects of Learning, Social Interaction in Learning and Instruction
Charles Crook, LSRI, United Kingdom

This paper will theorise a collaborative experience of learning in terms of the overarching concept of 'togetherness'. The advantage of this conception is that it makes contact with comparative and developmental observations of the human appetite for shared experience. It also invites us to work with a more generous definition of the 'social' in accounts of collaborative learning. In particular, the framework will be deployed to draw attention to the impact of new forms of educational mediation. That is, how a variety of new designs and technologies disturb communication in established educational arena that furnish togetherness. This will be illustrated with unpublished material relating to conversational, expository and communal contexts of learning. It is argued that technologies for managing formative feedback, and technologies for supporting expository presentation can undermine structures of intersubjectivity. On the other hand new designs for the socialisation of learning spaces can create new forms of intersubjectivity in terms of learners' interest in conditions of social ambience during study.

In recent years, a wide range of intellectual traditions concerned with human action have adopted a "social turn". That is to say, theorists have turned away from perspectives centred upon individual minds and turned towards perspectives that highlight social interaction and social practice. Of course such perspectives had already flourished in certain sectors of scholarship. Yet, even in social psychology and sociology, familiar issues of identity, relationships, and authority have now come to be understood in terms of the detailed dynamic of interacting with others (Schiffrin, 1994). More surprising, the mainstream of cognitive psychology increasingly theorises human thinking 'outside of the box': that is, as human activity distributed over social and cultural resources (Clark, 1997).

That the experience of learning should be 'social' is an idea whose time has truly come. Yet it is an idea that deserves further theorising - if policy, practice and design are now to be so clearly guided by it. In particular, it will be important to establish if celebrating the social in human learning can mean something deeper than simply the routine of responding to 'social stimuli' - a perspective that treats the social very much in the manner of other forms of 'input' to learning. It will be argued here that there is indeed an element of human learning that goes beyond such 'social stimuli' simplification: there is something about the social in the human experience of learning that is distinctive and powerful. Simply put: it arises from our natural motive to achieve shared experiences. The realisation of that motive will be discussed in this paper in terms of the experience of 'togetherness'.

This paper will highlight how such experiences of togetherness can be located within a wide range of educational contexts. It will be suggested that young people enter formal education with natural experience of participating in broad three formats of social communication: these are conversational structures, expository structures, and community structures. Educational practice usefully appropriates our familiarity with these formats. Each of them offers the possibility of learning together but offering different routes towards creating a sense of shared experience.

The discussion will stress how such togetherness is inevitably mediated. That may be through distinctive ways of talking but also through the use of particular communication tools, or engagement with particular ecological designs. Several examples remind us how the quality of togetherness in interpersonal communication might be disturbed by re-mediation. For example: by new tools for managing feedback conversations, new tools for supporting expository talk, and newly designed spaces in which students may gather for study.

The paper will report unpublished examples in the three broad formats for social experience identified above as central to the young learners everyday sociality. First, in relation to togetherness achieved within conversational contexts: here it will be noted how new technologies for managing feedback on student assignments disrupt the sense of shared experience. Second, in relation to togetherness that can be achieved in exposition: here we note how new technologies for the visual and virtual support of lecturing disturb the intersubjectivity that is possible in those contexts. Finally, new designs for learning spaces and how they create new forms of togetherness by catering to the student's appetite for a social ambience in learning.

The examples are taken to stress how, with proper attention to the working of such mediation, it should be possible to create educational experiences that take advantage of a human appetite for shared experience and to avoid those that disrupt it..

Identifying and overcoming tension in interdisciplinary teamwork in professional development Collaboration, Knowledge Creation, Social Aspects of Learning

Klas Karlgren, Karolinska Institutet, Sweden

Patrick Sins, Leiden University, Netherlands

A central interest in developing professionalism resides in the potential for practitioners to learn from and with one another in ways that support transformations of their knowledge practices. However, negotiation between multiple perspectives, interests, practices and traditions intertwines cognitive-epistemic with socio-relational and affective aspects, which may lead to tension and conflict. While tension can disable learning, we argue that identifying these tensions should be viewed as a significant source for change and development. We will present two cases, which show similar patterns. Tension in medical teams is a threat to patient safety. However, an uncritical attitude does not foster learning, and instructors at simulation training courses may therefore put focus on tensions through questioning. Eventually learners may develop skills in analysis, which cover explanations and strategies and which provide a fruitful approach to the problems. The second case investigated teacher-researcher collaboration at a secondary school, and focuses on the design of a learning module. Identification of tensions during meetings helped participants to focus their efforts on the root causes of problems, which led to a reconceptualisation of the current work practices. This subsequently helped team members to deviate from established norms and improve their practices.

A frequently stated argument in collaborative learning research is, that diversity in collaboration between learners is a significant resource for learning. However, negotiation between multiple perspectives, interests, practices and traditions may lead to tensions and conflicts that can possibly disable learning. Nevertheless, several authors have argued that identifying these tensions should be viewed as a significant source for learning (e.g. Engeström, 1987; Wenger, 1998).

Drawing upon the seminal works of Heidegger (1962), Dewey (1966) and Leont'ev (1981), tensions are viewed as a means for revealing the nature of our understanding and are conceptualized as the antecedents of opportunities for creative efforts in collaboration and are as such the driving forces behind learning. The underlying mechanism that explains how tensions can result in learning is based on the premise that awareness of ignorance motivates learning. This means that, in order to overcome tensions, learners have to reflectively analyze their collaborative activities and question and deviate from established norms and practices. This awareness of shortcomings and subsequent search for solutions to overcome these tensions may lead to creative externalization or new ways of doing. This suggests that tensions are not only an opportunity to improve, they are also of crucial importance to coordinate the process of learning. In sum, tensions help learners to counter the blindness that is inherent to the way things are normally done and they may uncover a space of alternative actions in taken-for-granted activity.

However, what is still lacking in accounts and studies of tensions and conflicts as conditions for learning is a (a) consensus on defining and operationalizing terms and (b) complementary description of how tensions get resolved. With respect to the former, several constructs have been put forward from cognitive, sociological as well as sociocultural epistemologies that more or less point in a similar direction but which have not yet been related to one another. Secondly, although some quantitative and qualitative studies have investigated the relation between particular types of tensions or conflicts on learning outcomes, no cross-referencing could be found regarding the way(s) in which learners overcome tensions and how this relates to learning.

In the present paper, we will present the data of two studies in the fields of medical simulation training and of a school-university partnership at a secondary school, respectively, which show similar patterns in the cognitive-epistemic consequences and resolution of tensions.

Method

Multiple, intertwined methodological approaches to data collection and analysis were combined to elaborate dynamics of incremental changes which reflect practice transformations resulting from patterns of tension resolution. The two cases involved ethnographic studies with participatory observation, developmental intervention approaches interviews and event sampling to follow processes towards new practices. Our analyses took tensions in professionals' activities as a point of departure. We look for episodes in the material that express problems and materializes as developmental tensions. Then we can investigate discursive activities between professionals (micro level), elaborate on episodes of tension resolutions over time (meso-level) and examine how patterns of tension resolution relate to transformations of practices at the level of trajectories (macro-level).

Results

The findings show that the interaction between different knowledge trajectories occurred on both the individual and collective platform and showed how professionals stabilized out of flux by changing their practices accordingly. This means that during the meetings of respectively the medical teams and the pedagogical design team, different modes of knowledge intersected and tacit knowledge (represented as the network of implicit epistemological beliefs, attitudes and knowledge) was explicated. We observed that the work around shared objectives and the tensions that emerged from this process, served to elaborate and refine existing knowledge practices, and develop new ones.

In both cases, we have identified similar patterns of managing or resolving tension, namely:

1. Highlighting the tension: Often, tensions are not about the issue at hand (e.g., scheduling a meeting) but rather about what it represents, such as the experience of disrespect or the illegitimate exercise of authority. A tension could only arise as the consequence of one of the partners during their knowledge construction work to describe a particular problem at hand;
2. Identifying the contradiction: as a result of partners knowing what the tension is at hand, the contradiction(s) in perspectives, knowledge, attitudes or affects come to the fore explicating the problematic features of existing practices. These are explicated in the voices of the several partners in their collaborative knowledge construction work;
3. Framing the contradiction: subsequently, the contradiction is framed employing the self-created language, norms and rules of the design team. This framing is necessary for creating a shared understanding of the tension and for constructing a representation of the forces acting in preserving and causing the problematic practices at hand. This eventually enabled teachers to adapt their practices to be able to overcome the tension;
4. Constructing solutions: Finally, partners transform their own or shared practices, construct new tools and implement them in their ongoing knowledge construction work.

Conclusion

In the present paper we aimed at describing patterns of tension resolution in two research cases from the fields of respectively medical simulation training and pedagogical design in the context of a school-university partnership. Based on socio-historical perspectives on learning and development, we have appropriated the notion of developmental tensions as a driving force of change and development. Although we do not claim that developmental tensions are the sole impetus of transformations of work practices, the investigation of tensions and their resolution helps to identify the dynamic forces of change and comprise an important constituent and starting point for investigating such processes.

Knowledge co-construction - epistemic consensus or relational assent?

Crina Damsa, University of Oslo, Norway; Sten Ludvigsen, University of Oslo, Norway

In this contribution, we investigate learning in collaboration by examining how university students deal with concepts and ideas in the educational research domain. We seek to understand how students co-construct a conceptual system that allows them to pursue their investigation, and how they externalize and appropriate concepts related to a specific domain and task. We analyze the social interaction of a small student group, involved in a collaborative research project as part of their Bachelor thesis. The findings show that students had no problems to attribute meaning to each concept, but that establishing the position and role of these concepts in relation to each other, and to the investigated context, was a challenging task. Co-constructing a conceptual system led to repeated attempts of the individual members to make the others understand and accept their own view. What appeared important was that (tacit) discrepancy was explicated and acknowledged in a considerate way by collaborating partners. Contradictory ideas did not seem to lead to conflict or breakdown in the group's discourse or at relational level, but to participants explicating their thoughts and ideas, becoming aware of the implications of these ideas and creating ground for joint epistemic efforts. In this sense, the disagreements were used as means to challenge the ideas expressed.

Introduction

In this contribution, we investigate learning in collaboration by examining how university students deal with concepts and ideas in the educational research domain. We seek to understand how students co-construct a conceptual system

that allows them to pursue their investigation, and how they externalize and appropriate concepts related to a specific domain and task. The rationale is that, in order to develop pedagogical contexts that increase the occurrence of interactions that may contribute to co-constructing knowledge, we need to understand the elements that allow participants to reach a joint solution and to balance the epistemic, social-relational and affective elements in the collaborative process.

We do not take collaboration for granted but conceive it as a 'phenomenon' that must analytically be accounted for, based on the empirical data at hand. Our stance is based on socio-cultural and dialogical perspectives on human activities and reasoning. In social interaction, participants involve themselves with language, concepts or objects, which become relevant in the interaction. When social interaction breaks down or misunderstandings appear, participants must use repair strategies to continue communication and the knowledge co-construction process.

While various conceptualizations of collaboration capture important aspects of the knowledge co-construction process (i.e., people use each other and each others' expertise and skills to accomplish common goals), many seem to overlook the social-relational aspects inherent to collaboration. A number of studies (Barron, 2003; Engle & Conant, 2002) showed that relational issues can hinder or stimulate participants in dealing with and capitalizing on the insights constructed in the group. Resuming disagreements in a productive manner involves innately addressing these relational issues, but ultimately in a way that creates premises for interaction that assures epistemic progress. This necessitates more than simple accumulation of individual contributions, but negotiation, joint understanding and building on each other's ideas (see Baker, 2009). We can not take for granted that participants have developed their capacity to use key concepts specific to the knowledge domain in a coherent way, i.e., whether they developed their own thematic patterns and communicative repertoire. These capacities develop gradually, through active involvement with the domain knowledge and in interaction with peers.

Methods

The participants in this case study were four female students (average age 25,3, SD=1,6) enrolled in the Bachelor Thesis course at a large Dutch university. This is a 20-week course that aims to support students in applying previously acquired scientific research knowledge and skills. The course was organized according to a project-based model and participants were required to collaboratively set-up and conduct a research project, with research article as final product. This contribution discusses primarily group discussions held throughout the project period. In the analysis, we selected interaction episodes from students' talk, with an episode corresponding to a logical sequence of collective action. We used the concepts of orientation (what students talk about), elaboration (how they talk), and confirmation (uptake of ideas) to make sense of the data. We also used disagreement as analytic concept, depicting a mode for communication that allows the participants to express and problematize divergent ideas.

Findings and discussion

The interaction sequences displayed students' attempts and struggle to understand the concepts they work with. As such, they had no problems to attribute meaning to each concept, but establishing the position and role of these concepts in relation to each other and to the investigated context, was a challenging task. Co-constructing a conceptual system led to repeated attempts of the individual members to make the others understand and accept their own view. Analyses revealed students developing a basic orientation on the concepts they knew and domain-knowledge they possessed. They tried to construct and elaborate thematic patterns by employing domain-specific language and terms (e.g., feedback, motivation, measuring, receiving positive or negative feedback, questioning people, higher motivation, etc.). Elaboration and confirmation were employed at two levels. At linguistic level, students used language devices to make themselves clear or to indicate they understood others' ideas. At content level, when elaborating on their ideas, students employed 'technical' research terms and attempted to present ideas in a scholastic manner. Confirmation was visible from a cross-episode perspective, which revealed that ideas were taken up and elaborated mostly after consensus was verbally expressed.

Various ways of addressing knowledge gaps were identified in the analyzed material, such as posing own views and providing arguments, providing own elaboration or inviting the others to adjust or elaborate further. What appeared important was that (tacit) discrepancy was explicated and acknowledged in a considerate way between collaboration partners. Some of the group members made conscious decisions to overcome communicational breakdown caused by disagreements. As the discussion progressed, this commitment to consensus diminished. Nevertheless, contradictory ideas did not lead to conflict or breakdown in group's discourse or interaction, but to participants explicating their thoughts and ideas, becoming aware of the implications, and creating ground for joint epistemic efforts. In this sense, disagreements were used as means to challenge the ideas expressed. Through negotiation, argumentation and clarification, the group worked toward a convergence of meaning, and partly a shared account of the conceptual system constructed.

Theoretical and practical significance

The theoretical significance of this paper is related both to the empirical findings and the methodology used. By using the described approach we are able to discriminate how interaction makes conceptual understanding possible through social and relational moves. From an educational practice perspective, we maintain that these findings can support teachers to develop interventions that are directed towards guiding students in their efforts to attend joint understanding and build on each others' ideas when working with complex conceptual systems.

SYMPOSIUM

Deaf children and mathematics learning

Chairperson: Ines Borges, Universidade Nova de Lisboa, Faculdade de Ciencias e Tecnologia, Portugal

Organiser: Beatriz Vargas Dorneles, Universidade Federal do Rio Grande do Sul, Brazil

Terezinha Nunes, University of Oxford, United Kingdom

Discussant: Margarida Cesar, Universidade de Lisboa, Portugal

Research on young deaf children's mathematical knowledge can help understand why many deaf children are delayed in mathematical achievement throughout their schooling. This symposium considers young deaf children's mathematical knowledge.

It is common to distinguish numerical representations not mediated by counting (iconic) from those mediated by counting (symbolic). One explanation for mathematical difficulties is poor iconic representations, detectable at young ages. Barbosa analysed deaf children's number representation; deaf children are as good as hearing children in iconic representations but underperform in symbolic representations.

Symbolic representation involves understanding additive composition, crucial for learning number systems with a base. Dorneles and Vargas analysed whether deaf children of deaf parents (DoD) differ from those of hearing parents (DoH) in learning additive composition and counting. DoD have greater experience with counting routines in sign and were expected to learn faster during the intervention. However, they found more similarities than differences between the children's response to intervention.

Nunes et al. developed an intervention to promote deaf children's learning of key mathematical concepts at the start of primary school. The intervention was effective in improving the children's mathematical achievement.

Together, these papers suggest that the mathematical delay starts early, and make a strong case for early interventions to promote deaf children's mathematical learning, while indicating specific forms that interventions could take.

An early intervention to improve deaf children's mathematical learning

Terezinha Nunes, University of Oxford, United Kingdom; Peter Bryant, Department of Education, University of Oxford, United Kingdom; Deborah Evans, Department of Education, University of Oxford, United Kingdom; Rossana Barros, Department of Education, University of Oxford, Peru; Diana Burman, Department of Education, University of Oxford, United Kingdom

Deaf children lag behind hearing children in mathematics in standardised assessments and in tests of early mathematical concepts learned informally. We report two intervention studies in which deaf children were taught about three key informal mathematical concepts that are difficult for them: (1) the addition-subtraction inverse relation; (2) additive composition; (3) multiplicative reasoning. We hypothesized that, if the deaf children were able to progress on these concepts, their mathematics achievement could be raised.

Both studies used a quasi-experimental design, with teachers and their pupils assigned to the intervention or comparison group as a unit. In the first study, 75 children from 16 schools participated, and in the second, 86 children from 23 schools.

All children were pre-tested in a Mathematical Reasoning Test (MRT) and a measure of cognitive ability (BAS-Matrices subtest). These measures were covariates in the analyses of the effectiveness of the intervention. At post-test, the children completed the MRT and the Performance Indicators in Primary School (PIPS-Mathematics). In both studies, teachers implemented the intervention after a day of professional development.

Significant differences between the groups were found at post-test in both outcome measures and in both studies; Cohen's d effect sizes ranged from 0.52 to 1.13.

Thus, early interventions on key informal mathematical concepts can significantly improve deaf children's mathematical reasoning and learning in the first years of school.

Deaf children lag behind hearing children in mathematics in standardised assessments as well as in basic informal mathematical concepts constructed by most hearing children before school. Our hypothesis was that, if deaf children learn these concepts in school, they will make substantial progress in mathematics.

We report two intervention studies in which deaf children were taught about three of these key concepts in school: (1) the inverse relation between addition and subtraction; (2) additive composition; (3) multiplicative reasoning. Deaf children are behind in these concepts at school entry. Thus, it was reasoned that, if the deaf children were able to progress on these concepts through an intervention, their mathematics achievement could be raised.

In both studies, a quasi-experimental design was employed. Teachers of the deaf were recruited for participation through an advert in their professional magazine and through emails sent to schools that cater to deaf children. The aims of the intervention were to improve the children's understanding of the inverse relation between addition and subtraction, additive composition, and the use of one-to-many correspondence in multiplicative reasoning. Teachers and students were assigned to the intervention or comparison group using a waiting list model. Statistical analyses appropriate for quasi-experimental designs (ANCOVAs) were used in both studies.

Study 1

Participants: Children ($N=75$) from 16 different schools were recruited. Eight intact classes ($n=30$ children) were assigned to the intervention and eight ($n=45$ children) to the comparison group. The children's mean age at the start of the intervention was 6.5 years ($SD = 1.07$); their hearing loss was at least moderate; 16 had cochlear implants. Unfortunately, there was a loss of 30% of the participants due to different reasons (parents took early holidays, illness); at the end of the year, there were 22 children in the intervention group and 23 in the control group.

Method

Before the intervention, all the children were tested in a Mathematical Reasoning Test (MRT; Nunes & Bryant, 2000) and the British Abilities Scale matrices subtest (BAS, Elliott, 1997). These measures, and the children's post-test age, were covariates in the ANCOVAs. At post-test, the children completed the Mathematical Reasoning Test again and the Performance Indicators in Primary School (PIPS), a standardised mathematics test (Tymms et al, 2003) that has been adapted for deaf children and correlates highly and significantly with the MRT ($r=.81$).

Intact classes were assigned to each group. The intervention teachers participated in a professional development (PD) day before the start of the project; the comparison group teachers participated in a PD after the post-test. Project implementation was monitored through phone calls, emails and visits. The design was an "intention to treat" design so completion and faithfulness of the intervention are not analysed.

Results and conclusion

There were no significant differences between the groups at pre-test in hearing loss, BAS matrices, and MRT. Hearing loss did not correlate significantly with any of these measures, and thus was not entered in the analyses.

The ANCOVAs had three covariates: age at post-test, BAS and MRT at pre-test. Significant differences between the groups were found at post-test in both outcome measures: for the MRT, Cohen's $d=0.99$, and for the PIPS, Cohen's $d=0.52$.

Thus the children benefited significantly from the intervention both in terms of mathematical reasoning, which we set out to improve, and mathematical learning, measure by the PIPS.

Study 2

Participants: Participants were recruited using the same procedure as previously. Because no changes had been made to the national mathematics curriculum since the previous, we decided to include all schools in the intervention group in this year and use the data from the previous year as a comparison group. As inclusion criteria, we restricted the children's age, BAS matrices and MRT to the same range as the comparison group. The intervention group (N=56) came from 23 schools. The mean ages were 6.6 years (SD = 1.17) for the comparison group and 7.59 (SD=0.96) for the intervention group. There was a significant difference between the groups in age and MRT; the BAS matrices scores did not differ significantly. Hearing loss was at least moderate in both samples, but the average loss was significantly higher in the intervention group. The level of hearing loss did not correlate significantly with the BAS matrices scores or with MRT, so it was used as a selection criterion or as a covariate in the analyses. The proportion of children with cochlear implants was 26% in the control and 36% in the intervention group. The difference between children with and without cochlear implants at pre-test was not significant in the BAS matrices but there was a trend in the MRT ($p=.059$) so we decided to control for the presence of a cochlear implant when analysing the intervention effects.

Method

This intervention had the same aims as in study 1; participating teachers were prepared through a PD day. The materials were enhanced with the addition of computer games played on the web, which gave the children further opportunities for working with the target concepts.

Results

Two ANCOVAs with age, BAS matrices, presence of a cochlear implant, and pre-test results on MRT were run; in both, the only significant covariate was MRT. The groups differed significantly at post-test in the MRT and the PIPS; for MRT, Cohen's $d=1.37$; for the PIPS, Cohen's $d=0.76$.

Conclusions and implications

When deaf children start school, they have not developed some key concepts that form the basis for mathematics learning. These concepts are not taught in school, but are required for understanding what is taught. Interventions that promote the learning of these concepts can have significant effects on their mathematical reasoning and learning in the first years of school. The replication of the group differences with two cohorts of teachers and children gives us great confidence in the possibility of improving deaf children's mathematical achievement.

The development of counting in deaf children: comparing a native signer and an oral child

Beatriz Vargas Dorneles, Universidade Federal do Rio Grande do Sul, Brazil; Rosane Vargas, PUC, Rio Grande do Sul, Brazil

This case-study investigated whether deaf children from deaf parents (DoD) are at an advantage to learn number concepts in comparison to deaf children from hearing parents (DoH). The hypothesis was that DoD develop an understanding of the regularities of the counting system and additive composition faster than DoH due to their earlier experiences with sign language. We compared the response to intervention of two six-year old children: a DoD boy and a DoH girl. Both had the same IQ, had attended school for one year, and respected the five counting principles at pre-test.

They participated in a brief intervention (five sessions) designed to improve their understanding of additive composition and their use of appropriate counting strategies in problem solving. Each child worked in individual sessions with an experienced teacher of the deaf. After the five sessions the children were re-assessed. Both improved the use of economic counting strategies and in understanding of additive composition; their counting range also increased to a similar level. The similarities in learning by the DoD and the DoH children suggest that both groups may benefit from the same sort of teaching and show that these interventions do not have to be differentiated according to the hearing status of the parents.

Young children's number knowledge involves recognizing quantities perceptually, without counting, and also learning to count. Counting is the first mathematical cultural tool learned by children. Learning to count requires respecting the counting principles, understanding the regularities of the counting system and using numbers in different situations to quantify sets; thus it involves linking reasoning schemas with language (RESNICK, 1989). Around age three, most hearing children can count to five as they point the objects and respect the first five counting principles: one-to-one correspondence, stable order of labels, cardinality, order irrelevance and abstraction. Less information is available regarding the early mathematical skills of deaf children in the same age range and when they begin to use these first principles. In the domain of number representation without counting, Zarfaty, Nunes & Bryant (2005) observed that deaf children performed as well as hearing children in a number reproduction task in the absence of the model. They also found that the deaf children performed better than the hearing children when the set to be reproduced was

presented as a simultaneous, visual display. Deaf children seem to learn how to count more slowly than hearing children, but within their limited counting range, deaf children aged three to six years are as able as hearing children to use the counting principles (Leybaert & Van Cutsem, 2002). However, they seem to be at a disadvantage in understanding the regularities of the number system (Nunes, 2004).

A recent study (KRITZER, 2009) confirmed that deaf children prior to the onset of formal schooling count to a lower number than hearing children and are already at a disadvantage on informal mathematical concepts. Although Kritzer did not report whether the differences between deaf children were related to their exposure to sign language from an early age, his study contains sufficient information to allow for examining the relationship between the parental hearing status and the children's mathematics results. Of the 29 participants, 17 had at least one deaf parents, and 5 were classified as higher in mathematical ability within the group, 10 as average, and 2 as lower; 12 children had hearing parents, and 1 was classified as higher in mathematical ability, 6 as average and 5 as lower. Assuming ordinal measurement, Kendall's tau for this distribution of scores shows a significant association between parental hearing status ($T=2.26$; $p=.02$). However, it is possible that this association would be due to other factors, such as differences in IQ or previous exposure to schooling.

The present study aimed to investigate, using a case study approach, whether deaf children from deaf parents are at an advantage to learn further number concepts in comparison to deaf children from hearing parents. The concepts investigate here were understanding additive composition and the regularities of the counting system.

Methods

The main hypothesis is that deaf children of deaf parents (DoD) develop an understanding of the regularities of the counting system and additive composition faster than deaf children of hearing parents (DoH) due to their earlier experiences with sign language. To test this hypothesis, we compared the response to intervention of two six-year old children: a DoD boy and a DoH girl. The children had the same measured IQ (by the WISC-R), had attended school for one year, and respected the five counting principles at pre-test.

They then participated in a brief intervention (five sessions implemented over three weeks) designed to improve their understanding of additive composition (which we expected would increase their counting range) and their use of appropriate counting strategies in problem solving. Each child worked in individual sessions with an experienced teacher of the deaf (the second author). During the intervention, the children used counting to represent quantities presented spatially and to "buy" objects in the Shop Task (see Nunes, 2004). These interventions used principles which were shown to be beneficial for hearing children's learning. After the five sessions the children were re-assessed.

Results

Contrary to our expectations, there were more similarities than differences in the children's learning. Both improved the use of economic counting strategies (i.e. in an addition situation, counting up from the larger addend) and in understanding of additive composition; their counting range also increased to a similar level. Being DoD did not turn out to be a crucial factor in how much the children benefited from the intervention.

Conclusions

The study converges with previous investigations that shown that processed in the development of counting are similar in deaf children and hearing children. It also replicates previous findings that brief interventions can help deaf children to improve their understanding of the number system. The similarities in learning by the DoD and the DoH children suggest that both groups may benefit from the same sort of teaching to improving their counting skills and understanding of the number system. This is an important result for education as it underscores both groups' needs for early intervention in number knowledge and shows that these interventions do not have to be differentiated according to the hearing status of the parents.

From iconic counting to symbolic cardinality in young deaf Brazilian children using sign language

Heloiza Barbosa, Universidade Federal de Santa Catarina

Studies have demonstrated that deaf children have difficulties acquiring the numerical sequence used in counting. In this investigation, we look at the ability of 6-year old deaf children ($N=11$) using sign language to iconically represent numerical information presented either spatially or temporally, as well as, at their knowledge of the counting sequence and procedures. Two groups of hearing children ($N= 22$) controlling for age and schooling were tested in this study. There was no difference between deaf and hearing children in their ability to iconically represent and recall sets from 2 to 6 items presented spatially and temporally. Deaf signers showed better performance in spatial condition. Regarding the counting abilities, deaf signers and 5-year olds had a low counting range and were more likely to recite a numerical sequence to answer a cardinality question than the 6-year-olds. These results suggest that deaf children and 5-year olds might benefit from educational interventions that support the passage from iconic to symbolic thinking.

Young deaf children have difficulties acquiring the numerical sequence used in counting (Leybaert & Van Cutsem, 2002). It was suggested (Wiese, 2003) that the numerical counting sequence of young children has an iconic function initially, and become symbolic, when they use the last word of the counting to indicate cardinality. The hypothesis in this investigation is that the counting by deaf children maybe be iconic for a longer period than for hearing children. The present study, first, provides data on number representations and sequence recall of Brazilian young deaf children educated in sign language. Second, it investigates the acquisition of the counting sequence and its link with numerical representations.

The participants ($N= 33$) were deaf preschoolers ($n=11$) attending state schools with the mean age in months 73.5 ($SD= 8.5$) and educated in a signing environment. Two groups of hearing children from state preschool programs were selected as comparison groups: (a) age: 6-year olds ($n= 11$; $M= 73.7$; $SD= 3.0$), who have the same chronological age but have been in preschool for a year longer than the deaf children; (b) 5-year olds ($n= 11$; $M= 64$; $SD= 3.0$), who are younger but have been in preschool as long as the deaf children

Task 1- Representation of sets: spatial and temporal.

The children were presented with sets of 2 to 6 heterogeneous objects and asked to reproduce the stimuli set with the items in the same order after the set was no longer visible. The objects were either presented together, as a spatial group, or sequentially, as a temporal group. This task assesses the children's iconic numerical representation and ability to reproduce a sequence.

No differences were found between deaf and hearing children in reproducing sets presented either spatially ($p= .60$) or temporally ($p= .20$), although they took longer in the temporal condition ($p= .009$). The set of six items, which is beyond subitizing skills in this age, was reproduced correctly by 27.3% of both deaf signers and hearing 6-year olds. In contrast, the six-items spatial set was represented by only 9% of 5-year-old hearing children. Thus deaf signers and hearing children are able to represent numerical information presented in both conditions, although the spatial condition seemed easier to deaf children. Deaf and hearing children did not differ in their ability to recall a sequence and in their iconic numerical representation.

Task 2 - Counting sequence and symbolic numerical representations

Participants were requested to count to the highest number they knew and also to count sets of objects (with 6, 10 or 15 items) and printed figures (6, 10, 15 or 30) and say how many items were in the sets, after the sets had been removed from view.

The children were classified as showing basic (1-10), median (11-59) or advanced (60-100) knowledge of the counting sequence. 82% ($N=9$) of the deaf signers were at the basic level; the majority of the deaf children did not know number signs above 10. The majority of the hearing 5-year olds were in the low end of the median level; they stopped counting between 12 and 19. In contrast, the majority of the hearing 6-year olds were in the higher median or advanced levels. The mean difference in the counting score between groups is significant.

When the deaf children were asked to count objects or pictures and say how many there were, they rarely use number signs to count and to inform the cardinality. Instead, they counted by matching fingers and items in an iconic fashion. In sets bigger than ten, they also counted in an iconic fashion and, to inform the cardinality, they unfolded fingers, one at time, up to ten followed by the sign of "many". Surprisingly, the same pattern of results was found in the hearing 5-year olds: they produced counting words sequence in the low range and, in sets beyond their knowledge of counting, they repeated number words to complete the counting by matching word-item; they rarely used referent

number words to inform the cardinality, instead, they recited an unconventional numerical sequence. The older hearing children performed at ceiling on both counting tasks.

Discussion & Implication

Deaf signers and hearing children do not differ in the ability to represent numerical information iconically and to recall a sequence. However, deaf children and hearing 5-year olds with less educational experience have a lower counting range than children with a longer educational history, irrespective of age (5 or 6 years). The former groups also have difficulty with the symbolic representation of cardinality whereas the latter group does not. Wiese (2003) argued that the passage from iconic to symbolic representation is supported by routines, which could be learned in preschool settings. Deaf and hearing children might benefit from mathematics programs that support the passage from iconic to symbolic thinking.

SYMPOSIUM

Effects of early education on children's academic progress in Primary: UK, Finland, and Germany

Chairperson: Kathy Sylva, University of Oxford, United Kingdom

Organiser: Kathy Sylva, University of Oxford, United Kingdom

Discussant: Pamela Sammons, University of Oxford, United Kingdom

The importance of early education experiences during the pre-school years is well known, and there is now widespread agreement that high quality home and pre-school environments provide children with a 'head-start' in cognitive and academic development. Children who begin Primary school with a stronger foundation in emergent literacy and numeracy skills are often able to maintain their initial lead in academic achievement compared to their peers. What remains unclear, however, is whether early education experiences fundamentally change children's learning capacity, and if pre-school effects interact with primary schooling to shape individual growth trajectories. This symposium seeks to address these questions through three papers on large-scale longitudinal studies conducted in England, Finland, and Germany. The British study investigates whether high quality pre-school experiences actually enhance children's ability to learn, i.e. not only giving them a stronger 'profile' at school entry, but also enabling them to make greater gains in academic achievement (in English and Mathematics) over the primary school years (ages 7-11). The Finnish study focuses on children deemed to be at-risk for reading disability in kindergarten, and examines how factors in their pre-school 'profile' (i.e. better pre-reading skills, self-concept, and less task-avoidant behaviour) influence the effectiveness of teacher support and remedial reading instruction in Grades 1-2 of Primary school. Finally, the German study explores children's early numeracy development from ages 3 to 7 (preschool to first year of Primary), and examines the interactive effects of pre-school process quality (in fostering early academic skills) and primary school instructional quality.

The effects of pre-school on the rates of academic progress children make during the primary years

Kathy Sylva, University of Oxford, United Kingdom; Edward Melhuish, University of London, Birkbeck, United Kingdom; Pamela Sammons, University of Oxford, United Kingdom; Iram Siraj-Blatchford, Institute of Education - University of London, United Kingdom; Brenda Taggart, Institute of Education - University of London, United Kingdom

Much research has shown that high quality pre-school experiences provide young children with a stronger pre-academic 'profile' upon school entry, and this advantage remains over the Primary school years. Few studies, however, have examined whether early learning actually enhances children's ability to learn, enabling some students to make greater gains in academic subjects compared to their peers who had less favourable pre-school experiences. This paper presents findings from a longitudinal study on a representative sample of 3000 children in the UK. Using an 'educational effectiveness' design, the study examined the 'value-added' by pre-school quality (as measured by the Early Childhood Environment Rating Scale-Extension) to children's academic gains between ages 7 and 11 (i.e. Years 2 to 6 of Primary school) in English and Mathematics. Results from hierarchical linear models showed that pre-school attendance alone (irrespective of quality) was associated with better academic attainment at age 11, but this did not translate into a predictor of better progress in either subject. Instead, the key to becoming a more effective learner was the quality of the pre-school provision. Furthermore, high quality pre-schools also acted as protective or compensatory mechanisms against poor quality home learning environments, giving those children an extra boost. In short, children who had experienced higher quality pre-school provision not only maintained their lead in academic achievement compared to their peers, but they also made greater gains over the primary school period. The benefits

of quality early learning experiences are therefore long-lasting and cumulative, fundamentally improving children's capacity to learn.

Aims:

The contribution of early education to children's cognitive development has been researched for decades. It is often shown that high quality pre-school experiences provide young children with a stronger pre-academic 'profile' upon entry to school, and that this advantage remains over the Primary school years. Few studies, however, have explored whether early learning actually enhances children's ability to learn, fundamentally changing their academic development trajectories. This paper contributes to the literature by presenting findings from the Effective Pre-school and Primary Education (EPPE) Project, a longitudinal study on a representative sample of 3000 children in the UK. The aim was to examine the contribution of pre-school to children's academic progress between ages 7 and 11 (i.e. Years 2 and 6 of Primary) in English and Mathematics.

Methodology:

The EPPE project is Europe's largest longitudinal investigation into the effects of pre-school and primary education on children's developmental outcomes. It was commissioned by the British government and adopts an 'educational effectiveness' design (anonymous, 2007a, 2007b; anonymous, 2004) using mixed methods. Using multilevel modelling, the authors examined the contribution of child, family, home environment, and school characteristics to children's cognitive development in the period of 3 to 11 years. The view of reciprocal influences owes much to the work of Bronfenbrenner (1979), whose theory puts the child at the centre of a series of nested spheres of social and cultural influence, including home and education (anonymous, 2010).

Research questions

The research questions addressed in this paper are as follows: Do the effects of pre-school on children's academic development remain throughout primary school? Does the quality of pre-school have an effect on children's academic progress during primary school? How does pre-school quality interact with the home learning environment to shape children's academic progress over time?

Sample

Five regions in the U.K were strategically selected (including urban, suburban and rural areas, with social and ethnic diversity), and a total of 141 pre-school centres were randomly sampled from different types of provisions (e.g. playgroups, nursery schools, private day nurseries). Over 2800 children were recruited at age 3 and followed until school entry (age 5), when they were joined by an additional 310 'home' children with no pre-school experience. Approximately 2700 of these children were then followed for a further six years until the end of Primary school (age 11).

Child assessments

Children's results in Years 2 and 6 of Primary school on the statutory National Curriculum Assessments in English and Mathematics were collected, and the Year 2 scores served as baseline measures. The correlations between prior and later attainment were 0.77 for English and 0.73 for Mathematics.

Pre-school quality measure: Early Childhood Environment Rating Scale-Extension (ECERS-E) (anonymous, 2003).

Co-variates: Child, family, and home environment variables

Parental interviews and questionnaires were conducted at ages 3 and 7. Information was collected on parental characteristics (socio-economic status, educational level, employment and age), family characteristics (lone parent family and number of children), and child characteristics (ethnicity, birth weight, perinatal difficulties, child's first language, early developmental problems). An index of the Early Years Home Learning Environment (HLE) was also constructed, consisting of the following items rated on an 8-point scale (anonymous, 2001):

- .. Reading to child
- .. Painting and drawing with child
- .. Playing/teaching numbers/shapes to child
- .. Library visits with child
- .. Playing/teaching alphabet/letters
- .. Playing with letters/numbers with child
- .. Playing/teaching of songs/nursery rhymes etc.

Analytic strategy

Multi-level value-added models were used to investigate children's progress over time (i.e. cognitive gains) by controlling for their prior attainment, as well as a wide range of demographic and environmental influences. They also

take into account the amount of variation in the data that is due to the clustering of children within the same pre-school centre (Goldstein, 2003).

Findings:

There was clear evidence that pre-school attendance alone (irrespective of quality or effectiveness) was associated with better attainment in English and Mathematics during Primary school, but this did not translate into a predictor of better progress in either subject. However, there was evidence of the importance of pre-school quality for progress: for English, children who attended high quality pre-schools made greater progress between Years 2 and 6 than 'home' children (See Table 1). Similar effects were found for Mathematics (See Table 2). This suggests that quality pre-school experience not only provides children with an initial boost to attainment levels at school entry, but also helps promote progress (possibly by fostering children's capacity to learn and their motivation). The HLE was one of the most important background factors relating to children's academic attainment and progress in Primary school. Children who enjoyed a rich HLE made greater gains in both subjects over the 4-year period than those who experienced poorer provision. Finally, high quality pre-schools also compensated for the effects of experiencing poor quality home learning environments (See Figures 1 and 2).

Theoretical and educational significance:

This study has shown that children who had experienced higher quality pre-school provision not only maintained their lead in academic achievement compared to their peers, but they also made greater progress over the period. In other words, the benefits of early learning experiences are long-lasting and cumulative, fundamentally changing children's developmental trajectories.

There are three implications for policy and practice: (1) continue to support free pre-school education for all 3 and 4 year old children, (2) ensure good quality of pre-school education, and (3) support parents/carers in providing a high quality HLE (e.g. through structured parenting programmes). This research is therefore relevant to the monitoring of equity in education, and to policies that seek to raise standards, reduce the equity gap and promote inclusion.

The effects of teacher support on at-risk children's reading skills development in early primary

At-risk students, Reading, Remedial education; Marja-Kristiina Lerkkanen, University of Jyväskylä, Finland; Noona Kiuru, University of Jyväskylä, Finland; Anna-Maija Poikkeus, University of Jyväskylä, Finland; Minna Torppa, University of Jyväskylä, Finland; Timo Ahonen, University of Jyväskylä, Finland; Pekka Niemi, University of Turku, Finland; Jari-Erik Nurmi, University of Jyväskylä, Finland

The present study examined at-risk children's reading skill development and its longitudinal associations to the amount of teachers' individual support and attention and remedial reading instruction received at the Grades 1 and 2. The participants were 257 children who were identified at-risk for reading disability on the basis of their preschool pre-reading skills. Further reading skills were assessed twice in the first grade and once in the second grade. The teachers reported the amount of support and attention they gave to at-risk child in their classroom and the amount of remedial reading instruction the child received at school. The results showed, first, that the poorer the reading skills were, the more support and attention the child received from the teacher. Further analyses revealed that the amount of teacher's support and remedial reading instruction decreased across time among those at-risk children whose skills progressed so that they were at age level in reading by the end of grade 2, but teacher support increased and the amount of remedial reading instruction remained stable among children who lagged substantially behind the age level in reading by the end of grade 2. Moreover, children who were found to reach age level skills had better pre-reading skills and self-concept and less task-avoidant behavior in comparison to other at-risk children in preschool. The findings indicate that at-risk children with stronger preskills at school entry show greater progress over the early school years and are better able to benefit from teacher support than other at-risk children.

The Aims

Previous studies have shown that teachers' instruction and high classroom quality contribute to child outcomes (e.g., Howes et al., 2005; Pianta et al., 2008, Stipek et al., 1998). However, classroom instruction often seems to fail to support adequately at-risk children (Hatcher, Hulme, & Snowling, 2004) who require a high extent of individualized support (Torgesen, 2005). Within the tradition of reading intervention studies, little research has been carried out to analyze the extent to which classroom teacher individualized support enhances the reading skill development of at-risk children. The aim of the present study was to examine the longitudinal associations between at-risk children's reading skill development and the amount of teacher support and attention and remedial reading instruction at Grades 1 and 2. The research questions were:

(1) To what extent does the level of reading skills of at-risk children predict the amount of teacher support and remedial reading instruction that the child receives?

- (2) To what extent does the amount of teacher's support and remedial reading instruction predict the development of reading skills among children at-risk for reading disabilities (RD)?
- (3) Is the role of the amount of teacher's support and remedial reading instruction different for three subgroups of children at-risk for RD: those who caught up the age level in reading skills, those with a moderate lag behind the age level, and those with a substantial lag behind the age level by the end of the second grade?
- (4) To what extent do the subgroups of children at-risk for RD differ in factors related to the child (pre-skills and motivation) and to the home environment (parental education, parental teaching, shared reading)?
- (5) To what extent does the development of pre-reading skills at preschool differ between the subgroups of children at-risk for RD?

Methods

The present study used data from the ongoing longitudinal First Steps study, a prospective follow-up of 2057 Finnish children from the beginning of their preschool year (6 years of age) to the end of Grade 4 with simultaneous data gathering from the parents and teachers. The analyses involved 257 children (76 girls, 181 boys) who were identified being at-risk for RD based on scoring lower than 15th percentile in the preschool Spring pre-reading tests. Measures of children's pre-skills (phoneme awareness, letter knowledge, vocabulary, listening comprehension, memory), motivation (self-concept in reading, task-avoidant behavior), and home environment (parental education, parental teaching, shared reading) were derived from preschool Spring assessments. Reading skills (word recognition, word list reading fluency, text reading fluency) were assessed in the Grade 1 Fall and Spring, and Grade 2 Spring. Teacher ($n = 99-105$) measures included classroom teacher ratings on a 5-point scale on the amount of support and attention that they gave to child in reading and the amount of remedial reading instruction that the child received at school, and preschool teachers ratings on the children's task-avoidant versus task-focused behavior.

The first two research questions were analyzed with a longitudinal path model by using the Mplus statistical package. Repeated measures MANOVA analyses were used to investigate the third research question, i.e., whether the amount of teacher support and remedial reading instruction would show mean-level change across time and whether the three subgroups of children at-risk for RD: children who caught up the age level in reading (> -0.75 SD; $n = 108$), children with a moderate lag behind the age level (> -1.5 SD & ≤ -0.75 SD; $n = 78$), and children with a substantial lag behind the age level (≤ -1.5 ; $n = 56$) by the end of Grade 2, would differ in regards to these mean-level changes. Fourth, cross-tabulations and 1-ANOVAs were used to analyze whether the three subgroups of children at-risk for RD would differ in factors related to the child and to the home environment. Finally, repeated measures MANOVA was used to analyze whether the development of pre-reading skills from preschool Fall to Spring differed between the three at-risk subgroups.

Findings

The results showed, first, that the poorer the reading skills were, the more teacher support and attention the child received in the early grades. Further analyses revealed that the amount of teacher support (p partial $\eta^2 = .26$) and remedial reading instruction (p partial $\eta^2 = .18$) decreased across time among children who caught up the age level in reading by the end of Grade 2, but teacher support increased ($p = .05$, partial $\eta^2 = .20$) and the amount of remedial reading instruction remained stable among children who lagged behind the age level by the end of Grade 2. Moreover, children who were found to reach age level reading skills had better phoneme awareness, letter knowledge, listening comprehension skills and self-concept in reading and less task-avoidant behavior in comparison to other at-risk children prior to school entry. No differences between the subgroups were found in vocabulary, memory, and in the home environment measures (parents' education, maternal teaching of reading, or shared reading). Finally, the results revealed that although phonemic awareness and letter knowledge of all the three groups showed increasing lag behind the age level during the preschool, the lag in letter knowledge was smaller among children who caught up the age level in reading than among the other at-risk children.

Theoretical and educational significance

The findings indicate that at-risk children with stronger preskills at school entry showed greater progress over the early school years and were better able to benefit from teacher support than other children at risk. The findings suggest that the benefits of preschool experiences have cumulative effects for children's subsequent learning. They also have implications for recommendations of preschool programme quality and provision of preventive early support and individualized classroom teacher support to prevent later learning difficulties. The findings emphasizing the need for early individualized support complement our previous findings of the First Steps preschool observations (Pakarinen et al., 2010; Pakarinen et al., in press) using the CLASS (Pianta, LaParo, & Hamre, 2008) which has showed associations between high classroom quality and high motivation, and, further, between motivation and academic pre-skills.

The effects of preschool and primary school quality on children's early numeracy skills

Yvonne Anders, University of Bamberg, Germany; Christiane Große, Otto-Friedrich-Universität Bamberg, Germany; Hans Guenther Rossbach, University of Bamberg, Germany; Susanne Ebert, University Bamberg, Germany; Sabine Weinert, University of Bamberg, Germany

Only few studies have investigated so far how preschool and primary school experiences interact in shaping young children's cognitive development. The present investigation is part of the longitudinal study BiKS and explores children's development of early numeracy skills between age 3 (first year of preschool) and age 7 (first year of primary school) in Germany. Three research questions are addressed. First, the study seeks to identify the influences of child, family background and the early years home learning environment on children's developmental progress over that age range. Second, measures of preschool experience are tested as predictors. Third, we look at how influences of preschool and primary school quality interact when children have moved from preschool to primary school. The study draws on a sample of 547 children who attended 97 preschools in Germany. Latent growth curve analyses identify various child and family background factors that are related to numeracy skills at first year and growth over four assessments, particularly gender, migration background, SES, mother's education and the quality of the home learning environment. The effects of preschool quality on the development of numeracy skills persist until the end of the first year of primary school. Value-added regression analyses show that the qualities of preschool and of the mathematics lessons at primary school have independent impacts on progress in the first year of primary school. For policy makers and practitioners in Germany findings point to strengthen the efforts to ensure high quality of preschool and primary school education.

Aims

With regard to children's cognitive development and educational careers, it is well known that a number of child, family, home learning and preschool characteristics are significant influencing factors (e.g. NICHD ECCRN, 2002). But only a limited number of studies have investigated how preschool and primary school experiences interact in shaping young children's development. Until a couple of years ago, public and research interest in early years education was particularly low in Germany and little is known about the effects of preschool programs in this country. This paper seeks to investigate how preschool and primary school experiences interact in shaping the development of numeracy skills of children between the ages of 3 and 7 years in Germany. This age range covers three years of preschool and one year of primary school. Precisely, the paper addresses three research questions: First, it seeks to identify the influences of child, family background and the early years home learning environment on developmental progress. Second, measures of preschool experience are tested as predictors. We are especially interested if beneficial effects of the process quality of preschool settings persist until the end of the first year of primary school. Third, we look at how the instructional quality of the primary school further influences children's progress and how preschool and primary school quality interact when children have moved from preschool to primary school.

Methodology

Procedure and sample: The study is part of the longitudinal project BiKS – 3-8 (Educational Processes, Competence Development and Selection Decisions at Pre- and Primary School Age). The study follows the acquisition of competencies of 547 children in Germany who attended 97 preschool settings since 2005. The project collected a wide range of data on cognitive outcomes of the children, their background, their families and the preschool and primary school settings they attended (von Maurice et al., 2007). The development of early numeracy skills over four measurement points (age 3, 4, 5 and 7 years) is examined.

Measures: Outcome measure: Early numeracy skills were assessed by the subscale "arithmetics" of the Kaufman Assessment Battery for Children (K-ABC, Melchers & Preuss, 2003).

Predictors: Child and family background factors included age in months, gender, migration background, socioeconomic status of the family, maternal education and age at entry to preschool.

Early years home learning environment (HLE): One scale measure to assess the quality of the home environment in terms of promoting verbal literacy and numeracy skills was used considering information from home observations, parental interviews and questionnaires.

Preschool measures: A number of structural characteristics were included: number of children with migration background in the class, class size, child-staff-ratio, m³ per child and average age of children in the class. Process quality indicators were based on environment ratings using ECERS-E (Sylva, Siraj-Blatchford & Taggart, 2003).

Primary school measures: Instructional quality in the first year of primary school was assessed using classroom observations. The study focused on the level of cognitive activation in mathematics lessons.

Statistical analysis: Two sets of analyses were carried out: The first set examined the influences on the development of numeracy skills over time fitting latent linear growth models with four repeated measurements. First child, family background measures and early years HLE were tested as predictors of initial attainment and growth. Subsequent analyses tested the influence of preschool characteristics controlling for child, family background measures and HLE. The second set of analyses further investigated the impact of quality of instruction in primary school on developmental progress between age 5 and 7 years using value-added regression analyses. The sample size for the first string of analyses was $n = 532$ children with at least one valid outcome measure and predictor, $n = 396$ for the second string of analyses respectively.

Findings

Boys, children with migration background, children who grow up in low SES families or with less educated mothers show lower initial numeracy skills (gender: $b = -0.29$, p With respect to the influence of structural characteristics of preschool settings, analyses revealed that a number of structural characteristics like class size ($b = -0.13$, p The effects of preschool quality on the development of numeracy skills persist until the end of the first year of primary school (ECERS-E: $b = 0.19$, p Preschool quality in terms of fostering academic skills (ECERS-E: $b = 0.12$, p

Theoretical and educational significance

This research documented clearly that the development of numeracy skills is associated with the process quality of the preschool setting and confirmed the strong impact of preschool quality also in Germany. Effects of preschool quality on children's progress persist until the end of the first year of primary school, although the quality of instruction at primary school starts to shape children's development at this time. Children not only start with better skills but also move forward faster in primary school when they attended high quality preschool. For policy makers and practitioners findings point to strengthen the efforts to ensure high quality of preschool and primary school education.

SYMPOSIUM

Converging, complementing or contradicting? Multiple theoretical approaches to classroom interaction

Chairperson: Shirley Booth, University of Gothenburg, Sweden

Organiser: Ake Ingerman, University of Gothenburg, Sweden

Discussant: Ference Marton, Goteborg University, Sweden

This symposium focuses researching student learning as constituted in classroom interaction. All contributions report on studies in mathematics and science education aiming to generate instructional advocacy from research findings, and ground that argument in the application of several theoretical perspectives to a body of empirical data.

Xu & Clarke report on parallel analyses of a secondary science classroom using distributed cognition and variation theory as two lenses. They identify similar student learning difficulties, but generate different interpretations for both the nature and the potential source of these difficulties.

Ingerman & Berge report on parallel analyses of university students discussing science problems using variation theory and position theory. Thus they relate an analysis focusing on what is learned to an analysis focusing the context. Sahlström & Melander draw on several studies in primary science and secondary mathematics classrooms and pilot training to demonstrate advantages and disadvantages of content-oriented analytical approaches, such as variation theory, and the recent socio-cultural and conversation analytical approaches, such as conversation analysis. They argue for considering content as an empirically intrinsic aspect of participation.

Each paper approaches the issue of connecting multiple theoretical perspectives in different ways, from discussing the consequences of converging results but complementing/contradicting explanations (Xu & Clarke), to complementing focus of analyses (Ingerman & Berge), and to arguing for a theoretically integrated approach (Sahlström & Melander). In combination, the papers allow for examining the multifaceted ways of making use of the diversity of theoretical perspectives as resources to understand learning and inform instructional practice.

On generating instructional advocacy from research grounded in different theoretical perspectives

Lihua Xu, The University of Melbourne, Australia; David Clarke, University of Melbourne, Australia

This paper discusses issues related to generating instructional advocacy from research findings that are grounded in different theoretical perspectives. Multi-camera on-site video technology and post-lesson video-stimulated interviews were used in a purposefully inclusive research design to generate a complex data source amenable to multiple analyses. Two different theories were employed as analytical lenses to examine lessons on the topic of "States of Matter" from a 7th grade Australian science classroom. This paper illustrates how parallel analyses of same classroom events, employing different theoretical lenses, can identify similar student learning difficulties, but generate different interpretations for both the nature and the potential source of these difficulties. Based on this example, we discuss challenges involved in comparing and connecting research findings of parallel analyses for the purpose of instructional advocacy.

As theories in the field of education become increasingly diversified, a central question is how we can make use of this diversity as resources to inform educational practice. The task of generating instructional advocacy from research findings with different theoretical groundings becomes a very challenging one, especially when we take into account the interdependency of theoretical choice and research findings (Cobb, 2007; Even & Schwarz, 2003).

In this paper, rather than considering convergence or compatibility as the definitive result of the particular combination of theories, we focus on the compatibility of the interpretive accounts generated by their application to a common source of classroom data. In attempting to meet the challenge of providing evidence-based instructional advocacy, we address the question "under what conditions are the interpretive accounts compatible?" In this context, compatibility of the interpretive accounts would strengthen the authority of any recommendations for instructional practice arising from that research. We suggest that such compatibility must be considered as contingent on the events, objects or actions being analysed and on the specific question being addressed by the analysis. This contingent compatibility focuses our attention on the use of theories as interpretive tools. In this paper, we provide an example of parallel analyses of lessons on the topic of "States of Matter" from a Grade 7 Australian science classroom, employing two different theoretical perspectives: Distributed Cognition (Hutchins, 1995) and Variation Theory (Marton & Tsui, 2004). This paper illustrates how parallel analyses of the same classroom events, employing different theoretical lenses, can identify similar student learning difficulties, but generate different interpretations for both the nature and the potential source of these difficulties. In particular, the Distributed Cognitive analysis attends to the affordances and the constraints of physical, conceptual, and symbolic resources in student sense making, and highlights the limited connections between the microscopic model and the macroscopic phenomena. The Variation Theory analysis suggests that the lack of variation in the key attributes of the concepts, such as Changes of State, was a contributing factor to student difficulties in making the differentiations required for effective learning. Based on this example, we discuss challenges involved in comparing and connecting research findings that are differently positioned theoretically for the purpose of instructional advocacy.

The comparison of the two accounts demonstrates that each theory has its strengths in revealing particular aspects of teaching and learning in the particular classroom studied. The two analytical accounts are complementary in several respects (e.g. the use and the sequencing of instructional resources). But in other respects, the two theories appear to emphasize different aspects of the classroom and embody different and potentially conflicting assumptions about the key contributing factors to student learning (e.g. the establishment of common ground). These differences might direct us towards the adoption of divergent instructional and intervention strategies, which may not always be in harmony with each other (e.g. the role of practical work). In this regard, Variation Theory and Distributed Cognition seem to be too differently positioned with respect to their aspirations and the aspects of the classroom to which they attend for integration into a single theory to be either feasible or desirable. However, we suggest that the complementarity (rather than their convergence) of the two theories holds the possibility that in combination, analyses employing the two theories separately should attend to, describe, and explain a broader range of classroom phenomena than might be accomplished by the separate application of either alone. In the case reported in this paper, the results generated from the parallel analyses can be usefully juxtaposed and combined to provide a richer understanding of the teaching and learning of science in this particular classroom.

Learning science in groups – on constituting and participating in spaces of learning

Ake Ingerman, University of Gothenburg, Sweden; Maria Berge, Chalmers University of Technology, Sweden

What can be learned by whom in groups discussing physics? This paper offers results based on empirical material from audio and video recorded small groups of three to four university students discussing and solving physics problems in Newtonian mechanics. In addressing the question, we have foregrounded aspects in relation to the knowledge content. However, in order to more fully understand the situation, we have applied two distinct analytical frameworks – phenomenography and position theory – which are primarily focused on how the learning possibilities are constituted in the group discussion and the discursive and social aspects of the group work, respectively. Bringing the results of these two analyses together reveal some interesting connections, like that the character of the storylines links to certain characters of learning possibilities. We will also discuss the basis for and implications of addressing the same learning events with parallel theoretical perspectives, phenomenography and variation theory on the one hand and situated learning and position theory on the other hand, in relation to a pragmatic aim of improving university science teaching and learning and in relation to a research-framed aim of understanding learning processes in science education.

What can be learned by whom in groups discussing physics? This paper offers results based on empirical material from small groups of university students discussing and solving physics problems in Newtonian mechanics. In addressing the question, we have foregrounded aspects in relation to the knowledge content. However, in order to more fully understand the situation, we have applied two distinct analytical frameworks – variation theory and position theory – which are primarily focused on how the learning possibilities are constituted in the group discussion and the discursive and social aspects of the group work, respectively. The purpose of this paper is to discuss the results offered by the two analyses in relation to each other, and what conclusions we might draw for learning science in groups at university.

The empirical material concerns natural small groups formed within pedagogical settings in Swedish university teaching in a first-year engineering context. Discussion meetings, with a selection of groups of three to four students, were audio and video recorded and the subsequent analyses relies on detailed transcriptions and the students' notes as well as the original recordings. The seven groups were distributed across two engineering programmes – Engineering physics and Bioengineering – that both took a course in mechanics with equivalent content and partially the same teachers. The problems discussed concerned force and friction.

In the first analysis, we characterize possibilities for learning in group work as a function of the pedagogical situation (primarily in terms of the design of the task and the group format) taking variation as the basic mechanism for learning. Variation theory, originating from the phenomenographic research tradition, offers tools (see Booth & Hult  n, 2003; Ingerman, Linder & Marshall, 2009; Marton & Booth, 1997; Marton & Tsui, 2004) to understand how the students, working in groups, constitute their space of learning. We look at the object(s) of learning – potentially in the task and empirically activated by the students – classify the kind of possibilities the students develop in terms of (patterns of) variation in dimensions of variation, and look at how the students through experiences of relevance develop their understanding of the physics situation, as externalised in their discussion. We characterize the spaces of learning and associated patterns of variation constituted in the group work in order to explore what may be seen as important qualities (based on qualitative differences) of learning possibilities. The enacted space of learning is also analysed in relation to the potential space of variation of what the problem offers. In other words, we use phenomenography in two layers: one use variation theory as an analytical tool for analysing students' conversation in terms of objects of learning, patterns of variation (and in the end learning possibilities/learning) and one where more traditional phenomenographic thinking is used to look at qualitative differences between patterns of variation.

The seven groups are distributed across two Master's programs at the same University of Technology in Sweden, and we discern some reoccurring differences between the two programs. The physics students tend to formalise the problem, giving possibilities for some learning, while the bioengineering students tend to focus quite more extensively in particular on contextualising the problem in other situations, thus pointing their learning possibilities differently.

In the second analysis, we characterise how the frame of the group work is constituted in the students' interaction. By using situated learning theory as a theoretical framework and positioning theory (Harr   & van Langenhove, 1999) as an analytic tool, we explore methodological grounds for describing the complex and dynamic processes of group work, focusing simultaneously on the person and the community and how they constitute each other. Our approach can be seen as a synthesis of individual and social views of learning.

The results are presented in terms of storylines, which can be said to reflect different facets of the practice represented in both the Engineering Physics program and the Bioengineering program. Further, they all represent 'narrative forms' that exist within this culture. Not surprisingly, the dominating storylines in our data deal with how the students handled the actual problem solving and how the students oriented themselves towards the task given.

These storylines resemble both how students narrowly focus on finding a correct solution to the physics problem as well as attempts to bring understanding for the physics behind the questions to the group. Other storylines deal with how the students position themselves and each other in relation to their communities. The task oriented storylines and the community constituting storylines are interlinked.

We will also discuss the basis for and implications of addressing the same learning events with parallel theoretical perspectives, phenomenography and variation theory on the one hand and situated learning and position theory on the other hand, in relation to a pragmatic aim of improving university science teaching and learning and in relation to a research-framed aim of understanding learning processes in science education.

The content of learning in interaction-oriented approaches to learning

This paper aims at taking part in the development of interaction-based approaches to studying learning in interaction. In focus are the differences in treatments of learning content in recent socio-cultural and conversation analytic studies of learning. Despite a growing interest in learning from approaches such as Conversation Analysis (CA) and interactional linguistics, the treatment of aspects of content in these analyses is still non-existing or at best limited. And despite increased collaboration between approaches focused on interaction, such as CA, and approaches focused on contents of learning, such as variation theory, the efforts have often had limited success. In this paper, we use parts of three sets of video recordings – mathematics teaching in eight grade, science in second grade, and pilot training – to demonstrate advantages and disadvantages of the different approaches. We argue that for an internally coherent approach, the most fruitful way to proceed is to consider content as an emically intrinsic aspect of participation, where the analysis to substantial extent can rely on epistemic stance displays by participants, carried out both verbally and nonverbally. This argument is made possible through the fine-grained participant perspective-based conversation analysis. The reported work also demonstrates how issues of topic and content can be integrated into micro-analyses of learning.

Within variation theory (Marton, Runesson, & Tsui, 2004), there has been a fruitful interest in addressing the question of what is learned. This theoretical and empirical development shares a long-standing interest for the content of learning with other approaches and draws especially upon the phenomenographic approach. However, variation theory research has not been focused on the interactional details of interaction.

In sum one can say that, interaction analyses of learning have not so far to a large extent pursued a stringent, empirical and precise way of reasoning on what is learned, and how differences in learning can be systematically discussed. In variation theory in turn, analyses of interaction have had a poor understanding of the detailed organization of the interaction studied, thus disabling its possibilities of understanding important aspects of how variation comes about.

Our approach here, supported by and generated in work with our data, is to continue already initiated work (Emanuelsson & Sahlström, 2008; Melander & Sahlström, 2009) at dissolving the dichotomy of what and how, by understanding topical orientation as a constituent aspect of participation (for this, we rely to a large extent on the later work of Charles Goodwin, i.e. 2000). Topic is in other words considered an intrinsic element of action. This is an understanding of content which obviously stands in sharp contrast to notions of content as a fixed pre-existing body to be learned, and to understandings of the children's learned content as something of a second-order outcome of the interaction. But it also stands in contrast to most of the prior CA research on learning, where participation generally has been conceptualized more or less solely within a sequential-structural framework.

We use parts of three sets of video and audio recordings – mathematics teaching in eight grade, science in second grade, and pilot training – to discuss ways of approaching learning content in interaction-based analytical approaches, such as Conversation Analysis and variation theory. The results show that when participants take part in interaction, they do not seem to be oriented to the dichotomy of what and how, but rather seem to simultaneously rely upon topical, sequential and other resources for establishing, sustaining and changing their situated understandings. In particular, topical orientation seems to provide a major resource for establishing longitudinal links between different interaction situations. The results of the analyses thus seem to support the proposed internally coherent approach. Analytically, a fruitful way for research on learning in interaction to proceed is to consider content as an emically intrinsic aspect of participation, where the analysis to substantial extent can rely on epistemic stance displays by participants, carried out both verbally and nonverbally. This argument is made possible through the fine-grained participant perspective-based Conversation Analysis.

To educational research, any development in relation to ways of treating how-what relationships is of immediate theoretical value. The results also contribute to the development of methods for studying learning.

SYMPOSIUM

EXPLAINING STUDY SUCCESS IN THE FIRST YEAR OF HIGHER EDUCATION

Chairperson: Jan Nijhuis, University of Maastricht, Netherlands

Organiser: Jan Nijhuis, University of Maastricht, Netherlands

Discussant: Bart Rienties, University of Surrey, United Kingdom

Study success in the first year is a major topic in higher education for several reasons; 1) it is an indication of study progress through the curriculum; 2) it can be an indicator of the quality of the students or the educational institute, and 3) the lack of study success results in dropout, which means a loss of money and time for both student and the society. This symposium will deal with research on factors influencing study success from different perspectives and different countries. Three empirical papers will be presented and discussed in this mini-symposium. The paper from Finland focuses on learning approaches and study success, the contribution from Belgium analysis the role of academic motivation and learning strategies; the paper from the Netherlands discusses the impact of adaptation as an explanatory variable for dropout. The findings are relevant for educational practice in terms of designing the learning

environment and student counseling. At a theoretical level the papers provide more insight in different factors influencing study success

Relationships between first-year law students' approaches to learning and study success

Anne Haarala-Muhonen, The University of Helsinki, Finland; Sari Lindblom-Ylänne, University of Helsinki, Finland

The present study explores first-year law students' study success in terms of earned study credits and grade point average, as well as the relationship between study success and approaches to learning, using a modified version of the Approaches to Learning and Studying Inventory. More than 550 first-year law students participated in the study. The students were divided into four clusters on the basis of their scores on scales measuring approaches to learning. The results showed significant differences among the clusters in terms of study success. Students applying a deep approach and Organised students earned the highest number of credits and the highest grades, whereas Students applying a surface approach and Unorganised students received the lowest. A more detailed analysis of students' study success showed that the profiles of the approaches to learning were more homogenous among successful students than less successful students.

A deep approach to learning has been suggested to be related to good study success, whereas a surface approach is more likely to be associated with poorer study success (Entwistle & Ramsden 1983; Entwistle et al. 2001; Watkins 2001). On the other hand, some studies have found no relation between a deep approach to learning and study success (Diseth, 2003; 2007; Rytkönen et al. 2009). Furthermore, a combination of deep and strategic approaches has been found among successful students (Entwistle et al. 1991; 2001, Lindblom-Ylänne & Lonka 1999; Meyer et al. 1990) as well as a deep-achieving combination (Biggs 1994; 1988).

Aim of the study

The aim of this study is, firstly, to explore first-year law students' study success from the point of view of both earned study credits and average grades and, secondly, to analyse the relationship between study success and different student groups representing various combinations of approaches to learning.

Method

The questionnaire used was a modified 18-item version of the Approaches to Learning and Studying Inventory (ALSI) which contains items relating to approaches to learning and studying (Entwistle & McCune 2004). Students were asked to response on a 5-point Likert scale to each item. The data were collected from the first-year law students after seven months of studying at the Faculty. A total of 553 first-year students answered the questionnaire from three different cohorts in 2005, 2006 and 2007. The response rate was very high (86.3%). The students were divided into homogeneous subgroups on the basis of their approaches to learning (18 items), using the latent profile analysis in a Mplus statistical program. Four clusters emerged from the data: 1) Organised students, 2) Students applying a deep approach, 3) Students applying a surface approach, and 4) Unorganised students applying a deep approach. The clusters and their features are presented in Table 1. The same cluster structure has been used in a previous study at the University of Helsinki (Parpala et al. 2010).

The students' study success was measured in two ways: by using the number of earned study credits (ECTS= European Credit Transfer System) and the grade point average (GPA). In order to clarify students' study success in more detail, the students were divided in to three equal-sized groups on the basis of their earned study credits and average grades

Findings

The MANOVA analysis showed that the clusters ($f^2 = .034$) significantly explained the variables of study success. Moreover, the univariate analysis (ANOVA) showed that study success variables, study credits ($p = .044$) and study grades ($p = .038$) were significant although the effect sizes remained small. Further, a Scheffé's post-hoc test showed that Students applying a deep approach were the most successful whereas Students applying a surface approach earned significantly less study credits and achieved the lowest grades.

Figure 1 clearly shows in more detail that the relationship between the clusters and study success was not straightforward; all four clusters are represented in all study success groups. The Organised students cluster was relatively constant in every group. The profiles of the good study success groups ECTSaverage/GPAhigh, ECTShigh/GPAaverage and ECTShigh/GPAhigh were very similar. However, there was more variation between the poor study success groups. The groups ECTSslow/GPALow, ECTSslow/GPAaverage and ECTSaverage/GPALow were compatible regarding the Students applying a surface approach and Unorganised students applying a deep approach, whereas the profiles were different in Students applying a deep approach. Further, the profiles in the group ECTSslow/GPAhigh and group ECTShigh/GPALow clearly deviated from the other low study pace groups.

Theoretical and educational significance

Our results are in line with previous studies where a deep approach and organised study methods have been shown to be related to good study success and surface approach to poor study success (Entwistle & Ramsden 1983; Lindblom-Ylänne & Lonka 1999; Vermunt & Van Rijswijk 1988; Watkins 2001).

This more detailed method using nine study success groups showed a variation in terms of study success in each cluster group, and for example Students applying a surface approach were represented in all study success groups, not only among the poor study success groups. This indicates that other factors as well are related to students study success, such as personal characteristics, motivation and family life (Haarala-Muhonen et al. in press; Pintrich 2000). However, our results showed that the profiles of successful students were more homogeneous than the those of students with poor study success. In particular, students' profiles in groups ECTSlow/GPAhigh and ECTShigh/GPALow differed from other profiles of poor study success groups. Similar results has been shown in a previous study where fast and slow study pace law students were interviewed (Haarala et al. in press).

The participants of this study were first-year students' and their transition to the Faculty was incomplete. Therefore the students might not yet have recognised the demands of the teaching-learning environment and their approaches to learning may not have been fully established (Biggs 1993; 2003; Entwistle et al. 2001; Entwistle 1988; 2009; Richardson 2005). During part of this study teacher tutor counselling had begun at the Faculty and the teacher tutors were expected to enhance the first-year students' adjustment to the new teaching-learning environment and promote a clearer understanding of the course requirements and academic skills needed at the Faculty.

Academic motivation, learning strategies and first year students' study progress

David Gijbels, University of Antwerp, Belgium; Gert Vanthournout, University of Antwerp, Belgium; Liesje Coertjens, University of Antwerp, Belgium; Vincent Donche, University of Antwerp, Belgium; Peter Van Petegem, University of Antwerp, Belgium

The present study explores whether learning strategies and academic motivation predict persistence and study-progress in the first year of higher education. 780 Students in a professional bachelor teacher-training programme participated in this study. Students' motivation and learning strategies were assessed using the Learning and Motivation-questionnaire. Logistic regression and linear regression were applied to predict persistence and study-progress respectively. In each case a stepwise approach in data-analysis was used. First, the direct effects of learning strategies and motivation were explored. Second, significant predictors from the initial models were combined into a more encompassing model. Finally, student-characteristics were added to this model. Results on persistence indicate that concrete processing, analysing, lack of regulation and lack of motivation are significant predictors. When these predictors are combined into one model, only concrete processing and lack of motivation are retained. When student-characteristics are added to the model, gender proves to be an additional predictor. After controlling for student-characteristics the effect of concrete processing became non-significant. The final model explains 6.5% of variation in persistence. For study-progress results show that relating and structuring, external regulation, lack of regulation and lack of motivation are meaningful predictors for study-progress. Both gender and study delay are additional significant predictors. The final model explains 8.6% in the variance of study-progress. Results show that learning strategies and motivation are small, but significant factors in predicting study-progress and persistence, in addition to student-characteristics. Especially dimensions signifying 'a lack of' appear to be important indicators. Predicting these outcomes, however remains complex.

Aims

Recently, there is an increasing research-interest in students' persistence and study-progress in the first year of higher education (Berge & Huang, 2004). Previous studies showed that student-characteristics and academic motivation are significant predictors of persistence (e.g. Tinto, 1993; Allen, 1999) and study-progress (e.g. Hofman & Van den Bergh, 2000). It is likely, however, that the quality of student learning also influences these outcomes. However, students' learning strategies have only scarcely been related to persistence or study-progress. Moreover, as initiatives aimed at decreasing drop-out and increasing study-progress in first year of higher education, often focus on enhancing the quality of learning and motivation, it seems valuable to investigate whether and how strongly these variables are linked to persistence and study-progress. This study aims to explore the predictive value of learning strategies and academic motivation for persistence and study-progress in the first year of higher education. The following research questions are addressed: · (RQ1) Do students' learning strategies and motivation at the start of higher education predict students' persistence in their first year; · (RQ2) Do students' learning strategies and motivation at the start of higher education predict students' study-progress in their first year; · (RQ3) To what degree do students'

learning strategies and motivation at the start of higher education predict their persistence and study-progress in their first year, after controlling for other students-characteristics (gender, prior education, study delay).

Methodology

Participants were 780 first year students enrolled in a professional bachelor teacher-training programme. Students were questioned on their motivation and learning strategies using the Learning and Motivation questionnaire (Donche & Van Petegem, 2010). This instrument combines adapted scales from Vermunt's Inventory of Learning Styles (Vermunt, 1998) with adapted and selected items and scales from the Academic Self-Regulation Scale (Ryan and Conell, 1989) and the Academic Motivation Scale (Vallerand et al., 1997). Persistence is measured through the fact whether a student re-enrolled in the same program for the next academic year. Study progress is defined as the ratio between the amount of study credits a student obtained after the first year and the total amount of credits the student was enrolled in during that first year. Prior education refers to the type of secondary education a student was enrolled in. A distinction was made between general, technical and vocational prior education. Study delay alludes to whether the student encountered any delays during his or her prior education. Information on student-characteristics, enrolment and study-progress was obtained through the student administration office. Logistic regression was applied for analyses with persistence as dependent variable and linear regression was used for analyses on study-progress. In each case, a stepwise strategy in data-analysis was used. In a first step the 'unique/direct' effects of processing strategies, regulation strategies and motivation on persistence or study-progress were investigated. In a second step significant predictors from the first step were brought together into a more encompassing model. In a final step, the students-characteristics were added to this model.

Results

Results of the logistic regression analyses show that concrete processing and analyzing are cognitive processing strategies that significantly predict persistence. Students who apply the learning-content onto real-life situations and students who thoroughly work themselves through the learning content have a higher chance of persisting in their first year. Lack of regulation proved to be the single significant regulation strategy. Students who experience problems in regulating their learning process have a higher chance of dropping out. With regard to motivational factors, analyses demonstrate that students who lack motivation have a lower chance of persisting. When these variables are brought together in a single model, only concrete processing and lack of motivation are retained as significant predictors. Lack of regulation proved marginally significant. The entire model explains about 5% in of the variation in persistence. When student-characteristics are added to this model, gender was found to be a significant predictor. Female students have a higher chance of persisting in their first year. As a result of the addition of student-characteristics, the effect of concrete processing became non-significant. The third model explains 6.5% of the variation in persistence. Results of the linear regression on the cognitive processing strategies indicated that relating and structuring as a deep processing strategy significantly predicts study-progress.. For regulation strategies, both external regulation and lack of regulation were found to be significant predictors. Students who are more teacher-dependent when learning obtain more credits, while students who report problems in regulating their learning processes, acquire less credits. Finally, students who generally lack motivation for the program, have a slower study-progress. When these significant predictors are combined in one model, they all remain significant, except for external regulation. The model explains 5% of the variance in study-progress. When adding student-characteristics, both gender and study delay proved significant predictors. Female students and students without a delay in their prior education, progress faster. All learning strategies and motivational factors are retained as predictors. The final model explains 8.6% in the variance of study-progress.

Significance

Results of our analyses show that learning strategies and motivation are small, but significant factors in predicting study-progress and persistence in the first year of higher education, in addition to student-characteristics. Especially dimensions signifying 'a lack of' appear important indicators and seem to be meaningful factors regarding the boundary crossing between first and second year in higher education. The actual quality of learning strategies or motivation seems to matter less in this stage. For research, these results show the value of combining various factors in predicting persistence and progress, but also raise new research-question, e.g. how to enhance these outcomes through instructional methods or study trajectory-coaching For practice, they show the complexity of factors determining in whether students persist or not in the first year. Moreover, they provide practitioners with a glimpse on what factors actually determine study-success in the first-year of higher education.

The grass is greener abroad? The impact of adaptation on dropout; local versus foreign students.
alexandra niculescu, Maastricht University, Netherlands; Jan Nijhuis, University of Maastricht, Netherlands

Dropout in higher education is an issue of emerging interest. In the context of ongoing internationalization and globalization, dropout among international students is nowadays recognized as a reason of particular concern. One of the key factors in explaining dropout is how students are able to adapt in a period of transition. The present study analyses the impact of adaptation in a new learning environment as an explanatory variable for student learning and dropout. The participants were a cohort of 521 Dutch and German students in their first year of bachelor studies at a Dutch University, who were asked to answer the Student Adaptation to College Questionnaire (SACQ). The results of both logistic and linear regression analyses indicate two separate effects of nationality and adaptation on the students' marks and dropout. Being German has a positive effect on the probability of dropping out yet, a positive impact on marks. Furthermore, we found that although nationality is a relevant predictor for the personal-emotional and social adaptation, it is the academic adjustment which explains students' dropout and marks most. Overall, adaptation plays a role, but not as an explanatory variable for the mechanism by which nationality has an impact on students' marks and the probability of dropping out.

Dropout in higher education is an issue of emerging interest. For example, in The Netherlands, a substantial proportion of students who enroll in a study program are leaving university without completing the 1st year (Beekhoven, de Jong & van Hout, 2003; van den Berg & Hofman, 2005). However, dropout is not only a problem in Europe but also worldwide (OECD, 2009). One of the key factors in explaining dropout is how students are able to adapt in a period of transition (Baker & Siryk, 1999). Nowadays, higher education systems are stimulated by government measures to attract foreign students and, at the same time, to encourage local students to gain experience abroad (European Commission 2009). In this context, dropout among international students is recognized as a reason for concern (OECD, 2009). Students studying abroad face not only problems with the transition from high school to university, but have also to adapt to another country. As Tinto (1987) argues, individuals enter institutions with a variety of personal attributes (such as nationality) which can directly impact their adaptation. However, the majority of studies on adaptation were conducted in national samples in the US and only recently, concerns were raised if international students are confronted with the same problems when studying in a new learning environment (Morrison et al., 2005). Although students from abroad may have adaptations problems, it is also known that foreign students sometimes perform better than local students (Tempelaar et al., 2006). Aim and research questions This study analyses the impact of adaptation in a new learning environment as an explanatory variable for student learning and dropout. Therefore we are interested in the following research questions: To what extent does students' adaptation mediate between nationality and dropout? To what extent does students' adaptation mediate between nationality and study marks?

Method

Setting and sample The research setting was a faculty of Economics and Business at a Dutch University, which offers an international program, having English as the language of instruction and a large proportion of students coming from abroad. The participants were a cohort of 521 Dutch and German students in their first year of bachelor studies. The students were asked in November 2007 to complete a questionnaire about their first impressions on university life. **Measures** Information about nationality was collected through the university database. Adaptation was measured through the Student Adaptation to College Questionnaire (SACQ) developed by Baker and Siryk (1999). For the purpose of the present study, dropout was defined as students who leave university without completing the first year. In order to have more variance in the output variable, instead of only dropout information, we also used the marks a student acquired over the academic year. Information of study results was also available via the university database.

Analysis

A series of linear and logistic regressions were carried out to test each of the four criteria mentioned in the Causal Steps approach (Baron & Kenny, 1986). First we checked the zero-order correlations between nationality and outcome variables, dropout and marks. Second we checked the relation between nationality and adaptation domains. Next we conducted a hierarchical regression, predicting the outcome variables, dropout and marks from nationality and adaptation. We then looked at the partial effect of adaptation (controlling for nationality). Fourth we analyzed the direct effects of nationality on the dependent variables, dropout and marks.

Findings

The results of the logistic regression looking for the extent to which nationality influences students' adaptation, which in turn determines the probability of dropping out, provided no evidence for the adaptation variable acting as a mediator. There was indeed a significant relation between students' nationality and dropout, in the sense that being German had a positive effect on the probability of dropping out. Nationality was significantly related to some of the adaptation domains, namely German students were less Personal-Emotional but more socially adjusted than their local colleagues.

When all the variables were tested in one model, after controlling for nationality in step 1, in step 2 was tested the effect of each of the adaptation domains on dropout. In the first step we entered nationality. This model explained 3.8% variance in a student's probability of dropping out. When the adaptation domains were added in step 2, so controlling for nationality, the academic adjustment was the only significant predictor. In other words, students who were more academically adjusted had a lower chance of dropping out. This model explained 14.1 % variance in dropout. The results of the linear regression testing the marks against all the adaptation domains are similar to the findings of the logistic regression. In step 1 we entered nationality and this model explained 5.3 % variance in students' marks. This time, being German had a positive impact on the marks. When the adaptation domains were added in step 2, again only the academic adjustment was a significant predictor of study results. This model was able to explain 17.1 % variance in students' marks. However, since no relation was found initially between students' nationality and their academic adjustment – as required by the Baron & Kenny (1986) approach, there was no evidence for a mediation effect.

Educational and Theoretical Significance

Both analyses indicate two separate effects of nationality and adaptation on the students' marks and dropout. These findings imply that although nationality is a relevant predictor for the personal-emotional and social adaptation, it is the academic adjustment which explains students' dropout and marks most. From an educational perspective the results indicate that in order to reduce dropout it might be worthwhile to design interventions that improve students' academic adjustment. From a theoretical perspective the assumed mediating effect of adaptation on dropout is not present. Furthermore, the role of nationality in our particular educational context deserves consideration. It is probably the case that the German and Dutch differ in some aspects that influence the adaptation, such as the fact that foreign students already made a choice to study abroad. Overall, adaptation plays a role, but not as an explanatory variable for students' marks and dropout.

SYMPOSIUM

The Individual and the Social in Democratic Citizenship Education

Chairperson: Horst Biedermann, University of Fribourg, Liechtenstein

Organiser: Wiel Veugelers, University of Amsterdam, Netherlands

Discussant: Wiel Veugelers, University of Amsterdam, Netherlands

Central issues in citizenship and in citizenship are the interplay between the individual and the social, and the relation of the moral and the political. In theory, in practice and in empirical research people are analyzing the interplay of these concepts. Their interrelatedness shows the kind of citizen people are oriented to and teachers' methodology and learning processes and outcomes of students. Three papers address these issues. The aim of the study of Pnevmatikos and Papadopoulou was to investigate whether schoolchildren and adolescents who adopt collectivist attitudes hold different beliefs on how they resolve contradictions than individualists. They found that the more collectivist the attitudes, the more possible it is for them to compose contradictions and accept a solution in the middle. Biedermann and Oser ask how politic can be combined with morality. They use data from the ICCS 2009 with approximately 130 000 8th grade students (38 countries). Based on the ICCS-results they explore in an interpretative frame why lower rating of value related issues have a moral core. Veugelers found in several empirical studies differences in the combination of autonomy and social involvement which resulted in different types of citizenship and citizenship education. In this paper he will focus on how the academic subjects pedagogy, sociology and psychology contribute to these outcomes. And how they could contribute to a more democratic type of citizenship. In the papers and in the discussion the focus will be on the relationship of the individual and the social, and of the moral and the political.

The interplay between individual and social aspects in children's and adolescents' beliefs about how

Dimitris Pnevmatikos, University of Western Macedonia, Greece, EIRINI PAPADOPOULOU, UNIVERSITY OF WESTERN MACEDONIA, Greece

The way people resolve contradictions within a democratic society is of great importance. Attitudes towards collectivism and individualism as well as the accompanied holistic and analytical reasoning respectively are considered amongst the possible factors that influence the way individuals resolve contradictions. The aim of the present study was to investigate whether schoolchildren and adolescents who adopt collectivist attitudes hold different beliefs on how they resolve contradictions in a different way than individualists. 308 schoolchildren from 10 to 18 years old participated in the study. A well-structured questionnaire consisting of three subscales was used to explore participants' attitudes towards collectivism, individualism and beliefs towards contradiction. The Pearson correlation revealed significant positive correlation between contradiction and collectivism scale and a negative significant

correlation between contradiction and individualism scale. In other words, the more collectivist the attitudes are held by individuals, the more possible it is for them to compose contradictions and accept a solution in the middle. In contrast, the more individualistic the attitudes are held by individuals, the less effort is endeavored to manipulate contradictions and construct a synthesis of two aspects being found in a contradiction. ANOVAs revealed that children and females are more collectivists than the adolescents and males, and children less individualists than adolescents. Females across all age groups were found to be more tolerant towards contradictions than males. Implications for the education are discussed.

Introduction

The way people resolve contradictions is of great importance within any society. Attitudes towards collectivism and individualism and the holistic and analytical reasoning respectively are considered amongst the possible factors that influence the way individuals resolve contradictions. Nisbett and his colleagues (Nisbett, Peng, Choi, & Norenzayan, 2001) described two modes of reasoning that characterize West and East cultures: holistic vs. analytical reasoning. Holistic reasoning, a characteristic of collectivistic societies, is characterized by an orientation to the field as a whole involving attention to relationships between a focal object and the field, and a preference for explaining and predicting events on the basis of such relationships. Furthermore, the preference for holistic approaches to rely on experience-based knowledge than to abstract logic have as a result for individuals with holistic tendencies to be dialectical and tolerant since the emphasis is given on the dynamic and changeable aspect of the reality than to its static one. As the change is constant and inherent part of the nature and the emphasis is given on the change, there is a need for multiple perspectives. Therefore, contradictions are expected while they are acceptable and constant as well. Contradictory propositions may both contain some truth, and there is a need for searching the "Middle Way" between opposing propositions. On the contrary, analytic reasoning, a characteristic of individualistic societies, is characterized by a detachment of the object from its context, a tendency to focus on attributes of the object in order to assign it to categories, and a preference for using rules about the categories to explain and predict the object's behavior. Therefore, the need for decontextualization of structure from the content and the emphasis on logical consistency press individuals to avoid contradictions.

Modern societies are characterized by pluralism and the phenomenon of globalization has transformed the cultural entities into non-homogeneous ones. Thus, there is an increased interest to investigate the differences that appear between the East and West, within West or East contemporary societies or even between subgroups within the same national group. For instance, Loose (2008) showed that although French parents appreciate individualism in their children, French teachers devalued the expression of individualism for their students and encouraged more relatedness and taking others into consideration.

Aims and hypotheses:

The aim of the present study was to investigate the possible effect of attitudes towards collectivism and individualism to beliefs on the best way to resolve contradictions in childhood and adolescence. It is predicted that collectivists should denote more tolerant ways to resolve contradictions than individualists. Moreover, we were interested to examine possible differences in their attitudes as children are growing up, as well as possible gender differences.

Method

Participants: 308 schoolchildren and adolescents from five age groups (10-, 12-, 14-, 16- and 18-year-old) participated in the study.

Instruments: A well-structured questionnaire consisting of three subscales was used to explore participants' attitudes towards collectivism (10 items, $\alpha = .72$), individualism (9 items, $\alpha = .65$) and beliefs towards contradiction (5 items, $\alpha = .69$). Collectivism and individualism subscales come from the INDCOL scale (Singelis, Triandis, Bhawuk, Gelfand, 1995; Triandis, 1996). The subscale "contradiction" comes from the Analysis-Holism Scale (AHS) constructed by Nisbett and his colleagues (2001). Participants were asked to express their point of agreement or disagreement on a 5-point scale (1=strongly disagree, 5=strongly agree).

Findings

Three Univariate Anovas applied to the data [5 (age group) x 2 (gender)] using the means of the three subscales as a dependent variable. Children were found to be more collectivists than adolescents ($F(4,308)=2.823$, $p=.025$, $\eta^2p2=.037$) and females more collectivists than males ($F(1,308)=17.241$, $p.001$, $\eta^2p2=.055$). No significant interaction was found between age and gender ($F(4,308)=.341$, $p=.850$, $\eta^2p2=.005$). Moreover, children were found to be less individualists than adolescents ($F(4,307)=7.144$, $p.001$, $\eta^2p2=.088$), while no significant difference was found between males and females ($F(1,307)=2.078$, $p=.150$, $\eta^2p2=.007$), nor significant interaction between age and gender ($F(4,308)=1.580$, $p=.180$, $\eta^2p2=.021$). Finally, participants' attitudes towards contradictions did not differ across the examined age groups ($F(4,308)=1.137$, $p=.339$, $\eta^2p2=.015$). In general, however, females ($M=3.65$,

SD=.82) reported to be more tolerant towards contradictions than males ($M=3.65$, $SD=1.01$) ($F(1,308)=10.167$, $p=.002$, $\eta^2p2=.033$) and this difference was stable across the age groups ($F(4,308)=1.971$, $p=.099$, $\eta^2p2=.026$). The Pearson correlation revealed significant ($pr=.562$) between contradiction and collectivism scale and a negative significant ($pr=-.298$) between contradiction and individualism scale.

Based on the ascending mean scores on the collectivism and individualism subscales we divided participants in two equal groups, representing the low and high collectivists ($n_{Low}=157$, $n_{High}=151$) and individualists ($n_{Low}=157$, $n_{High}=150$) respectively. Two one-way Anovas were conducted using the means on attitudes towards contradictions subscale as dependent variable and the two levels (low vs. high) we created on the collectivism and individualism subscales. As it was expected, high collectivists ($M=4.22$, $SD=.75$) were found to be more tolerant towards contradictions than the low ($M=3.44$, $SD=.92$) collectivists ($F(1,307)=65.272$, $p.001$). On the contrary, high individualists ($M=3.63$, $SD=.95$) were found to be less tolerant towards contradictions than the low ($M=3.99$, $SD=.87$) individualists ($F(1,306)=11.988$, $p=.001$).

Discussion

As it was predicted, collectivists were found to be more tolerant in resolving contradictions than the individualists. In general, the more highly collectivists the individuals are, the more tolerant to their attitudes towards contradictions they are, compared to low collectivists. The above correlation was found to be evident within all age groups and gender.

The high correlation between collectivist attitudes and tolerance towards resolving contradictions, especially during childhood and among females, allow us to stress out the importance of implementing teaching practices that could enhance children's attitudes towards collectivism. This enhancement could help them to develop more open-minded attitudes and be more tolerant to their everyday life. One of the important aims of the primary education should be the establishment of collectivistic attitudes and every relevant collectivist aspect, so when later in their lives adolescents step to more individualistic attitudes, they will keep their tolerance as an efficient way of thinking.

The Impact of Political Thinking on Morality and Politics of a Society

Horst Biedermann, University of Fribourg, Liechtenstein; Fritz Oser, Universitat Freiburg, Switzerland

In recent years primarily developmental psychologists and later on educational psychologists accepted that different domains have each an independent core structure. Thus political thinking is not the same like moral thinking or social reflecting etc.; and this because of the underlying basic reference. With other words to solve a moral problem refers to different needs as justice, care, and truthfulness; whereas political thinking refers to power, law enforcement and to the concept of maintaining democracy. In 2009, Biedermann and Oser presented empirical evidence that the two structures of thinking and judging are uncorrelated. – In this presentation we explore this topic from the opposite. For instance we ask how low acceptance of gender equality can be morally framed (or blamed). This is not an easy approach: on the one hand it refers to comparative data where different countries have different political and value conceptions; on the other hand it requires interpretative processes (as judging a certain attitude or behaviour in itself – quasi from an universal point of view – as morally problematic. – In this paper we use data from the ICCS 2009 with approximately 130 000 8th grade students (38 countries). Based on the ICCS-results we explore in an interpretative frame why lower rating of value related issues have a moral core and need to be judged from this different point of view. We will elicit the difficulties and pitfalls to do so.

Researchers from different psychological convenience begin to accept that domain differences become a very subtle scientific issue (see Nucci, 2006). At the 13th Biennial Conference EARLI 2009 in Amsterdam we asked whether moral judgment is correlated with political thinking respectively aspects of political identity. Based on a quantitative study (IEA CIVED older population: 1270 16- to 18-years old students in Switzerland) and a qualitative study (Development of Political Understanding: 40 22- to 60-years old people) our main finding revealed no meaningful relationship (Oser & Biedermann 2009). Considering these findings our then-hypothesis, that the moral judgement and political judgment have their own cognitive structures and therefore their own categories of thinking took corroboration. In this presentation we would like to go in the opposite direction asking how politic can be combined with morality without being either an "unhappy moralist" or a "blind politician".

Recently initial findings of the IEA-Study ICCS (International Civic and Citizenship Education Study) were published (Schulz et al., 2010; Biedermann et al. 2010). ICCS studied "the ways in which countries prepare their young people to undertake their roles as citizens" (Schulz et al., 2010, p. 9). Thereby it investigated student knowledge and

understanding, attitudes, perceptions, and activities related to civics and citizenship in 38 countries. As one important finding ICCS provided the thinking of students about civic society and their roles as citizens. With regard to gender equality, equal rights for immigrants, and attitudes towards the own country as well as the perception of the importance of conventional citizenship, perception of the importance of social movement related citizenship, and interest in political or social issues parameter values varied across countries; similar to the situation in CIVED about ten years ago (Torney-Purta et al., 2001). Does it mean, being very low in these important political issues, that these kids are less morally sensitive? Can we infer from results comparing country means in political thinking to moral judgment?

The purpose of this paper is to interlink (a) our finding about the two different cognitive structures of political and moral thinking and (b) the thinking of students about civic society and their roles as citizens. We discuss the political, moral and social impact of political attitudes and thinking in an international perspective.

Methodology

The paper is based on the random sample of ICCS. In 2009 ICCS gathered data from more than 140'000 Grade 8 students (approximately 14 years of age) from 38 countries (five from Asia, 26 from Europe, six from Latin America, and one from Australasia) (Schulz et al., 2010). The ICCS assessment framework was organized around the three dimensions (a) content domains (civic society and systems, civic principles, civic participation, and civic identities), (b) cognitive domains (knowing, and analysing and reasoning) and, (c) affective-behavioural domains (value beliefs, attitudes, behavioural intentions, and behaviours). As aforementioned in this paper we focus on value beliefs and attitudes. All scale considered have an international mean of 50 points and a standard deviation of 10 points.

Results and conclusion

In ICCS we find wide differences between countries regarding student political attitudes and value beliefs. For instance almost all students agree with gender equality, and also the average students in all participating countries tended to agree with equal rights for immigrants. However, there were considerable differences among countries. With respect of gender equality support was highest in Chinese Taipei, Sweden, Spain, Ireland, Denmark, and Norway (scores 54 and 55). Lowest scale score were found in Indonesia, Thailand, Dominican Republic, and Russian Federation (44 and less points). With regard to students' attitudes towards equal rights for immigrants Chinese Taipei, Mexico, Colombia, and Chile, had the highest mean scores (54 points at least). In contrast Belgium (Flemish), England, Indonesia, and Latvia had the lowest national averages (47 and less points). Finally concerning interest in political or social issues there also is wide variation between countries: the highest levels of student interest were found in the Dominican Republic, Guatemala, Indonesia, and Thailand (55 points at least); the lowest interest scores had Belgium (Flemish), Finland, Norway, Slovenia, and Sweden (47 and less points).

Unquestionable, ICCS provided interesting descriptions and comparisons of students' political and social thinking in different countries. But what is the political and morally impact of a country for instance when their next generations little endorse equal rights for immigrants little, express attitudes towards their country moderate, agree with importance of social movement related citizenship moderate, and express interest in political or social issues moderate as in Switzerland? And what does it mean politically and morally when young people value high gender equality, equal rights for immigrants, when they are on one hand interested in political or social issues highly, but on the other express positive attitudes towards their country only little as in Chinese Taipei? As one example only, it seems morally problematic to not accept the integration of immigrants, but from the political will of the nation this issue is taboo. Can we say this people is political positively active, but immorally in the deepest meaning of the word? When can we frame politically criticism as immoral? How can we set limits to the respective "democratic will"?

In this regard we explore why lower rating of attitudes and value beliefs have a moral core and therefore need to be judged from different points of view. Concerning this matter we introduce the concept of "framing politically or morally" as one solution possibility, the concept of "political share" as an other one. The presentation ends with conclusions and recommendations with regard to civic education.

Autonomy and Social Involvement in Practice and Theory of Citizenship Education

Wiel Veugelers, University of Amsterdam, Netherlands

Citizenship education is a concept encountered in many discussions and publications. This concept though is often very differently addressed in politics, in conversations in schools, in public opinion and among scholars. Also pedagogical goals and educational practices differ. In our empirical studies we could distinguish between three types of citizenship: adaptive, individualizing and critical democratic citizenship (Veugelers, 2007; Leenders, Veugelers, & De Kat, 2008a, 2008b). These three types have different combinations of clusters of pedagogical goals: discipline, autonomy and social involvement. It is remarkable that parents, teachers and students alike, evaluate that the cluster of discipline is better learned than the clusters of autonomy and in particular social involvement.

In analyzing these results we look at different levels. In educational practice we analyze the results from the point of view of social and cultural diversity and the way school culture reflects society and functions as a learning environment for citizenship education. At the system level, we consider: the educational policy discourse; curriculum policy; civil society; autonomy of schools; differences between schools, and the pedagogical discourse. In the paper we will focus on the pedagogical discourse in different academic disciplines: pedagogy, sociology and psychology.

Introduction and Method

It is often suggested that everyone attaches the same meaning to citizenship, that we all know what good citizenship is. In many empirical studies though, we have found that there are different understandings of citizenship education. We find these differences among teachers, school leaders, parents, and students as well. In our data-analysis we could distinguish between three types of citizenship: adaptive, individualizing and critical democratic citizenship (Veugelers, 2007; Leenders, Veugelers, & De Kat, 2008a, 2008b). These three types have different combinations of clusters of pedagogical goals: discipline, autonomy and social involvement. The adaptive type combines discipline and social involvement, the individualizing type combines autonomy and social involvement, and the critical democratic type combines discipline and social involvement.

It is remarkable that parents, teachers and students alike, indicate that the cluster of discipline is more easily realized than the clusters of autonomy and in particular social involvement. A survey among teachers in secondary education showed that 53 % of the teachers aim at a critical democratic type of citizenship, 39 % at an adaptive type, and 18 % at an individualizing type. In vocational education the emphasis was slightly more on adaptation, while in pre-university education an individualizing type was slightly preferred (Leenders e.a., 2008a).

The three types of citizenship education have a differing emphasis in their goals and are connected with differing pedagogical and didactical practices. Methodically, the adaptive type emphasizes the transfer of values and the regulation of behavior; the individualizing type independent learning and developing critical thinking, and the critical democratic type cooperative learning and developing critical thinking through inquiry and dialogue (Veugelers, 2007). Westheimer and Kahne (2004) found a similar three-split (see also Westheimer, 2008 and Johnson & Morris, 2010). They identify a personally responsible citizen, a participating citizen and a citizen who strives for social justice. These studies show that developing citizenship is not a linear process from passive to active, but that citizenship can have different meanings.

In analyzing these results we look at different levels. In educational practice we analyze the results from the point of view of social and cultural diversity and the way school culture reflects society and functions as a learning environment for citizenship education. At the system level, we consider: the educational policy discourse; curriculum policy; civil society; autonomy of schools; differences between schools, and the pedagogical discourse. In the paper we will focus on the pedagogical discourse in different academic disciplines: pedagogy, sociology and psychology.

The dominant pedagogical discourse in Dutch secondary education is a combination of child centred, advancing personal autonomy, and an individualized form of equal opportunity thinking. These pedagogical accents are also promoted in academic disciplines. In pedagogy the center stage is taken by the individual and his development and well-being. In educational psychology it was until recently that self-regulated learning was dominant. A more social and dialogical oriented organization of learning processes hardly received any attention. Sociology of education is characterized by promoting individualization by a strong focus on selection and equal opportunities and the complete disappearance of any attention for socialization processes and outcomes and for curriculum issues.

Presently it seems that a rectification might be underway in those academic disciplines, possibly out of criticism on over-the-top individualization in Dutch society. The problem though lies as much at a more theoretical level, where the individual is disconnected from the social, where the person is not situated and society is not characterized by connections and social and political power relations but by a total of freely floating individuals (Mouffe, 2005).

The individual oriented pedagogical discourse even in its advanced contemporary expressions does not succeed to make practical connections between the individual and the social. Attention for the social is demanded within the dominant approach of individualization. Therefore this attention for the social will remain limited to regulating in an instrumental way the behaviors between individuals. From the perspective of democratic citizenship it would be desirable to regard the individual as being situated and connected. This means a central place for democracy, not only as a political concept but as a life-style or 'way of life' (Dewey, 1923). For education this means more learning, inquiry and dialogue in groups, society-oriented by connecting persons and institutions, also outside one's own community, analyzing persons in their social and political power relations, and empowering all students not only the elite..

The assessment of competences requires an approach where knowledge, abilities and attitudes are integrated, naturally implying the resource to a variety of assessment strategies. Within this context, we have seen the emergence of what has been called by several authors the Assessment Culture.

The methods, techniques and criteria traditionally used in psychometrics, are recognized as insufficient to assess learning in competence based programs, framed by contexts strongly influenced by technology use. So being, we have

watched the emergence of new edumetrical strategies, targeted at redefining the concepts of validity and reliability and so assuring the quality of the current assessment strategies.

Within this framework, this symposium is composed by three studies, one presenting a theoretical framework supported by four dimensions – authenticity, consistency, transparency and practicability, aimed at promoting the quality of the assessment strategies being used; and two empirical studies, one evaluation the quality of Competence Assessment Programmes (Baartman et al. 2007) developed in 7 faculties of Higher Education, and another one presenting research on three new modes of assessment targeted at enhancing student learning through assessment, with students in the areas of public-law, international business strategy and elementary teacher training. Our goal with this symposium is to promote the discussion of the dimensions and criteria that enhance assessment quality, in the assessment culture, based on the three presented studies. We hope to contribute to the development of new assessment quality criteria sustained by an edumetric approach, and support the quality of the assessment strategies being used.

Enhancing student learning through assessment: research on three new modes of assessment

Katrien Struyven, University of Brussels (VUB), Belgium; Mien Segers, Maastricht University, Netherlands; Filip Dochy, K.U.Leuven, Belgium; David Gijbels, University of Antwerp, Belgium

During the past decade traditional assessment practices in schools have been advocated to be replaced by so-called new modes of assessments. As learning environments are redesigned according to constructivist principles, it seemed that traditional examinations are no longer appropriate (Macdonald, 2006). This paper gives information on three empirical studies, recently conducted by this research group. The first study explores if student performance can be improved by formative assessment, through the use of embedded assessment tasks. The second study addresses students' learning approaches and how they are influenced by the assessment practice. It focuses on the relation between the students habitual study strategies, the perceived assessment demands and students' approaches to learning. The third study explores the influence of student hands-on experiences with a mode of assessment on their assessment preferences. The aim is to emphasise assessment as a vehicle to encourage student learning; the 'assessment for learning' purpose.

Although assessment is high on the international agenda at various levels (e.g. government, schools, parents), assessment is merely implemented as a tool of learning instead as a 'tool for learning'. Today's students face a world that will demand new –continuously changing– competencies to become life-long learners. In this 21st century, students need to understand and update the basic knowledge of their domain of study and need to be able to use this knowledge base as a tool to handle ill-structured problems. Helping students to develop these skills will also require changes in the assessment practice at the school and classroom level.

Three studies are represented, conducted by our research group. The three studies try to unravel how assessment influences student learning, defined in terms of performance as well as approach to learning. The first study explores if student performance can be improved by formative assessment, through the use of embedded assessment tasks and which conditions influence this effect. The second study addresses student's learning approaches and how they are influenced by the assessment practice. The third study explores the influence of student hands-on experiences with a mode of assessment on their assessment preferences.

Study 1: Integrated assessment tasks and students' performance

The first empirical study aimed to investigate the effects of written assessment-tasks integrated in a problem-based learning environment on students' performance. The following question is central to the study: do students who work on the integrated assessment tasks do better in their final exam compared to students who do not?

A total of 164 students, following a course on public law in the second year of their law study, participated fully, completing all six assessment-tasks. Assessment in the course was twofold. The final exam consisted of 40 multiple-choice questions and took place at the end of the course. During the course, students had the opportunity to complete the six assessment-tasks on a voluntary basis, which could result in an extra 'bonus point', added to the score of the final exam.

Results showed that working with assessment tasks has a significant positive influence on the performance of students, not only of the related topics in the tasks, but also of the non-related topics. This is confirmed by the results of the survey, indicating that students in the integrated assessment tasks condition worked in a different way, in terms of learning approach as well as time management. A crucial condition for the integrated assessment tasks to

affect learning seemed to be the feedback students receive; the clarity of goals and criteria of the assessment tasks and the implementation of the assessment tasks.

Study 2: Case-based assessment and students' learning strategies

As Biggs (1996) states, assessment can only steer learning when there is a constructive alignment between learning, instruction and assessment. Therefore, in order to enhance deep learning with students, in the present study not only the mode of assessment was changed, but also the learning environment. The research question central to this study is to what extent these changes result in students adapting their learning strategies.

The participants in this study are two subsequent cohorts of second-year students attending the course International Business Strategy of the International Business Program. An assignment-based format was used for the course in year 1 (N=406). In the following year, the course was redesigned according to the problem-based learning format (N= 312).

The findings of the study tend to be disappointing as in the new learning and assessment environment the students used more surface learning strategies. A plausible explanation is found in the linear relation between students' perceived workload of the learning environment and surface approaches to learning (Kember, 2004). Moreover, results indicate that in both conditions, students who enter the course with the intention to employ a deep study strategy, perceive the assessment demands as deep and employ a deep study strategy. Students, who intend to employ surface strategies, show a higher tendency to employ surface strategies.

Study 3: The effects of hands-on experience on students' preferences of assessment

Though innovation is a key concept of educational policy, the associated processes are often a source of anxiety and concern for many teachers. It is only when familiarity grows that fears are allayed and the new, changed situation is accepted. This fearful disposition towards changes and the process of allaying these fears are central to this study, which investigates the effects of student teachers' hands-on experience of new evaluation modes on their assessment preferences.

The investigation had a quasi-experimental pre-test/post-test design. A Child Development course was delivered to five research conditions involving 669 students in their first year of elementary teacher training. The first group of pre-service teachers was instructed within a lecture-based learning environment, assessed by means of a multiple choice examination. The remaining four groups learned in the same student-activating learning environment. The assessment mode that accompanied this learning setting distinguished between conditions, namely: (1) a multiple choice test, (2) a case-based assessment, (3) a peer/co-assessment, and finally (4) a portfolio assessment.

Results show that unknown assessments become positively regarded when familiarity grows and the hands-on experience is positive. Interestingly, conclusions do apply to both traditional tests and new modes of assessment. The good use of the assessment method and its orientation towards knowledge construction serve explanatory purposes. As such, students' assessment perceptions are not stable, unchangeable student characteristics and evidence is provided that hands-on experience with "new" assessment tools serves as an incentive for change to occur.

In conclusion to the three studies, it is clear that the statement 'assessment steers learning' is surely correct (Gijbels et al., 2005) but at the same time far too simple (Segers et al., 2006). Simply changing the mode of assessment does not always result in changes in learning strategies, nor in improved performance (Struyven et al., 2008).

Does self-evaluation of CAP quality lead to improvements in assessment and curriculum?

Liesbeth Baartman, Eindhoven University of Technology, Netherlands; Asha Dijkstra, Avans University of applied science, Netherlands; Han Blankert, Avans Hogeschool / Avans University of Applied Sciences, Netherlands

Many institutions for higher vocational education are implementing competence-based education. The literature often suggests to start these development processes by changing the assessment, which should work as a leverage for changing the entire curriculum. Therefore, this paper focuses on the evaluation of the quality of Competence Assessment Programmes (CAPs). A self-evaluation method was used to stimulate institutions to reflect on and improve the quality of their CAP. It is unclear, however, if such self-evaluations lead to concrete points for improvement of CAPs – and the entire curriculum.

In this study, seven faculties of a University of Professional education evaluated their CAP. Evaluators were 5-7 teachers and 3-5 students per faculty. Evaluation was based on 12 quality criteria and quantitative ratings and qualitative examples were collected. Research questions were: (1) How do the seven faculties evaluate their CAP on the 12 quality criteria, (2) What are the effects of the self-evaluation in terms of concrete points for improvement of the CAPs?

Preliminary results show that the CAPs were generally thought to be transparent, fair and feasible. Knowledge and skills are assessed integrally, but attitudes are not generally assessed. Concrete points for improvement were identified. For example, when criteria were not clear to students, the teachers decided to integrate them into their lessons by presenting the assessment at the start of a course and discussing the criteria. In general, the self-evaluation seemed to cover and influence the entire curriculum, corroborating the literature on this topic.

Theory and aims

Higher vocational education aims for students to become competent professionals, integrating knowledge, skills and attitudes to master relevant job situations. At the moment, many institutions for higher vocational education are implementing competence-based education. The literature often suggests to start such development processes by changing the assessment. This will work as a leverage on the entire curriculum (Barnes et al., 2000) and influence learning and instruction processes (Gibbs, 1999). Therefore, the focus of this paper is on the evaluation and improvement of assessment. As single assessments are only seldom used to assess competence, the quality of entire Competence Assessment Programmes or CAPs is evaluated (Baartman, Bastiaens et al., 2007). In such CAPs, different assessment methods – both traditional and newer ones – are combined depending on the context and the goals of the educational programme.

Concerns have been expressed about the quality of new assessment methods and the ways to establish their quality. Different quality criteria have been suggested, including psychometric (Messick, 1995) and edumetric ones (Dierick & Dochy, 2001). This paper uses 12 quality criteria developed by Baartman, Bastiaens et al. (2007), including ideas of validity and reliability, complemented by criteria deemed important in competence-based education specifically, for example authenticity, meaningfulness and self-regulated learning. To stimulate institutions to evaluate and improve the quality of their CAP, a self-evaluation method was developed. A self-evaluation method was chosen because it is assumed to stimulate reflection and internal school improvement (McNamara & O'Hara, 2005). However, it is unclear whether self-evaluation leads to concrete points for improvement that can actually be used by institutions to improve their assessments – and eventually the curriculum as a whole. Therefore, this study follows seven faculties of an institute for higher vocational education. They evaluated the quality of their CAP using the self-evaluation method. Research questions are: (1) How do the seven faculties evaluate their CAP on the 12 quality criteria, (2) What are the effects of the self-evaluation in terms of concrete points for improvement of the CAPs?

Data and Methods

Participants: This study was carried out at a large University of Professional Education in the Netherlands, a type of higher vocational education. Seven faculties carried out a self-evaluation of the quality of their CAP: teacher education, Marketing & Business Management, ICT & Business, Construction & Infrastructure, Social studies, School of International studies, Education for healthcare. In each faculty, the evaluators were about 5-7 teachers and 3-5 students (numbers varied slightly depending on availability).

Self-Evaluation Procedure: The self-evaluation procedure consisted of three phases. First, the evaluators received a short training on the 12 quality criteria and the CAP to be evaluated was defined. Second, all evaluators individually evaluated their CAP by giving a rating and an example for all criteria, using a web-based questionnaire. Third, all individual evaluations were collected and summarised by the researchers in a short powerpoint-presentation, to be discussed in a two-hour group interview. The goal of the group interview was to identify strengths and weaknesses and formulate concrete points for improvement of the CAP.

Data analyses: The results of the individual evaluations and the group interview were summarised in a report for each faculty, which was checked by the evaluators for correctness (member checking). To compare the seven self-evaluations, Miles and Huberman's (2003) method of cross-case comparison was used. The qualitative and quantitative data were first meaningfully reduced, then organised into different matrices, from which conclusions were drawn and verified on the original data. To answer the first research question, matrices were ordered for the 12 quality criteria. For the second research question, points of improvement that were mentioned in the individual evaluation or group interview were noted down and verified on the original data by two of the researchers.

Preliminary results

First results show that most CAPs are deemed transparent, fair and feasible. Knowledge and skills are integrally assessed, but attitudes are not generally included in the assessments. Students want more and deeper feedback, while teachers do not explicitly address feedback during the assessments. In general, the evaluators learned about new forms of assessment, such as peer assessment. They mentioned various points of improvement of their CAP. Some examples are:

- integrating the assessment criteria in the lessons, to familiarize students with the criteria;
- giving feedback according to SMART goals;
- starting lessons with the assessment and using the assessment to explain learning goals.

Also, the self-evaluation seemed to influence the entire instructional design process, not only the assessments. Full results, including citations of the evaluators, are presented at the conference.

Theoretical and educational significance

The self-evaluation used in this study seems to be a valuable method to get a grip on the strong and weak aspects of a CAP. It seems to provide concrete handles for improvements and influence the entire development process of competence-based education, corroborating the literature on this topic (e.g., Barnes et al., 2000).

Assessment Culture dimensions: contributions for quality development

Alda Pereira, Universidade Aberta, Portugal; Isolina Oliveira, Universidade Aberta, Portugal; Luis Tinoca, University of Lisbon, Portugal

The assessment of competencies requires an approach where knowledge, abilities and attitudes are integrated, naturally implying the resource to a variety of assessment strategies. Within this context we have seen the emergence of what has been called by several authors the Assessment Culture. Furthermore, higher education e-learning environments have also promoted the used digital assessment strategies. It is important to consider the concept of quality in education and e-learning, and particularly how to develop it in the present learning landscapes. For this reason, we propose a theoretical framework supported by four dimensions – authenticity, consistency, transparency and practicability – each composed by a set of parameters, aimed at promoting the quality of the assessment strategies being used. This proposition, framed by an edumetric approach, aims to set the stage to a Competency Assessment Program (Baartman et al., 2007), and in this way contribute to the discussion of assessment quality in higher education, particularly in the case of e-learning.

The new learning culture has promoted the implementation of new assessment strategies aligned with the most recent paradigm of assessment design (Birenbaum, 2003; Brown, Bull & Pendlebury, 1997). Assessment tasks communicate to students the kind of intellectual work which is valued and thereby influence the way students behave

as learners (Maclellan, 2004). Given the recognition of traditional assessment forms inability to promote learning, as a consequence of their focus in classification and ranking of the participants, the last two decades have seen the emergence of a variety of alternative assessment strategies. Dierick and Dochy (2001) label this new culture as the assessment culture as opposed to the testing culture.

The assessment of competencies requires a new approach where knowledge, abilities and attitudes are integrated (Baartman, Bastiaens, Kirschner and van der Vleuten, 2007; Gulikers, Bastiaens and Kirschner, 2004). It should make use of a variety of different assessment strategies and tools (Dierick and Dochy, 2001; Maclellan, 2004), so as to better assess performance in authentic activities. Moreover, given the complexity of the concept of competence, one single assessment mode is recognized as insufficient to assess the development of competencies (Baartman et al., 2007; Pereira, Tinoca and Oliveira, 2010; Pereira et al., 2009). For this reason, other criteria have been proposed in order to measure and promote the quality of these new assessment strategies, and so contribute to the implementation of quality control and establish new lines in edumetrics based in the assessment culture.

Assessment Culture: dimensions

We propose four dimensions for the assessment culture to be considered in the definition of competence based assessment strategies: authenticity, consistency, transparency, practicability (see figure 1). These dimensions represent the main domains for the characteristics of the assessment strategies to be developed, contributing in this way to the definition of the implemented assessment culture, and its impact in the educational process. We now present the main criteria contributing to the definition of each of the four dimensions (see figure 2). These criteria are important not as contributors to the characterization of each of the dimensions, but also to illustrate their degree of implementation.

The concept of authenticity is related to the degree of similarity between the competencies being assessed by a competency assessment program and the ones required in real/Professional life. It includes:

Similarity – refers to the way in which the assessment strategy is related to the real life context, meaning that assessment should reflect the competencies needed in real/professional life.

Complexity – refers to the nature of the assessment tasks, more specifically, to the cognitive challenges that are imposed by its resolution/development.

Adequacy – is connected with the need to provide adequate performing conditions (time, resources, etc.) for the assessment tasks, in accordance with their complexity.

Significance – includes the significative value of the assessment task for students, instructors and employers.

The consistency dimension emerges as answer to the traditional demands for validity and reliability, usually associated with psychometric indicators. It includes:

Alignment instruction-assessment – refers to the need to provide assessment scenarios that are representative of the learning situations experienced by the students.

Multiplicity of indicators – is related to the need of employing a variety of assessment methods, contexts, moments, and assessors.

Adequate criteria – considers the correspondence between the assessment criteria being used and the competencies that are being assessed.

Alignment competencies-assessment – is related to the need of assuring the coherency between the competencies that are intended to be developed and the assessment strategy being used.

The transparency dimension intends to make the entire competency assessment program visible and comprehensible for all the participants. It includes:

Democratization – refers to the availability and possible participation in the definition of the assessment criteria.

Engagement – is related to the availability and possible participation in the definition of the learning goals and performance criteria.

Visibility – refers to the possibility of presenting/sharing their learning processes and/or products with others.

Impact – is related to the effects that the assessment strategies have in the learning process and in the design of the educational program.

The practicability dimension is related with the feasibility of the assessment strategy. It implies an effective management in terms of time and cost/efficiency balances to both assessors and organizations. It includes:

Costs – referring to the time costs, as well as the resources or additional investments.

Efficiency – goes beyond costs, to consider the relationship costs/effects of the assessment strategies for the institutions, instructors and learners, particularly considering the expected results.

Sustainability – is related to the need of assuring that it's possible to successfully implement and sustain the proposed assessment strategies.

The presented dimensions can be used as a framework for the development of a competency assessment program and as guidelines for the quality evaluation of the assessment strategies being used. The criteria allow for the operational description the stage of implementation, and so contribute to the evaluation of the achieved assessment strategy quality level. Finally, even though the present work is included in a still ongoing debate, it intends to contribute to the clarification of the Assessment Culture and introduce/develop a theoretical framework to support decisions related to the assessment strategies to be used.

SYMPOSIUM

What Explains the Development of Interest and Intrinsic Motivation for Learning?

Chairperson: Birgit Spinath, Heidelberg University, Germany

Organiser: Birgit Spinath, Heidelberg University, Germany

Discussant: Katariina Salmela-Aro, Helsinki Collegium for Advanced Studies, Finland

Interest and intrinsic motivation are both important prerequisites for learning and desired outcomes of learning processes in their own right. Therefore, there is a vital interest among researchers and educators to understand how these motivational variables develop. The present symposium brings together three studies that investigate determinants of interest and intrinsic motivation development in high school students and undergraduates. All studies rely on theoretical approaches with a focus on goals, values, and expectations. To detect potential causal mechanisms, two studies use a longitudinal design (Spinath & Steinmayr; Harackiewicz et al.) whereas the third employs an experimental approach (Sansone et al.). Katariina Salmela-Aro will discuss the findings with regard to their implications for motivation theory building and educational practices.

The Roles of Competence Beliefs and Goal Orientations for the Change in Intrinsic Motivation

Birgit Spinath, Heidelberg University, Germany; Ricarda Steinmayr, University of Heidelberg, Germany

The present study investigates three theoretically plausible explanations for changes in school-related intrinsic motivation. A sample of N = 348 German 11th grade students was followed over one year. At two measurement occasions, students completed self-reports on their school-related intrinsic motivation, goal orientations, and competence beliefs. In line with previous studies, cross-lagged analyses provided little evidence for the hypothesis that prior competence beliefs affect subsequent intrinsic motivation after controlling for prior intrinsic motivation. Considering goal orientations as a moderator did not change this result. Instead, it could be shown that learning goals, but not performance goals, directly predicted the change in students' intrinsic motivation, but not vice versa. Findings are discussed with regard to motivational theory development and practical implications.

Intrinsic motivation is not only an important prerequisite for learning but also a desired outcome of education. Therefore, there is a vital interest among researchers and educators to understand the reasons underlying characteristic changes of intrinsic motivation observed throughout school trajectories. It is consistently observed that intrinsic motivation for school-related learning diminishes throughout elementary school and beyond. This development stagnates when students are about 16 years old and afterwards even an increase in intrinsic motivation

can be observed in some disciplines. While this developmental trajectory of intrinsic motivation has been established in many studies, the reasons for these characteristic changes are still unknown. The present study investigates the roles of competence beliefs and goal orientations for the change in intrinsic motivation.

In the present study, three theoretically plausible ways in which competence beliefs and goal orientations might affect intrinsic motivation are investigated. First, it is tested whether competence beliefs are not only closely associated with intrinsic motivation but might also predict changes in intrinsic motivation. Second, it is tested whether the association between competence beliefs and intrinsic motivation varies systematically according to students' goal orientations. Specifically, theory suggests that in the presence of learning goals, competence beliefs should be less important for the development of task enjoyment than in the presence of performance goals. Third, the assumption is put to a test that goal orientations directly predict changes in intrinsic motivation. To our knowledge, this is the first study that assessed competence beliefs, goal orientations and intrinsic motivation at more than one point in time which is a prerequisite for a cross-lagged design and the analysis of reciprocal effects.

Method:

A sample of $N = 348$ German 11th grade students was followed over one year. At two measurement occasions in March 2007 and 2008, students completed self-reports on their school-related intrinsic motivation, goal orientations, and competence beliefs. To cross-validate the results for different domains, self-reports were collected for school in general, math, and German. Data were analysed on a latent basis with three or four manifest indicators per latent construct and by means of cross-lagged structural equation models.

Results:

Results indicated that intrinsic motivation was stable in terms of absolute, mean changes (for the domains math and German) or even increased (for school in general) over the time investigated. Moreover, performance-approach and performance-avoidance goals for school in general slightly decreased over time. All other variables showed no significant mean changes. In terms of relative stability (auto-correlations), both intrinsic motivation (ρ between .53 and .70) and competence beliefs (ρ between .65 and .83) were moderately stable over time.

With respect to the first theoretical explanation of change in intrinsic motivation, inspection of the cross-lagged paths indicated that prior intrinsic motivation did not predict subsequent competence beliefs in any domain. Complementary to this, prior competence beliefs did not predict subsequent intrinsic motivation in two out of three domains (school in general and math) but did so for German. Thus, only weak support was found for the hypothesis that competence beliefs affect intrinsic motivation.

The second research question focused goal orientations as potential moderators of the association between competence beliefs and intrinsic motivation. Multi-group analyses were used to compare cross-lagged paths between competence beliefs and intrinsic motivation in groups of either high or low expressions of goal orientation. Taken together, results of multi-group analyses provided no support for the assumption that goal orientations moderate the association between competence beliefs and intrinsic motivation.

The third research question addressed the question whether goal orientations have direct effects on intrinsic motivation. The temporal stability of the three goal orientations across the three domains was moderate (ρ between .53 and .73). In all three domains, prior learning goals predicted change in intrinsic motivation (ρ between .21 and .35) but not vice versa. None of the performance goals predicted change in intrinsic motivation in neither domain or vice versa. Taken together, the results of the cross-lagged analyses supported the hypotheses that learning goals but not performance goals directly affect change in intrinsic motivation.

Implications:

The present study provides further evidence that it is not the absolute level of normatively-based ability self-perceptions that stimulates task enjoyment and sustained motivation. Instead, the goal frame under which learning takes place and achievement outcomes are interpreted is important for the development of intrinsic motivation. This means that even in the face of realistically held low ability self-concepts, learners can develop an optimistic, learning-oriented perspective in which they consider low competencies as learning opportunities and learning as an end in itself.

For educational practice it might be followed that educators should put emphasis on creating a learning oriented environment when they want to foster intrinsic motivation. This can be achieved by choosing methods that let students experience their learning progress. For example, educators can encourage students to intra-individually compare their work results and competences over time and see the learning progress. This technique requires an

honest appraisal of initial competences because only a realistic appraisal allows for perceiving learning progress. On the grounds of the present findings, educators need not fear that confronting students with initial competence deficits might undermine their intrinsic motivation, as long as a learning goals framework is set.

Moreover, learning goals can be highlighted by evaluating students' performance in terms of criterion-based standards and individual progress instead of social norms. Offering information about individual progress and the degree to which task-inherent criteria were met leads students attention to learning goals. In contrast, comparing students' performance with a social norm distracts attention from individual learning progress. Although it will not always be possible to avoid evaluations according to social norms, criterion-based and individual feedback can counterbalance a predominant social comparison perspective.

My Obsessions Come and Fade as Opposed to Come and Go': Young Adults with/out AS and their Interest

K. Ann Renninger, Swarthmore College, United States; Idit Katz, Ben-Gurion University, Israel

People diagnosed with Asperger's Syndrome (AS) typically have an intense interest for specific subjects. Such interest has been described as both an obstacle to learning new material and interpersonal relations, and, more recently, as potentially important to the development of self-esteem and social relations. The structure and form of AS interest has not been detailed, as such, it is an open question as to whether and how interest supports the learning of populations with AS, and what its potential as a scaffold for the development social relationships is. Semi-structured in-depth email interviews that included a retrospective component were conducted with 10 young adults with AS (19-28 years-of age) and 10 young adults without AS (20-28 years-of age). Both nonparametric analyses and discourse analysis were employed in order to evaluate: (a) cognitive and affective components of interest, (b) change in the structure and form of interest over time, and (c) the role of the environment in interest development. Briefly, findings from this study suggest that interest may be a tool for supporting and working with population with AS in ways that have not previously been identified. Interest for participants with and without AS is central, although differences in its structure and form are apparent. For both groups, interest appears to provide a scaffold to working with and learning from others. Similarities and differences between the interest and learning trajectories of both groups are summarized.

Regulating Interest: The Role of Utility Value, On-Task, and Off-Task Behavior

Carol Sansone, University of Utah, United States; Jonathan Butner, University of Utah, United States; Joseph Zachary, University of Utah, United States; Tamara Fraughton, University of Utah, United States; Sarah Ripley, University of Utah, United States

The Self-regulation of Motivation (SRM) model suggests that both goals-defined motivation (i.e., value and expectancy of learning), and experience-defined motivation (i.e., whether interesting) are key to sustained learning. It is thus important to understand how students regulate their interest experience via on-task AND off-task behavior. We used data from the Regulating Motivation and Performance Online (RMAPO) project. Undergraduates (N = 108) worked on an online HTML programming lesson in the lab, and their time spent off-task and on-task was recorded. The initial lesson description described the skills to be learned (no value added), or further described how these skills could be used when creating personal or organizational web pages (value added). We examined whether, relative to students in the no value added condition, students in the value added conditions: 1) spent more time on-task; 2) spent more or less time off-task; and 3) accessed off-task sites more during the lesson or after assignment submission. Compared to the no value added condition, students in the value added conditions spent more time on-task and off-task before submitting their assignment, and submitted their assignment later. Both on-task and off-task time predicted greater interest at lesson's end. These results suggest that when given reasons to value learning, students will engage in behaviors that enhance their experience, even if some of these behaviors are off-task.

Summary:

The Self-regulation of Motivation (SRM) model (Sansone & Thoman, 2005) suggests that two kinds of motivation are important for maintaining learning: Goals-defined (i.e., value and expectancy) and experience-defined (i.e., whether interesting while working towards goals). Although initial actions may be directed by goals, these actions also affect the experience. Moreover, subsequent (maintenance) actions may be in service of reaching goals or in service of enhancing the experience, particularly over time. The SRM model thus suggests that in order to understand the development of interest, it is important to understand how students regulate the process of learning over time.

To examine this process, the Regulating Motivation and Performance Online (RMAPO) project created a paradigm in which undergraduates complete an online HTML lesson in the lab. The lesson session was designed to maximize the role of self-regulation, with measures that allowed us to examine how students regulated the process. The session

was of sufficient length (1 ½ hours) to ensure that students needed to maintain their attention and effort over a period of time. In addition, students were told that at the end of 90 minutes the final survey would start whether or not they had submitted the assignment (i.e., making it clear that they were responsible for managing their time). Students were also told that 90 minutes should be enough time (i.e., downplaying time pressure), that they could take breaks, and that if they finished prior to 90 minutes they should sit quietly until the post-lesson survey began. We subsequently recorded the sites (on-task and off-task) that students accessed while working through the lesson, when they accessed them, and the time spent on each.

In the first variation in this paradigm, we varied the initial description of the lesson such that it just described the skills to be learned (no value added), or further added how these skills could be used when creating personal or organizational web pages (value added). Initial results (Sansone, Zachary, et al. 2010) suggested that the added value information was associated with more active engagement while working on the lesson (i.e., more manipulating and modeling sample HTML codes in optional examples and exercises). Higher levels of engagement predicted greater interest at lesson's end.

These previously reported results thus suggested that subsequent interest was associated with the use of optional on-task sites that enhanced the experience while working. However, the SRM model suggests that off-task behavior may also be relevant to regulating the experience. The present paper thus used data from the RMAPO project to examine students' off-task as well as on-task behavior. We examined whether, relative to students in the no value added condition, students in the value added conditions: 1) spent more time on-task; 2) spent more or less time off-task; and 3) accessed off-task sites more during the lesson or after assignment submission. Finally, we examined the relationship between these patterns and subsequent interest.

Methods/Data sources:

Undergraduates (n=108; 67% female) were randomly assigned to one of the three conditions described previously. We measured the total amount of time (minutes) students spent on on-task lesson sites. We then identified the point at which students submitted their assignment, and calculated the total amount of time (minutes) spent on off-task sites prior to assignment submission. Finally, we calculated the total amount of time (minutes) students spent on off-task sites during the entire session. At lesson conclusion, lesson interest was assessed via self-reported ratings (5 items, rated on 1 to 5 scales, $\alpha=.88$).

Results: We created the condition contrast code Value Added v. No Value Added. This contrast was significant in predicting total time spent accessing on-task sites, indicating that students in value added conditions spent more time on-task. When we examined time spent off-task prior to submitting the assignment (controlling for time spent on task), the contrast was also significant, showing that students in the value added conditions spent more time off-task. However, when total time off task was regressed on the same model, the model was not significant. This suggests that the point at which students accessed off-task sites differed by condition, such that students in the value added conditions were more likely to access off-task sites while they were still working on the lesson. A survival analysis of the point during the 90 minutes session that students submitted their assignment further showed that students in the no value added condition submitted their assignment sooner than students in the value added condition. Finally, we regressed interest on the time measures. Greater interest was significantly associated with both greater time spent on-task and off-task prior to assignment submission.

Theoretical/Educational Significance.

Together, these data suggest that when students had greater motivation to learn HTML (utility value added), they spent more time while working through the lesson both on-task AND off-task. This pattern was associated with taking longer to complete the lesson and assignment, but also with greater interest. In contrast, in the no value added condition, students spent less time both on-task and off-task while working through the lesson, and finished sooner. These students appeared to be more likely to wait to access off-task sites until they had finished their "work." However, this pattern was associated with lower interest. Over time, when students believe what they will learn is useful, they may be more likely to engage in behaviors that enhance the experience, and this may include both on-task and off-task behaviors. This may come at a cost in terms of time needed to complete an assignment, but also with the benefit of developing greater interest.

SYMPOSIUM

Improving science education for young children in pre- and primary school

Chairperson: Paul Leseman, Utrecht University, Netherlands

Organiser: Paul Leseman, Utrecht University, Netherlands

Discussant: Paul Leseman, Utrecht University, Netherlands

Playful science education for young children is increasingly considered to lay the fundament for science learning in the later grades of primary school and in secondary school. However, although several approaches to an early childhood science curriculum are available, few have been empirically tested. This symposium brings together three studies on science education in early pre- and primary education, examining complementary approaches and using randomized controlled trials to determine their effectiveness. Leuchter and Saalbach present the results of a four-week curriculum for kindergartners and first and second graders on floating and sinking, involving sequenced exploration of counter-evidence. Children in the experimental condition revealed better understanding at posttest. Henrichs and Leseman focus on the ways in which kindergarten teachers can support children in learning to map language representations onto their intuitive understanding of science. After the training, both teachers and children used more domain-specific vocabulary, more complex multi-clause sentences, and higher-level scientific reasoning. Koerber and Sodian compare the use of verbal explanations and graphic information to improve children's reasoning in the domain of biology, in particular concerning how to take evidence into account. Both providing explanations for counter-evidence and the use of graphics improved their scientific reasoning substantially. The three papers together outline essential building blocks of an effective early childhood science curriculum. Guided sequenced exploration of counter-evidence can be supplemented by providing explanations and graphics, and by training teachers in domain-specific knowledge and academic language.

Science teaching in pre- and primary school: The role of situational domain-specific knowledge

Miriam Leuchter, University of Munster, Germany; Henrik Saalbach, ETH Zurich, Switzerland

Research on competencies of secondary and late primary school teachers suggests that teachers' domain-specific knowledge has a high impact on the students' learning gains. However, research on early science teaching in kindergarten and early primary school shows that teachers lack knowledge about the concepts to be taught and about children's learning processes and have a low self-concept regarding science teaching. This may be one of the reasons why analyses of instructional situations in kindergarten and early primary school show that teachers seldom take into account children's naïve conceptual understanding and neither promote children's conceptual change. In order to gain insight into the relation between teachers' situational domain-specific knowledge and children's learning within early science instruction we developed a four-week curriculum in the context of "floating and sinking" for kindergarten and primary school which we implemented in 15 Kindergarten and 15 primary school classes (first and second school year) with all in all 444 children. Results reveal a decrease in children's misconceptions from pre-test to post-test due to the curriculum. The children were able to produce significantly more correct predictions about the sinking or floating of objects after the curriculum than before, also in comparison to the control group. More importantly, we found a negative impact of teachers' errors on children's learning gains, which strongly emphasizes the role of the teacher's domain-specific knowledge for a successful support of children's learning processes.

Aim

The understanding of learning and teaching processes in kindergarten and primary school has been significantly enhanced by research on learning and instruction. (Sylva et al., 2004). Research in the field of teachers' competencies show that the instructional action of teachers is closely linked to their professional knowledge about teaching and learning, and that situational knowledge related to concrete subjects, contents and instructional situations and actions plays a distinctive role (Mena Marcos & Tillema, 2006). Furthermore, it is well known that teachers' domain-specific knowledge has a high impact on the students' learning gains. However, research on teaching in kindergarten and primary school shows that teachers a) lack knowledge about the concepts to be taught and about children's learning processes and b) find it hard to take into account children's naïve conceptual understanding. This seems to be especially relevant for early science teaching. Teachers' low self-concept regarding science indicates that they are aware of their shortcomings (Appleton, 2006)

In order to gain insight into the relation between teachers' situational domain-specific knowledge and children's learning within early science instruction we developed a four-week curriculum in the context of "floating and sinking"

for kindergarten and primary school. This learning environment consisting of four sequential and problem-based units was devised in cooperation with experienced teacher educators to support the development of children's concept of material kind as a precursory knowledge of a density concept. The material of the first and second week was designed in a manner to challenge children's misconceptions concerning shape, size and weight. In the third week, learning activities aimed to develop children's conception of material kind. In the fourth week, children's understanding of the relevance of material was challenged by introducing the concept of buoyancy. Teachers were instructed to support children's construction of knowledge by, for example, stimulating comparison processes, emphasizing material labels, activating prior knowledge and assisting conceptual restructuring through sustained shared thinking.

Method

The curriculum was implemented by trained pre-service and in-service teachers in 15 preschool and 15 primary school (1st and 2nd) classrooms with a total of 444 children (mean class size 19 children) in two age-mixed cohorts. Children of both cohorts attended a school located in middle-class rural areas of Central Switzerland. The age of the preschool children was between 4.4 – 7.1 years (mean: 5.1 years); the age of the primary school children was 6.2 – 9.6 years (mean: 7.9 years). Although, from a developmental psychological perspective, it can be assumed that children at this age do not acquire the concept of material kinds by themselves, we wanted to rule out that the potential learning gain took place due to natural learning processes or maturation processes, or a test repetition effect. For this purpose, twenty-two children were randomly assigned to a control group.

A series of individual pre-tests and post-tests were carried out to capture children's learning progress. 15 minutes of the teachers' support of the children during the first implementation week was videotaped. Due to the standardized content, the videotaped lesson units showed a very high degree of comparability, thus providing a basis for a microanalysis of teachers' instruction. Instruction during implementation underwent a video analysis by two raters where the domain-specific errors made by the teachers were identified, thus allowing us to capture the teachers' situational professional knowledge in the scientific domain of floating and sinking. This design allowed us to use frequency analysis as well as correlation and regression analysis to test whether and to what extent teacher's instruction was supporting or hindering children's construction of knowledge and how it determines children's learning gains.

Results

Our results reveal a decrease in children's misconceptions from pre-test to post-test. Initially, no difference in prior knowledge could be found between the experimental and the control group with regard to the classification of the material ($F(1,240)=.133$, $p=.72$, $\eta^2=.001$). In the classification of items to floating or sinking, the experimental group showed a significantly higher rise between pre- and post-test than the control group ($F(1,227)=46.98$, $p2=.171$). The results at the teacher level show that 50% of the teachers made major domain-specific errors during the videotaped interaction time. Hierarchical linear modelling shows significant negative effects of the observed teachers' domain-specific errors on the children's learning gains ($b = -.39$, $p=.00$) to a similar degree as the positive effects of the previous knowledge of the children ($b = .30$, $p=.00$).

Implications

The results show that children were able to produce significantly more correct predictions about the sinking or floating of objects after the curriculum than before, also when compared to the control group. This suggests that a well-structured curriculum which promotes comparison and scientific reasoning by means of inquiry learning supports children's conceptual change in a specific domain. More importantly for the present research question, the negative impact of teachers' errors on children's learning gains emphasizes the role of the teacher's situational domain-specific knowledge for a successful support of children's learning processes. These findings not only provide a deeper insight into the structure of kindergarten and primary school teachers' competencies enhancing science learning but may also have important practical implications for teacher training and teachers' professional development.
